Abstract: Our conceptual understanding of memory encoding places a great deal of emphasis on the recruitment of sparse neural ensembles, sometimes referred to as "engram cells", whose reactivation during recall plays an important role in memory expression. Trace formation is primarily assumed to be the function of excitatory projection cells that populate these ensembles. However, the cellular composition of memory-related ensembles remains largely unexplored, and therefore the contribution of discrete cell types is in fact poorly understood. Here we show that fear conditioning activates a heterogeneous neural ensemble in the medial prefrontal cortex (mPFC), comprised to a large degree of GABAergic interneurons immunoreactive for somatostatin (SST-INs). Using intersectional genetics in combination with electrophysiological and optogenetic approaches, we found that fear learning-activated SST-INs exhibit distinct circuit properties, are preferentially reactivated during memory retrieval, and mediate the expression of defensive freezing. We further established that a rewarding experience, morphine treatment, activates an orthogonal SST-IN population that exerts opposing control over fear. Overall, our results point to an unappreciated capacity for functional specialization among SST-INs and suggest microcircuit mechanisms by which they orchestrate selective control over excitatory populations. In particular, these findings suggest that SST-INs coordinate the firing of memory-related projection neurons as part of a functional "subnetwork", which has important implications for stimulus processing by mPFC under normal and pathological conditions.

Title: Prelimbic somatostatin neurons control binge drinking

Authors: *N. CROWLEY;
Biol., Penn State Univ., University Park, PA

Abstract: Somatostatin (SST) neurons have been implicated in a variety of neuropsychiatric disorders such as depression and anxiety, but their role in substance use disorders, including alcohol use disorder (AUD), is not fully characterized. In addition, little work has been done to explore the role of SST peptidergic signaling in behaviors related to substance use. Here, we found that repeated cycles of alcohol binge drinking via the Drinking-in-the-Dark (DID) model led to hypoactivity of SST neurons in the prelimbic (PL) cortex. We found that both DREADD-induced excitation and silencing of PL SST neurons reduced alcohol binge drinking in males and females. In addition, we established that alcohol binge drinking disinhibited pyramidal neurons by augmenting SST neurons-mediated GABA release and synaptic strength onto other GABAergic populations and reducing spontaneous inhibitory transmission onto pyramidal neurons. Pyramidal neurons additionally displayed increased intrinsic excitability. Direct inhibition of PL pyramidal neurons via DREADD activation was sufficient to reduce alcohol binge drinking. Together these data revealed an SST-mediated microcircuit in the PL that modulates the inhibitory dynamics of pyramidal neurons, a major source of output to subcortical targets to drive reward-seeking behaviors and emotional response. Our next step was to characterize the role of SST peptide signaling in this circuit. Bath application of physiologically-relevant concentrations of SST reduced the intrinsic excitability of pyramidal neurons in both male and female PL layer 2/3 pyramidal neurons, supporting the role of this peptide as a mechanism to dampen PFC output activity. This effect was more pronounced in pyramidal neurons projecting to the nucleus accumbens, as compared to those projecting to amygdalar regions, suggesting a key role in modulating reward circuitry. We then further investigated whether administration of SST receptor targeting compounds themselves could augment behaviors related to anxiety- and depression. Using an SST analogue, we show that modulating SST activity directly in the PL cortex reduces anxiety-like behavior, with clear implications for alcohol use. Overall, we provide a mechanistic role for both SST neurons and SST peptide signaling in PL circuit function and AUD.

Title: Combined dopaminergic and gabaergic regulation of prefrontal cortex activity by the cerebellum in anesthetized mice

Authors: *D. DI DOMENICO, I. MONTAGNA, L. MOSCATO, S. TRITTO, L. MAPELLI, E. D'ANGELO;
Dep. of Brain and Behavioral Sciences, Unit of Neurophysiol., Univ. di Pavia, Pavia, Italy

Abstract: The existence of a functional interconnection between the cerebellum and neo-cortical areas subserving cognitive functions, such as the medial prefrontal cortex (mPFC), strongly stands for a cerebellar role in cognition. Alterations in cerebello-prefrontal cortex (mPFC) connections characterize several cognitive dysfunctions (such as schizophrenia), suggesting that the cerebellum might have a crucial impact on proper mPFC functioning. Cerebellar activity might impact on mPFC neuronal activity through two different projection pathways: the dopaminergic one, through the ventral tegmental area (VTA), and the glutamatergic one, through the mediodorsal and ventrolateral nuclei of the thalamus. Despite these findings, the impact of cerebellar activity on mPFC still remains to be elucidated. To get a deeper insight into the cerebello-mPFC connection we performed single-unit recordings *in vivo* from the prelimbic area (PrL) of mPFC in anesthetized mice and electrically stimulated the contralateral cerebellar dentate nucleus (DN). DN stimulation mainly elicited a pause in PrL background neuron firing, sometimes followed by an excitatory rebound. Furthermore, to investigate the nature of PrL responses, we used surface application of selective dopamine D1-like and D2-like receptor antagonists (SCH23390 and sulpiride, respectively) and of a $GABA_A$ receptor antagonist (gabazine). The D1-D2 receptor blockade modulated PrL neuron background discharge without affecting the pause usually observed in response to DCN stimulation. Conversely, this pause was suppressed by gabazine superfusion, suggesting a prominent role of local inhibition in controlling the phasic response of PrL neurons. Interestingly, the effect of $GABA_A$ receptor block on the pause was correlated with that of D1-D2 receptor block on background frequency. In summary, our data show that cerebellar activation silences PrL activity through local inhibitory circuits that remain to be identified. Possibly, cerebello-thalamic projections activate local cortical inhibitory interneurons. Moreover, PrL neuron background discharge is modulated by the dopaminergic system. Eventually, the interplay of the dopaminergic and GABAergic pathways regulates the signal-to-noise ratio in PrL neuron responses, revealing complexity in the cerebellar functional control of PrL.

Title: In vivo plasticity between ventral hippocampal inputs and medial prefrontal cortex microcircuits in a mouse model of 22q11.2 deletion syndrome

Authors: T. T. CLARITY[1], R. M. MIKOFSKY[1], M. V. MYROSHNYCHENKO[1], K. GILCHRIST[1], *D. A. KUPFERSCHMIDT[1], J. A. GORDON[2,1];
[1]Integrative Neurosci. Section, Natl. Inst. of Neurolog. Disorders and Stroke, Bethesda, MD;
[2]Office of the Director, Natl. Inst. of Mental Hlth., Bethesda, MD

Abstract: Functional connectivity between rodent ventral hippocampus (vHPC) and medial prefrontal cortex (mPFC) supports cognitive functions such as spatial working memory (SWM), and is disrupted in *Df(16)A*$^{+/-}$ mice with a microdeletion syntenic to the schizophrenia-predisposing 22q11.2 microdeletion. Optogenetic inhibition of direct vHPC-mPFC neural projections or somatostatin-positive (SST+) interneurons in mPFC of wildtype (WT) mice impairs vHPC-mPFC connectivity and SWM performance, mimicking the effects of the microdeletion. To examine how functional interactions between these circuit elements may contribute to vHPC-mPFC dysconnectivity in *Df(16)A*$^{+/-}$ mice, and how these interactions may be altered to promote vHPC-mPFC connectivity, we tested the ability of vHPC-mPFC inputs to modulate *in vivo* activity of discrete mPFC neuronal populations in WT and *Df(16)A*$^{+/-}$ mice using an all-optical approach. ChrimsonR was expressed in vHPC neurons of adult male and female WT and *Df(16)A*$^{+/-}$ mice. GCaMP6f was expressed in mPFC SST+ or parvalbumin-positive (PV+) interneurons in separate cohorts (n=5-13). Red light pulses were delivered to the mPFC to excite vHPC terminals, and postsynaptic activation of GCaMP6f was monitored using fiber photometry. Stimulation-evoked photometric responses in SST+ interneurons varied systematically with pulse number (1-40) and frequency (1-40Hz), with maximal responses achieved by 40 pulses at 40Hz. SST+ interneuron responses in *Df(16)A*$^{+/-}$ mice were weaker than those in WT mice (p=0.03, main effect of Genotype, 3-way ANOVA). Repeated daily high-frequency stimulation over 12 days increased evoked SST+ interneuron responses for up to 50 days in both genotypes (p=0.006, Day x Stimulation, 3-way ANOVA). High-frequency stimulation in *Df(16)A*$^{+/-}$ mice potentiated SST+ interneuron responses to levels observed in WT mice without such stimulation. PV+ interneuron responses to high-frequency stimulation in WT mice were weak and biphasic; the negative component of this response was enhanced across stimulation days (p=0.03, main effect of Day, one-way ANOVA). These findings suggest that the capacity of vHPC inputs to engage mPFC SST+ interneurons may be impaired in *Df(16)A*$^{+/-}$ mice, and that repeated high-frequency stimulation of vHPC-mPFC inputs induces *in vivo* plasticity that may involve recruitment of SST+ interneurons. Future work will assess how this plasticity influences SWM performance. Together, these data reveal properties of cell-type-specific functional connectivity within intact vHPC-mPFC circuits that inform how discrete circuit elements may interact to mediate normal and disordered cognitive function.

Title: Dynamic filtering of habenulo-raphe inputs by a serotonergic recurrent inhibitory network acting over behavioral timescales

Authors: *M. LYNN[1], S. D. GEDDES[1], M. CHAHROUR[1], S. MAILLÉ[1], E. HARKIN[1], E. HARVEY-GIRARD[1], S. HAJ-DAHMANE[3], R. NAUD[1], J.-C. BEIQUE[2];

Abstract: The habenulo-raphe pathway is believed to be implicated in orchestrating optimal behavioral responses to aversive, threatening or stressful environments. Here, we consider how long-range inputs from lateral habenula (LHb) influence circuit dynamics in the dorsal raphe nucleus (DRN) using electrophysiological, computational and behavioral strategies. We find that habenulo-raphe afferents triggered classical monosynaptic excitation of 5-HT neurons, as well as strong disynaptic inhibition whose induction was steeply frequency-dependent and which persisted for seconds. This novel inhibition was mediated by a GIRK conductance activated by 5-HT1A receptors. To determine the network motifs underlying this protracted inhibition, we undertook optogenetic and pharmacological manipulations in DRN. These experiments revealed, unexpectedly, that 5-HT neurons are organized in a recurrent inhibitory network, refuting the classical model of autocrine activation of 5-HT1A autoreceptors. Electrical stimulation approaches revealed that these inhibitory connections exhibited robust, dramatic short-term facilitation that we formalized with a linear-nonlinear plasticity model. To examine how this nonlinearity affects input-output transformation, we constructed an experimentally-constrained network model of DRN which incorporated the experimentally-fitted plasticity model at inhibitory connections. We find that excitatory inputs led to paradoxical inhibition of DRN at high frequencies, and that this polarity switch was dependent on plasticity dynamics and not on recurrent inhibition itself. To test the physiological relevance of this computation for processing threat information from the LHb, we developed a simple auditory classical conditioning paradigm and tested key predictions of our model through *in vivo* optogenetics. We uncovered a nonlinear transformation where stimulating the habenulo-raphe pathway at high-frequency, but not at low frequency, *depressed* goal-directed anticipatory licking behavior. We suggest that the computation sustained by this circuit motif in the DRN categorizes synaptic inputs to implement optimal adaption of behavioural policies in threatening environments.

Title: Regiospecific knockout of PACAP expression and its impact on endocrine and behavioral consequences of restraint stress

Authors: *S. Z. JIANG[1], L. E. EIDEN[2];
[2]Sec Molec Neurosci, [1]NIMH/NIH, Bethesda, MD

Abstract: The neuropeptide PACAP is implicated in stress responding throughout the nervous system. PACAP in brain mediates both *behavioral* and *endocrine* responses to stress. PACAP deficiency has no effect on CORT elevation after 1-2 hr of restraint stress or even for 1 hr restraint stress repeated for 7 days, but does attenuate CORT elevation when stress occurs continuously for 2-3 hr of restraint stress repeated over several days. On the other hand, CRH mRNA and Fos elevation in PVN are PACAP-dependent even after just 1 hr of restraint (Jiang and Eiden, STRESS 19: 374, 2016). We deduce that PACAP is required not to *release* CRH, but rather to *sustain* the ability of CRH neurons to produce and secrete CRH by augmenting CRH mRNA production, thus allowing a higher rate of CRH peptide biosynthesis during stress. However, restraint-induced hypophagia even after 1 hr restraint is PACAP-dependent, indicating that this effect requires PACAP actions within circuits other than those controlling the HPA axis. In addition to activation of CRH PVN neurons, restraint stress also activates neurons of the centrolateral amygdala (CeL) and oval nucleus of BNST (ovBNST) that receive PACAPergic inputs from the extended lateral parabrachial nucleus (elPBn). PACAP terminals appear to synapse predominantly on PKCδ- and to some extent on CRH-expressing neurons of extended amygdala. Fos activation in ovBNST and CeL after 2 hr restraint is abolished in $PBn^{AAV\text{-}Cre}$::$PACAP^{fl/fl}$ mice, in which PACAP is ablated in nerve terminals of ovBNST and CeL, concommitant with attenuation of restraint-induced hypophagia. Fos activation in PVN, and CORT elevation after chronic restraint stress were maintained in $PBn^{AAV\text{-}Cre}$::$PACAP^{fl/fl}$ mice. Additional PACAPergic circuits participate in restraint stress responses. Sim1-Cre::$PACAP^{fl/fl}$ mice, in which PACAP expression throughout hypothalamus is ablated, showed attenuated hypophagic response to acute restraint stress. CamK2a-Cre:: $PACAP^{fl/fl}$ mice, in which PACAP expression is ablated in forebrain, but not in hypothalamus and brain stem, did not show

attenuation of restraint-induced hypophagia, but did exhibit deficits in restraint stress-induced HPA axis activation. Thus, Fos activation in PVN at 2 hr of acute restraint stress was attenuated in CamK2a-Cre::PACAP$^{fl/fl}$ mice, and this is reflected cumulatively in attenuated CORT elevation after chronic restraint stress (2 hr restraint stress repeated over 4 days). These results suggest that anatomically distinct PACAPergic circuits separately control endocrine and behavioral responses to stress.

Title: The use of seeded models of tau propagation for evaluating nSMase2 inhibitors in Alzheimer's Disease

Authors: *M. M. MALVANKAR[1], B. S. SLUSHER[3], B. J. BELL[2], C. TALLON[1]; [2]Human Genet., [1]Johns Hopkins Sch. of Med., Baltimore, MD; [3]Neurol., Johns Hopkins Drug Discovery, Baltimore, MD

Abstract: Accumulation of amyloid-β (Aβ) peptide into plaques and aggregations of the microtubule associated binding protein Tau (MAPT) into neurofibrillary tangles (NFT) are key pathological hallmarks of Alzheimer's Disease (AD). Importantly, the degree of spread of phosphorylated tau is strongly correlated with AD's progressive neurodegeneration, as well as cognitive and functional impairments. Therefore, there is a high clinical need for novel therapeutics which aim to limit the propagation of tau and may stop or slow the progression of AD in patients. Recent evidence has highlighted the importance of extracellular vesicles (EVs) in enabling the transcellular transmission of pathological tau in the brain in a 'prion-like' manner and identified the inhibition of EV biogenesis via small-molecule inhibitors of nSMase2 as a potential avenue for clinical intervention. However, drug discovery efforts have been hampered by the use of transgenic mouse models which express human Tau in the majority of neurons, making it difficult to study the propagation of phosphorylated tau from neuron to neuron along defined pathways as occurs in AD patients. To better assess the preclinical efficacy of nSMase2 inhibitors, our lab has operationalized a rapid tau-seeded model of tau propagation, in which the gene for mutant human tau is packaged in an AAV vector and stereotaxically injected

unilaterally into the mouse hippocampal CA1 region. The mice are then treated with test compounds or control for 6 weeks, at which time the mice are sacrificed, and the spread of tau and its phosphorylated species is quantified via histology in the contralateral dentate gyrus (DG). We have demonstrated that both total tau and the phosphorylated tau species pThr181 are consistently observed in the neurons of the granule cell layer of the ipsilateral DG, and spread to neurons and $GFAP^+$ astrocytes in the contralateral DG hilus. Histological examination allows for quality control of the injected mice, and propagation quantification is performed by measuring the contralateral/ipsilateral ratio of mean fluorescence intensity and positive cell count for phosphorylated tau species. Preliminary treatment studies utilizing the potent nSMase2 inhibitor 1-(3-(3,4-dimethoxyphenyl)-2,6-dimethylimidazo[1,2-b] pyridazin-8-yl) pyrrolidin-3-yl) carbamate (PDDC) have confirmed that the inhibition of nSMase2 significantly reduces the tau spread between hemispheric hippocampi. These results demonstrate the unique value of this rapid propagation AD mouse model for drug discovery efforts focused on attenuating the propagation of pathological tau *in vivo*.

Title: Extracellular Tau Oligomers Disrupt the Axon Initial Segment by a Mechanism Dependent on Intracellular Tau

Authors: *M. N. BEST, K. H. SILLER, Y. LIM, N. KIM, N. N. FERENC, D. BIGLER WANG, J. W. MANDELL, G. S. BLOOM;
Univ. of Virginia, Charlottesville, VA

Abstract: BACKGROUND. Mislocalization of tau, a protein normally enriched in axons, into the somatodendritic compartment is an early event in Alzheimer’s disease (AD) and non-AD tauopathies, and can be caused by extracellular tau oligomers (tauOs) (Swanson, et al. 2017. J Alz Dis 58: 803-820). Recent studies focusing on the role of the axon initial segment (AIS) as a diffusion barrier between the somatodendritic compartment and the axon point towards a mechanistic role for AIS disruption in tau mislocalization. We, therefore, sought to determine if

extracellular tauOs adversely affect AIS structure.
METHODS. Tau oligomers were prepared using purified human recombinant 2N4R tau, which aggregated in the presence of the polyunsaturated fatty acid, arachidonic acid. Quantitative immunofluorescence microscopy of cultured neurons for the AIS structural proteins, ankyrin G, βIV-spectrin, and TRIM46, was used to analyze AIS morphology in primary cortical neurons derived from wild type and tau knockout (KO) primary cortical mouse neurons. Following ~18-hour incubations with tauOs or vehicle, cells were labeled with antibodies to tau, the somatodendritic marker, MAP2 and the three AIS structural proteins. Blinded imaging and data analysis were completed to assess immunofluorescence intensity, AIS length, and distance of the AIS from the soma.
RESULTS. TauOs caused substantial loss of AIS structural proteins and shortening of the AIS in wild type mouse neurons, but not in tau KO neurons. Lentiviral expression of human 2N4R tau in tau KO neurons rescued these effects of tauOs on the AIS.
CONCLUSIONS. Endogenous cytoplasmic tau is not required for AIS formation, but extracellular tauOs cause a major loss of structural proteins along the entire length of the AIS, coupled with AIS shortening from its distal end. Remarkably, this AIS disruption caused by extracellular tauOs requires intracellular tau. These collective results raise the possibility that tau mislocalization in AD and non-AD tauopathy neurons is a consequence of AIS disruption by extracellular tauOs.

Title: A mechanism for DEK loss and its association with Alzheimer's disease

Authors: *A. GREENE[1], M. B. SOLOMON[1], L. PRIVETTE VINNEDGE[2];
[1]Univ. of Cincinnati, Cincinnati, OH; [2]Cincinnati Children's Hosp. Med. Ctr., Cincinnati, OH

Abstract: DEK, a chromatin remodeling, nuclear protein, has been linked with neurodegenerative disorders such as Alzheimer’s disease (AD) (Ghisays et al., 2018), Huntington’s disease (Christodoulou et al., 2020), and age-related dementias (Ghisays et al., 2018, O’Donovan et al., 2018). In the periphery, DEK has cellular functions in DNA replication

and repair, cell proliferation, and apoptosis inhibition. Recently, we reported that DEK expression is necessary for proper neurite formation and that its deficiency leads to cell death and both Tau overexpression and hyperphosphorylation (Greene et al., 2020). The purpose of the current study is to elucidate the mechanism by which DEK loss leads to Tau hyperphosphorylation, with the goal of illuminating novel pathways of Tauopathy in Alzheimer's disease. To identify a functional role for DEK in AD-related phenotypes, SH-SY5Y cells were transduced with DEK-targeting lentivirus (DEKsh) or non-targeting lentivirus (NTsh) and subsequently differentiated into a neuronal-like phenotype. One week before the end of the differentiation process, cells were treated with kinase inhibitors for CamKII, ERK, PKC, PKA, DYRK, CDK5, or GSK3β; these kinases are associated with Tau pathology in Alzheimer's disease. At the end of differentiation, the relative expression levels of phosphorylated Tau and kinase activation markers were determined via immunofluorescence and western blotting. We found that the inhibitors of ERK, DYRK, CDK5, and GSK3β reduced phosphorylated Tau (Ser262) to control levels, while treatment with other kinase inhibitors did not rescue the Tau pathology phenotype in the DEK-deficient (DEKsh) cells. We observed increased activation of these same kinases in DEKsh cells. Previous reports showed that DEK overexpression leads to decreased extracellular glutamate, and that CDK5 can be activated upon the presence of excess extracellular glutamate. Therefore, we used a glutamate bioluminescent assay and found that DEKsh cells showed elevated levels of extracellular glutamate. Our results indicate that DEK loss leads to increased glutamate secretion from neuronal cells, which may have downstream consequences such as the observed activated CDK5 and cell death. Further potential downstream effects include ERK and GSK3β activation, contributing to hyperphosphorylated Tau after DEK loss in this cell model. These data may inform us of the molecular mechanism(s) by which DEK loss leads to cellular and molecular phenotypes associated with Alzheimer's disease or other age-related dementias.

Title: Assessing pathogenic conformations of tau in primary neurons seeded with human-derived pathological tau

Authors: *R. L. MUELLER[1,2], N. M. KANAAN[1,2,3];
[1]Translational Neurosci., Michigan State Univ., Grand Rapids, MI; [2]Michigan State Univ., Neurosci. Program, East Lansing, MI; [3]Mercy Hlth. St. Mary's, Hauenstein Neurosci. Ctr., Grand Rapids, MI

Abstract: One of the pathological hallmarks of Alzheimer's disease (AD) is the accumulation of pathological tau inclusions, and the multimerization of tau is likely a critical part of tau's role in disease pathogenesis. Tau is capable of seeding aggregation in cells; however, the extent to which specific disease-associated pathogenic conformations can be effectively seeded remains an area of active investigation. To help address this gap, we seeded aggregation in primary neurons and assessed known pathogenic tau conformations that are linked to mechanisms of tau-induced toxicity. We used hippocampal primary neurons derived from tau knock-in mice that express all six human tau isoforms. We seeded aggregation by treating neurons with human AD brain-derived tau (AD-tau). The AD-tau samples were characterized by transmission electron microscopy (TEM) and biochemical assays that measure total tau and pathological modifications, such as phosphorylation (e.g. PHF-1+ tau) and two conformation specific antibodies (TNT1 and TOC1). TNT1 labels conformation-dependent display of an N-terminal domain known as the phosphatase activating domain (PAD) and TOC1 labels oligomeric tau, both of which are linked to toxicity. The AD-derived material showed morphologies consistent with small pieces of the characteristic paired helical filaments of AD on TEM, phosphorylation at the PHF-1 site on western blot, and the presence of oligomeric tau and PAD-exposed tau species in sandwich ELISAs. Following treatment of neurons with AD-tau, we used immunostaining to label TNT1 and TOC1 conformations at multiple time points. We observed a robust increase in TNT1 labeling over time in AD-tau-treated primary neurons, but little to no evidence of TOC1+ oligomeric tau species. To begin assessing consequences of tau seeding in this model, we determined whether overt cell loss occurred up to 28 days after seeding. There were no significant effects on the number of neurons or astrocytes in seeded cultures suggesting that robust degeneration did not occur. Ongoing studies will assess additional functional consequences (e.g. axonal transport impairment) and potentially earlier measures of toxicity (e.g. synaptic and axonal toxicity) in seeded neurons. Together, our results suggest that seeding primary neurons with AD-tau drives some of the pathogenic conformations observed in human disease, but overt degeneration does not occur within 28 days of seeding. The presence of pathological forms of tau but lack of overt degeneration could indicate that more time is needed and/or that the functional consequences of these tau species are more subtle leading to synaptic loss or axonal degeneration.

Title: Tau^{Agg}: a luminescence-based in vivo system to detect tau protein aggregation in drosophila

Authors: *S. A. LEVY, E. M. GONZALES, B. FROST;
Cell Systems and Anat., UT Hlth. San Antonio, San Antonio, TX

Abstract: Tauopathies are characterized by fibrillar tau protein aggregates. In Alzheimer's disease, the most common tauopathy, these tau aggregates form neurofibrillary tangles, one of the major pathological hallmarks of the disease. Strikingly, tau pathology propagates through the brain hierarchically over time and appears to spread along circuitry, suggestive of a prion-like mechanism. In recent years, tau has been shown to spread between cells *in vitro* and *in vivo* and to recruit soluble, non-pathogenic tau into new aggregates. However, the mechanisms mediating and regulating these processes have not been well characterized. We have developed a *Drosophila* model of tau protein aggregation, termed tau^{AGG}, to provide a tool to study the processes underlying it in a short-lived, cost-effective animal model with a large genetic toolkit. We found that the P301L mutant of full-length human tau (tau^{P301L}) forms oligomers in *Drosophila* neurons, suggesting a capacity to seed aggregation. Based on this, we created the tau^{AGG} system, where tau^{P301L} fused to either the C-terminal or N-terminal portion of luciferase is expressed pan-neuronally. In this split-luciferase assay, the close proximity of C-terminal and N-terminal luciferase fragments caused by aggregation will produce luminescence and allow us to quantify tau-tau interaction *in vivo* in a screenable manner. We found that tau^{AGG} animals exhibit significantly higher luminescence signal than non-transgenic control animals and animals expressing a control construct, where EGFP is fused to the split-luciferase components, indicating that tau^{AGG} selectively quantifies tau-tau interaction. A *Drosophila* model of tau aggregation allows us to investigate the mechanisms controlling this phenomenon in adult, aging brains. The genetic tools available to *Drosophila* research, as well as straightforward delivery of drugs through *Drosophila* food make it possible to screen genetic and pharmacological modifiers of tau aggregation with the long-term goal of developing treatment strategies targeting the prion-like spread and seeding of pathogenic tau. In this context, a luminescence-based model of tau seeding is well-suited for screening approaches to interfere with putative mechanisms, since luminescence can be acquired in living animals, making longitudinal studies feasible.

Title: Investigating the effectiveness of galantamine hydrobromide in reducing symptoms of Alzheimer's disease in Drosophila melanogaster

Authors: *E. R. NIEMAN, S. L. FOX, H. B. SHAH, D. D. LENT;
Biol., California State University, Fresno, Clovis, CA

Abstract: Impaired sleep schedules, difficulty with spatial learning and memory, and reduced ability to plan activities have all been noted symptoms of patients with Alzheimer's disease (AD). AD pathology is characterized by an accumulation of neurofibrillary tangles, tau aggregates, and beta-amyloid plaques. One common characteristic of patients with AD is a reduction of acetylcholine (ACh), a neurotransmitter associated with memory and learning processing, which is broken down in the synapse by the enzyme acetylcholinesterase (AChE). Our research focused on analyzing and quantifying changes in behavioral patterns in flies expressing human tau in the mushroom bodies and ellipsoid body, brain regions that have a role in learning and memory and spatial cognition, that have been treated with an AChE inhibitor. We hypothesized that, similar to humans and vertebrate models, inhibiting AChE would slow the progression of the disease and help improve behavioral function in the fruit fly model. Fruit fly lines were created to express tau in either the mushroom bodies or the ellipsoid body. The AChE inhibitor galantamine hydrobromide was used as a treatment and its treatment effect on the progression of early tau pathologies was studied. Flies expressing tau from 1-7 days old were treated and compared to untreated and control flies in three assays. To assess sleep, the Drosophila Activity Monitor was used to monitor the fly's day-night activity and circadian rhythms. To assess visual place learning, flies were trained to locate a hidden cool spot on a hot surface using visual cues and were then tested for memory of that location. To assess visuo-motor planning, flies were analyzed in a tap-down apparatus that required them to negotiate a high-contrast visual barrier. The results from the behavioral assays revealed quantifiable differences in behavior between control flies, diseased flies, and flies receiving the galantamine hydrobromide treatment. In the sleep study, the flies of different lines and experimental conditions had differing levels of activity and sleep patterns. In the visual place learning experiment, treatment had a demonstrable effect on diseased flies' ability to associate a cool spot with patterns on walls of the thermal maze assay. Finally, in the visuo-motor planning study, the flies' efficiency in navigating the assay as a function of time varied considerably between the three groups but results showed an impact of treatment on performance. Ongoing experiments suggest that drug treatment may rescue diseased phenotypes and bring them closer to the controls. This helps advance the fruit fly model as a viable method for studying AD.

Title: Functional validation of the cytoskeletal protein Plectin in Alzheimer's disease

Authors: *T. V. LEE[1], K. ALLISON[2], N. T. SEYFRIED[3], A. I. LEVEY[4], J. M. SHULMAN[2]; [1]Neurol., [2]Baylor Col. of Med., Houston, TX; [3]Human Genet., Emory Sch. Med., Atlanta, GA; [4]Dept Neurol., Emory Univ. Sch. of Med., Atlanta, GA

Abstract: Alzheimer's disease (AD) is a progressive neurodegenerative disease and the most common form of dementia. The genetic causes for the majority of AD cases and the underlying biology of pathogenesis remain unknown. Recent large scale proteomics studies on AD patient brains have identified multiple novel protein networks and targets that are highly correlated with AD diagnosis and neuropathology. One of the most significantly AD-correlated protein networks identified in this analysis contains the cytoskeletal protein Plectin as a protein network hub. Plectin functions to crosslink different components of the cytoskeleton and plays a role in axonal transport of synaptic proteins. To validate Plectin as potential AD target of analysis, we performed functional studies in the animal model, *Drosophila melanogaster* and human neuronal cell culture. Expression analysis in *Drosophila* exhibit ubiquitous Plectin expression within the adult brain with strong enrichment in neuronal rich regions. Using *Drosophila* models of AD overexpressing human Tau, altering neuronal levels of Plectin enhances age dependent Tau-induced neurotoxicity and locomotor dysfunction. In addition, Plectin modulates Tau-phosphorylation and aggregation in both *Drosophila* brains and human neurons. Moreover, in the absence of Tau overexpression, decreasing neuronal Plectin levels result in abnormal neuronal transmission as measured by the electroretinogram, confirming Plectin's role in neuronal function. Taken together this data identifies and functionally validates Plectin as a regulator of Tau-induced neurodegeneration and identifies Plectin as regulator of Tau dynamics and neuronal function. Continued mechanistic analysis in both *Drosophila* and human neuronal cultures with determine Plectin's role in AD neuropathogenesis and elucidate the underlying role of the cytoskeleton in Tau-induced neurodegeneration.

Title: Reduction of tau to baseline levels and rescue of motor impairment in a therapeutic study in aged JNPL3 mice treated with small molecule OLX-07010 targeting tau self-association

Authors: *J. MOE[1], P. LOPEZ[2], D. PATEL[2], H. JIMENEZ-BRAVAR[3], L. ADRIEN[3], A. WOLIN[3], J. KOPPEL[3], P. DAVIES[3], *E. DAVIDOWITZ[1];

Abstract: Tau has been implicated in the pathogenesis of multiple neurodegenerative diseases associated with the accumulation of abnormal species of tau, collectively called tauopathies. Mutations in MAPT can cause a range of rare inherited tauopathies to develop due to overproduction of specific tau isoforms or changes in the structure of tau, both of which can cause tau to aggregate. In AD, tau pathology is driven by numerous posttranslational modifications that lead to loss of normal function and/or gain of toxic function. Neurofibrillary tangles, composed primarily of tau, accumulate in a highly reproducible spatiotemporal order demonstrating a close association between tau aggregation and AD progression. Tau oligomers have neurotoxic effects on the genome, mitochondria, cell signaling, synaptic plasticity, microtubule assembly, the cytoskeleton and protein clearance mechanisms. Oligomerix has shown that tau oligomers cause disruption of neuronal signaling and inhibit the formation of memory in mice (Fá, M. et al., 2016). We have found that certain forms of tau oligomers are toxic when applied to cultured neurons, whereas tau monomer was not toxic at the same concentrations (Tian, H. et al., 2013). This program seeks to discover and develop disease modifying therapeutics for AD and related dementias using a small molecule approach targeting tau self-association to impact the accumulation of all tau aggregates. The in vivo efficacy of our proprietary small molecule OLX-07010 in this therapeutic study builds upon results from the preventive studies in the htau (Davidowitz, E. et al., 2020) and tau P301L JNPL3 mouse models of tauopathy. This blinded study was independently performed using homozygous female JNPL3 mice that were aged to 7 months and treated for 5 months with compound administered in feed for daily doses of 40 and 80 mg compound per kg mouse. A vehicle feed control group and

baseline cohort (7 months-of-age) were also included in the study. Treatment with OLX-07010 caused a decrease in the accumulation of heat stable, self-associated, Sarkosyl-insoluble tau aggregates, and phosphorylated tau with statistical significance to baseline levels. Moreover, the reduction in tau aggregation in the cortex and its aberrant phosphorylation correlated with improved motor performance in the Rotarod assay and in open field arena analyses. Preclinical studies are being performed for an IND submission to the FDA to enable planned first-in-human studies.

Complutense, Madrid, Spain; [2]Ctr. de Investigación Biomédica en Red de Enfermedades Neurodegenerativas (CIBERNED), Madrid, Spain; [3]Inst. Ramón y Cajal de Investigación Sanitaria (IRYCIS), Madrid, Spain

Abstract: TAR DNA-binding protein 43 (TDP-43) is involved in the regulation of RNA stability, transport, and splicing. Its dysregulation has been linked with some forms of frontotemporal dementia (FTD). The therapeutic outcome in FTD is currently limited. Our group

has recently initiated studies aimed at exploring cannabinoid-based therapies as a promising option for the treatment of FTD, given their relevant neuroprotective and anti-inflammatory profile demonstrated in other neurological disorders. For this objective, we have used mice that overexpress TDP-43 in forebrain neurons under the control of α-CaMKII promoter, which recapitulate important neuropathological signs of FTD (provided by Shen; Tsai et al., J Exp Med 2010). The analysis of the endocannabinoid system in these mice in a preliminary study proved adaptive changes in some elements of this system (e.g., increase in the anandamide-synthesizing enzyme NAPE-PLD, and reduction in the hydrolyzing enzyme FAAH) in some key CNS structures in FTD (e.g., medial prefrontal cortex, hippocampus), which may be interpreted as an endogenous protective response aimed at elevating anandamide levels in these CNS structures. Given these results, our follow up studies have tried first to inactivate FAAH enzyme using the selective inhibitor URB597 administered i.p. at the dose of 0.2 mg/kg on alternate days from pre-symptomatic phases (PND45) to symptomatic stages (PND90). Our data proved that URB597 delayed the appearance of FTD signs (e.g. cognitive deterioration measured in the NOR test), whereas preserved pyramidal neurons in the medial prefrontal cortex and in the hippocampal CA1 layer (measured with Ctip2 and NeuN immunostaining, respectively), and attenuated the elevated glial immunoreactivity (measured with the marker of reactive astrocytes, S100-β, in the medial prefrontal cortex, and with the marker of microglia, Iba-1, in the CA1 layer). To explore whether these effects may involve the activation of the CB_1 receptor, we conducted a second experiment by treating FTD mice with the selective CB_1 receptor agonist ACEA administered i.p. at the dose of 1.5 mg/kg daily during the same time range. The treatment with ACEA also delayed the appearance of FTD signs and these effects were eliminated by co-administration of ACEA with the selective CB_1 receptor antagonist rimonabant. In summary, our data confirm the potential of modulating the endocannabinoid system as a therapy against TDP-43-induced neuropathology in FTD, in particular by activating the CB_1 receptor which serves to preserve neuronal integrity and to limit glial reactivity, resulting in an improvement of cognitive deficits.

Title: Cola nitida ameliorate cardiometabolic dysfunction and amnesia induced by dexamethasone and scopolamine in male mice

Authors: *L. ADEDAYO[1], O. MICHAEL[2], F. AWOBAJO[5], O. OLUMOROTI[3], O. BAMIDELE[3], N. AITOKHUEHI[6], O. MORAKINYO[4], S. ONASANWO[7];

Abstract: Abstract Accumulative evidence has indicated that vascular risk factors including cardiometabolic disorders have been shown to be predictors of amnesia. *Cola nitida* is natural nuts with numerous bioactive compounds that have shown tremendous therapeutic potentials such as antioxidants, anti-nociception and anti-inflammatory properties. The precise reason why cardiovascular and cardiometabolic conditions are risk factors for dementia remains unknown. However, this study investigated the therapeutic potentials of the methanol extract of *Cola nitida* on cardio-metabolic dysfunction and amnesia induced by dexamethasone and scopolamine in mice. Male mice aged 14 weeks were given (p.o.) vehicle, (3mg/kg i.p) scopolamine (SCO), 0.2 mg/kg dexamethasone (DEX) plus 3mg/kg SCO, 50mg/kg *Cola nitida* (CN) plus 3mg/kg SCO, 0.2mg/kg DEX plus 3mg/kg SCO plus 50mg/kg CN, 0.2 mg/kg DEX plus 3mg/kg SCO plus (1mg/kg p.o.) donepezil daily for 7 days (n=5 per group) using Morris water maze (MWM) and Y-maze tests to assessed memory impairment. Glucose dysmetabolism was assessed by elevated fasting blood glucose, impaired glucose tolerance test. Treatment with CN led to significant increase in time spent in the quadrant in the probe trial (MWM) and increase in percentage alternation (Y-maze) tasks. On the other hand, CN led to decrease in escape latency time in MWM. Also, *Cola nitida* significantly decrease the acetylcholinesterase activity in the brain, Malondialdehyde, lactate dehydrogenase, triglycerides and glucose levels, however, CN improved glutathione reductase, reduced glutathione in the heart and brain homogenates. This result demonstrates that *Cola nitida* enhances memory through neuro-behavioural, acetylcholinesterase and antioxidant activities. On the other hand, CN ameliorate cardiometabolic dysfunction by antioxidant activity, decrease triglyceride accumulation and reduced glucose level in the heart. Therefore, *Cola nitida* would impact positively on cardiometabolic disorders and memory impairment.Keywords: Cola nitida, cardiometabolic dysfunction, amnesia, scopolamine, dexamethasoneWord count:284

Title: A branched-chain amino acid (BCAA)-lowering compound reverses metabolic dysregulation and enhances cortical insulin signaling in a mouse model of Alzheimer's disease

Authors: *C. A. MULLINS, H. SHAH, R. B. GANNABAN, M. B. SIDDIK, A. C. SHIN; Texas Tech. Univ., Lubbock, TX

Abstract: Metabolic dysregulation including abnormal glycemic control and insulin resistance is associated with age-related cognitive decline, thus these markers may be a promising target for prevention and treatment of neurodegenerative diseases such as Alzheimer's disease (AD). Studies show that BCAAs can induce insulin resistance and impair glucose metabolism. Based on our recent findings that plasma BCAAs are elevated in AD mice and humans compared to healthy subjects, we hypothesized that lowering BCAAs will correct metabolic impairments leading to alleviation of AD-related brain pathology and cognitive deficits. To this end, we treated 2-month-old C57BL/6J SJL wild-type (WT) and 5xFAD mice with either vehicle or 3,6-dichlorobenzo[b]thiophene-2-carboxylic acid (BT2), a small molecule that lowers plasma BCAAs by indirectly activating branched-chain α-keto acid dehydrogenase (BCKDH), the rate-limiting enzyme for BCAA degradation. Animals were separated into either WT vehicle (n=6), WT BT2 (n=6), 5xFAD vehicle (n=4), or 5xFAD BT2 (n=4) group. Blood was collected at baseline and 30 days after daily intraperitoneal injection of BT2 or vehicle to measure blood glucose and plasma insulin. Y-maze and novel object recognition test were also conducted to assess cognitive function. Insulin was injected systemically before sacrifice to assess insulin signaling in the brain.

We confirmed the stimulating effect of BT2 on BCAA breakdown in the liver by observing a reduction in phosphorylated BCKDH, the inactive form of the enzyme. Our results show that BT2 significantly lowered plasma insulin in 5xFAD mice compared to baseline. Likewise, 5xFAD mice had significantly higher blood glucose compared to WTs at baseline, but BT2 was able to completely normalize glucose. While there was no change in Abeta-42 in the cortex or cognitive function between groups, 5xFAD mice displayed enhanced insulin-stimulated insulin signaling following BT2 treatment.

Our findings suggest that BT2 is a novel therapeutic compound that may correct metabolic dysregulation and brain insulin resistance which may in turn slow AD progression. We are currently investigating potential effects of BT2 on neuronal health, mitochondrial and oxidative stress, inflammation, and neurotransmitter synthesis in AD mice. We did not observe any effects of BT2 on cognitive function most likely due to the early age of 5xFAD mice employed here. We plan to repeat this study with older mice in future studies.

Title: The role of long-chain acyl-CoA synthetases 3 (ACSL3) in age-induced vascular dementia

Authors: C. CITADIN[1], G. CLEMONS[1], C. ACOSTA[1], M. S. UDO[2], W. CARR[2], R. H.-C. LEE[2], H. LIN[2], ***C. Y.-C. WU**[2];
[1]Cell. Biol. and Anat., [2]Neurol., LSU Hlth. Sci. Ctr. - Shreveport, Shreveport, LA

Abstract: Alzheimer's disease (AD) is one of the most common neurodegenerative diseases in the United States. Risk factors for AD are associated with age and gender. Women are more likely to develop a rapid progression of dementia than men with a greater risk of developing vascular dementia as compared to males. Cerebral blood flow derangements found in AD are thought to be the major cause of brain dysfunction and neurological deficits. AD-mediated hypoperfusion plays a vital role in vascular dementia-related neuroinflammation, mitochondrial dysfunction, neuronal cell death, and neurological deficits. Therefore, the major challenge is to alleviate the development and progression of vascular dementia. We previously discovered that mRNA and protein expression of long-chain acyl-CoA synthetase 3 (ACSL3) in brain regions were significantly decreased with the aged AD mice. Specific agonist of ACSL3 alleviated AD-mediated hypoperfusion, neuroinflammation, and mitochondria dysfunction, with enhanced neuronal survival and improved functional learning/memory. Our preliminary data suggest that decreased ACSL3 is detrimental in an aged 3xTg-AD mouse model (enhanced β-amyloid and tau aggregation and accumulation). Our central hypothesis is that ACSL3 is critical for age-related brain function to maintain cerebral blood flow and the mitochondria, and prevent neuroinflammation and learn/memory degradation. We propose to explore the pathophysiological role of ACSL3 in the aged brain. The present study can lead to novel therapies/targets against AD brain progression by investigating the pathophysiological role of ACSL3 in cerebral blood flow regulation and neuroprotection.

Title: Phenotypic characterization of a novel zebrafish model of Wolfram syndrome, a rare genetic disease

Authors: *L. CROUZIER, C. DIEZ, E. M. RICHARD, M. DENUS, T. MAURICE, B. DELPRAT;
MMDN, Univ. Montpellier, EPHE, INSERM, Montpellier, France

Abstract: Wolfram syndrome (WS) is a rare neurodegenerative disease associating deafness, optic atrophy, diabetes and neurological disorders. Currently, no treatment is available for patients and only medical devices can improve their quality of life. The mutated gene, *WFS1*, encodes an endoplasmic reticulum (ER)-resident glycoprotein, Wolframin. We previously demonstrated that Wolframin regulated Ca^{2+} transfer from the ER to the mitochondria, thus modulating mitochondrial function. In WS condition, WFS1 is not functional and can no longer ensure its essential cellular functions, leading to cell death in different tissues. Zebrafish, which are vertebrate models of disease, have become established tools for drug discovery throughout the organism. The zebrafish genome is duplicated with two, *wfs1a* and *wfs1b*, genes. We developed a zebrafish mutant line by ENU mutagenesis, *wfs1ab*^{KO}, with mutation in both genes to completely invalidate Wolframin's function. The *wfs1ab*^{KO} line was fully characterized at these behavioral and cellular levels. We investigated vision, hearing, locomotion, morphological markers, ER stress factors, glycaemia and mitochondrial function. The *wfs1ab*^{KO} line showed an increased locomotion in visual motor response and in touch escape response, showing visual deficit and/or exacerbated anxiety. Acoustic startle response was unchanged thus suggesting an absence of hearing loss. ER stress response markers were analyzed by qPCR and Western blot. The absence of Wfs1 decreased the expression of *eif2s1* and *chop* in physiological condition but also impacted Tunicamycin-induced ER stress response, as revealed by the interaction between the genotype and tunicamycin treatment for *atf6* and *ire1* genes. Metabolic analysis using the Seahorse analyzer showed an increase in basal and maximal mitochondrial respiration and in ATP production in *wfs1ab*^{KO} larvae compared to controls. Taken together, these data validated the *wfs1ab*^{KO} zebrafish line as a model of WS and confirmed the impact of WFS1 on ER stress and mitochondrial pathways. Our ultimate goal is to use the *wfs1ab*^{KO} line as an efficient screening model to identify small active molecules able to correct or block WS symptoms.

Abstract: *Objectives*: Evidence is accumulating that Alzheimer's disease (AD) and Parkinson's disease, two of the most common neurodegenerative disorders, might share signaling pathways that could account for common pathology and symptomology. We previously described how genetically ablating *SNCA* encoding alpha-synuclein (αSyn) in a mouse model of AD improved survival and spatial memory. Antisense oligonucleotides (ASOs) are a clinically tested method of transiently lowering target gene transcripts. We investigated whether treatment with an ASO targeting murine *SNCA* mRNA improved cognition in mice overexpressing human amyloid precursor protein. *Methods*: Five-month-old male and female mice were injected with ASO^{SNCA} and learning and memory were tested at 6 months using the Barnes circular maze. *Results*: The murine ASO^{SNCA} was successful at lowering both *SNCA* mRNA and protein, and improving cognition in male mice. Female mice, however, displayed impaired memory retention. In addition, constitutive ablation of *SNCA* in female mice also worsened spatial memory. Since mediators of *SNCA* and its abundance might impact responses to ASO^{SNCA} treatment, we used

human samples from the Religious Orders Study to investigate potential sex differences in αSyn protein and its modulators. While confirming that soluble αSyn was increased in male and female AD brains, we also observed sex-specific differences in beta-synuclein (βSyn), an endogenous regulator of αSyn. βSyn was decreased in female AD brains but not in male brains, and cognitive scores for women in the AD group were inversely correlated with βSyn abundance. *Conclusions*: These results highlight a novel sex difference in our understanding of AD pathogenesis and may have profound implications for future translational studies.

Abstract: Alzheimer's Disease (AD) is the most common neurodegenerative disease in humans and is predicted to have an increasing societal impact in coming years. There are currently no pharmaceutical treatments proven to slow the progression of this disease. This emphasizes the need to explore novel drug targets in AD. Our lab identified Agomelatine (AGO) through a high-throughput drug screening algorithm that identifies possible treatments for AD by analyzing off-target effects of pre-existing pharmaceuticals. AGO was selected for its beneficial effect on mitigating neurodegeneration and inflammation both of which contribute to AD progression. AGO, also under the brand name Valdoxan, has been previously used to treat clinical depression.

Its mechanism of action lies in its ability to act as both an agonist for the MT1/MT2 melatonin receptors and an antagonist for the $5HT_{2C}$ serotonin receptor. This synergistic action leads to reduced neurodegeneration, inflammation, and anxiety. Our lab uses a transgenic rat model (TgF344-AD) that develops cognitive deficits and AD pathology, including extracellular amyloid plaques, tauopathy, gliosis, and neuronal loss due to the expression of the mutant human amyloid precursor protein (APPsw) and presenilin 1 (PS1ΔE9) genes. Male and female TgF344-AD and their wild type littermates were included in our studies. Oral treatment with AGO (dose 8-10 mg/kg/day), started at 5 months of age (pre-pathology) and continued for 6 months until the endpoint at 11 months of age. The effect of AGO on cognitive decline was assessed using the hippocampal dependent active place avoidance test performed at 9 and 11 months of age. Transgenic treated rats showed an improvement in learning when comparing 9 month performance to 11 month performance. This suggests AGO treatment is mitigating the cognitive decline we would expect to observe with aging of the animals. Immunohistochemistry and western blot analyses on brain tissue will determine the effect of AGO on amyloid plaques, activated microglia, tauopathy, and inflammation to determine how AGO treatment affects AD pathology. In these studies, we show that AGO rescues cognitive function in the TgF344-AD rat model. Based on our data, we propose that AGO, through its role as both an MT1/MT2 agonist and $5\text{-}HT_{2c}$ antagonist, is a drug that can be repurposed to treat AD.

Title: Effects of histone deacetylase inhibitors on memory and behaviors in app/ps1 mice

Authors: *B. MCCLARTY, H. DONG;
Psychiatry and Behavioral Sci., Northwestern Univ. Feinberg Sch. of Med., Chicago, IL

Abstract: Introduction: It has been demonstrated that histone modifications regulate memory and behavior, and histone deacetylase **(**HDAC) inhibitors display promising beneficial effects in aging and Alzheimer’s disease (AD) models. However, currently there are no studies for cross comparison of pan and selective HDAC inhibitors to evaluate their effects on memory, affective

behaviors and AD-like pathologies in a temporal and spatial manner. **Methods:** In this study, we compared a pan (VPA) and two selective HDAC inhibitors (CI-994, targeting HDAC1, 2 and 3; and MS-275, targeting HDAC1 and 3) in APP/PS1 mice and age matched controls. We administered VPA, CI-994, and MS-275 and vehicle to 12-, and 18-month-old APP/PS1 mice and controls daily for 30 days (IP). Then, executive memory (novel object recognition), short-term working memory (Y maze) and the long-term spatial reference memory (Morris Water Maze (MWM)) tests, anxiety (light/dark box) and depression-like behaviors (tail suspension test) were assessed. **Results:** We found executive memory deficits in 12-month and 18-month-old (both $p<0.0001$) APP/PS1 mice. Chronic treatment of VPA, MS-275 and CI-994 in both 12-month and 18-month-old APP/PS1 mice significantly improved executive memory as compared to age matched controls (both $p<0.0001$). We found working memory deficit in 12-month and 18-month-old APP/PS1 as compared to age matched controls (both $p<0.001$). However, only APP/PS1 at 18-month of age improved working memory by VPA ($p<0.01$), CI-994 ($p<0.0001$), and MS-275 ($p<0.01$). Finally, we found spatial reference memory deficits in both 12-month ($p<0.05$) and 18-month-old ($p<0.001$) APP/PS1 mice. MS-275 ($p<0.001$) and CI-994 ($p<0.01$) could improve this memory at 18-months of age. For affective behaviors, we found 12-month ($p<0.001$) and 18-month-old ($p<0.05$). APP/PS1 mice showed increased anxiety-like behaviors when compared to age matched controls. VPA ($p<0.05$), MS-275 ($p<0.01$), and CI-994 ($p<0.01$) decreased anxiety-like behaviors in 12-month-old APP/PS1 mice, but only MS-275 ($p<0.0001$) and CI-994 ($p<0.001$) decreased anxiety like behaviors in 18-month-old APP/PS1 mice. We did not find depressive-like behaviors and drug effects in APP/PS1 mice at any age we tested.**Conclusions:** Our study indicates that APP/PS1 mice displayed variety of memory deficits in APP/PS1 mice at both 12 and 18 months of age. HDAC inhibitors, especially CI-994 and MS275 could rescue memory deficits in APP/PS1 mice with memory domain specifics and decrease anxiety behavior. Next, we will determine the impact of HDAC inhibitors on AD pathogenesis in APP/PS1 mice.

Abstract: A better understanding of the changes in neural activity that contribute to the prodromal progression and onset of overt symptoms of Alzheimer's disease (AD) is essential to the discovery of effective therapeutics. These experiments explore prodromal neural network dysfunction in the hippocampal trisynaptic circuit by using an orally bioavailable established memory enhancer (α5IA) that acts as a selective negative modulator of extrasynaptic α5GABA-A receptors in TgF344-AD transgenic rats which express human amyloid-beta precursor protein (with the Swedish mutation) and human presenilin-1 (with a Δ exon 9 mutation). The results demonstrate that oral administration α5IA (1.0 mg/kg) increases CA1 pyramidal cell mean firing rates and peak CA1 ripple amplitude during wakeful immobility in wild type F344 rats. By contrast, the ripples of young adult TgF344-AD rats are nonresponsive to α5IA indicating network dysfunction prior to the onset of plague formation but when oligomers have been shown to be elevated in the brain. We also show that TgF344-AD rats, exhibit high serum Aβ42 and Aβ40 levels by 3 months of age. These results demonstrate, to the best of our knowledge, the first evidence for prodromal α5GABA-A receptor dysfunction in the AD hippocampal trisynaptic circuit of this rat model. Moreover, as α5GABA-A receptors are located extrasynaptically and subserve the function of tonic inhibition we posit that an early stage of memory dysfunction involves the disruption of tonic inhibition in the hippocampus.

Abstract: Alzheimer's disease (AD) is a devastating, progressive neurodegenerative disease that causes loss of memory and executive function, and is the leading cause of dementia worldwide. Neuropathologic hallmarks of AD include deposition of amyloid plaques, neurofibrillary tangles (NFTs) and paired helical filaments in the brain. Mutations in the microtubule-associated protein Tau, a component of the NFTs, cause its hyperphosphorylation and aggregation in AD. Here we show that cystathionine γ-lyase (CSE), the biosynthetic enzyme for the gaseous messenger molecule, hydrogen sulfide (H_2S), binds wild type Tau, which enhances its catalytic activity. By contrast, CSE fails to bind Tau P301L, a mutant that is present in the 3xTg-AD mouse model of AD. We further demonstrate that signaling by H_2S is dysregulated in AD. H_2S signals via a posttranslational modification termed sulfhydration/persulfidation, wherein -SH groups of reactive cysteine residues are converted to -SSH groups. Sulfhydration regulates a plethora cellular processes ranging from response to inflammation to cardiovascular function. Using the newly developed dimedone switch assay, we show that sulfhydration is diminished in 3xTg-AD mice as well as in human AD brains. Furthermore, H_2S prevents hyperphosphorylation of Tau by sulfhydrating its kinase, glycogen synthase kinase 3β (GSK3β) and inhibiting its catalytic activity. Finally, we demonstrate that sulfhydration is diminished in AD, while administering the H_2S donor sodium GYY4137 (NaGYY) to 3xTg-AD mice ameliorates motor and cognitive deficits in AD. Aging is a risk for developing AD and we further show that H_2S signaling and sulfhydration is compromised during aging, which leads to impaired stress responses.

Title: Regulation of cholesterol biosynthesis by the ER stress-sensor, PERK, and its implications for neurodegeneration

Authors: *R. VISWANATHAN[1], B. J. STOVEKEN[2], H. GUDLAVALLETI[2], S. T. WEINTRAUB[2], J. D. LECHLEITER[2];
[1]Univ. of Texas Hlth. Sci. Center, San Antonio, San Antonio, TX; [2]UT Hlth. Sci. Ctr., San Antonio, TX

Abstract: Misfolded proteins are a common phenotype of many neurodegenerative diseases including Alzheimer's, frontotemporal dementia, and progressive supranuclear palsy. When misfolded proteins accumulate in the endoplasmic reticulum (ER), the unfolded protein response (UPR) is activated in an attempt to restore cellular homeostasis. Interestingly, the UPR stress-sensor, PERK, is activated in the brains of patients with neurodegenerative tauopathies. However, both positive and negative modulation of PERK activity can be therapeutically beneficial. The specific mechanisms by which PERK signaling contributes to neurodegenerative diseases need to be more clearly defined.
We performed global proteomics to identify pathways that were differentially regulated by PERK knockout (PERK-KO) in mouse embryonic fibroblasts (MEFs) using data-independent acquisition mass spectrometry (DIA-MS). Protein identification and relative quantification were accomplished with Scaffold DIA (Proteome Software). The results for comparisons among experimental groups were submitted to Reactome for pathway analysis. DIA-MS analysis of wild-type and PERK-KO MEFs identified > 5900 proteins. Cholesterol biosynthesis was the top over-represented pathway for proteins with ≥ 1.5x down relative abundance (9 of 26 entities found; entities p, 4.46E-6, entities FDR, 4.89E-3). Of note were lanosterol 14-alpha demethylase (> 4x down) and 24-dehydrocholesterol reductase (DHCR-24)(> 2x down). Cholesterol plays an important role in cellular homeostasis and is an essential component in various metabolic pathways. Its dysregulation has been linked to a variety of diseases, including cardiovascular disease, diabetes, neurodegenerative disorders and cancer. An elevation of the level of cholesterol has been shown to correlate with ER stress and activation of the stress response pathway. However, the relationship between PERK and cholesterol biosynthesis has been under-investigated. Our preliminary data suggest PERK regulates key enzymes in the cholesterol biosynthesis pathway. Experiments are underway to examine the mechanism by which PERK is influencing the cholesterol biosynthesis pathway and how this impacts pathology in a neurodegenerative disease model. Additional cell types to be studied include neurons and astrocytes. This study uncovers an important role for PERK in regulating cholesterol biosynthesis, potentially revealing a mechanistic link to various neurodegenerative diseases.

Title: Loss of aly genes (ALYREF) suppresses toxicity in transgenic Caenorhabditis elegans models of tau or TDP-43

Authors: *R. KOW[1,2], A. H. BLACK[3], A. D. SAXTON[3], N. F. LIACHKO[1,2], B. C. KRAEMER[1,2,2];
[1]GRECC, Veterans Affairs Puget Sound Hlth. Care Syst., Seattle, WA; [2]Med. - Gerontology, Univ. of Washington, Seattle, WA; [3]Seattle Inst. for Biomed. & Clin. Res., Seattle, WA

Abstract: Both the microtubule-associated protein tau and the DNA and RNA binding protein TDP-43 accumulate into toxic aggregates in multiple neurodegenerative diseases such as Alzheimer's disease and frontotemporal dementias. We have used transgenic *Caenorhabditis elegans* models of human tau and TDP-43 toxicity to discover novel genes that modulate their toxicity. These transgenic models have significant locomotor deficits, progressive loss of neurons, shortened lifespan, and accumulation of hyperphosphorylated and insoluble tau or TDP-43 protein. We previously found that the RNA binding protein *sut-2/MSUT2/ZC3H14* is a strong suppressor of tau toxicity in *C. elegans* models as well as mammalian models. To better understand the mechanism in which *sut-2/MSUT2* suppresses tauopathy, we investigated the *aly* genes (3 genes in *C. elegans*), whose mammalian homolog ALYREF has been shown to interact with *MSUT2/ZC3H14* (Morris & Corbett (2018) Nucleic Acids Res 46:6561-6575). Additionally, research in *Drosophila melanogaster* of TDP-43 toxicity showed that loss of the fly homolog *ref1* could suppress TDP-43-induced toxicity (Berson et al (2019) Acta Neuropath Commun 7:65). Therefore we determined whether loss of *aly* genes suppressed tau and/or TDP-43 toxicity in our *C. elegans* models. We found that loss of *aly-1* or *aly-2* alone, but not *aly-3*, caused mild suppression of tau-induced locomotor deficits, while loss of *aly-1* and *aly-3* or *aly-2* and *aly-3* together caused the strongest suppression of locomotor deficits. Loss of *aly*-2 and *aly*-3 reduced total and insoluble tau protein accumulation as well as neuron loss with age in tau transgenic *C. elegans*. This was not due to a reduction in tau mRNA levels; in contrast, tau mRNA levels appeared to be increased with loss of *aly-2* and *aly-3.* In TDP-43 transgenic *C. elegans*, loss of *aly-2* and *aly-3* also suppressed behavioral deficits induced by TDP-43 but did not significantly alter total TDP-43 or phosphorylated TDP-43 protein levels. The results here

suggest that although the *aly* genes modulate both tau and TDP-43-induced toxicity, they do so via different mechanisms.

Title: MAPT mutations induce dysregulation of the cholesterol biosynthesis pathway in human forebrain organoids

Authors: *S. M. K. GLASAUER[1], S. K. GODERIE[2], J. N. RAUCH[3,1], E. GUZMAN[1], M. AUDOUARD[1], T. BERTUCCI[2], S. JOY[2], E. ROMMELFANGER[1], G. LUNA[1], S. LOTZ[2], S. BORDEN[2], K. ONANUGA[2], S. TEMPLE[2], K. S. KOSIK[1];
[1]Neurosci. Res. Inst., Univ. of California Santa Barbara, Santa Barbara, CA; [2]Neural Stem Cell Inst., Rensselaer, NY; [3]Dept. of Biochem. and Mol. Biol., Univ. of Massachusetts Amherst, Amherst, MA

Abstract: Mutations in the MAPT gene, encoding tau, are well-known genetic causes of neurodegenerative diseases including Frontotemporal Dementia. However, the molecular and cellular mechanisms of MAPT mutations leading to disease are poorly understood. Brain organoids generated from patient-derived pluripotent stem cells carrying MAPT mutations offer a novel tool to track the earliest effects of MAPT mutations in a complex cellular context, including cortical pyramidal neurons and astrocytes among other cell types found in the human brain. Forebrain organoids from induced pluripotent stem cells of five different heterozygous carriers of MAPT mutations (R406W mutation: 2 individuals, V337M mutation: 3 individuals) were generated and assayed using droplet-based single-cell RNA sequencing at various timepoints during their maturation (2, 3, 4 and 6 months of age). CRISPR-corrected isogenic lines served as controls. In organoids that carry the V337M and R406W mutations, the

cholesterol biosynthetic pathway in astrocytes was the top upregulated gene set compared to isogenic controls. The 15 upregulated genes involved in cholesterol metabolism included HMGCS1, encoding the rate-limiting step for cholesterol biosynthesis, ACAT2, converting cholesterol to its storage form cholesteryl esters, and SREBF2, a master transcriptional regulator of cholesterol biosynthesis genes. Organoids generated from a homozygous R406W mutant cell line similarly showed upregulation of the cholesterol biosynthesis pathway. Furthermore, this result was confirmed by immunohistochemistry of the organoids, and by loading tau protein into primary astrocytes. Our study is the first to link MAPT mutations to altered cholesterol metabolism. Cholesterol homeostasis in the brain is tightly regulated by efflux and levels of cholesterol biosynthetic enzymes. Furthermore, cholesteryl esters can increase tau phosphorylation. Our findings thus suggest that cholesterol dyshomeostasis is an early event in the etiology of neurodegeneration caused by tau mutations.

Title: Nucleocytoplasmic Transport and Nuclear Pore Disruption in Tauopathies

Authors: J. CHEW[1], ***L. RUAN**[1], C. COOK[2], L. PETRUCELLI[2], J. D. ROTHSTEIN[3]; [1]Johns Hopkins Med. Institutions, Baltimore, MD; [2]Mayo Clin., Jacksonville, FL; [3]Brain Sci. Inst., Johns Hopkins Univ., Baltimore, MD

Abstract: As human life expectancy continues to increase, the two most common dementias, Alzheimer's Disease (AD) and Frontotemporal Dementia (FTD), are becoming more prevalent with no cure and no effective medicine or significantly alter disease progression. When compared to to intercellular amyloid plaques, intraneuronal accumulations of neurofibrillary tangles constituted by insoluble, filamentous, hyperphosphorylated Tau is better correlated with neuronal loss and the clinical progression of AD. In addition, the burden of Tau aggregation is also positively associated with the progression of Frontotemporal lobar degeneration (FTLD), the pathologic diagnosis for clinical FTD. However, it remains unclear how Tau accumulation contributes to the devastating neuronal dysfunction and/or death characteristic of these disorders.

Therefore, understanding the cellular mechanisms underlying Tau-mediated neuronal toxicity during aging may provide much needed therapeutic targets. Our previous studies discovered that hyperphosphorylated Tau interacts with nucleoporins and disrupts the nuclear pore complex (NPC) (Neuron, 2018). The pathological accumulation of Tau in mice and human patients impedes nuclear transport and may disrupt the NPC. Furthermore, our studies in Amyotrophic Lateral Sclerosis (ALS) have suggested that rescuing the NPC injuries prevents various defects in human disease models. Here, we sought to determine the cellular and molecular mechanisms underlying Tau mediated nuclear pore injuries in AD and FTD-Tau. We found that nucleoporin 210 (NUP210) mislocalized to cytosol in both AD patients and the PS19 mouse model. In addition, we provide evidence suggesting that FG-repeat containing nucleoporin NUP62 directly interacts with pTau both *in vivo* and *in vitro*, whereas other nucleoporins such as NUP50, NUP54 and POM121 were not affected. Currently, we are evaluating if reducing levels of NUP210 or NUP62 in rodent disease models and induced pluripotent cell lines would reduce/delay pTau accumulation. Moreover, we will determine how loss of NUP210 and NUP62 from NPC in tauopathies specifically affect nuclear transport of protein and RNA. Eventually, we will develop mechanism-based therapy to rescue NPC defects, in order to ameliorate neuronal injury in tauopathies.

Abstract: A small molecule Hyperphosphorylated tau inhibitor probing for Possible Therapeutic development in Alzheimer Disease and Tauopathies Jangampalli Adi Pradeepkiran[1], Arubala P Reddy[2], P. Hemachandra Reddy[1,3,4,5,61]Department of Internal Medicine,[2]Nutritional Sciences

Department,[3]Department of Pharmacology and Neuroscience, [4]Department of Neurology, [5]Department of Public Health, Graduate School of Biomedical Sciences, [6]Department of Speech, Language, and Hearing Sciences, TTUHSC, Lubbock, TX 79430, USA**Abstract**The purpose of our study is to understand the protective effects of small molecule ligands for phosphorylated tau (p-tau) in Alzheimer's disease progression. Many reports evidenced that phosphorylated tau (p-tau) is reported to be an important contributor to the paired helical filaments (PHFs) and neurofibrillary tangles (NFTs) formation in Alzheimer Disease (AD).**Methods:** In the present study, we rationally selected and validated small molecules (ligands) for p-tau that binds to the phosphorylated tau at SER23 (Ser 285) responsible for GSK3β, CDK5 and TYR44 (Y310) DYRK1A, which cause phosphorylated kinase upregulation in AD. In our present study, we assessed the molecular dynamics, and validated molecular dockings for the three best ligands. Based on docking scores -8.09, -7.9 and -7.8kcal/mol, we found that ligand 1 binds to the key hyperphosphorylation residues of p-tau and predicts to inhibit abnormal PHF-tau, DYRK1A, and GKS3β that reduce p-tau levels in AD. Using biochemical, molecular, immunoblotting and immunofluorescence transmission electron microscopy, analyses, we studied the p-tau ligand inhibition and mitochondrial protective effects against mutant tau induced synaptic and mitochondrial toxicities in hippocampal neuronal (HT22) cells. **Results:** We found interaction between NAT10-262501 (ligand 1) and p-tau at key phosphorylation sites and these ligand-based inhibition decreased PHF-tau, DYRK1A, and GSK3β levels. We also found increased mitochondrial biogenesis, mitochondrial fusion and synaptic activity and reduced mitochondrial fission in ligand 1-treated mutant tau HT22 cells.**Conclusions:** Based on these results, we cautiously conclude that p-tau NAT10-262501 (ligand 1) reduces hyperphosphorylation of p-tau based CDK5 and GKS3β kinase regulation in AD, and helps to maintains neuronal structure, mitochondrial dynamics and biogenesis with a therapeutic function in AD.***Key words*:** Hyperphosphorylated tau, small molecules, PHF-tau, Alzheimer Disease.

Title: Exploring mechanisms for xbp-1s-mediated suppression of tauopathy in C. elegans

Authors: S. M. WALDHERR[1], ***M. HAN**[2], A. SAXTON[1], M. BAUM[1], T. STROVAS[1], P. MCMILLAN[1], J. WHEELER[1], B. KRAEMER[1];

[1]Geriatrics Res. Educ. and Clin. Center, Veterans Affairs Puget Sound Hlth. Care Syst., Seattle, WA; [2]Univ. of Washington Grad. Program In Neurosci., Seattle, WA

Abstract: Protein homeostasis (proteostasis) is required for neuronal function over the lifespan. Disrupted proteostatic mechanisms, such as the unfolded protein response (UPR), are associated with protein aggregation and neurodegeneration. The UPR contains three branches: PERK, IRE1, and ATF6. Collectively, they regulate translational capacity and ER-associated degradation in response to ER stress. Previous work has shown that XBP-1s, a transcription factor downstream of IRE1, mediates suppression of disease phenotype in a *C. elegans* model of human tauopathy through a mechanism requiring ATF6. To identify the molecular mechanisms of this phenotypic rescue, we conducted a transcriptomic analysis of *xbp-1s* gain-of-function versus non-transgenic *C. elegans*. We found five upregulated human gene homologs that are also associated with ATF6: *csp-1*, *dnj-28*, *hsp-4*, *ckb-2*, and *lipl-3*. CSP-1, DNJ-28, HSP-4, and LIPL-3 loss of function abolished *xbp-1s*-mediated rescue of tauopathy phenotype, proving they are necessary for *xbp-1s*-mediated tauopathy suppression. Further, *xbp-1s*-mediated reduction of tau accumulation requires functional *hsp-4*, a *C. elegans* homolog of BiP. Also, *hsp-4/BiP* loss of function exacerbates behavioral phenotype of a low-expressing tauopathy model, while *dnj-28* loss of function does not. Interestingly, low level neuronal expression of *hsp-4/BiP* can mildly suppress tauopathy behavioral phenotype without *xbp-1s* overexpression, but high level neuronal overexpression of *hsp-4/BiP* is not well tolerated. While investigation of other *xbp-1s* target genes is still in progress, we have thus far presented a novel mechanism of *xbp-1s*-mediated suppression of tauopathy involving *hsp-4/BiP*. Understanding the molecular mechanisms responsible for UPR-mediated changes in tauopathy can inform mammalian studies and eventually lead to more precisely targeted treatments for neurodegenerative disease.

Title: Role of alpha-synuclein and caspase-2 mediated cleavage of tau in LTD

Authors: *Z. CRABTREE[1], K. ASHE[2];
[1]Univ. Of Minnesota Undergraduate Program In Neurosci., Minneapolis, MN; [2]Univ. of Minnesota - Twin Cities, Minneapolis, MN

Abstract: The neurons of patients with Lewy body Diseases (LBD) often contain high levels of misfolded tau protein and α-synuclein, and many patients develop dementia. Caspase-2 is a cysteine-aspartic protease that has been shown to mediate long-term depression (LTD), a form of synaptic plasticity characterized by the internalization of AMPA receptors, which leads to synaptic weakening that is believed to underlie forgetting. Recently, we found that in mice, caspase-2 cleaves tau at aspartate 303, and this process mediates LTD (unpublished data). The A53T α-synuclein variant linked to familial Parkinson's disease increases the internalization of AMPA receptors in a tau-dependent manner, but the role of caspase-2 and the effect of this process on LTD are unknown. Here, we provide evidence to test the hypothesis that in LBD caspase-2 cleavage of tau leads to excessive synaptic weakening. We measured LTD in hippocampal slices from transgenic mice expressing A53T α-synuclein and non-transgenic littermates in which mouse tau was wild-type or mutated (aspartate-303-glutamate) to render tau resistant to caspase-2 cleavage. Our preliminary data indicate that in mice with wild-type tau, A53T α-synuclein is associated with enhanced LTD, supporting our hypothesis that there is excessive synaptic weakening in LBD. We are obtaining LTD measurements in mice with caspase-2 resistant tau to determine if this enhanced LTD depends on caspase-2 cleavage of tau.

Title: Activity- and Phosphorylation-dependent Release of Endogenous Tau from Human Neural Progenitor Cell line ReNCell VM

Authors: G. SINDI[1], R. A. COLVIN[2], ***D. LEE**[1];
[2]Dept Biol. Sci., [1]Ohio Univ., Athens, OH

Abstract: A key pathological hallmark of Alzheimer's disease (AD) and related dementia is the formation of neurofibrillary tangles (NTFs), which are aggregates of hyper-phosphorylated tau. Tau is a microtubule-associated protein but, if hyper-phosphorylated, it becomes pathogenic causing tauopathies including AD. Tau is an intracellular protein but also known to be released to the extracellular fluid. Released tau can have both physiological and pathological roles in the nervous system, but its release mechanism remains to be further explored. Tau undergoes several posttranslational modifications and phosphorylation is the most commonly observed. Phosphorylation of specific tau phosphorylation sites (pSites) is important for its association with

microtubules and normal function, but its hyper-phosphorylation is a common feature of tauopathies. Tau phosphorylation is also known to increase its release from neurons. Several studies have shown that tau release can be activity-dependent. Interestingly, disruption of neuronal activity is involved in AD pathogenesis. Therefore, the impact of activity- and phosphorylation-dependent release of tau on tauopathy is of significant interest as disruption of neuronal and synaptic activity is involved in AD pathogenesis. In this study, we developed an in vitro model to study activity-dependent tau release using immortalized human *ReNCell VM* line, which was derived from the fetal mid-brain and recently used to study pathological mechanisms underlying AD. *ReNCell VM* line was differentiated into neurons for 14 days in vitro to study activity-dependent tau release. Our results showed that differentiated human neurons express tau, which can be released by KCl-induced depolarization (50mM for 1 hr). We are currently studying how tau phosphorylation contributes to its activity-dependent release. Since a protein kinase GSK-3β is known to phosphorylate multiple tau pSites, we used a selective GSK-3β inhibitor SB216763 (10μM, 2 hrs). Our results showed that SB216763 decreased activity-dependent tau release compared to untreated neurons. Lastly, a selected group of pSite-specific tau antibodies (e.g., AT8) has been used to examine the phosphorylation profiles of extracellular tau released by neuronal stimulation. We found that released tau is phosphorylated at multiple pSites in proline-rich domain and C-terminal. Taken together, *ReNCell VM* showed activity- and phosphorylation-dependent release of endogenous tau and thus can be used to study the mechanism underlying activity-dependent tau release and its propagation in AD.

Abstract: Tau aggregates are critical pathological features of Alzheimer's disease (AD) and other tauopathies. An important focus of research has been to understand the pathological tau propagation in AD patient brains that follow neuronal networks. Despite the knowledge acquired, the cellular mechanism involved in tau propagation and seeding are still unclear. Unfortunately, the nature of the tau species involved in the spreading and the precise seeding/template remains unknown. Despite this uncertainty, some studies suggest that a high molecular weight tau (HMW-tau) is the form of tau involved in trans-synaptic propagation. It remains unresolved whether these HMW-tau particles are made exclusively of tau or contain other constituents such as proteins necessary for propagation. Here, by using a 3-months old PS19 mouse model harboring the human tau^{P301S}, we developed a strategy to identify proteins that interact with tau in PS19 mice, as well as in human AD and PSP cases. TBS-soluble brain extracts were passed through a Size Exclusion Chromatography (SEC) column. We then measured the tau seeding activity of each SEC-fraction using a well-described bio sensor cell line that relies on flow cytometry detection of FRET signal. We determined that tau from fraction-9 (F9) forms an HMW-tau complex *in vivo* (>2,000KDa) with the strongest seeding activity. Interestingly, the tau present in F9 is less than 4.4% of the total tau in the brain of PS19 mice and adopt a protofibrillar morphology. To identify other constituents or interactors of this tau- seed, we IP human tau using the HT7 antibody from fraction-9 and subjected it to TMT-tag quantitative Mass Spectrometry. Through quantitative Mass Spectrometry, we were able to identify the protein-interactome of the tau- seed and the interactome of monomeric tau isolated from the same brains. Bioinformatics from both interactomes revealed an enrichment of a specific set of proteins in the tau-seed in comparison with monomeric tau. To further analyze the HMW tau-seed interactome, we developed a strategy using SEC and the biosensor cell line to detect seeding activity in a *Drosophila* model of tauopathy, that will allow us to screen critical interactors that confer the tau seeding ability and spreading.

Abstract: Obesity rates have nearly tripled in the past 45 years affecting globally close to 2 billion adults which are either overweight or obese1, cocurrently, the worldwide prevalence of dementia has also tripled in that same span2. One of the mechanisms that is thought to play a major role in obesity induced cognitive decline is the consumption of a High Fat Diet (HFD). HFD has been shown to activate neuroinflammation, which can result in neuronal injury3, and can lead to a decline in cognitive performance5,9-11. Neuroinflammation has been shown to be a common denominator of many neurodegenerative and neuropsychiatric disorders8. Diet induced neuroinflammation, is mediated by activation of the CNS resident immune cells, the microglia3-7. Recently an important role for the alfa-7-nicotinic acetylcholine receptor (α7-nAChR) has been found in the control of both systemic13,14 and CNS inflammation15-17. This receptor is a

key component of the cholinergic anti-inflammatory response which is a neural system that controls both systemic and neuroinflammation. To study the therapeutic potential of the α7-nAChR for diet induced neuroinflammation we used the allosteric modulator PNU-120596. Mice were fed either a control or a HFD and their cognitive performance was characterized using the novel location recognition test. Furthermore, the activation of neuroinflammation was also studied using western blot and ELISA. Our data indicate that mice that received PNU-120596 had no significant difference to control groups that received either the control or the HFD alone. However, both western blot and ELISA analysis shows that PNU was able to prevent the inflammatory changes that result from the HFD. So far, we can conclude that PNU is effective at reducing the inflammatory response to an HFD, however we could not observe cognitive effects of this diet under our experimental conditions.

Title: Minimal detection of microglia-derived extracellular vesicles in different in vivo pathological models in the CNS

Authors: *X. CHEN[1], S. JIN[3], J. DUNNELL[4], Y. YANG[2];
[2]Neurosci., [1]Tufts Univ. Sch. of Med., Boston, MA; [3]Neurosci., Tufts Univ. school of medicine, Boston, MA; [4]Tufts university, Boston, MA

Abstract: Microglia are resident immune cells responsible for surveying the parenchyma and clearing debris/invaded pathogens in the CNS. Activated microglia contribute to elevated neuroinflammation and subsequent disease pathology. In recent years, microglia-derived extracellular vesicles (EV) and especially exosomes (size 50-200 nm) that are either shed from plasma membrane or originated from multi-vesicular body (MVB), have been implicated to propagate disease-causing protein formed aggregates, potentially contributing to disease progression. Currently, most if not all studies employ culture models and ultracentrifugation technique to isolate microglia-derived EVs which have been shown to be often associated with

secreted proteins. In the present study, by employing size-exclusion chromatography (SEC), we first purified microglia-derived exosomes from primary cultured wild type (WT) and SOD1G93A microglia. Immunoblotting of exosome markers shows that SEC-based purification is able to clearly separate exosomes from microglia-secreted proteins. To examine how immunoactivated microglia may alter their EVs secretion and property, both WT and SOD1G93A^{+} microglia were treated with LPS, which found selectively increased release of CD63^{+} exosomes from WT but not SOD1G93A^{+} microglia based on fluorescence Nanoparticle tracking analysis (fNTA). Although microglia-derived EVs have been implicated in propagating protein aggregates, it has not been directly characterized in vivo. To further characterize microglia-derived EVs in vivo, we bred our recently generated cell-type specific exosome reporter CD63-GFP$^{f/f}$ mice with Cx3cr1-CreER^{+} mice to selectively label microglia-derived EVs/exosomes following 4-OHT injections. Surprisingly, we observed vast majority (>95%) of induced CD63-GFP puncta signals inside Iba^{+} microglia with only sparse extracellularly localized CD63-GFP signals. Subsequent LPS injections (i.p.) have no effect in stimulating extracellular localization of microglia-derived CD63-GFP^{+} puncta signals even microglia have become highly activated. We further generated Cx3cr1-CreER^{+}CD63-GFP$^{f/+}$SOD1G93A^{+} mice to examine the extracellular localization of microglia-derived EVs in ALS model. Consistently, we observed minimally extracellularly localized microglia-derived EVs. Taken together, although cultured microglia secrete typical EVs/exosomes, microglia-derived EVs are only minimally observed in the exosome-reporter model in different physiological and pathological conditions. Our study calls for the need for further characterization of microglia derived EVs in vivo in the CNS.

Biology, Physiol. and Immunol., Fac. of Biology, Univ. of Barcelona, Barcelona, Spain

Abstract: Neuroinflammation has shown to play a key role in the development of neurodegenerative disorders, specifically in cognitive decline. For this reason, the inhibition of this process could represent a potential therapeutic target for these diseases. Recently, Licochalcone-A (LCA), a chalcone extracted from the root of *Glycyrrhiza glabra,* has shown multiple therapeutical properties including anti-inflammatory effect. This highlights its potential preventive effect reducing the inflammation responsible of cognitive dysfunction. However, the biological mechanism underlying the relationship between LCA and cognitive decline is still unknown. At the same time that no effective treatment able to stop the neurodegeneration has been found to date. Therefore, the aim of the present study is focused on analysing the role of inflammation in cognition and the potential preventive effect of LCA in C57BL6 mice treated with Lipopolysaccharide (LPS), a neuroinflammation mice model. To perform this study, six-week-old male mice were intraperitoneally treated with LCA at a dose of 15 mg/kg/day 3 times per week for two weeks. The last day of treatment the subjects received a final injection of 1 mg/kg of LPS, 24 hours before sacrifice. Therefore, mice were divided into 4 different experimental groups, classified in mice treated with saline or LCA and receiving or not the last LPS injection. Before sacrifice, short term memory and depression were evaluated by Novel Object Recognition test and Forced Swimming test, respectively. Afterwards, the expression of mRNA and protein levels of molecules related to inflammation, cognitive decline and dendritic spine analysis among others, were analysed in hippocampus. Our results corroborated that LPS administration induced neuroinflammation, which was effectively prevented by LCA treatment. Moreover, mice pre-treated with LCA also showed a significant improvement of memory decline and depression state in comparison to those only exposed to LPS. In agreement, LPS administration demonstrated a significant decrease in the number of dendritic spines which was ameliorated with LCA pre-treatment, in accordance with the results obtained in other analysed biomarkers. In conclusion, our results demonstrated that preventive treatment with LCA confers neuroprotection against pathological mechanisms induced by LPS, placing LCA as a potential preventive treatment for neuropathological diseases where neuroinflammation plays a key role.

Sch. of Med., New York, NY; [7]Otolaryngology, NYU Med., New York, NY; [8]Howard Hughes Med. Inst., Chevy Chase, MD

Abstract: The increase of lipopolysaccharide (LPS) concentration in the brain leads to neuroinflammation, a major determinant for cognitive impairment in many neurodegenerative diseases (Ransohoff, 2016; Zhao, 2019). Levels of LPS in the gut flora can be correlated with LPS levels in the central nervous system in patients with schizophrenia, Parkinson's disease, and Alzheimer's disease (Bhattacharyya, 2020). Here we studied the effects of systemic LPS injection (e.g., to mimic intestinal infection) on behavior.We first asked if and how much LPS would enter the central nervous systems after systemic injection. We used LPS conjugated to a far-red emitting dye (Cy5.5) and imaged LPS trafficking from the gut to the nervous system in live C57Bl6, albino, and nude adult mice. To optimize imaging from the abdominal region, mice were fed a diet without chlorophyll to decrease autofluorescence. After clearing autofluorescence, mice were injected with an LPS-Cy5.5 (N=5) or saline (N=5). In the periphery, we found that the LPS localized in the spleen, kidney, and colon. We also found that conjugated LPS could pass the blood-brain barrier and accumulate in the hippocampus.We then asked how LPS injection affected the overall behavioral profiles of isolated and socially-housed mice, using a system we developed for continuous 24/7 behavioral monitoring and neural recording (Carcea et al., 2021). Mice demonstrated a range of sickness behaviors (Hart, 1988), including reductions in arousal level, less time spent foraging, and significant time spent hunched over. Continuous recordings of videos for 24 hours pre-injection and over 72 hours post-injection were scored for LPS-injected socially-housed mice in which one of the two animals was injected (N=5), compared to saline-injected socially-housed controls (N=3), LPS-injected singly-housed mice (N=6), and saline-injected singly-housed mice (N=3). We found that co-housing an infected mouse with a healthy conspecific reduced mortality and shortened the duration of expressed sickness behaviors. Thus LPS might enter the brain to directly impact neural processing and behavior, interacting with internal state factors that might be positively regulated by social buffering or social interactions.

Title: A Magnetic Resonance Imaging Study of Prenatal Zika Virus Infection Using a Novel Rat Adapted Zika Virus

Authors: *E. LEMANSKI[1], J. MELCHOIRRE[1], M. PARCELLS[2], J. M. SCHWARZ[1];
[1]Psychological and Brain Sci., [2]Animal and Food Sci., Univ. of Delaware, Newark, DE

Abstract: Zika Virus (ZIKV) is a flavivirus that, in cases of in utero fetal infection, is known to cause microcephaly and other neurological and developmental disorders. Like humans, rats exhibit immunosuppression during pregnancy which allows the Zika Virus to infect fetuses in utero. Building on our previously developed model of prenatal ZIKV infection, we are currently using a novel rat-adapted virus that has been passaged on rat cochlear microglial cells (Mocha). This virus is expected to produce a stronger infection in rats than a human-derived virus and will possibly be more neuro invasive. Pregnant rats were infected at gestational day 18 as previously established by our model. They were inoculated either with the virus, a diluent control, a UV-inactivated virus (iZIKV), or a non-neutralizing antibody combined with the virus. This antibody was included to increase infection in vivo through antibody-dependent enhancement (ADE). This process can drive entry of the virus into cells that express an Fc receptor. Fc receptors are expressed on immune cells and are involved in antibody recognition. Nonpregnant female rats were also inoculated with diluent, iZIKV, ZIKV, or antibody+ZIKV. Febrile response was measured for seven days post-injection. This was to replicate prior results in which non pregnant rats exhibited an increase in temperature following ZIKV inoculation that pregnant females did not. This is likely due to the natural immunosuppression in pregnancy. These results will also allow us to identify the timeline of infection in the adult animals. Pups were born to pregnant females at five days post-injection. At postnatal day 2 (P2), one male and one female were selected from each litter for ex-vivo structural magnetic resonance imaging (MRI). Regions associated with cognitive and motor deficits common in prenatal ZIKV infection were chosen for assessment. Cortex, hippocampus, and cerebellum will be segmented and volume relative to overall brain size will be compared. Animals exposed to either ZIKV or antibody+ZIKV are expected to have overall decreased brain volume as well as possible decreased relative volume of these regions. These findings will validate our model as etiologically relevant for ZIKV induced microcephaly and will allow us to identify which brain areas are more affected by the virus. In

the future, we plan on using immunohistochemistry to validate any observed volumetric differences as well as quantify amount of apoptosis in the cortex and hippocampus.

Title: Macrophage-specific expression of 18 kDa translocator protein (TSPO) regulates acute neurological outcomes in a mouse model of intracerebral hemorrhage

Authors: *S. SUKUMARI RAMESH, F. BONSACK, R. DASARI, A. THOMAS;
Augusta Univ., Augusta, GA

Abstract: Spontaneous intracerebral hemorrhage (ICH) is a stroke subtype with devastatingly high morbidity and mortality rates. ICH has complex pathophysiology and as there are no effective treatments for ICH, it is imperative to identify molecular targets for therapeutic intervention. Employing an in-vitro approach, previous studies from our laboratory demonstrated that TSPO could regulate inflammatory brain response after ICH. Moreover, ICH resulted in profound induction of TSPO in brain-infiltrating macrophages and microglia, the cells that contribute to neuroinflammation. However, despite the prevalence of TSPO in neuroinflammatory response, the precise functional role of TSPO remains largely enigmatic. To investigate the role of TSPO in macrophages, we developed a novel animal model, macrophage-specific conditional knock out (TSPOfl/fl: LysMCre), using Cre-Lox technology. TSPOfl/fl: LysMCre mice exhibited augmented neurological deficits and neurodegeneration as opposed to TSPOfl/fl mice, the experimental control, at 3 days post-ICH. Furthermore, TSPOfl/fl: LysMCre mice demonstrated enhanced hematoma volume measured using susceptibility-weighted magnetic resonance imaging and hemoglobin assay compared to control. Also, TSPOfl/fl: LysMCre mice exhibited increased brain expression of proinflammatory cytokine IL-1β in comparison to TSPOfl/fl mice at 3 days post-ICH. Altogether, the data implicate that macrophage-specific expression of TSPO after ICH could be an intrinsic mechanism to regulate exacerbated brain damage, warranting further investigation.

Title: Neuronal stress induces inflammasome mediated microglial reactivity in a model of c9orf72 FTD/ALS

Authors: *K. TRAGESER[1], C. SMITH[1], U. H. IQBAL[2], U. RAVAL[3], G. M. PASINETTI[4]; [1]Icahn Sch. of Med. At Mount Sinai, North Salem, NY; [2]Ichan Sch. of Med. At Mount Sinai, New York, NY; [4]Dept. of Neurol., [3]Icahn Sch. of Med. at Mount Sinai, New York, NY

Abstract: Background: Frontotemporal dementia and amyotrophic lateral sclerosis (FTD/ALS) are most commonly caused by G_4C_2 repeat expansions in the promoter region of the *c9orf72* gene. Produced from these expansions, dipeptide repeat proteins (DPR) have multiple negative effects on cellular homeostasis, producing neuroinflammation and cellular death. Arginine containing aggregates are amongst the most toxic, and Glycine-Arginine (GR) are significantly present in brain regions associated with FTD/ALS. Here, we identify a mechanism by which neuronal stress induced by the C9orf72 DPR, GR, can induce an inflammasome mediated reaction in microglia. Targeting this mechanism provides significant protection from musculoskeletal impairment, cognitive function, and death *in vivo*.**Methods:** Intracerebroventricular injection with either AAV9-GFP or AAV9-GFP$(GR)_{100}$ was performed on postnatal day 0 wild-type C57BL6/J and *Nlrp3* deficient (*Nlrp3*$^{-/-}$). At 14 weeks, animals were tested for motor function and memory, and were humanely euthanized for tissue collection. Microglia density and activation were measured by immunofluorescence and 3D reconstruction of Iba1 immunopositive cells. qPCR for CXCL10, a regulator of chemotaxis and inducer of proinflammatory phenotypes of microglia, was performed on cortical tissue. Next, primary neurons were transfected with GFP-$(GR)_{100}$ and CXCL10 was measured via ELISA. Primary microglia were next incubated with concentrations of CXCL10, and the resultant production of IL-1β was measured via ELISA.**Results:** Wild-type GFP-$(GR)_{100}$ mice display significant motor impairment, contextual memory deficits, and eventually significant mortality. Microgliosis and activation of microglia was present in the cortex, along with an increase in cleaved caspase-1 and IL-1β. CXCL10 was found to be highly upregulated in the cortex in GFP-$(GR)_{100}$. Genetic ablation of *Nlrp3* provided significant protection to motor impairment, contextual memory deficits, and mitigated mortality seen in wild type GFP-$(GR)_{100}$, coinciding with protection of the

cleavage of caspase-1. *In vitro*, primary neurons transfected with GFP-$(GR)_{100}$ significantly produced CXCL10 compared to GFP controls. Primary microglia incubated with CXCL10 exhibited a significant production of IL-1β.**Conclusions:** Neurons in C9orf72 FTD/ALS can induce inflammasome activation in microglia. Targeting these responses provides significant phenotypic protection, including the protection of muscle function, cognitive function, and mortality. These data implicate this neuronal-microglial crosstalk mechanism as a novel target for the treatment of FTD/ALS.

Abstract: Multiple sclerosis (MS) is an inflammatory demyelinating disease that results in the disruption of neuronal transmission and ultimately neurodegeneration. Current treatments focus on suppressing the immune system to limit inflammation and the further loss of the myelin sheath. The next advance in the treatment of MS has focused on molecules that regulate remyelination. Lysophosphatidic acid (LPA) is a naturally occurring inflammatory lipid and its dysregulation has been implicated in inflammatory diseases, such as MS. Recent studies have shown that MS patients have elevated levels of LPA in serum and in the cerebrospinal fluid. Furthermore, LPA was observed to significantly increase in patients during disease flares compared to periods of remission. We believe this elevation drives local inflammation and limits remyelination through activation of LPA1 receptors located on oligodendrocyte precursor cells (OPCs). In early validation studies we first showed that an LPA1 antagonist, AM152 (BMS-986020) produced robust effects in OPCs driving them towards differentiation and expression of myelin basic protein. Based on these results we initiated a medicinal chemistry effort to discover a novel brain penetrant LPA1 antagonist. These efforts led to the identification of OPC2791. Significantly, this compound produced robust effects in a diverse set of in vitro assays, including OPC differentiation, cortical myelination, and organotypic brain slice. These data suggest that LPA1 receptor antagonists show promise as inducers of oligodendrocyte differentiation and maturation.

Abstract: Parkinson's disease (PD) is a progressive and incurable neurodegenerative disease and the deep brain stimulation (DBS) of the subthalamic nucleus (STN) is currently the gold-standard *symptomatic* treatment for patients with levodopa therapy-induced complications. However, even though the efficiency of DBS is well recognized, to this date, it is not clear how the treatment with subthalamic stimulation modulates the debilitated dopaminergic system in PD. Hence, the aim of this study was to investigate the effect of STN-DBS on the striatal dopaminergic system in a rodent model of PD. For this, male Wistar rats were injected with 6-hydroxydopamine (6-OHDA) neurotoxin, implanted or not with plastic guidance cannula in the left striatum and stainless-steel electrodes in the left STN. Seven days after the surgery, the nigrostriatal lesion was validated by apomorphine-induced rotational behavior. Six-OHDA+DBS ON animals were stimulated 2 hours a day for 5 days (130 Hz, 60 µs, 0.1 mA). Saline, 6-OHDA and 6-OHDA+DBS OFF animals were used as control. After the last stimulation, animals were reevaluated in apomorphine-induced rotation and evaluated in the immobility test. Fresh and fixed striatum were collected 13 days after the surgical procedures. For microdialysis assay, samples of intracerebral extracellular fluid were collected before, during, and after the 1st and 5th DBS session, or 8 and 12 days after the surgical procedures in the control animals. We confirmed our PD model by decreased expression of tyrosine hydroxylase (TH) in the substantia

nigra. The nigrostriatal lesion also induced motor deficits, decreasing of TH labeling, and increasing D2R expression in the striatum. STN-DBS treatment reversed the motor deficit and reduced the dopamine concentration during and especially after the first and last stimulation. Furthermore, STN-DBS treatment inhibited the DR2 overexpression without interfering with DR1 levels. Our results suggest, so far, that STN-DBS treatment induces a modulation in the dopaminergic circuitry mediated principally by indirect striatal pathway, without induces a neuroprotective effect of the remaining dopaminergic neurons.

Title: β-funaltrexamine modulates lipopolysaccharide-induced inflammation and sickness behavior in male c57bl/6j mice

Authors: *S. MYERS, D. BUCK, K. MCCRACKEN, J. T. CURTIS, R. L. DAVIS;
OSU-CHS, Tulsa, OK

Abstract: Neurological disorders often involve inflammation in the brain, as well as in the periphery. Considering treatment options, many of the medications available do not have potent anti-inflammatory properties. Consequently, identification of novel therapeutic options for such disorders is crucial. We previously discovered that a selective mu-opioid receptor (MOR) antagonist, beta-funaltrexamine (β-FNA), inhibited inflammatory signaling *in vitro* in human astroglial cells. Interestingly, the anti-inflammatory properties of β-FNA do not seem to involve actions at the MOR. In a preclinical model, β-FNA was also found to inhibit lipopolysaccharide (LPS)-induced sickness behavior and neuroinflammation in mice when administered immediately post-LPS. In the present study, we explore the extent to which β-FNA is protective when treatment occurs 4 hours after LPS administration. Male C57BL/6J mice were administered LPS (0.83 mg/kg, i.p.) followed by treatment with β-FNA (50 mg/kg, i.p.) immediately or 4h post-LPS, depending on the experiment. Sickness behavior was assessed using a 10-min open-field test, followed by collection of the brain, spleen, and plasma. Levels of inflammatory chemokines/cytokines (interferon γ-induced protein, CXCL10; monocyte chemotactic protein 1, CCL2; and interleukin-6, IL-6) in tissues were measured using an

enzyme-linked immunosorbent assay. β-FNA treatment immediately after LPS administration inhibited LPS-induced CCL2 and CXCL10 (but not IL-6) levels in the brain and plasma at 24h; whereas only CCL2 was inhibited in the spleen. LPS-induced sickness behavior at 24h was also reduced by immediate β-FNA treatment. β-FNA treatment 4h post-LPS was less protective. Inflammation and sickness behavior were more pronounced at 8h than at 24h post-LPS, and β-FNA was overall not protective in the brain or peripheral tissues. One exception was CCL2 expression in the brain at 8h post-LPS, which was inhibited by β-FNA treatment at 4h. The results of this study suggest that the timing of β-FNA treatment is critical for neuroprotection and that β-FNA may have differential central and peripheral effects. Further examination of β-FNA's anti-inflammatory and neuroprotective actions is still necessary.

Title: The impact of exercise prior to stroke in cathepsin B knockout mice

Authors: *K. M. COTTER[1], J. TURCHAN-CHOLEWO[1], M. K. MALONE[1], T. A. UJAS[1], S. J. MESSMER[2], L. J. SCHMIDT[3], A. J. PARKER[3], G. J. BIX[4], A. M. STOWE[1];
[1]Neurol., [2]Univ. of Kentucky, Lexington, KY; [3]Queensland Univ. of Technol., Brisbane, Australia; [4]Tulane Univ., New Orleans, LA

Abstract: Background: LG3 is a peptide derived from the C-terminus of perlecan, a proteoglycan in the vascular extracellular matrix, and plays a neuroprotective/neuroreparative role in the brain after ischemic stroke (PMID: 24323378, 21747167). Crucial to this derivation is cathepsin B, a ubiquitous cysteine myokine protease, which increases in plasma post exercise in both humans and mice. In addition, increased cathepsin B levels contributes to beneficial effects on memory and neurogenesis (PMID: 27345423). Cathepsin B knockout (ctsbKO) mice do not benefit from exercise due to the inability to derive LG3 (PMID: 27345423). **We hypothesize that the neuroprotective benefits of exercise before stroke is lost in ctsbKO mice.**Methods: 3-9 mos.-old ctsbKO male (n=23) and female (n=24) mice were split into sedentary (Sed) and exercise (Ex) cohorts for 3 wks prior to transient middle cerebral artery occlusion (tMCAo), with inclusion criteria &<80% baseline cerebral blood flow (CBF via laser Doppler flowmetry) reduction, returning to <50% baseline CBF at reperfusion. Euthanasia occurred 3 days post-tMCAo. Ex cages contained a monitored running wheel to measure distance run. Submandibular blood was drawn weekly and spleen, blood, and brain collected for flow cytometry (spleen),

histology (brain), and ELISA (plasma). Data were analyzed using FlowJo v10.7.2 Software and stats using GraphPad Prism v9.1.0.Results: ctsbKO mice had significant exclusion based on CBF values with tMCAo in Sed vs Ex cohorts for both sexes (both $p>0.05$), including a high incidence of reperfusion and hemorrhagic transformation. There was no difference in post-stroke neurological deficit score (NDS) between cohorts. All female mice exhibited increases in activated B and CD4 T cells, and innate cells in the spleen. Ex increased monocyte and neutrophils while decreasing macrophages, again only in female mice. There was no correlation to pre-stroke exercise intensity for splenic populations, and male mice did not show differences in post-tMCAo splenic immune cell populations.Conclusion: Sed ctsbKO mice have underlying pathology that precludes successful tMCAo induction similar to other strains previously published (e.g. PMID: 32051245). Exercise had no beneficial effect on the post-stroke NDS of ctsbKO mice, and no peripheral immune effect in male mice. Future studies will confirm infarct volume by histology, and plasma LG3 levels by ELISAs to determine loss of pre-stroke intervention benefit in the absence of cathepsin B.

Title: Transcriptomic hallmarks of ischemia-reperfusion injury

Authors: *M. MOVAHED[1,2], S. BROCKIE[2,1], J. HONG[1], M. G. FEHLINGS[3,2,1];
[1]Krembil Res. Inst., Toronto, ON, Canada; [2]Inst. of Med. Sci., Univ. of Toronto, Toronto, ON, Canada; [3]Div. Neurosurg., Toronto Western Hosp., Toronto, ON, Canada

Abstract: Ischemia reperfusion injury (IRI) is associated with a broad array of life-threatening medical conditions including myocardial infarct, cerebral stroke, and organ transplant. Although the pathobiology and clinical manifestations of IRI are well reviewed by previous publications, changes at the transcriptomic level are extremely lacking. This study aims to reveal a transcriptomic hallmark of IRI using publicly available RNA-sequencing data from 5 experimental organ models. We focused on the acute injury time frame by investigating transcriptional changes up to 48 hours following IRI. We compiled a list of highly reported genes in the current literature that are affected in the context of IRI across various organs and conducted Gene Ontology (GO) and Kyoto Encyclopedia of Genes and Genomes (KEGG) enrichment analyses of IRI responses both within and across organs. We observed both organ-

specific and shared effects, illustrated by 38 genes that were commonly dysregulated across organ models. Among the shared genes, *Bcl3, Icam1, Itag5, Atf3,* and *Myc* were highly affected, suggesting preserved cellular survival and apoptotic responses to IRI across organs. Specifically, we found up-regulated genes to be involved in cell survival, cell surface signaling, response to oxidative stress, and inflammatory response, while down-regulated genes were predominantly involved in ion transport and synaptic transmission. We also observed specific enrichment of Tumor necrosis factor alpha, Nuclear Factor kappa-light-chain-enhancer of activated B cells, and mitogen-associated protein kinase signaling pathways following IRI across organs. In the final section, we discuss treatment approaches for IRI and their mechanisms of effect by comparing RNA sequencing data from therapeutic interventions with the results of our analyses. This analysis is the first to compare IRI transcriptional changes across organs and provide a comprehensive overview of shared and specific responses. Our findings provide insight on the mechanisms of IRI and offer potential targets for therapeutic interventions.

USA[5]Adrienne Helis Malvin Medical Research Foundation, New Orleans, LA 70130,
USA[6]Diana Helis Henry Medical Research Foundation, New Orleans, LA 70130,
USA**Abstract**Ischemic stroke is a common neurological disorder worldwide, in which the loss ofblood, oxygen, or nutrition supply cause permanent disability or death. Glutamate-mediated excitotoxicity induces neuronal injury following stroke through activation ofpoly (ADP-ribose) (PAR) polymerase-1 (PARP-1) and generation of the death moleculePAR, which has been designated as parthanatos. Previously we identified a cell survivalE3 ligase, Iduna (*Rnf146*) that protects against neuronal injury, we aimed to identifysubstrates that are responsible for neuronal injury. Here we identified the ZZ-type Zincfinger-containing protein 3 (ZZZ3), which is a core regulatory component of Ada-two-A-containing (ATAC) histone acetyltransferase as a potential substrate of Iduna that isinvolved in PAR dependent cell death. Depletion or loss of PAR binding of ZZZ3 showedprotection against parthanatos by disrupting ATAC recruitment to histone H3, leading to asignificant decrease of acetyl-H3K9 after DNA damage. We found that expression ofmacrophage migration inhibitory factor (MIF), a key nuclease in the parthanatos deathcascade, is regulated by PAR binding activity of ZZZ3. Our finding suggesting that PARis involved in epigenetic regulation via ZZZ3-dependent histone modification duringparthanatos. Depletion of ZZZ3 is protective in vivo against middle cerebral arteryocclusion-induced stroke in mice. Inhibition of ZZZ3 could be a potential therapeuticstrategy for the treatment of neurologic disorders where parthanatos plays a pivotal role.

Title: Ischemic preconditioning upregulates major molecular players involved in mitophagy

Authors: *T. JOVER-MENGUAL[1,2], H.-R. BYUN[1], B. L. COURT-VAZQUEZ[1], J.-Y. HWANG[3], R. ZUKIN[1];
[1]Albert Einstein Col. of Med. Dominick P. Purpura Dept. of Neurosci., Bronx, NY; [2]Dept. de Fisiología, Univ. de Valencia, Valencia, Spain; [3]Dept. of Pharmacol. and Neurosci., Creighton Univ. Sch. of Med., Omaha, NE

Abstract: Transient global ischemia affects millions of people each year and arises as a consequence of cardiac arrest, cardiac surgery, profuse bleeding, near drowning, and carbon monoxide poisoning. Global ischemia in humans or experimentally induced in animals causes selective, delayed death of hippocampal CA1 pyramidal neurons resulting in severe cognitive deficits. To date, there is no known treatment for the neurodegeneration associated with this devastating insult. Loss of mitochondrial function is an early event during cerebral ischemia, ultimately triggering neuronal cell death. Mitochondria are involved in ATP production, ROS generation, inflammation, as well as apoptosis. Selective degradation of damaged or dysfunctional mitochondria through autophagy is known as mitophagy. Ischemic preconditioning is a well-known phenomenon in which a brief, sublethal ischemic insult confers robust neuroprotection to hippocampal CA1 neurons against a subsequent severe ischemic challenge. The molecular mechanisms underlying ischemic tolerance by preconditioning are not fully understood. We recently showed that global ischemia triggers a transient increase in biochemical markers of autophagy, pS317-ULK-1, pS14-Beclin-1, and LC3-II, a decrease in the cargo adaptor p62, and an increase in autophagic flux, a functional readout of autophagy, in selectively vulnerable hippocampal CA1 neurons. However, the role of mitophagy in neuronal death after cerebral ischemia is as yet unknown. Here we show that mitophagy is activated in response to global ischemia in the hippocampal CA1 pyramidal neurons *via* the PINK/PARKIN/p62 signaling pathway together with an increase in phosphorylation at Ser616 of dynamin-related protein-1 (Drp1), a marker for mitochondrial dynamics**.** Additionally, ischemia induces phosphorylation of NFκB and increases expression of the proinflammatory IL-1β in the cytoplasmic fraction. However, no translocation of NFκB to the nucleus was observed. Instead, NFκB increased in the mitochondrial fraction suggesting a role of NFκB signaling in the mitochondria, possibly via p62. We further show that ischemic preconditioning induced an increase of PINK, PARKIN, and BNIP3 expression in the mitochondrial fraction and a decrease of IL-1β expression on the CA1 neurons indicating that mitophagy can be activated by ischemic preconditioning. These findings indicate that activation of the NFκB/p62/mitophagy pathway may be related to mitochondrial dynamics in ischemic preconditioning.

Title: Effect of estradiol benzoate on the expression of interleukins 6 and 10 in the rat model of acute global cerebral ischemia, determined by optical biosensors based on planar silicon arrays.

Authors: *O. MONTES[1], M. GARCIA[1], O. GONZALEZ[1], R. J. DELGADO[2], G. MORALI[3]; [1]Ctr. de Investigación en Reproducción Animal, Univ. Autónoma de Tlaxcala-CINVESTAV., Tlaxcala, Mexico; [2]Ctr. de Investigación en Biotecnología Aplicada, Inst. Politécnico Nacional., Tlaxcala, Mexico; [3]Inst. Mex. Seguro Social, Mexico City, Mexico

Abstract: The Acute Global Cerebral Ischemia (AGCI) is one of the most important pathologies worldwide in public health due to its high mortality and morbidity rates. The role of molecules such as interleukins (IL) in ischemic patients is known, IL-6, for example, has pro-inflammatory effects and IL-10, on the contrary, decreases the processes of the inflammatory cascade. It has been shown that Estradiol Benzoate (EB) modulates negatively and positively respectively these ILs, however, it is still not known how the concentrations are at different post-ischemia times in rats that have received a pharmacological treatment of (EB). This is important since if it is known, more effective pharmacological treatments could be implemented with the intention of reducing cell damage. In addition to this, our research team search to determine the concentrations of these ILs with a novel spectrometry methodology that will achieve real quantitative measurements of these cytokines, this same technique, already completed, could be used to quantify them interleukins or other molecules of interest in other inflammatory diseases such as SARS-CoV2.
For this study, male rats of the Sprague Dawley strain, young, with on average weights of 350g each have been used. A global ischemic episode was induced in these study subjects, subsequently they were sacrificed at 2,4,6,12 and 24 hours post-ischemia and their blood serum was obtained, the same was measured in a macro-infared spectrophotometer. Finally, we are establishing a new methodology that will allow us to assemble biosensors in flat silicon matrices for the quantification of these ILs (6 and 10) through their interaction with specific antibodies.

Title: The neurotrophic response of B cells to extracellular glutamate following ischemic stroke

Authors: *J. TURCHAN-CHOLEWO[1], V. O. TORRES[3], M. K. MALONE[1], J. F. SIMPSON[1], S. ESTUS[4], E. J. PLAUTZ[5], M. P. GOLDBERG[6], A. M. STOWE[2];
[2]Neurol., [1]Univ. of Kentucky, Lexington, KY; [3]UT SouthWestern, Dallas, TX; [4]Physiol., Sanders-Brown Ctr. Aging, Lexington, KY; [5]Neurol. & Neurotherapeutics, [6]Neurol., UT Southwestern Med. Ctr., Dallas, TX

Abstract: Background: We previously showed that B cells exhibit a cell-specific migration pattern in the post-stroke brain, and post-stroke B cell depletion impedes neurogenesis, increases anxiety, and exacerbates memory deficits in young male mice; deficits mediated by brain regions outside the infarct. N-methyl-D-aspartate (NMDARs) play a critical role in neuronal excitotoxicity after stroke and the presence GluN2A and GluN2B subunits on B cells could be affected by exposure to extracellular glutamate (glu). We hypothesized that the post-stroke microenvironment, including extracellular glu at physiologic levels (i.e. 1µM), can enhance the neurotrophic capacities of B cells to promote recovery. Methods: Splenic B cells were isolated from 3-5 mo-old male uninjured C57Bl/6J mice and 4 days following a 60-min transient middle cerebral artery occlusion (tMCAo; n=6-10/group). B cell NMDAR subunits (GluN2A and Glun2B) were identified by confocal microscopy. B cell viability, NMDARs, and neurotrophin (NT)-related genes were assessed by flow cytometry and qPCR, respectively, in B cells (+/- 5µg/mL LPS) treated with glu (1µM) +/- NMDAR antagonists for 24h. Data were analyzed by BioRad CFX maestro and two-way ANOVA determined in Graphpad Prism.Results: Confocal image analysis revealed that glu treatment decreased surface expression of GluN2A ($p<0.05$), but not GluN2B, in uninjured B cells and increased GluN2A ($p<0.05$) in post-stroke B cells. Stroke also increased GluN2A mRNA, without effect on GluN2B. Furthermore, glu treatment increased NT expression (brain-derived neurotrophic factor (BDNF): 2.28-fold), NT receptor (TrkB: 1.33-fold) and NMDAR subunit (GluN2A: 2.01-fold, GluN2B: 1.27-fold) mRNA expression in LPS-stimulated B cells (vs. untreated controls). LPS treatment increased interleukin (IL)-10 mRNA in B cells independent of glu exposure. Similarly, p75 mRNA level is decreased in LPS-stimulated B cells that was also unaffected by tMCAo or glu treatment. Conclusions: Our data suggest that stroke and exposure to glu alters GluN2A-containing NMDARs on B cells. B cell NMDAR activity is concomitant with upregulation of key NTs and NT receptors. Unlike BDNF, IL-10, a B cell-derived anti-inflammatory cytokine and NT, is not altered by glutamate. These results are the first to identify a mechanism for a glu-induced neurotrophic role for B cells following ischemic injury. Future studies will confirm intracellular protein levels of NTs and NT receptors, as well as determine whether B cell-derived NTs can protect neurons after stroke.

Title: Intranasal erythropoietin protects CA1 hippocampal cells, modulated by specific time pattern molecular changes after ischemic damage in rats

Authors: *R. MACIAS-VELEZ, M. RIVERA CERVANTES;
Lab. de Neurobiología Celular, Dept. de Biología Celular y Mol., Univ. de Guadalajara, Guadalajara, Mexico

Abstract: Global cerebral ischemia causes damage to various brain areas; among those vulnerable regions, the hippocampus has shown a selective neuronal death within its parts, particularly Cornu Ammonis 1 (CA1) region is very susceptible to ischemic damage. Erythropoietin (EPO), a multitarget molecule has exhibited neuroprotective properties, especially against cerebral ischemia. However, little effort has been made to determinate both the administration pathway and doses that attenuate neuronal damage. In this study, we investigate the effect on CA1 region of 3 different intranasal doses of recombinant human erythropoietin (rHuEPO) (500, 1000 and 2500 IU/kg) administrated in 3 distinct post-damage temporal schemes (1, 6, and 24 h) against ischemic cellular damage. Furthermore, most effective dose and time were used to evaluate gene and protein expression changes of 3 crucial EPO signaling molecules (EPO, EPOR, and βcR). Under this ischemia model, we observed histopathological damage on CA1-region but rHuEPO administration protected cells against ischemic damage, particularly at 1000 IU dose. Molecular data shows that EPO and its receptor (EPOR) gene expression are upregulated in a short term after damage treatment with rHuEPO (1 h); oppositely, BcR is upregulated in ischemic and Isc + EPO groups in a late scheme. Protein expression data displays no significant changes on EPO expression on evaluated times after treatment, but a tendency to increase 24 h after damage; in the opposite way, EPOR is upregulated significantly 6 h after treatment and this effect last until 24 h. So, our data suggest that a single intranasal dose of rHuEPO (1 h post-injury) provides histological neurorestoration in CA1 hippocampal region, even if we did not observe a dose-dependent effect, the medium dose evaluated (1000 UI/kg of b.w.) was more effective and sufficient to induce molecular changes that provides the initial platform for neuroprotection. Further experiments including βcR protein expression and other related molecules are required to fully understand the protection mechanisms of EPO against ischemia

Title: Microrna mir-7 availability is essential for promoting the post-ischemic functional recovery

Authors: *S. L. MEHTA[1], A. K. CHOKKALLA[1], S. BATHULA[1], B. KLEAVELAND[2], R. VEMUGANTI[1,3];

Abstract: Transient focal ischemia rapidly alters the expression of microRNAs in the brain, including a sustained decrease in the abundance of miR-7a-5p irrespective of age and sex in rodents. We previously showed that miR-7 regulates the levels of α-synuclein (α-Syn), a protein that promotes ischemic brain damage by mitochondrial fragmentation, oxidative stress, and autophagy leading to neuronal death. In addition, we observed that deletion of α-Syn gene curtailed miR-7 mimic-dependent neuroprotection and functional recovery following focal ischemia. In mice, miR-7a and miR-7b (95% homologous) are transcribed from 2 genomic loci. To further understand the active role of miR-7 in the brain, we evaluated the effect of transient middle cerebral artery occlusion (MCAO) in mice that lack both miR-7a and miR-7b (double knockouts; miR-$7^{-/-}$). These mice followed the predicted Mendelian frequency and showed similar sensorimotor and cognitive function to wild-type (miR-$7^{+/+}$) mice measured by the rotarod, beam walk, and Morris water maze tests. However, when subjected to even mild transient MCAO (45 min), miR-$7^{-/-}$ mice showed worsened motor function and significantly increased lesion volume compared to miR-$7^{+/+}$ mice. Furthermore, replenishing miR-7 with a miR-7 mimic (IV injection at 30 min of reperfusion following transient MCAO) restored miR-7 mediated protection and improved motor impairments, potentially through lowering the levels of α-Syn. Our findings suggest that the presence of miR-7 is essential for the recovery of post-stroke brain function.

Title: Inhibition of TREM1-mediated neuroinflammation confers neuroprotection against global ischemia-induced neuronal death.

Authors: *R. URQUHART, T. NILLES-MELCHERT, H. KIM, G. P. JADHAV, J.-Y. HWANG;
Dept. of Pharmacol. and Neurosci., Creighton Univ. Sch. of Med., Omaha, NE

Abstract: Global ischemic stroke is comorbid with cardiac arrest, where loss of cerebral blood flow creates a hypoxic environment in the entire brain. Transient global ischemia drives selective, delayed loss of hippocampal CA1 neurons, contributing to deficits in hippocampal based learning and memory. Elucidating molecular mechanisms underlying global ischemia is essential for development of novel therapeutic strategies to prevent and ameliorate global ischemia induced cell death and cognitive deficits. RNA-seq and Ingenuity Pathway analysis performed on rat hippocampal CA1 following global ischemia induced in vivo via 4-vessel occlusion revealed that within 48HR of ischemic insult expression of triggering receptor expressed on myeloid cells-1 (TREM1) was elevated. TREM1 is a pivotal innate immune receptor that initiates and amplifies neuroinflammation via synergism with Toll like immune receptors. Thus, it was hypothesized that global ischemia promotes TREM1-mediated neuroinflammation, and inhibition of TREM1 can prevent neuroinflammatory signaling and attenuate global ischemia-induced cell death and cognitive deficit. Here we show that hippocampal CA1 TREM1 expression was evaluated following global ischemia, revealing that mRNA and protein levels were increased within 24 and 48HR respectively. We further show that immunolabelling of hippocampal CA1 tissue revealed that TREM1 was localized in CD31+ positive cells, but not Iba1+, NeuN+, or GFAP+ cells, suggesting that TREM1 mediated neuroinflammation is initiated by CD31+ immune cells trafficked into the brain following ischemic insult. Additional immunolabelling is being performed to identify the cell type responsible for TREM1 action. We tested TREM1 inhibitors to determine if TREM1 inhibition can rescue global ischemia-induced cell death and cognitive deficit. We are currently collecting the data assessing the ability of TREM1 inhibition to rescue neurons and cognitive deficit via hippocampal-based learning and memory tests. Our results will document a causal role for TREM1- mediated neuroinflammatory signaling in global ischemia-induced neuronal death. This research illuminates the molecular mechanisms underpinning TREM-1 mediated neuroinflammation and advances approaches for treating global ischemia.

Title: Inflammatory responses provide critical support for neurogenesis and functional recovery following cerebral ischemia

Authors: D. R. HERNANDEZ[1], P. M. BOUDREAUX[1], K. C. SIMPSON[1], *K. M. RODGERS[2];
[1]Cell. Biol. and Anat., [2]Cell. Biol. and Anatomy, Neurol., LSU Hlth. Shreveport, Shreveport, LA

Abstract: Introduction: Replacement of dead neurons following ischemia, either via enhanced endogenous neurogenesis or stem cell therapy, has been highly sought, but the low survival rate of newly generated neurons has left doubt about the therapeutic potential of adult neurogenesis. However, stroke in the young injured brain reveals a greater degree of plasticity and capacity for repair, along with enhanced post-ischemic functional outcomes compared to the adult. Our findings suggest that a possible mechanism is the immune response in the acute phase of stroke, which has a powerful age-related influence on neurogenesis and functional recovery. Our preliminary studies reveal an anti-inflammatory microglial signature during the acute phase of stroke in juveniles and proinflammatory in adults. While microglial responses have been shown to be both neuroprotective and neurodegenerative following brain injury, it has been generally accepted that activation of microglia during the acute response to stroke is detrimental for neurogenesis and neuronal replacement. However, our findings indicate that early microglial responses are key to survival of newborn neurons in juveniles.
Objective: We utilized a juvenile stroke model to study the paracrine signaling triggered by ischemia in activated microglia and its consequence on newborn neuron survival and post-ischemic functional outcomes.
Methods: Electrocorticography (ECoG) was recorded from cortical surface electrodes and striatal depth electrodes implanted following transient middle cerebral artery occlusion (MCAO). Microglia were attenuated with Ibudilast (10 mg/kg), a glial cell activation inhibitor. Neurogenesis and inflammatory markers were examined and functional outcomes assessed with neurobehavioral measures and ECoG recordings.
Results: Short-term inhibition (4d) of microglial activation during the acute phase after stroke resulted in reduced neurogenesis and reversal of motor recovery and neuroplasticity in MCAO-injured juveniles. In contrast, treatment in MCAO-injured adults improved neurogenesis and

functional outcomes revealing age-related differences in post-ischemic immune responses. **Conclusions:** These striking findings provide evidence of a supportive role for microglia in neurogenesis and improved functional recovery following stroke in juveniles. This novel insight into early, anti-inflammatory microglial responses after stroke may alter strategies for effective stroke treatment, promoting substantial post-ischemic neuronal replacement and functional recovery in both juveniles and adults.

Authors: *Q. A. WHITSITT[1], B. K. PATEL[2], B. HUNT[1], E. K. PURCELL[2];
[1]Biomed. Engin., [2]Michigan State Univ., East Lansing, MI

Abstract: The foreign body response to implanted electrodes in the brain has been identified as an important area of research for the future development of brain-machine interfaces and in vivo electrophysiology. Due to many mechanisms such as reactive astrogliosis and neuron cell death, the functional makeup of tissue immediately surrounding the electrode after implantation is significantly altered from its original state. To discover possible functional changes affecting device function and longevity, spatial transcriptomics was implemented to identify relevant clusters of differential gene expression driven by electrode implantation. This RNA-sequencing technique (10x Genomics, Visium) uses spatially coded, RNA-binding oligonucleotides on a microscope slide which, after cDNA synthesis, are used to spatially identify each sequencing read. For these experiments, sections of rat motor cortex implanted with Michigan-style silicon electrodes were mounted on the Visium slide for processing. Each tissue section was labeled for neuronal nuclei (NeuN) and astrocytes (glial fibrillary acidic protein, GFAP) using immunohistochemistry to provide a spatial reference for mapping each sequencing read relative to the device tract. Preliminary results from rat motor cortex at 1 week and 6 weeks post implantation have shown up to 886 differentially expressed genes within 350μm of the device tract compared to tissue greater than 500μm from the device tract. Many of these genes are related to biological mechanisms previously reported in studies of the foreign body response to

implanted electrodes, while others are novel to this study. These results will provide a foundation for future reprograming approaches to both improve and measure the effects of gene expression on the long-term stability of recording from implanted electrodes in the brain. Ongoing work will include additional timepoints and more samples per timepoint as we gain a better understanding of the dynamic changes taking place in the brain at a cellular level in response to electrode implantation.

Title: Gene Expression Changes and Adhesion in Cultured Reactive Rat Astrocyte Models in Comparison to Device-Associated Effects in the Brain

Authors: *T. RIGGINS[1], E. HUNTER[2], B. HUNT[1], E. K. PURCELL[1];
[1]Biomed. Engin., [2]Computer Sci., Michigan State Univ., East Lansing, MI

Abstract: Intracortical electrode arrays have great promise to treat many neurodegenerative diseases. However, device performance can decrease sharply post-implantation, where one report suggests that over half of those failures are attributed to meningeal and astroglial encapsulation around the probe. To address this, many researchers have moved to making softer, smaller implants, in hopes of minimizing the mechanical mismatch between the brain and the device interface. In parallel, new observations suggest that reactive astrocytes encompass a spectrum of functional states, which can be partially delineated by assessing differences in their gene expression. The purpose of our studies is to develop *in vitro* models of reactive astrocytes that can be used to understand changes in gene expression surrounding devices in the intact brain as well as the interaction with specific features of electrodes. Using a working tissue culture model of inflammation, we are directly measuring device surface roughness and correlating it to astroglial activity. To understand the impact of surface roughness on how astrocytes encapsulate probes, atomic force microscopy technique offers a venue to image topological probe features, measure nanoscale roughness and bending stiffness. These measurements are being used to correlate with astroglial cellular adhesion to probe materials, determined with immunohistochemistry methods. In addition, we are using RNA-sequencing to compare changes

in genetic expression in our reactive models to that of intact brain, and to that of rat tissue harvested from implanted probes. This cross comparative study will be used to improve our understanding of the functional identity of reactive astrocytes surrounding devices and determine an optimal surface roughness range that may reduce cell adhesion and indirectly support device longevity. This new information could inform potential guidelines for designing intracortical electrode arrays.

Title: Spatiotemporal Protein Expression Patterns of RNA-Sequencing Identified Genes Around Implanted Silicon Electrode Arrays

Authors: *C. H. THOMPSON, N. HEELAN, E. K. PURCELL;
Biomed. Engin., Michigan State Univ., East Lansing, MI

Abstract: Implanted neural interfaces enable numerous clinical and research applications but are often hindered by long-term signal instability. The tissue response of the brain to implanted device is a suspected contributor to inconsistent performance. The tissue response has been traditionally characterized by inflammation, glial scaring, and neuronal cell death. New RNA-sequencing data from our lab suggests that mechanisms of the tissue response are more complex than previously anticipated and that broad spatiotemporal changes in gene expression drive the biological response to implanted devices. We identified numerous differentially expressed (DE) genes associated with synaptic function (Bsn, Arc), myelin formation (Plp1, Mbp, Tf), and cellular identity (Ptbp1) which have significant biological implications in neurodegenerative disease and traumatic brain injury but are novel in the context of implanted cortical devices. However, the mRNA-to-protein expression relationships, protein localization, and possible functional changes associated with the DE of these genes are not yet well understood. To provide greater understanding of how these genes influence the tissue response to implanted electrodes we implanted Michigan style probes into motor cortex of male Sprague Dawley rats to evaluate tissue response at 24 hours, 1 week, and 6 weeks post-implantation (n=6 per timepoint). By utilizing immunofluorescence and quantitative fluorescence intensity analysis we have systematically evaluated the spatiotemporal expression and cell-type specific localization of

these proteins relative to naïve brain tissue. The results of this study suggest that in many cases, the protein expression of these genes mirror the spatiotemporal patterns of gene expression identified by our previous RNA-sequencing results. Importantly, we were able to identify the cellular localization and specific cell types primarily expressing these proteins of interest. This study expands upon previous understandings of the tissue response to implanted devices while also providing evidence for the dynamics of these proteins and their role in tissue response.

Title: Synchronization of wireless electrophysiology and markerless kinematics for large, unconstrained animals

Authors: *M. P. SILVERNAGEL[1], A. L. LING[1], P. NUYUJUKIAN[2,3,1,4,5];
[1]Electrical Engin., [2]Bioengineering, [3]Neurosurg., [4]Wu Tsai Neurosciences Inst., [5]Bio-X Inst., Stanford Univ., Stanford, CA

Abstract: Motor systems neuroscience studies in large animals typically constrain body movement from regions not under study, thus minimizing the presence of confounding variables. This promotes consistent, repeatable behaviors, providing robust datasets that have fueled neuroscience studies for decades. The downside to this approach is that the observed neural data may differ between constrained and more naturalistic, unconstrained movements. Utilizing a markerless motion tracking and kinematic extraction platform developed by our group, we present the first recordings of wireless electrophysiology synchronized to full-body kinematics. Recordings were obtained from 96 channels in both premotor (PMd) and motor (M1) regions of an adult, male rhesus macaque. Sessions took place in a large, 2.1 x 2.1 x 2.4 m (l x w x h) enclosure and lasted 10 to 20 minutes. The animal then performed a sterotyped walking task or engaged in unstructured, neuroethologically relevant behaviors, including foraging, object interaction, and hunting for insects. By sending data acquisition signals used by the motion tracking platform to the commercial wireless neural data acquisition system, kinematic and neural data were aligned within 50 us. With this synchronized neural and kinematic data--which contains movement tasks that have not been previously explored by the motor systems

neuroscience community--we look to generate novel insights into the functioning of the mammalian motor system.

Title: A neuroelectrophysiology-compatible platform for lesioning through a microelectrode array

Authors: *I. E. BRAY[1], S. E. CLARKE[2], P. NUYUJUKIAN[2,3,1,4,5];
[1]Electrical Engin., [2]Bioengineering, [3]Neurosurg., [4]Wu Tsai Neurosciences Inst., [5]Bio-X, Stanford Univ., Stanford, CA

Abstract: Lesion studies have established causal connections between brain and behavior, providing fundamental insights in medicine and neuroscience. Intracortical neuroelectrophysiology from microelectrode arrays, a technique that has transformed motor systems neuroscience, could further impact our causal understanding of the brain if seamlessly integrated with lesioning. Although many lesioning methods exist, most are not compatible with stable neuroelectrophysiology pre- and post-lesion. Here we present a platform for creating precise electrolytic lesions through chronically implanted microelectrode arrays without compromising neuroelectrophysiological recordings. We create the lesion by applying direct current through two electrodes of the microelectrode array. A custom-built current source provides stable current in the face of variable electrode impedance and allows for controlled, repeatable lesions in awake-behaving animals. The choice of the electrode pair and the duration and intensity of the current affects the location and the extent of the lesion. This platform was validated through testing in multiple species. *Ex vivo* and *in vivo* lesions through Utah electrode arrays in sheep and pigs (eleven *ex vivo* and five *in vivo*, with a total of 61 lesions) were performed to validate device performance and calibrate parameters. Histology from a lesion (150µA of DC current for 45 seconds) in one adult male rhesus macaque, shows an ablated core surrounded by rarefied tissue. These parameters were used for fourteen subsequent in vivo

lesions in two awake-behaving adult male rhesus macaques. Variable voltage traces and stable current traces during this *in vivo* lesioning demonstrate that the feedback circuit operates as intended. Measurements of spiking activity before and after lesioning confirm that this approach is compatible with neuroelectrophysiology. In summary, this electrolytic lesioning method avoids disruptive procedures, provides sub-millimeter control over the extent and location of the injury in cortex, and permits neuroelectrophysiological recording of single-unit activity from the same neuronal population after lesioning. The electrolytic lesioning technique presented here results in a behavioral deficit during reaching, seen in the two awake-behaving adult male rhesus macaques, facilitating causal investigations of the recorded neuronal population's role in generating behavior. As the animals behaviorally recover, this technique simultaneously provides insight into local reorganization after injury.

Title: Electrolytic lesion with microelectrode arrays

Authors: *S. E. CLARKE[1], I. E. BRAY[2], P. NUYUJUKIAN[1,3,2,4,5];
[1]Bioengineering, [2]Electrical Engin., [3]Neurosurg., [4]Wu Tsai Neurosciences Inst., [5]Bio-X Inst., Stanford Univ., Stanford, CA

Abstract: Background: Emerging brain interfacing technologies hold promise for treating disease throughclosed-loop neuromodulation. However, a major scientific knowledge gap exists between the recordedactivity of large neuronal populations and their related function. This disconnect prevents identificationof the mechanisms necessary to restore a damaged network, prompting calls from the US NationalInstitutes of Health for primate models of brain injury that advance the translation of basicneuroscience findings into viable clinical therapies. **Methods**: Electrolytic lesions are performed in awake-behaving adult male rhesus macaques throughchronically implanted Utah arrays in motor cortex. This approach allows for otherwise undisturbedneuron population recordings before, and immediately after spatially precise damage

that targets theneuronal correlates of a standard reaching task. Thousands of reaches are performed every 24 hoursduring electrophysiological recordings, providing ample statistical power to track the time course ofrecovery. **Results**: Histology indicates a lesion volume of approximately 1.77 mm^3, consisting of an ablated coreand partially damaged tissue reminiscent of human brain injury. A data set of 14 lesions has beengathered from two animals demonstrating changes in single neuron activity and population structurethat accompany slower, less accurate reaches. Specifically, we observe a strong correlation between theextent of behavioral deficit and changes in the variance explained by the top five principal componentsof neuron population spiking activity. During behavioral recovery, local reorganization of the damagednetwork is recorded by the microelectrode array. **Conclusion**: By seamlessly integrating lesions with existing recording capabilities, we present aunique opportunity to study causal cortical dynamics and neuronal circuit reorganization usingchronically implanted microelectrode arrays.

Title: Markerless pose tracking for task-based and free behavior

Authors: *A. LING[1], M. P. SILVERNAGEL[1], P. NUYUJUKIAN[2,3,1,4,5];
[1]Electrical Engin., [2]Bioengineering, Stanford Univ., Stanford, CA; [3]Neurosurg., [4]Wu Tsai Neurosciences Inst., [5]Stanford Bio-X, Stanford, Stanford, CA

Abstract: Studies of unconstrained and ambulatory behavior are necessary to observe the full richness of neural activity associated with movement. However, no platforms exist to capture full-body markerless natural macaque behavior synchronized with neural data in a large space. We present the first markerless, full-body motion tracking and synchronized wireless neural electrophysiology platform for large, ambulatory animals, consisting of four RGB-D cameras that provide a 360 degree view of a 4.5m^2 observational enclosure. With this platform, a wide range of freely moving and naturalistic full body kinematics can be extracted providing novel insights into the functioning of the mammalian motor system. A large observational enclosure, measuring 2.1x2.1x2.4 meters, was outfitted with four RGB-D cameras. High resolution depth

data acquired on a single Linux desktop. Point clouds were generated for each camera by converting every depth pixel to a 3D coordinate space, and resulted in a full volumetric point cloud created by aligning point clouds from each camera to a single reference frame. Three dimensional full body kinematics were extracted from the point cloud data using an articulated skeletal model and an optimization algorithm for one macaque. The skeleton was created in a bottom-up fashion in Blender from primitive meshes made in MeshLab. Bayesian Optimization maximized the number of points inside each segment to return the best fit joint angle and location. Full body kinematics were extracted for a variety of behaviors ranging from task-based to unprompted, naturalistic behaviors. Multiple kinematic trials were captured of the gait cycle and arm reaching during a freely moving walking task, two behaviors we will further explore with neural data. Additionally, kinematics were extracted for predatory behavior and interactions with large objects, naturalistic behaviors that are challenging to capture in a constrained space. Kinematics for a macaque were extracted for 150 frames as he walked over a large tire to forage in its center and 36 frames as he swiftly attempted to catch a fly, highlighting the platform's ability to capture dexterous movements. To validate the performance of the algorithm, error was calculated from 300 frames of the walking task. The mean Euclidean distance in cm between the algorithm's and the hand-labelled position summarized the error was between 3-5 cm, surpassing other 3D markerless platforms' accuracy. Subsequent effort has led to neural synchronization of the kinematics to wireless electrophysiology.

Title: Long-term intracortical microelectrode array performance in a human: a five-year retrospective analysis

Authors: S. COLACHIS[1], C. DUNLAP[3], *D. FRIEDENBERG[2];
[1]Battelle, Ohio, OH; [2]Battelle, Worthington, OH; [3]The Ohio State Univ., Columbus, OH

Abstract: Microelectrode arrays (MEAs) used to record neural signals for intracortical brain-computer interfaces (BCIs) are subject to biological, material, and mechanical disruptions that degrade BCI performance. While these MEA disruptions have been well-studied in non-human primates, less is known about long-term signal quality in humans due to a limited number of

chronic implantations. Our group has collected one of the largest neural recording datasets from a Utah MEA in a human subject, spanning over five years (2014-2019). We analyzed signal quality and BCI performance across 448 clinical recording sessions during this period. Signal quality was assessed for each session using metrics including signal-to-noise ratio, spike peak-to-peak voltages, channel correlation, electrode impedance, and others. Signal quality decreased rapidly in the first year, then more gradually through the remainder of the study. Despite this signal degradation, BCI decoding accuracy in a four-movement motor imagery task remained stable throughout the study. We also identified several acute signal disruptions that affected signal quality on the time scale of hours to days. We characterized the signal effects of these disruptions then utilized this information to hypothesize or identify the disruptions' root cause. Drawing support from our analyses, we discuss potential identification and mitigation strategies for BCI signal disruptions. Our work addresses the knowledge gap around long-term MEA performance in humans, providing longevity and efficacy data points to better describe the performance of implantable neural sensors in a human population. Furthermore, characterizing both chronic signal trends and common signal disruptions will support researchers in developing automated countermeasures to maintain or rescue BCI performance following unexpected disruption events. The trial was registered on ClinicalTrials.gov (Identifier NCT01997125) and conformed to institutional requirements for the conduct of human subjects research.

Title: Device testing and initial clinical use of thin film electrodes for intracranial recording and monitoring of brain activity

Authors: *A. KULLMANN, S. MERTENS, M. CHRISTIANSON, D. ROSA, F. KULLMANN, C. DIAZ BOTIA;
NeuroOne Med. Technologies Corp., Eden Praire, MN

Abstract: Introduction. Invasive intracranial recordings are performed as part of pre-surgical work-up in patients suffering from drug resistant epilepsy (DRE). Strips and grids electrodes are

placed in the subdural space for several days and data are used to identify the extent of the epileptic region. Although these electrodes have been in the US market for decades, their fabrication, materials and properties have hardly changed. They are silicone based, thick (>0.5mm), manufactured by hand, and do not optimally conform to brain convolutions. Technological solutions that overcome these limitations are needed. **Objective.** Here we describe a battery of electrochemical, electrical and biocompatibility tests of new thin film electrode for use in clinical practice. We also present preliminary post-market user feedback data from initial clinical use. **Methods.** Thin film electrode (0.08mm) arrays were manufactured from polyimide with platinum contacts (2-16 contacts, 3 mm contact diameter, spaced 10 mm apart). Electrochemical and electrical testing included electrolyte interface impedance, cyclic voltammetry and other impedance and isolation tests for proving device safety and performance. Biocompatibility was assessed in in vitro and in vivo tests. Post-market data were collected employing a user feedback questionnaire using a rating scale (1 to 5, with 5 being the highest).**Results.** Thin film electrodes met all electrochemical, electrical and biocompatibility testing required for FDA clearance (obtained Nov 2019). Electrodes (n=19) were used in clinical practice between Nov 23, 2020 and May 3, 2021 in the epilepsy monitoring units and for intraoperative monitoring (IOM) for recording brain activity in (a) DRE patients undergoing evaluation for potential surgical resection, and (b) patients undergoing tumor resection. Neurosurgeons (users; n=6) rated the electrodes between 3 and 5 in regard to their properties (thickness, flexibility, weight), features (ease of placement, conformability to the brain areas) and performance (qualitative signal recording quality) during surgical implantation.**Conclusions.** These results demonstrate safety and performance of the first thin film electrode technology cleared by the FDA for use in clinical practice. Initial clinical use indicated that the technology is feasible for surgical implantation with greater flexibility compared to silicone based cortical electrodes. This technology has the potential to minimize invasiveness of subdural recordings and improve surgical outcomes.

Title: Two-photon visualization of novel CX3cr1+/Cspg4+ reactive cell population around chronic intracortical neural electrode interfaces

Authors: *S. M. WELLMAN[1,2], M. M. DOUGLAS[1], T. D. Y. KOZAI[1,2,3,4,5];
[1]Dept. of Bioengineering, [2]Ctr. for Neural Basis of Cognition, [3]Ctr. for Neurosci., [4]McGowan Inst. for Regenerative Med., [5]NeuroTech Ctr., Univ. of Pittsburgh, Pittsburgh, PA

Abstract: Development of advanced neural interfacing technology is accelerating our understanding of nervous system health and disease at a rapid pace. Yet, despite their potential as tools for neuroscience discovery and clinical rehabilitation, intracortical electrodes regularly suffer from depreciations in detecting and modulating brain activity as a result of severe biological responses to a foreign body. Due to the inherent complexity of the brain's immune response to device injury, the mechanisms which govern biological failure modes of neural implants are currently unknown. Efforts to pinpoint exact biological correlates of device performance are confounded by a poorly understood heterogeneity of immune cells (i.e. myeloid cells) within the brain which are known to regulate tissue homeostasis, inflammation, and wound repair following injury. To elucidate the spatiotemporal behavior and fate of different myeloid populations within the brain after device implantation, we employed two-photon imaging of a dual fluorescent CX3cr1-GFP and Cspg4-DsRed mouse model around chronically implanted intracortical electrode arrays. With this model, we have identified a distinct population of dynamic cells around implanted devices separate from GFP+ microglia and DsRed+ glia and pericyte populations. These cells simultaneously express GFP+ and DsRed+ fluorophores denoting constitutive expression of both *CX3cr1* and *Cspg4* promoters. The emergence of dual-labeled CX3cr1+/Cspg4+ cells began 3-4 days following implantation and appeared in close spatial proximity (<100 μm) to the implanted probes. Additionally, these cells demonstrated active process extension and retraction and soma motility both in tissue regions adjacent to the implant and on the device surface itself within the initial weeks post-implantation. Whereas device coverage of individual CX3cr1+ or Cspg4+ cells have been previously recognized, here we report spatially and temporally distinct surface encapsulation by CX3cr1+/Cspg4+ cells, suggesting a potential role as a novel reactive cellular player around chronically implanted microelectrodes. Furthermore, dual-labeled CX3cr1+/Cspg4+ cells were not observed within

contralateral (unimplanted) brain regions, suggesting an injury-specific emergence and response to chronically implanted devices. Future work further characterizing the different heterogenous profiles of myeloid lineage cells and their pathological roles within the brain will facilitate the development of more biologically adaptive implants and engineer innovative therapeutic strategies to combat the body's inherent immune response to brain injury and disease.

Title: Reproductive State Modulates Visual Behavior and Retinal Spectral Tuning in the Green Treefrog

Authors: *W. G. WALKOWSKI[1], A. SANTANA[2], T. GASTON[2], W. C. GORDON[2], N. G. BAZAN[2], H. E. FARRIS[1];

Abstract: Hormones are known to affect CNS circuitry mediating behavioral responses to stimuli. Their effect on sensory receptor organs is less understood. This study focused on hormonal modulation of the retina and its consequences on the reproductive behavior of the green treefrog (*Hyla cinerea*). We examined the effects of reproductive status on retinal spectral sensitivity, or the ability to detect different wavelengths associated with visual signals. **Our hypothesis was that hormones modulate stimulus sensitivity in the retina during reproductively receptive phases, specifically influencing wavelength processing important to mate choice behavior**. *H. cinerea* are sensitive to wavelengths spanning the human visible light spectrum and beyond. Experiments used electroretinograms (ERGs) to compare stimulus threshold and response amplitude in the retina of reproductive and non-reproductive frogs. Our findings indicated that female reproductive state was correlated with an increase in spectral sensitivity and a broadening of spectral tuning. However, sensitivity to 530-570nm of light remained unchanged. Spectrometer measurements of the frogs' dorsal surface indicated that peak

reflectance is 540nm, suggesting sensitivity to dorsal coloration does not play a role in reproductive signaling. We propose that modulation of retinal tuning increases sensitivity to a lateral white stripe, which has broad spectral reflectance. Ongoing behavioral trials will test this hypothesis. Preliminary results suggest that modulation of relative wavelength sensitivity of the retina could function to alter visual responses to body parts with broadband reflectance, suggesting endocrine control of reproductive communication.

Title: Determining saccade-like turn refinement during the establishment of visually guided routes in Pogonomyrmex occidentalis

Authors: *J. DE LA PENA[1], T. R. LANGDON[1], E. CORREA[2], V. CO[1], L. ALVAREZ VALENCIA[1], D. D. LENT[1];

Abstract: Determining saccade-like turn refinement during the establishment of visually guided routes in *Pogonomyrmex occidentalis*
Authors: Joanna P de la Pena, Taylor R Langdon, Edward Correa, Vince Co, Leslye Alvarez Valencia, David D Lent
This research aims to better understand how animals learn to navigate in natural and complex environments. Ants are an ideal model to study navigational behavior and several species have been shown to utilize visual features and other sensory information in their environment to drive a range of navigational behaviors. Here we describe the early visual navigation behavior of the western harvester ant (*Pogonomyrmex occidentalis*). During foraging, the ants produce saccade-like turns (SLTs) towards learned features to maintain trajectory. This behavior allows the ant to sample the visual environment intermittently and correct their routes after encountering an obstacle or other disruptions. It has been shown that once SLTs have been established ants will reliably produce the corrective turns to stay on route, but how these SLTs develop and are refined during early learning is poorly understood. Our research investigated the development and refinement of SLTs in early route establishment within a naturalistic environment. The experiments were done in the laboratory using a high-resolution 360-degree naturalistic

panoramic environment. Ants were filmed during their learning walks and the direction and number of SLTs were recorded. We determined ants produce a greater number but less directed SLTs in their early foraging routes. As learning progresses, SLT production decreased and became more refined towards features and the goal. We identified certain visual features within the panorama that drive these SLTs, resulting in ants directing their orientation and foraging behavior to reach their goal. With the visual cues used by individual ants identified, we characterized the similarities and differences in strategies employed by ants to develop robust visually guided routes. Our data has provided novel insight into how different visual cues become the primary guidance stimulus, but we need to further investigate which individual cues or features are necessary and sufficient for visual guidance. This research, thus far, has provided us with a better understanding of the early behavioral mechanisms employed by ants in natural environments for robust navigation.

Title: Examining potential memory formation in cnidarians: a non-associative learning assay induces changes in mechanoreceptive behavior in two species of cnidarians, Nematostella vectensis and Hydra littoralis.

Authors: *A. N. TAMVACAKIS, N. NAKANISHI;
Biol., Univ. of Arkansas, Fayetteville, AR

Abstract: Does learning and memory formation occur in cnidarians, animals whichlack centralized nervous systems? Sensitization is a form of non-associativelearning in which a repeated stimulus results in enhanced behavioral responsesto related stimuli. Sensitization is hypothesized to be an evolutionarily earlyform of neuronal plasticity and memory formation. However, it has beenprimarily studied in bilaterians, animals with relatively organized,centralized nervous systems. Cnidaria (sea anemones, hydrazoans, jellyfish, and others) is thesister-taxon to Bilateria, and its members possess diffuse interconnected nervenets rather than centralized ganglia. Cnidarians exhibit simple, tractablebehaviors. One common behavior is body contraction in response to weak tentacletouch. We developed a nociceptive sensitization assay to determine whethercnidarian touch response is enhanced following a series

of noxious trainingstimuli. We examined changes in response to tentacle touch following nociceptivesensitization training in two species of cnidarians, the sea anemone *Nematostellavectensis* and the hydrazoan *Hydra littoralis*. Baseline bodycontraction times in response to tentacle touch averaged 54.01 seconds for *Nematostella*and 41.94 seconds for *Hydra*. Following sensitization training,both species significantly increased the amount of time in which their bodycolumns remained contracted in response to touch, while handled control animalsexhibited no difference from their baseline contraction times. The increasedcontraction time was observed at 18 and 24 hours following the trainingsession, but returned to pre-test levels by 48 hours after training. The enhanced response to tentacle touch following training resembledpreviously described changes in behavior occurring with nociceptivesensitization in bilaterian species. While more must be done to understand thepotential neurological and genetic underpinnings of this sensitization-likeresponse, this study provides a testing framework that can allow researchers todetermine whether a form of non-associative learning could occur in animalswith diffuse nervous systems. By identifying tractablemodels of learning-like behavior adaptations in species outside Bilateria, wecan better understand how learning evolved, and whether there are shared neuralmechanisms underlying learning across groups of animals with contrastingnervous system architectures.

Title: Can the Acoustic Parasitoid Fly Ormia ochracea Eavesdrop and Respond to Novel Cricket Songs?

Authors: *I. ABDULKARIM[1], M. CARLSON[2], J. H. GALLAGHER[3], A. W. WIKLE[3], R. M. TINGHITELLA[3], N. LEE[1];
[2]Biology, Music, [1]St. Olaf Col., Northfield, MN; [3]Univ. of Denver, Denver, CO

Abstract: The acoustic parasitoid fly Ormia ochracea eavesdrops on male cricket calling songs to locate appropriate host crickets for the development of their larval young. As parasitism by O. ochracea results in almost certain cricket death, the flies act as a strong source of selection against song production in host cricket species. In response to this selection pressure, some Hawaiian populations of Teleogryllus oceanicus have evolved changes in wing morphology resulting in a novel “purring” song type. The temporal and frequency characteristics of the new

song type differ from those of the ancestral calling song. Hawaiian O. ochracea are exposed to the new song type with a lower sound intensity (purrs= 53 dB SPL, ancestral= 70 dBA at a distance of one meter), while continental populations of O. ochracea are not. In the present study, we test the hypothesis that if Hawaiian O. ochracea have evolved to detect and respond to novel cricket songs, then detection thresholds across varying song characteristics, such as carrier frequency, should be lower than other populations, a story which has yet to be told.We presented Floridian and Hawaiian O. ochracea with synthetically generated cricket songs varying in carrier frequency and sound intensity. Behavioral response thresholds were evaluated using a spherical treadmill system, and excitatory neural response maps were generated from summed local field potential recordings from the cervical neck connective. Both populations exhibited response thresholds that were sharply tuned to 5 kHz, which matches the dominant frequency of ancestral cricket songs. While response thresholds were lowest at 5 kHz for both populations (FL: 32.22dB±7.36, HI: 36.53dB±11.17, mean±SD), Hawaiian flies exhibited significantly higher response thresholds at higher sound frequencies as compared to Floridian flies. Floridian and Hawaiian flies exhibited similar neural response thresholds, which were approximately 5-10 dB SPL lower than behavioral thresholds. Our findings suggest that the behavioral and neural response thresholds of Floridian O. ochracea are at lower intensities than those of Hawaiian populations, and that there are significant differences between the abilities of geographically separated populations of O. ochracea to detect and respond to novel cricket songs.

Title: Characterization of a rapid defensive behavior in a recently introduced model gastropod

Authors: *O. H. BERG[1], A. BOUTKO[2], V. K. MISTRY[3], W. N. FROST[2], J. W. BROWN[3]; [1]Neurosci., Lake Forest Col., Lake Forest, IL; [2]The Chicago Med. Sch., [3]Sch. of Grad. and Postdoctoral Studies, Rosalind Franklin Univ., North Chicago, IL

Abstract: The aeolid nudibranch *Berghia stephanieae* is a recently introduced model species being studied as part of a collaborative, NIH BRAIN Initiative project aimed at developing the first transgenic lines of a gastropod mollusk. With a central nervous system containing fewer than 10,000 neurons, *Berghia* represents an attractive system in which the correlations between

genes, brain, and behavior can be readily interrogated and manipulated at the level of individual neurons and complete neural circuits. Here, we characterize the most prominent of *Berghia*'s defensive behaviors, "bristling," which involves the rapid, targeted, coordinated elevation of the cerata, dozens of appendages emerging from the animal's dorsum, and draw basic inferences about the behavior's neural bases. *Berghia* internalizes nematocysts digested from its anemone prey into the tips of its cerata; bristling thus deters prospective predators by directing these noxious cells towards an offending stimulus, with the behavior likewise being observed during *Berghia*'s own predatory activities. In the present study, bristling and concomitant behaviors, such as body shortening and avoidance turning, were elicited through either aversive tactile or chemical stimuli (a poke from a von Frye hair or 1 M NaCl, respectively) applied to different parts of the body. Kinematic analysis of tactile stimulation trials in immobilized but freely bristling animals revealed that 1) the bristling response, although always initiated close to the stimulus, then propagated from the head to the tail, even when more caudal body parts were stimulated; 2) stimulation of decerebrated specimens evoked local bristling but abolished coordinated, full-body responses; and 3) repeated stimulation of individual body loci induced response habituation. Together, these observations implicate the peripheral and central nervous systems in mediating early and late components of the bristling response, respectively. Chemical stimulation of freely locomoting animals similarly provoked bristling behavior with an accompanying modulation of locomotion: stimulation of the head drove body shortening, followed by an abrupt turning away from the stimulus, while tail stimulation accelerated forward crawling. The findings in this study elucidate a repertoire of stereotyped behaviors whose neural correlates can be further characterized in upcoming neurophysiological investigations involving large-scale optical imaging of *Berghia*'s nervous system.

Title: Force feedback in walking uphill and downhill: mechanosensory encoding of 'naturalistic' joint torques in stick insects

Authors: *S. ZILL[1], C. J. DALLMANN[2], N. S. SZCZECINSKI[3];
[1]J.C. Edwards Sch. Med., Huntington, WV; [2]Dept. of Physiol. and Biophysics, Univ. of

Washington, Seattle, WA; [3]Dept. of Mechanical and Aerospace Engin., West Virginia Univ., Morgantown, WV

Abstract: Force feedback could be valuable in adapting walking to diverse terrains but the effects of changes in substrate inclination on sensory discharges have not been examined. In insects, force feedback is provided by campaniform sensilla, mechanoreceptors that monitor forces as cuticular strains. In previous studies, we have examined how campaniform sensilla on the stick insect tibia encode 'naturalistic' force stimuli derived from joint torques measured in animals walking freely on level ground. Here, we examine their responses to torques at the hind leg femur-tibia (FT) joint measured during uphill and downhill walking (Dallmann et al., J. Exp. Biol. 222, 2019). Dallmann et al. showed that FT torques are quite variable during level walking (including changes in torque direction from flexion to extension), but that torques are larger in magnitude and more consistent when traversing sloped surfaces: animals use predominately extension torque in propulsion on uphill slopes and consistently flexion torques to brake forward motion when going downhill. In the present study, we analyze the FT torques in more detail and record the responses of campaniform sensilla to the mean torques and the torques of individual steps that showed large variations (as naturally occurring 'perturbations'). We find that in level walking, FT torques in different directions tend to occur in different ranges of joint angles (flexion torques in ranges of joint extension, extension torques in ranges of joint flexion). In slope walking, FT torques reflect both the gravitational vector (Fz) and braking/accelerating forces exerted in the walking direction (Fx). The FT joint also generates large lateral forces (Fy) in downhill walking that could enhance substrate grip. Preliminary extracellular recordings of campaniform sensilla in response to these torques indicate that sensory signals encode the torque direction and strongly reflect the rate of change of force (dF/dt) in walking on all substrates. Discharges also reflect the force magnitude on slopes but are modulated and follow dF/dt. These findings are now being studied in a model that accurately simulates the properties of leg campaniform sensilla (Szczecinski et al., Living Machines, 2020). Future experiments are planned to examine the effects of sensilla on motor activities. Our working hypothesis is that sensory feedback indicating force dynamics (dF/dt) at the FT joint in the hindleg can be used to stabilize and adapt walking to diverse terrains.

Title: Behavioral effects to heat in the blow fly (Phaenicia sericata)

Authors: *N. MARGUERITE[1], R. L. COOPER[1], D. HARRISON[1], D. HARRIS[2];
[1]Biol., Univ. of Kentucky, Lexington, KY; [2]520 Ruddles Mill Rd, Paris, KY

Abstract: Larvae of Drosophila and other related insects, such as the medicinal blow fly (*Phaenicia sericata*), demonstrate a thermal preference which varies among species. What drives the differences in behavioral response among species is not fully understood but is likely driven by evolutional adaptive pressure. The larvae of *Phaenicia sericata* when placed in the cold, after a warm exposure, will aggregate which is assumed to be for warmth. Additionally, the larvae of *Phaenicia sericata* are attracted to heat when placed in a cold environment (10^{o}C). Neither aggregation or heat attraction are robust in larval *Drosophila melanogaster* with or without over expression of the TRPA1 receptor (i.e. the capsaicin or heat receptor) in sensory neurons. Larval *Drosophila* with over expression of genes coding for TRPA1 in sensory neurons are repelled by capsaicin or high heat (>28^{o}C), whereas the non-over expressers show no behavioral response to capsaicin or heat. The larvae of *Phaenicia sericata* are attracted to heat over a food source at 20^{o}C but showed no preference at 24-28^{o}C. Larvae Drosophila, with over expression of the TRPA1 receptor, reveal robust avoidance to heat or capsaicin even over starvation. These differences in behavior, thought to be driven by TRPA1 expression, may be a survival skill for *Phaenicia sericata* to find decaying animal material or a cooperative group when exposed to cold.

Title: Towards a computational ethology of web-making: quantifying movement sequences underlying stages of spider web-building

Authors: *A. CORVER[1], N. WILKERSON[3], J. D. MILLER[2], A. GORDUS[2];
[1]The Solomon H Snyder Dept. of Neurosci., [2]Dept. of Biol., Johns Hopkins Univ., Baltimore, MD; [3]Atlantic Vet. College, Univ. of Prince Edward Island, Charlottetown, PE, Canada

Abstract: The geometric complexity and stereotypy of spider webs have long generated interest in their algorithmic origin. Like other examples of animal architecture, web construction is the

result of several assembly phases that reflect different behavioral stages that must be properly coordinated to build a successful structure. Manual observations have revealed a range of sensory cues and movement patterns used during web construction, but methods to systematically quantify the dynamics of these sensorimotor patterns are lacking. Here, we apply an analytical pipeline to the web-making behavior of the orb weaver Uloborus diversus. Using an unsupervised clustering approach, we identify stereotyped leg movements both specific to and shared across stages of construction. A Hierarchical Hidden Markov Model reveals that stages of web-building are characterized by distinct and stereotyped sequences of actions largely shared across individuals. We will also share progress on ongoing work using semi-automated annotation of dynamic web geometry to model the spider's tactile sensory experience during web-making, and our progress towards developing two-photon calcium imaging in this spider.

Title: Acute and chronic anthropogenic noise exposure potentially affect Coenobita clypeatus' investigation and exploration of shell resources

Authors: *P. N. NEGRON-MORENO[1,2], A. D. GONZÁLEZ-COLÓN[2], F. J. TORRES-TORRES[2], N. RIVERA-ROSADO[2], A. FIGUEROA-GONZÁLEZ[2], N. RODRIGUEZ-MERCADO[2], M. A. GONZÁLEZ- DE JESÚS[2], L. L. VILLALOBOS-MILLAN[2], M. ROSADO-BURGOS[2], M. I. DE JESÚS-BURGOS[2];
[1]Yale, New Haven, CT; [2]Univ. of Puerto Rico, Cayey, Puerto Rico

Abstract: Noise pollution is recognized as a significant global environmental stressor. Studies suggest that noise exposure can alter animal behaviors related to reproduction, mating, resource assessment, and decision-making. The natural soundscape of littoral ecosystems is mainly affected by anthropogenic noise derived from tourism, urban development, and related activities. *Coenobita clypeatus* is a species abundant in the littoral zones of tropical and subtropical regions, that relies on basic behavioral patterns for survival. In particular, shell selection requires crabs to analyze the size, shape, nutrient content, and weight of the shell to decide whether it is worth acquiring as a resource. While the detrimental effects of noise pollution on animal behaviors are known, the implications of noise pollution on *C. clypeatus'* ability to gather information and assess resources remains unclear. We hypothesized

that exposure to anthropogenic noise would impair *C. clypeatus'* investigative patterns and decision-making abilities during shell selection. To evaluate the effects of noise exposure on *C. clypeatus'* shell selection behavior, animals were subjected to either an acute or chronic noise regimen. We analyzed the free exploration and investigation of a suboptimal, an optimal, and a supraoptimal shell resource by control, chronically- and acute-noise exposed animals. Preliminary results suggest that most animals regardless of the noise conditions opted for the optimal shell. Interestingly, animals that opted for suboptimal shells were only animals under chronic and acute noise regimens. These animals also spent more time investigating and occupying the suboptimal shell compared to animals under control conditions ($p<0.05$). Overall, these data seem to suggest that animals under noise exposure, either acute or chronic noise, display changes in their processing of investigation and exploration of key resources for survival. Future studies are necessary to provide a better understanding of the potentially detrimental effects of anthropogenic noise on the behavior and the neural substrates underpinning littoral organisms' behavior.

Title: Can't right, won't right - the differing roles of neurotransmitters in sea urchin righting behavior

Authors: M. MCDONALD, N. P. GRIFFIN, E. HOWELL, D. LI, S. HARNEW-SPRADLEY, P. RODRIGUEZ, A. LANCASTER, F. UMUTONI, J. BESH, ***C. SHELLEY**;
Univ. of the South, Sewanee, TN

Abstract: Sea urchins and other echinoderms occupy an unusual position in animal neurobiology as they lack a brain or a brain-like structure, but phylogenetically they are more closely related to vertebrates than virtually all other invertebrates. Despite the use of sea urchin gametes and larvae in developmental biology for over one hundred years, and the simplicity of the adult (metamorphosed) sea urchin nervous system, very little is known about how the adult

sea urchin nervous system functions, and in particular is utilized to produce behavior. One such behavior is the righting response, in which an inverted sea urchin rights itself within a few minutes. Here we determine roles in the righting response of some of the major neurotransmitters using antagonists of nicotinic acetylcholine, $GABA_A$, glycine, dopamine, and norepinephrine receptors. Antagonists of these receptors slowed the righting response in dose-dependent manners, with IC50s for righting, in order of potency of, 4.3 μM for glycine receptors, 10.7 μM for dopamine receptors, 39.8 μM for adrenergic receptors, 173 μM for $GABA_A$ receptors, and 7.8 mM for nicotinic acetylcholine receptors. It is also shown that inhibition of both glycine and adrenergic receptors inhibits tube foot movement independent of righting, and it may be that this inhibition of tube foot movement is responsible for the slowed righting seen when these receptors are inhibited. Conversely, although inhibition of dopamine receptors slowed the righting response, this inhibition had no effect on tube foot motility, indicating that these receptors play larger roles in the neural processing involved in the righting behavior, rather than the actual physical righting. Given dopamine's well characterized roles in motivation, these results raise the question of whether inhibiting dopaminergic signaling in sea urchins renders them unable to right (at the level of neural processing), or removes the motivation to right, and further raises the question of whether in this context, at the level of neural processing, there is actually any difference between these two states.

Title: Two-photon calcium imaging of orbitofrontal cortex in mice performing economic choices reveals stable activity profiles over many weeks

Authors: *A. LIVI, M. ZHANG, T. E. HOLY, C. PADOA-SCHIOPPA;
Washington Univ. of St Louis, Saint Louis, MO

Abstract: Lesion and neurophysiology studies established a strong link between economic choice and the orbitofrontal cortex (OFC). In particular, studies where monkeys or mice chose between different juices identified in OFC different groups of neurons encoding individual offer values, the binary choice outcome and the chosen value (Padoa-Schioppa and Assad, 2006; Kuwabara et al., 2020). It was proposed that these cell groups form a decision circuit, but the organization and mechanisms of this circuit are poorly understood. To shed light on this

fundamental question, we developed a new approach for two-photon calcium (Ca2+) imaging of OFC while mice engage in economic choices.In a single surgery, we inject AAV to express GCaMP6f and we implant a GRIN lens (diameter: 1 mm; A2.6 mm and L1.5 mm from Bregma). In each animal, we can thus record from 4-6 independent fields of view (FOVs). In each FOV, we routinely isolate 60-140 cells. We process Ca2+ activity with the CaImAn package (Pnevmatikakis et al., 2016; Giovannucci et al., 2019). For each cell, fluorescence traces are normalized by calculating $\Delta F/F$. Crucially, we can record from the same FOV in multiple sessions (different days). To match neurons, we register sessions to a common template, use locations defined in one session as reference for other sessions, and impose that $\geq$70% of cells be identified in all sessions. Using this approach, we can examine whether and how the neural population in OFC reorganizes over time.During the experiments, head-fixed mice choose between two juices (labeled A and B) offered in variable amounts. Each juice is associated with an odor, and the odor concentration indicates the juice quantity. In each trial, the two odors are presented simultaneously from the left and right sides, and the animal indicates its choice by licking a juice spout. The association between the juice type (A, B) and the spatial direction (left, right) varies pseudo-randomly. In each session, behavioral data are analyzed with a logit regression, which provides an estimate for the relative value of the juices. We recorded from 4 mice (21 FOVs; >1000 cells). Recordings started the first day in the choice task and continued for $\leq$4 months. We examined the activity profile of individual cells over the course of the trial. A cosine product quantified the similarity between activity profiles. We thus examined the distribution of cosine similarities obtained for repeated measures of the same cell and compared it with that obtained for different cells. The difference between the two distributions was highly significant even when sessions occurred >8 weeks apart. Hence, the activity profiles of individual neurons remained stable over time.

Title: Neuronal encoding of economic decision variables in the mouse orbitofrontal cortex is consistent across days

Authors: *M. ZHANG, A. LIVI, T. E. HOLY, C. PADOA-SCHIOPPA;
Neurosci. Dept., Washington Univ. In St. Louis, Saint Louis, MO

Abstract: An extensive literature indicates that the orbitofrontal cortex (OFC) plays an important role in economic choice behavior. In particular, neurophysiology studies where monkeys or mice chose between different juices identified in OFC different groups of cells encoding the value of individual options, the binary choice outcome, and the chosen value. These variables capture the input and output of the choice process, suggesting that OFC may host a decision circuit. To shed light on the organization of this circuit, we developed a new approach for two-photon calcium imaging of OFC in mice choosing between different juices (see companion abstract by Livi, Zhang et al.). Here we investigated whether the functional properties of individual neurons are stable over time.

We recorded from 3 mice and 10 distinct field of views (FOVs). Each FOV was imaged multiple times and we identified the same cell across sessions. Our data set included 767 neurons, each recorded twice and >7 days apart. Following the procedures of previous studies (Kuwabara et al., 2020), each cell was analyzed in relation to several decision variables. Tuned cells were classified independently in each session as encoding the spatial configuration, the ipsilateral offer value, the chosen side, or the chosen value. For a population analysis, we constructed a contingency table in which rows and columns corresponded to classes defined in the two sessions, and entries represented cell counts. We also derived a table of odds ratios. For all entries on the main diagonal, odds ratios were significantly above chance. Conversely, the vast majority of entries off the main diagonal were at or below chance level ($p<0.01$; Fisher's exact test). In other words, classification in the two sessions was generally very consistent, indicating that cells' functional properties are preserved over time.

Next, we examined whether neurons with similar functional properties form anatomical clusters. For each FOV, we calculated the spatial distance between each pair of cells encoding a particular variable. The resulting distribution was statistically indistinguishable from that obtained pairing cells in the same FOV randomly ($p>0.05$, one-way ANOVA test). Similarly, the distributions obtained for different cell groups were statistically indistinguishable. In other words, we did not find any evidence for spatial clustering.

In summary, our results indicate that the functional properties of OFC neurons encoding different decision variables are stable in time and not anatomically segregated. These findings and our approach pave the way to investigate in greater depth the neural circuit underlying economic decisions.

Title: Dissociable roles of basolateral amygdala and ventrolateral orbitofrontal cortex in flexible stimulus outcome and action-outcome association learning

Authors: *C. G. AGUIRRE[1], M. GOLDFARB[1], K. DAS[1], T. YE[1], J. J. MUNIER[2], M. GOMEZ[1], P. R. O'NEILL[3], I. SPIGELMAN[2], A. IZQUIERDO[1];

Abstract: Reversal learning methods in rodents often require animals to form associations between the spatial side (left vs. right) and reward (action-outcome, A-O). Other task types require animals to form associations between stimuli and reward (stimulus-outcome, S-O). Here we examined the roles of ventrolateral OFC (vlOFC) and basolateral amygdala (BLA) in flexible learning of S-O and A-O associations using chemogenetic manipulation. Male and female Long-Evans rats were required to discriminate the correct stimulus/action by nose-poking a touchscreen and assessed on measures of accuracy and speed. Rats were stereotaxically injected with either bilateral inhibitory hM4Di DREADDs on a CaMKIIa promoter in vlOFC or BLA, or with an eGFP virus in these same regions. Separately, Ca^{2+} imaging in slices co-expressing GCaMP6f and hM4Di DREADDs in BLA confirmed reduced activity following application of clozapine-N-oxide (CNO). vlOFC slice validation is ongoing. Rats were administered either CNO or vehicle (VEH) solution (3mg/kg, i.p.) 30 min prior to testing during reversal learning, using a within-subject, counterbalanced design for drug administration. Rats learned the initial S-O more slowly than A-O associations (S-O, 10.64 1.18; A-O, 2.250.11 sessions to 75%). During reversal phases, rats required more sessions to reach criterion on the S-O task relative to the A-O task, especially when vlOFC was inactivated, and exhibited poorer accuracy in S-O compared to A-O learning, with effects in the same direction (vlOFC poorer than BLA group). Rats were slower to initiate trials and to choose the correct and incorrect options in S-O than A-O learning (BLA slower than vlOFC group). Rats also took longer to collect reward after making a correct choice in A-O compared to S-O learning (BLA slower than vlOFC group). Overall, BLA inhibition enhanced A-O learning, whereas vlOFC inhibition slowed A-O learning. Finally, we fitted S-O and A-O reversal choice behavior with reinforcement learning models and found that a model with a single learning rate parameter (model 1) better captured S-O than A-O learning, and better than a model with two learning rates (model 2). There was a higher learning rate in S-O than in A-O across most virus/drug conditions. Animals exhibited greater Win-Stay strategy in A-O compared to S-O, consistent with a greater inverse temperature parameter in the A-O task in both model 1 and model 2. Overall, the pattern of results suggests different mechanisms for involvement of vlOFC and BLA in flexible learning, dependent on the nature of the associations, and reveal a need for different, more sensitive metrics to capture region-specific contributions.

Title: Contributions of ventrolateral orbitofrontal cortex to flexible stimulus-reward learning under delay conditions

Authors: *J. ROMERO SOSA[1], E. TREPKA[2], A. SOLTANI[2], A. IZQUIERDO[1];
[1]Dept. of Psychology, UCLA, Los Angeles, CA; [2]Psychological & Brain Sci., Dartmouth Col., Hanover, NH

Abstract: Stimulus-outcome learning can be influenced by changes in different reward attributes such as probability-of-reward or delay-to-reward, but the relationship between the two is unclear. To address this, we probed if stimulus-delay associations are learned similarly to stimulus-reward associations and the role and the role of the ventrolateral orbitofrontal cortex (vlOFC) in such learning. To that end, we trained male and female Long-Evans rats to discriminate two equiluminant visual stimuli, S_A and S_B, displayed on a touchscreen in pseudorandom left/right positions under two conditions: stimulus-reward discrimination where S_A results in reward (p=1.00) and S_B does not (p=0.00), both with a 1 s reward delay; or stimulus-delay discrimination where S_A results in a shorter wait time (0s) than S_B (8 s), both with 100% reward probability. Rats were prepared with bilateral inhibitory (hM4Di, G_i) DREADDs or eGFP null virus on a CaMKIIa promoter in vlOFC, and administered either clozapine-N-oxide (CNO) or vehicle (VEH) solution (3mg/kg, i.p.) 30 min prior to testing on all sessions following the initial discrimination phase. Rats learned stimulus-delay faster than stimulus-reward discrimination even when reward probabilities were fully predictive. To equate reward rate between stimulus-reward and stimulus-delay tasks, we introduced catch trials in the latter wherein 45% of all trials, regardless of which stimulus was chosen, were unrewarded. Introducing this uncertainty decreased stimulus-delay discrimination performance, flattening the learning curve. We then conducted a mixed-effects GLM with drug, virus, block, session, and task type (stimulus-reward vs. stimulus-delay) as predictors of accuracy. Our preliminary data suggest that vlOFC inhibition (hM4Di-CNO) enhances the choice of the stimulus associated with a shorter wait time. Finally, to probe behavioral strategy, we performed additional analyses using new entropy-based metrics

(Trepka et al. biorxiv) on each learning block's first and last sessions. Specifically, we compared surprise in animals' response based on association of outcome with chosen stimulus or chosen side, and separately after rewarded and unrewarded trials. We found that measures of entropy based on stimulus decreased on the last relative to the first session of the catch trial blocks, indicating that accumulation of experience on the contingencies leads to a more consistent response to reward. On the other hand, entropy based on side remained high throughout learning. Ongoing analyses are aimed at comparing hM4Di and eGFP groups on these measures across both probability and delay tasks.

Title: It takes a model to beat a model: keeping score for the neuroeconomics-based price heuristic hypothesis vs. price theory and the efficient markets hypothesis

Authors: *J. L. HARACZ;
Dept. of Psychological and Brain Sci., Indiana Univ., Bloomington, IN

Abstract: Objective: According to price theory (Jaffe et al., 2019) and the efficient markets hypothesis (EMH; Fama, 2014), supply and demand determine prices in markets that are at, or efficiently approaching, a self-stabilizing equilibrium (i.e., "price-equals-value markets" [Statman, 2017, p. 289]). This notion of price is challenged by the heuristics-biases literature, neuroeconomics, and bubble-crash instability, which suggest that prices deviate from economically fundamental values. Therefore, the present study seeks a more descriptively accurate reconceptualization of price. Methods: A systematic literature review of price theory, the EMH, neuroeconomics, heuristics, and biases used related search terms (e.g., demand curve, elasticity of demand, rule of thumb, trading, limits of arbitrage, and deliberation- or valuation-related brain areas) in the EconLit and PubMed databases, along with browsing abstracts of decision neuroscience meetings. Results: Over 30 years before Tversky and Kahneman (1971, 1974) analyzed heuristics and biases, Hall and Hitch's (1939, p. 18) survey revealed that price setters used a "full cost" "rule of thumb" rather than equating "marginal revenue and marginal cost" as in classical economic theory. This and many other examples of price-based heuristics (i.e., price heuristics) accrued before and after (e.g., price setters' "herding" [Kienzler, 2018, p. 86]) neoclassical economics came into prominence with an emphasis on price as a reliable indicator of fundamental value. In contrast, the novel price heuristic hypothesis (PHH) proposes that prices only occasionally indicate intrinsic values. Prices hypothetically act as heuristic

signals because: a) heuristics are embedded in prices (Hall & Hitch, 1939; Kienzler, 2018); b) prices guide market participants' decision making by serving as a signal for the use of heuristics. In the bubble-crash context, traders avoiding effortful deliberation (e.g., as in neural autopilot theory [Camerer et al., 2021]) could simply use asset-price changes as guides, or heuristics, to popular or unpopular assets, thereby letting traders fall under the spell of a bubble or crash bias, respectively. These biases may recruit habit-related basal ganglia mechanisms (Camerer et al., 2021), thereby promoting bubbles and crashes based on trend-following investment strategies. Conclusions: Price theory and EMH-inspired asset-pricing models are useful tools for analysts and policymakers, but they are not always descriptively accurate. The more descriptively accurate PHH is shown here to be relatable to neural mechanisms, but it has yet to be formalized as a tool for analysis and policymaking.

Title: Dissociable roles for basolateral amygdala (BLA) and anterior cingulate cortex (ACC) in the bias for information

Authors: *V. V. GONZALEZ, M. G. GOMEZ, A. P. BLAISDELL, A. IZQUIERDO; Psychology, UCLA, Los Angeles, CA

Abstract: When given a choice between a lean alternative that contains information about the outcome of a trial versus a richer alternative without information, most animals prefer the former: they prefer information even though that alternative yields lesser reward. This effect has been referred to as the suboptimal choice phenomenon or the 'bias for information' effect and it has been observed in pigeons, starlings, rats, and in humans. Most studies have focused on better understanding the behavioral limits of this phenomenon, yet there are few experiments directed at identifying the neural substrates of this preference. Value is computed by comparing the subjective value of the alternatives, after integrating all the features of the options, and perhaps also including information value, a process that may rely on corticoamygdalar circuits. In the present set of experiments, female Long-Evans rats were prepared with either bilateral inhibitory hM4Di DREADDs on a CaMKIIa promoter in basolateral amygdala (BLA) or anterior cingulate cortex (ACC), or administered an eGFP virus in these regions. Rats were administered either clozapine-N-oxide (CNO) or vehicle (VEH) solution (3mg/kg, i.p.) 10 min prior to behavioral

testing. We used a within-subject counterbalanced design for drug administration. We first evaluated the role of BLA and ACC during acquisition and performance of the basic effect: choosing between two alternatives by pressing the right or left lever, in which choice of one (suboptimal/informative alternative) resulted in 20% of the trials followed by a tone (S+) that lasted 60s and always ended with a sucrose pellet, and on the other 80% of the trials followed by another tone (S-) lasting 60s but never resulting in reinforcement. Choice of the other alternative always resulted in a third 60-s tone (S3) followed by reward on 50% of the trials. Then, we trained a new set of tones to be S+, S- and S3 to evaluate the role of ACC and BLA in the acquisition and performance of the informative and non-informative cues in preference. Finally, we reversed the spatial location of the two levers and assessed the contribution of both areas during learning and steady-state performance. We found that inhibition of ACC, but not BLA, reversed the preference of the rats. BLA inhibition, on the other hand, produced an attenuated acquisition of the preference for information when new cues were introduced, but we found no evidence for a contribution of BLA in learning the reversed location of the two levers. In replication cohorts, we expect ACC to similarly contribute to the learning and steady-state preference of new informative and non-informative cues, and on the spatial reversal of that choice.

Title: Probing hippocampal involvement in stimulus- and action-based reward learning using a combination of electrophysiological, chemogenetic, and behavioral tracking approaches

Authors: *A. G. HOWE, C. G. AGUIRRE, T. YE, A. M. WIKENHEISER, A. IZQUIERDO; UCLA, Los Angeles, CA

Abstract: The hippocampus (HPC) is famous for the “place” cell; a neuron that spikes vigorously when a rat moves through a particular subregion of a given physical space. Populations of place cells are theorized to form “cognitive maps” of physical behavior space. More recent data demonstrates that HPC function extends beyond maps of physical space, demonstrating HPC representations of non-spatial behavior (Aronov et al 2017) and elements of

the task structure itself (Samborska et al. biorxiv 2021). Results from the macaque demonstrate a HPC map of non-physical "value space" (Knudsen & Wallis, biorxiv 2021). Complementing single cell observations, disruption of the Theta local field potential (LFP) in either HPC or orbitofrontal cortex (OFC) in the macaque impairs flexible reward learning (Knudsen & Wallis, 2020). However, the mechanism by which HPC is involved in flexible stimulus-based and action-based reward learning and the degree to which OFC-HPC interaction supports similar behavior in the rat is unknown. Here, we attempt functional dissection of this circuit with simultaneous behavior, electrophysiology and chemogenetic inactivation in the rat. Male and female Long-Evans rats (N=6) received bilateral inhibitory hM4Di DREADDs on a CaMKIIa promoter in ventrolateral OFC (n=4) or in HPC (n=2) at the same time as implantation of a novel 8 tetrode (32 channel) adjustable-position drive in HPC. This drive provides single-unit and LFP data in a device suitable for free-movement in an operant chamber where we could precisely mark trial events including trial initiation, response selection, and reward collection. Rats discriminated the correct stimulus or action (left/right) by nosepoking a touchscreen. Rats received either clozapine-N-oxide (CNO; 3mg/kg, i.p.) or vehicle (VEH) solution 30 min prior to testing during reversal learning, using a within-subject, counterbalanced design for drug administration. Computer vision and machine learning techniques enabled the extraction of the rat's position and behavior state from live video; TTL pulses from the behavioral system facilitated synchronization of electrophysiological data with the other data streams. We found single units in HPC which encoded specific events such as trial initiation and correct/incorrect choice in the task sequence without encoding for a specific spatial location. We also confirmed placement of electrodes in CA1, as well as DREADDs expression in OFC. Analyses of resulting DREADDs inactivation of either vlOFC or HPC on single unit activity are ongoing.

Title: Theta oscillations in anterior cingulate and orbitofrontal cortex differentially modulate accuracy and speed in flexible stimulus- and action-based learning

Authors: *T. YE, A. M. WIKENHEISER, A. IZQUIERDO;
Psychology, UCLA, Los Angeles, CA

Abstract: Flexible reward learning relies on frontal cortex, with substantial evidence indicating the anterior cingulate cortex (ACC) and orbitofrontal cortex (OFC) play important roles. A systematic investigation of how rat ACC and OFC contribute to stimulus-based and action-based learning is lacking in the broader literature. Further, we recently suggested that a thorough consideration of both accuracy and speed during discrimination and reversal phases can be particularly informative when studying neural signatures of flexible learning (Aguirre et al., 2020; Harris et al., 2020), which we set out to study here. Recent studies in both rat and macaque suggest theta oscillations may be a spectral signature that coordinates this learning. However, causal network-level interactions between ACC and OFC in flexible learning remain unclear. We investigated the learning of stimulus-outcome (S-O) and action-outcome (A-O) associations using a combination of simultaneous *in-vivo* electrophysiology in dorsal ACC (dorsal area 32/24, van Heukelum et al. (2020)) and ventral OFC, partnered with bilateral inhibitory DREADDs in ACC. Using a within-subject design, we examined accuracy and speed across distinct and precisely-defined trial epochs including trial initiation, choice of the correct response, choice of the incorrect response, and reward collection. Using a series of mixed-effects GLMs, we found consistent and significant modulation of accuracy, not speed, by theta (5-10 Hz) power in ACC and OFC during S-O discrimination and reversal learning, respectively. Specifically, ACC and OFC theta in the discrimination post-choice epoch were significant moderators of the choice of correct stimulus. ACC theta in the pre-choice epoch was the only significant predictor of the correct choice ($p=0.01$). In reversal, OFC theta in the post-choice epoch was the only significant moderator of the choice of correct and incorrect stimulus. Correlation analyses did not reveal any significant relationships between theta power and movement speed for any of the trial epochs (all $p>0.05$). In contrast, in A-O learning an interaction of ACC x OFC theta predicted both speed and accuracy of the correct response, specifically in the reversal phase. Importantly, ACC inhibition affected A-O latency measures more profoundly than accuracy, suggesting that action-based reversal learning impairments reported in the literature may be primarily due to changes in deliberation speed. The pattern of results suggests there is less specialization of OFC and ACC (i.e., more shared roles) in flexible learning of both stimuli and actions in rats than in human/nonhuman primates.

Title: Representation of credit-deserving feature information and reward prediction errors across prefrontal cortical areas during credit assignment

Authors: *E. LEE[1,3], W. F. ASAAD[1,3,4,2];
[1]Neurosci., [2]Neurosurg., Brown Univ., Providence, RI; [3]Carney Inst. for Brain Sci., Providence, RI; [4]Norman Prince Neurosciences Inst., Rhode Island Hosp., Providence, RI

Abstract: The outcome of a choice must be attributed to a causal event or experience and properly adapted to the success or failure of that choice even the causal event is separated in time or intermingled with distractors. This is known as a credit assignment problem and the prefrontal cortex (PFC) is likely to play a major role in its solution. However, the precise areas involved, and the manner through which outcomes and credit-deserving features are integrated, are still unknown. To investigate this, we trained two monkeys to perform a credit assignment task and implanted large recording arrays (96 and 128 electrodes) over the PFC, including dorsomedial PFC (dlPFC), ventral lateral PFC (vlPFC) and Orbitofrontal Cortex (OFC). In the task, they learned to attribute a choice outcome to one of several earlier options, and correct choices were indicated by generic feedback (not revealing the causal feature) followed by juice reward. We fit a reinforcement learning model to behavior and then examined how neuronal activity weighted relevant task parameters using a multi regression analysis (parameters included cue identities, cue locations, cue values, reward prediction errors and spike history effects). Preliminary analyses revealed that vlPFC and OFC both carried information about the credit-deserving cue (14.6% and 12.4% fraction of recorded vlPFC units and 12.9% and 16.9% fraction of recorded OFC units, $p<0.05$) and about reward prediction errors (20.5% and 20.9% fraction of recorded vlPFC units and 23.6% and 19.1% fraction of recorded OFC units, $p<0.05$) during feedback period in each animal, respectively. These results indicate that both vlPFC and OFC were involved in resolving temporal credit assignment and further work will characterize interactions between credit-deserving features and reward prediction errors in these PFC areas.

Title: Multi-regional neural circuit mechanisms underlying the maintenance of action value and its reward-dependent update

Authors: *U. PEREIRA OBILINOVIC[1], H. HOU[2], K. SVOBODA[3], X.-J. WANG[1];
[1]New York Univ., New York, NY; [2]HHMI / Janelia Res. Campus, Ashburn, VA; [3]HHMI / Janelia Farm Res. Campus, Ashburn, VA

Abstract: During dynamic foraging, action values are stored in short-term memory over times of several behavioral trials (seconds to minutes), much longer than intrinsic neural time scales. The stored action values bias actions to maximize reward. In the frontal cortex (mPFC, OFC), neuronal representations of action value can persist for tens of seconds. After a choice is made, mPFC firing rates are proportional to the new estimated action value (Bari et al, 2019). Two neuronal mechanisms have been proposed for the memory trace of action values and their update: (i) reward-dependent synaptic plasticity and (ii) integration of action value by network dynamics. In the first mechanism, rewards trigger dopamine release, which enables Hebbian plasticity at corticostriatal or mPFC synapses (Soltani and Wang, 2006). This plasticity rule leads to matching behavior in the steady-state, as observed in multiple species. Since spiking activity is driven by synaptic inputs, neuronal activity is modulated by action values. In the second mechanism, neural populations integrate reward events for each of the two action values: a pulsatile input proportional to the reward prediction error (RPE) in the action value mode direction changes their firing rates by a specific amount, and the updated action value is maintained in short-term memory. Similar to a theoretical proposal of mPFC as a meta-reinforcement learning system (Wang and Kurth-Nelson et al, 2018), in this second model, action values are integrated into a line-attractor without the need for synaptic plasticity. We analyze these two models drawing contrasting predictions. We test some of these predictions in electrophysiological recordings during dynamic foraging in mice.

Title: The orbitofrontal cortex is necessary for forming outcome-specific representations during learning

Authors: *K. M. COSTA[1], R. SCHOLZ[2], K. LLOYD[2], M. P. GARDNER[3], P. DAYAN[2], G. SCHOENBAUM[1];

Abstract: The orbitofrontal cortex (OFC) is necessary for using learned representations of outcomes to guide behavior, i.e. model-based cognition. For example, lesions of the OFC have long been known to impair changes in conditioned responding following reinforcer devaluation. These findings, among others, have fueled the hypothesis that the OFC contributes to the use of mental representations that link cues to the incentive properties of outcomes and support inferential thinking (which is necessary for reinforcer devaluation effects). However, it is unclear whether the OFC is necessary for creating such representations or only for their use in guiding subsequent decision making. To answer this question, we conducted a simple experiment in which we used high-potency chemogenetics to inactivate OFC in rats only during the first, rather than in the final, phase of an outcome-specific Pavlovian reinforcer devaluation task. Rats were conditioned to associate two cues with two different rewards, during which OFC was inactivated in the experimental group. Subsequently, one reward was devalued by pairing with LiCl, and, finally, responding to the two cues was assessed in an extinction test. During conditioning, groups showed robust learning to both cues, although the experimental group responded less in the final two sessions. Both groups also similarly reduced consumption of the outcome paired with illness in taste aversion training. However, in the probe test, rats in the experimental group responded equally to cues predicting the devalued versus the non-devalued outcome. Importantly, they suppressed responding to both cues, indicating a loss in response specificity rather than an abolishment of devaluation effects. One interpretation is that, without OFC, rats were still able to form a model, but one without outcome-specific information. Therefore, transient and reversible OFC inactivation during conditioning affected the rats' ability to use the learned information to support selective response changes in the probe test. This result implicates OFC in the formation of appropriate model-based and outcome-specific representations during cue-outcome learning.

Title: Memory reactivation with sleep disruption harms specific memories

Authors: *N. W. WHITMORE, K. A. PALLER;
Northwestern Univ., Evanston, IL

Abstract: Sleep plays a role in stabilizing memories so they are not forgotten. A prevalent view is that this process depends on active consolidation during sleep; important memories are replayed in the hippocampus and cortex to drive the neural plasticity underlying consolidation. In recent years, Targeted Memory Reactivation (TMR) has emerged as a useful tool for investigating consolidation, allowing researchers to induce replay of specific memories using sensory cues presented during sleep. Memories are typically strengthened by TMR compared to control conditions. However, in some cases the opposite effect has been observed, with relatively increased forgetting for reactivated memories. We hypothesized that forgetting can occur when micro-arousals disrupt the consolidation process, perhaps due to noise injected into the memory trace at the time of reactivation. To test this hypothesis, we conducted an experiment in which 25 participants each learned 75 object-location associations before an afternoon nap. When each object appeared on the screen, its characteristic sound was also presented. Memory was tested by requiring participants to recall the screen location of each object. During the nap, 50 of the associations were reactivated during nonREM sleep using their corresponding sounds. Each sound was presented once during the nap, in random order. Half of these sounds were played at a relatively high volume, to disrupt sleep, and half were played quietly, to avoid any arousal from sleep. Participants recalled object locations both before and after the nap. The usual TMR effect, confirmed in a recent meta-analysis (Hu et al., 2019, Psychological Bulletin), is that locations are recalled more accurately following reactivation. We found a reversed TMR effect in the context of disrupted sleep, with less-accurate recall for reactivated object locations compared to those not reactivated. Sleep EEG revealed that only sounds that produced an arousal degraded memory. These findings showing that reactivation during sleep can harm specific memories have implications for understanding memory consolidation, for considering how to maximize the benefits of memory reactivation during sleep, and perhaps for constructing interventions to apply when weakening a memory would be appropriate

Title: The role of encoding context in memory reactivation during sleep

Authors: *E. SCHECHTMAN, J. HEILBERG, K. A. PALLER;
Dept. of Psychology, Northwestern Univ., Evanston, IL

Abstract: Throughout our waking lives, new memories are formed continuously. Such memories never exist in a vacuum; they may be interlinked with other memories that share semantic features and with those that share temporal proximity. In this study, we explored the role encoding context plays in offline consolidation during sleep. Memory was tested using 72 images of single objects, each presented with a related sound. Human participants first formed idiosyncratic narratives linking sets of objects together. Then, they learned the distinct 2D spatial location of each object. During non-rapid-eye-movement sleep, some object-specific sounds were unobtrusively presented, a technique termed targeted memory reactivation. This manipulation putatively reactivated object memories, thereby provoking consolidation. Results showed that sleep-related changes in memory for contextually linked memories were correlated, indicating that consolidation is impacted by encoding context. Moreover, multivariate pattern analyses revealed that context-specific electrophysiological patterns were reinstated following sound presentations during sleep. Overall, these results indicate that reactivation of memories during sleep is accompanied by the reactivation of features of encoding context and that this intervening processing impacts subsequent recall.

Title: A neural network model of sleep-dependent consolidation via autonomous hippocampal-cortical replay

Authors: *D. SINGH[1], K. A. NORMAN[2], A. C. SCHAPIRO[1];
[1]Psychology, Univ. of Pennsylvania, Philadelphia, PA; [2]Psychology, Princeton Univ., Princeton, NJ

Abstract: The Complementary Learning Systems theory posits that the hippocampus "teaches" neocortex about recent experiences during offline periods, including sleep (McClelland, et al., 1995, Psychol. Rev.). How are these systems able to interact during periods with no environmental input to accomplish useful learning and shifts in representation? We present a neural network model of autonomous replay that provides an account of how the hippocampus helps neocortex build representations of recent experience during sleep, and how this new information becomes integrated into existing neocortical knowledge structures. The network architecture incorporates biological details of hippocampal circuitry and includes a neocortical layer as the target of consolidation. To simulate sleep, we silence all external input and allow the model to move autonomously among memory attractors. We leverage sleep oscillations to reveal weaknesses in the attractors (Norman et al., 2005, Neural Netw.) and allow error-driven learning. Our first simulation examined how new information stored in the hippocampus shapes neocortical representations during Slow Wave Sleep (SWS). We simulated a human category learning study that found that memory for features shared among exemplars within a category improved across a night of sleep (Schapiro et al. 2017, Sci. Rep.). In our model, pre-sleep behavior was mainly supported by the fast-learning hippocampus, and hippocampal-cortical replay during simulated SWS helped to build neocortical representations. These new neocortical representations especially benefited the shared category structure, providing an account of the human data. Our second simulation explored how sleep may help integrate new information into existing knowledge, operationalized as a continual learning problem. We adopted the classic AB-AC list learning task. We first allowed AB knowledge to be consolidated in cortex, then evaluated whether interleaving SWS and Rapid Eye Movement (REM) sleep across a night of sleep could help avoid interference from new AC learning. SWS emphasized hippocampus teaching cortex AC information while REM involved cortex replaying its previously-learned AB information, helping to protect AB representations from catastrophic interference. Alternating between SWS and REM over the course of the night may thus permit effective continual learning. Together, our simulations demonstrate key mechanisms by which autonomous replay during sleep may facilitate the construction and maintenance of neocortical knowledge.

Title: Hippocampal-prefrontal neuronal synchrony during human sleep mediates memory consolidation

Authors: *M. GEVA-SAGIV[1,2,4], E. A. MANKIN[2], D. ELIASHIV[3], S. EPSTEIN[5], N. CHERRY[2], G. KALENDER[2], N. TCHEMODANOV[2], Y. NIR[5], I. FRIED[2];

Abstract: Systems-level memory consolidation during sleep is thought to depend on coordinated interplay of neocortical slow-waves, thalamo-cortical sleep spindles, and hippocampal ripples, but direct evidence is lacking. Here, we directly addressed this hypothesis by dynamically manipulating the temporal coordination between sleep activities in human medial temporal lobe (MTL) and neocortex. We implemented real-time closed-loop (RTCL) deep brain electrical stimulation in prefrontal cortex during MTL active periods, and tested how this intervention affects sleep electrophysiology and overnight consolidation of declarative memory. Upon informed consent, 14 pharmacoresistant epilepsy patients implanted with intracranial electrodes for clinical monitoring participated in intracranial stimulation and iEEG recording sessions of detailed neural activity during sleep. We examined the cognitive effects of this intervention in a subset of patients (N = 10) who learned paired associations between images in the evening and performed recognition tests immediately after learning and in the morning following sleep. Each patient participated in two night sessions (order counterbalanced) either with RTCL stimulation during sleep or without. RTCL stimulation, robustly locked to MTL slow-wave active phase, enhanced the synchronization between MTL-ripples, neocortical SW and sleep spindles (*P = 0.013). Moreover, neuronal units across multiple neocortical sites significantly synchronized their firing to MTL slow-wave activity, evident by increased phase locking to MTL field potentials (N = 64 neo-cortical units, $P<10^{-13}$). Enhancing the endogenous coordination between MTL ripples, neocortical slow waves and spindles by timed electrical stimulation resulted in higher memory accuracy on the next day (N=7 patients, $P < 0.05$). Importantly, we found a strong correlation between the extent of enhanced triple co-occurrence of MTL ripples and neocortical slow waves and spindles with overnight memory performance (N=8 patients, $\rho = 0.82$, *P = 0.017). Conversely, cognitive improvement wasn't correlated to a change in interictal spikes activity (P = 0.15). A control group (N = 3) with deep brain stimulation that was not locked to MTL active phase (but otherwise identical) did not show the electrophysiology and cognitive effects. Our results implicate fine temporal coordination between MTL ripples and neocortical slow waves and spindles as mediating mechanisms for declarative memory consolidation, and suggest potential avenues for treatment of memory disorders during sleep.

Title: Breaking down neural correlates of memory during sleep: An exploration of typical and atypical sleep oscillations

Authors: *E. ESPINAL[1,2], A. MISHRA[1], N. MARKOWITZ[1], E. G. CHRYSIKOU[2], A. D. MEHTA[1], S. BICKEL[1];

Abstract: Memory is a critical piece of the human experience and impairments in neural memory networks can have devasting consequences for the affected person. A subtype of memory, episodic memory generates context for the present based on past experience and allows us to make predictions about the future. It is thought that consolidation of episodic memory requires a dynamic interplay between connected hippocampal-cortical networks, a process which crucially continues during sleep. Hallmark sleep oscillations, slow oscillations and thalamocortical spindles, couple with hippocampal sharp wave ripples (SWR) were proposed to be mechanistically involved in establishing this cortical-subcortical dialog necessary for long-term memory consolidation. The current study aimed to determine alterations in typical sleep oscillations and oscillation coupling in patients with structural hippocampal damage and correlate them with neuropsychological measures. We used intracranial electroencephalography (iEEG) in 8 patients with epilepsy to directly record hippocampal and neocortical oscillations and neuropsychological measures obtained prior to implantation. Participants in this study were diagnosed with mesial temporal sclerosis in the left hippocampus and healthy tissue in the right hippocampus. We analyzed hippocampal SWR output from both hippocampi for each participant and found significant differences in the frequency, amplitude, and waveforms of SWR in the sclerotic versus healthy hippocampi. Additionally, we found differences between hemispheres in coupling of SWRs to spindles and SOs. To understand the relationship between electrophysiological biomarkers and memory performance, we correlated outcomes with behavioral measures captured through an auditory verbal learning task designed to assess long-term memory function. Results from this work will aid in establishing a criterion for

characterizing a relationship between subcortical and cortical oscillations as they relate to memory performance. Besides aiding our understanding of the neural mechanisms underpinning memory consolidation this will ideally help with developing a neurophysiological biomarkers that may predict possible memory decline in resective or ablative neurosurgery even if no structural lesion is present.

Abstract: In the two-stage model of memory consolidation, memories are first formed in the hippocampus and then transferred to neocortex for long-term storage (McClelland et al., Psychological Review, 1995; Rasch and Born, Curr Opin Neurobiol, 2007). This transfer is mediated by synaptic plasticity, for which co-occurrence of pre- and post-synaptic activity plays a critical role (Bi and Poo, J Neurosci, 1998). While it has become increasingly clear that sleep oscillations actively and causally contribute to this process, it remains unclear to what extent these oscillations coordinate activity across areas in neocortex. Based on early recordings in animals under anesthesia, sleep rhythms were generally considered to occur across a wide range of cortex, creating a state of large-scale synchrony (Andersen et al., J Physiol, 1967; Contreras et al., J Neurosci, 1997; Achermann and Borbély, Neuroscience, 1998).
Recent work, however, has challenged this idea by reporting isolated sleep rhythms such as slow-oscillations and spindles. What is the spatial scale of sleep rhythms in cortex? To answer this question, we adapted deep learning algorithms initially developed for detecting earthquakes and gravitational waves in high-noise settings to analysis of neural recordings in sleep (Perol et

al., Science Advances, 2018; George and Huerta, Physics Letters, 2018). We studied sleep spindles in non-human primate electrocorticogram (ECoG), human electroencephalogram (EEG), and clinical intracranial electroencephalogram (iEEG) recordings. Our approach, which detects a range of clearly formed large- and small-amplitude spindles during sleep, reveals that sleep spindles co-occur over a broad range of cortex. In particular, multi-area spindles, where more than 10 electrode sites exhibit this rhythm simultaneously, are much more frequent than previously estimated by amplitude-thresholding approaches, which tend to select only the highest-amplitude spindles and can miss events that temporarily fall below threshold. Because spindles are intrinsically related to sleep-dependent consolidation of long-term memories, these results have important implications for the distribution of engrams in primate cortex.
We next hypothesized that, if multi-area spindles are actively involved in consolidating distributed networks in cortex, they may exhibit an increased prevalence across areas following a memory task. To address this additional hypothesis, we analyzed human EEG recordings following a low- and high-load visual working memory task. Consistent with this hypothesis, we find our method detects an increase in multi-area spindles in the high-load memory condition.

Title: The Dream Affect: The Role of Dreaming in Emotional Processing

Authors: *N. DELANO[1], A. PENA[1], K. SIMON[1], N. SATTARI[1], A. SHUSTER[1], E. ALZUETA[2], T. DULAI[2], M. DE ZAMBOTTI[2], F. BAKER[2], S. MEDNICK[1], J. ZHANG[1]; [1]Univ. of California Irvine, Irvine, CA; [2]SRI Intl., Menlo Park, CA

Abstract: Introduction Prior studies suggested that rapid eye movement sleep strengthens emotional memory while attenuating the affective tone (Werner, et al., 2015), and is a sleep stage where dreams are reported most often (Scarpelli et al., 2019). However, the role of dreaming in emotional processing remains unclear. Furthermore, dreaming experiences tend to be emotionally-valenced, but the effect of dream emotionality on emotional processing has been largely ignored. The goal of this study is to investigate the role of dreaming and its emotionality on sleep-dependent emotional processing. **Methods** 58 healthy women participated in this remote study (M_{Age}=36.24, SD=12.15). Participants completed the Emotional Picture Task

(EPT) encoding and immediate test before bedtime (Test 1). The next morning, participants reported their dreams through a sleep diary and were retested on the EPT (Test 2). During encoding, participants viewed negative and neutral images (selected from IAPS) and rated arousal (low to high) and valence (neutral to negative) for each image. During testing, participants reported if presented pictures were old or new and rated their arousal and valence. To examine whether dreaming influences emotional processing, we ran an independent sample t-test on EPT performance, valence and arousal ratings between dreamers and non-dreamers. We further divided dreamers into positive and negative based on subjective dream mood ratings to examine the effect of dreaming valence on emotional processing. **Results** 22 participants reported dreaming, 15 of which reported positive dreams. There was no significant difference between dreamers and non-dreamers on arousal/valence or memory performance ($p>.05$). Negative dreamers reported increased valence for negative images at Test 1 ($t(20)=2.16$, $p=.04$), higher arousal for negative (Test 1 $t(20)=2.81$, $p=.01$, Test 2 $t(20)=2.17$, $p=.04$) and neutral images (Test 1$t(20)=3.54$, $p<0.01$ Test 2 $t(20)=2.22$, $p=.04$) during both tests, compared to positive dreamers. Compared to non-dreamers, negative dreamers had increased arousal for negative images during both tests (Test 1:$t(41)=-2.97$, $p<.01$, Test 2: $t(41)=-2.12$, $p=.04$), and for neutral images during Test 1 ($t(41)=-2.58$, $p=.01$). **Conclusion** Our results suggest that the emotionality of dreams, rather than the act of dreaming, is implicated in emotional reactivity during wake. Specifically, those who have negative dreams tend to have higher levels of emotional reactivity. Our findings are inconsistent with the hypothesis that dreaming attenuates emotional reactivity. Instead, we found a continuity between dream emotion and waking emotional experiences.

Title: Dopamine-based mechanism for transient forgetting

Authors: *J. SABANDAL, R. L. DAVIS;
Neurosci., The Scripps Res. Inst., Jupiter, FL

Abstract: Active forgetting is an essential component of the memory management system of the brain. Forgetting can be permanent, in which prior memory is lost completely, or transient, in which memory exists in a temporary state of impaired retrieval. Temporary blocks on memory seem to be universal, and can disrupt an individual's plans, social interactions and ability to make rapid, flexible and appropriate choices. However, the neurobiological mechanisms that cause transient forgetting are unknown. Here we identify a single dopamine neuron in Drosophila that mediates the memory suppression that results in transient forgetting. Artificially activating this neuron did not abolish the expression of long-term memory. Instead, it briefly suppressed memory retrieval, with the memory becoming accessible again over time. The dopamine neuron modulates memory retrieval by stimulating a unique dopamine receptor that is expressed in a restricted physical compartment of the axons of mushroom body neurons. This mechanism for transient forgetting is triggered by the presentation of interfering stimuli immediately before retrieval.

Title: “Tyrosine and Oxytocin Detection with Carbon fiber-microelectrodes and fast scan cyclic voltammetry.”

Authors: *N. GHASEM ARDABILI[1], I. BROWN[2], C. COOK[2], F. LIU[2], A. G. ZESTOS[3]; [1]American Univ. DC, Wasington, DC; [2]American Univ., Washington DC, DC; [3]Chem., American Univ., Washington, DC

Abstract: “Tyrosine and Oxytocin Detection with Carbon fiber-microelectrodes and fast scancyclic voltammetry.”During the past few decades, carbon fiber microelectrodes (CFMEs) have been used forthe detection of biomolecules with fast scan cyclic voltammetry. This method has beendeveloped within the electrochemical field for improving analytical techniques such asmeasuring dopamine and other neurotransmitters. Peptides are vital and essential for the humanbody as they perform physiological and metabolic functions. Neurotransmitters, which are

one ofthe important classes of biomolecules, are important for determining several diseases andadministering pharmacological treatments. Oxytocin is a pleiotropic, peptide hormone that has awide impact on general health, adaptation, development, reproduction, and social behavior. Thisneuropeptide has different functions such as serving as a stress-coping molecule, anti-inflammatory agent, and serves as an antioxidant with protective effects especially in the face ofadversity or trauma.Moreover, this hormone can enhance social interactions, sexual activity, affiliative preferences,and parental behaviors. One of the important implications of oxytocin is in women's labor andfacilitates the procedure of parturition in women.With this method, we show the first measurement of Oxytocin with carbon electrodes andfast scan cyclic voltammetry. We applied a triangle waveform, when scanned from the holdingpotential of -0.2V to the switching potential of +1.2V and back. This waveform was insufficientand was not able to solely measure Oxytocin. Therefore, we developed the ModifiedWaveform(MSW), with a holding potential of -0.2V to the transition potential of +0.7V andswitching potential of +1.2V, with two different scan rates applied. Finally, we then measuredexogenously applied oxytocin on rat brain slices using the MSW waveform. This technique seeks
to develop novel assays for neuropeptide detection on a fast, subsecond timescale with possibleimplications for *in vivo* measurements.

Title: Fscv and the novel carbon fiber multielectrode arrays for in vivo measurements of neurotransmitters

Authors: *H. RAFI[1], A. G. ZESTOS[2];
[2]Chem., [1]American Univ., Washington, DC

Abstract: FSCV, or fast scan cyclic voltammetry, is an electrochemical technique that measures the oxidation and reduction of various single molecules and proteins. They are oxidized/reduced at specific voltages which serve as a "molecular fingerprint" for detection. Carbon fiber microelectrodes (CFMEs) have been extensively used to measure neurotransmitters with FSCV due to their ability to adsorb cationic monoamine neurotransmitters. Although this method provides high temporal and spatial resolution, only single channel potentiostats and electrodes have been primarily utilized thus far. The need and use of carbon fiber multielectrode arrays has risen to target multiple brain regions. We characterized the novel carbon fiber multielectrode array (MEA), a four-channel electrode, and found it comparable to the single channel CFME. The MEA, when coupled with a commercially available multichannel potentiostat, had the additional capability of multiplexing neurotransmitter measurements *in-vitro* by multi-waveform application. The 4-channel potentiostat also allowed for the use and detection in multiple brain regions *ex-vivo*. In the present study we determined if the MEA could detect neurotransmitters endogenously when it was implanted *in-vivo* in anesthetized and freely behaving mice. Successful implantation of this electrode will aide in understanding complex brain heterogeneity, the dynamic neurochemical environment, and how disease states or drugs affect separate brain areas concurrently.

Title: All diamond microelectrodes for neurotransmitter measurement with fast-scan cyclic voltammetry

Authors: *J. R. SIEGENTHALER[1], R. RECHENBERG[1], A. HARDY[1], M. F. BECKER[1], E. K. PURCELL[2], W. LI[2];
[1]Fraunhofer USA, CMW, East Lansing, MI; [2]Michigan State Univ., East Lansing, MI

Abstract: Diamond is a versatile material that is biocompatible, chemically inert and has a wide potential window for electrochemical detection. Diamond has previously been grown on a tungsten wire and used to measure dopamine and other electroactive neurotransmitters both in vitro and in vivo with high spatial and temporal resolution using fast-scan cyclic voltammetry (FSCV). Here we report on the further development and optimization of an all diamond microelectrode that can electrochemically measure common neurotransmitters with a linear

response. The all-diamond microelectrode consists of a boron-doped polycrystalline diamond core encapsulated in a polycrystalline diamond insulating sheath improving on the biocompatibility, and flexibility in batch-wafer-fabrication. Using these electrodes, we characterized several common neurotransmitters for the linear dynamic range, detection limit and noise of the diamond electrodes, measuring dopamine, serotonin, 3,4-Dihydroxyphenylacetic acid, ascorbic acid, and hydrogen peroxide through FSCV. Using all diamond electrodes for neurotransmitter analysis is advantageous as it is the gateway to batch fabrication of microelectrodes, decreasing errors generated in the traditional hand fabrication methods, and building towards a scalable batch method for electrode array technologies.

Title: Multielectrode Arrays for Neurotransmitter Detection with Fast Scan Cyclic Voltammetry

Authors: A. G. ZESTOS[1], H. RAFI[2];
[1]Chem., [2]Neurosci., American Univ., Washington, DC

Abstract: The brain is by far the most heterogeneous organ, and it is critically important to monitor various brain regions simultaneously in order to understand complex pharmacological, drug, and behavioral states. Therefore, it is critically important to make high temporal resolution neurochemical measurements to study the phasic firing of neurons in several brain regions concurrently. Fast scan cyclic voltammetry (FSCV) and carbon-fiber microelectrodes (CFMEs) have been utilized used to detect several important neurochemicals *in vivo*. FSCV allows for high temporal measurements (< 100 msec) of neurotransmitter levels. Some of the many applications of this technique could be measuring neurochemical changes during epileptic seizures with simultaneous EEG measurements in rodents, drug abuse studies, measuring robust dopamine increases during deep brain stimulation in Parkinsonian models, and possibly many

others. This work will also discuss the development of multielectrode arrays (MEAs) for neurotransmitter detection with fast scan cyclic voltammetry in multiple brain regions simultaneously. Parylene and silicon insulated carbon fiber microelectrode arrays were shown to be able to measure neurochemicals in multiple brain regions simultaneously when coupled with multichannel potentiostats. Moreover, we have utilized techniques such as plasma enhanced chemical vapor deposition (PECVD) to deposit conductive carbon nanospikes onto the surface of existing metal multielectrode arrays to give them dual functionality as neurotransmitter sensors with FSCV in addition to being used primarily for electrical stimulation and recording. Other assays have shown the utility of electrodepositing carbon nanotubes and polymers such as PEDOT to coat metal arrays with carbon to give them dual sensing capabilities.

Title: Induction of Episodic Headache Phenotypes in Sprague Dawley Rats following DAGLa Inhibition

Authors: *A. LEVINE[1], E. LIKTOR-BUSA[1], K. KARLAGE[1], L. A. GIANCOTTI[2], D. SALVEMINI[3], T. W. VANDERAH[1], T. M. LARGENT-MILNES[1];
[1]Pharmacol., Univ. of Arizona, Tucson, AZ; [2]Sch. of Med., St. Louis Univ., Saint Louis, MO; [3]Pharmacol. and Physiological Sci., St. Louis Univ. Dept. of Pharmacol. and Physiological Sci., Saint Louis, MO

Abstract: OBJECTIVE This study examines the role of DAGL in headache development. We investigate the behavioral and physiologic changes associated with inhibition of DAGL in S/D rats.
BACKGROUND In two models of medication overuse headache, 2-AG levels were selectively depleted in the periaqueductal grey (PAG), suggesting distinct regulation of DAGL, the main biosynthetic enzyme for 2-AG, at times of headache pain. These results led to the hypothesis that reduction of 2-AG via blockade of DAGL would induce headache-like behaviors.
METHODS Inhibition of DAGL was performed via injection of non-selective DAGL (DH376, 10 mg/kg, IP) and selective DAGLα (LEI106, 20 mg/kg, IP) and DAGLβ (KT109, 20mg/kg, IP)

inhibitors. Following DAGL blockade, studies measured 2-AG and AEA levels via LC-MS as well as headache relevant behaviors, including periorbital and hind-paw allodynia, photophobia, anxiety-like behaviors, and the responsivity of induced pain behaviors to abortive antimigraine agents. Blood Brain Barrier (BBB) permeability following DAGLα inhibition was examined via an *in vitro* Trans-Endothelial Electrical Resistance (TEER) assay, followed by *in vivo* analysis of BBB permeability to radiolabeled sucrose.
RESULTS Injection of non-selective DAGL and selective DAGLα inhibitors induced facial sensitivity in 100% and ~60% of female rats, respectively, without induction of peripheral sensitivity. Induced periorbital allodynia was attenuated by administration of sumatriptan and olcegepant. Selective DAGLα inhibition induced significant photophobia, without anxiety-like behaviors or changes in voluntary movement. Analysis of AEA and 2-AG levels revealed reductions in 2-AG in the visual cortex and periaqueductal grey (PAG), without altering AEA. TEER analysis revealed significant decreases in endothelial resistance following DAGLα inhibition. Carotid artery perfusion with radiolabeled sucrose following DAGLα inhibition resulted in slight increase in C-14 sucrose permeation into CNS tissue.
DISCUSSION These results provide evidence for the induction of headache-like pain and light sensitivity without extracephalic allodynia, thus modeling the clinical presentation of episodic headache. DAGL inhibition was associated with increased permeability of the BBB, a physiologic change which has been correlated with migraine induction. DAGL inhibition, which reduces the time, cost, and invasiveness of currently accepted models of headache may fill the gap left by current models of headache that largely reflect manifestations of chronic migraineurs, and it may provide an avenue to study the transition from episodic to chronic headache.

Title: Cerebral open flow microperfusion vs microdialysis: differences in neuronal damage and gliosis during measurement of hippocampal extracellular insulin

Authors: *S. DOUGLASS, A. R. TASSONE, J. REITANO, E. C. MCNAY;
Behavioural Neurosci., Univ. at Albany, Albany, NY

Abstract: Sampling the brain's extracellular space requires an invasive approach, which risks damaging the tissue and hence potentially confounding results. The most common technique, microdialysis (MD), has been shown to cause neuronal loss and gliosis immediately surrounding the probe and cannulation site, although appropriate timing of measurements can to some extent potentially mitigate this issue. An alternative to MD is cerebral open flow microperfusion (cOFM), which uses a thinner probe and an open-sided cannulae. Frontal cortex studies have suggested that cOFM may reduce gliosis and tissue damage in comparison to MD and may also better preserve blood-brain-barrier integrity during sampling. The absence of a dialysis membrane when using cOFM may also permit better recovery of some molecules: one such is insulin, which is (i) large compared to traditional MD analytes and (ii) potentially trapped by adhesion to the membrane. Insulin is an important target: we have shown that it regulates hippocampal metabolism and cognition, and loss of hippocampal insulin signaling is also a key factor in diseases such as Alzheimer's.
We hypothesized that cOFM would cause less tissue damage and might improve recovery of insulin during hippocampal sampling. 15-week-old Sprague Dawley were dual-cannulated with MD and cOFM cannulae, one per hippocampus, counter-balanced across animals. Female rats underwent estrous staging while males underwent a control procedure. After recovery from surgery, probes were inserted and samples taken for 90 min, after which rats were euthanized and perfused with paraformaldehyde, with brains harvested, processed, and sliced. Slices were analyzed for transmembrane protein 119 (TMEM-119) to label microglia, cluster of differentiation 68 (CD68) to label phagocytotic microglia, glial fibrillary acidic protein (GFAP) to label astrocytes, and NeuroTrace to label Nissl bodies in neurons. As a qualitative measure, slices were visually inspected for signs of hemorrhaging and tissue damage at the probe sites. Extracellular insulin was analyzed via ELISA, and extracellular glucose was analyzed via glucose oxidase assay. Our next steps are to build on these baseline measurements and optimized technology to measure fluctuations in hippocampal ECF insulin caused by diet and/or cognitive demand.

Title: Regulatory effects of TGF-β1 canonical and non-canonical pathways on leukocyte extravasation across brain endothelium in X-linked Adrenoleukodsytrophy

Authors: *S. K. MCCARTHY[1], A. C. BERENSON[2], C. A. LUSK[1], A. LENAIL[3], N. SASIDHARAN[4], P. L. MUSOLINO[1];
[1]Neurol., Massachusetts Gen. Hosp., Boston, MA; [2]Boston Univ., Boston, MA; [3]MIT, Boston, MA; [4]Ludwig Maximilian Univ. of Munich, Munich, Germany

Abstract: X-linked adrenoleukodystrophy (ALD) is a devastating neurologic disorder caused by mutations in the ATP binding cassette subfamily D member 1 (ABCD1) gene, a half transporter responsible for the import of VLCFA into peroxisomes. A devastating form of cerebral demyelination occurs in up to 60% of males following disruption of the blood-brain barrier (BBB) and migration of leukocytes into the white matter. Central to the permeability changes and leukocyte extravasation is the control of endothelial tight-junctions (TJs). Claudin 5 (CLN5) constitutes the main TJ protein in human cerebral white matter vessels and is dynamically regulated by activation of divergent transforming growth factor beta 1 (TGF-β1) signaling pathways. Loss of ABCD1 is known to downregulate CLN5 and increase TGF- β1 levels. Little is known about how increases in TGF-β1 alter CLN5 expression brain endothelium in ALD. Here we set to test the hypothesis that increased permeability of ABCD1-deficient brain endothelium is caused by downregulation of CLN5 in TJ via activation of the TGF-β1 canonical pathway, translocation of SMAD4 to the nucleus and binging to FOX01 in the silencer region of the CLN5 promoter. Following siRNA silencing of HBMECs we found increased phosphorylation of SMAD3 (p=0.0015). Conversely, FOXO1 showed significantly lower phosphorylation ratios after loss of ABCD1 (p=0.018). Using SIS3 compound, TGF-β1 canonical signaling is inhibited by suppressing SMAD3 phosphorylation without affecting the non-canonical AKT/PI3-kinase signaling pathways. This allowed us to test the interaction between canonical and non-canonical TGF-β1 pathway. Following inhibition of SMAD3 phosphorylation, we found an increase in CLN5 mRNA and protein levels in ABCD1 silenced (p=0.0243). We did not observe significant differences in the phosphorylation ratio of AKT (non-canonical pathway). Our findings thus, support our hypothesis that following loss of ABCD1 there is higher activation of the TGF- β canonical pathway compared with the non-canonical PI3K/AKT pathway leading to transcriptional downregulation of CLN5 by stabilization of FOXO1/SMAD4-p complex in its promoter. Further studies evaluating its functional consequences in-vitro and in-vivo are necessary to assess its potential as therapeutic target.

Ctr. at San Antonio, San Antonio, TX

Abstract: The developmental origin, through which gene variants initiate cellular abnormalities and contribute to mental illness, is still poorly understood due to many technical constraints of human studies. Hemizygous deletion of human chromosome 22q11.2 is associated with social deficits of autism and schizophrenia. We found that constitutive heterozygosity of *Tbx1* impaired affiliative social communication and interaction and that Tbx1 protein was enriched in postnatal neural stem cells. We capitalize on this knowledge base to further identify the precise developmental time window, critical cell types and their functions and transcriptional target genes of Tbx1 in cell and mouse models. There were significantly fewer GFP-positive cells in the subgranular cell layer of the dorsal hippocampus of Tg(Nes-EGFP)33Enik/J;*Tbx1*$^{+/-}$ mice, compared to Tg(Nes-EGFP)33Enik/J;*Tbx1*$^{+/+}$ mice (N=5-6 mice per group), indicating that Tbx1 deficiency results in loss of postnatal/adult neural stem cells in the hippocampus. In culture of neonatal neural stem cells derived from neonatal hippocampus (N=4-6 cultures per group), Tbx1 protein expression peaked during the G1/S cycle shortly before the G2/M phase, indicating a Tbx1 surge precedes the onset of cell division in neonatal neural stem cells. *Tbx1* siRNA significantly reduced the rate of proliferation and the number of BrdU-positive neonatal neural stem cells without inducing apoptosis. When *Tbx1* heterozygosity was initiated in neonatal neural stem cells at postnatal days 1-5 (P1-5) in nestinCreERT;*Tbx1*$^{flox/+}$ mice (N=5-23 mice per group), it impaired social interaction without altering approach behaviors toward a novel object and social olfactory stimuli, an anxiety-related trait or motor activity. When tamoxifen was given at P21-25 (N=11-40 mice per group), it had no effect on social interaction. We next identified the transcriptional targets of Tbx1 in neonatal neural stem cells using ChIP-seq (N=7 clones). This analysis collectively identified 1,039 genes. Validation analyses identified *Pten* and *Tdo2* as Tbx1's functional target genes and transcriptional activity of *Pten* promoter was reduced by a deletion or mutations placed at its proximal 35 bp segment. Our data establish that *Tbx1* deficiency impairs social interaction via defective proliferation of neonatal stem cells and this gene is transcriptionally linked with *Pten* and other target genes, mutations of which are associated with autism, thereby revealing a new cellular substrate and molecular networks for

social interaction deficits associated with 22q11.2 hemizygous deletion, as well as TBX1 loss-of-function mutations.

Title: Behavioral and neuroanatomical alterations in CNTNAP2 mouse model of autism spectrum disorder

Authors: *T. GANDHI, C. LEE;
Comparative Biomed. Sci., Louisiana State Univ., Baton Rouge, LA

Abstract: Autism spectrum disorder (ASD) is comprised of a group of neurodevelopmental disorders characterized by social interaction and communication deficits and repetitive/restricted behaviors. In this study, we examined the behavioral and neuroanatomical alterations in a genetic mouse model of ASD, harboring a knockout of the contactin associated protein-like 2 gene (CNTNAP2-/-). One of the important neuropathological features in this mouse model of ASD is the abnormal developmental migration of neurons destined for superficial cortical layers. In our study, the laminar organization of somatosensory, auditory and visual cortical areas was analyzed by labeling with CUX-1, which is a marker for neurons normally localized to the superficial cortical layers (II-IV). Retrograde tract tracing was employed in order to map projections of these ectopic neurons. Finally, analysis of core behavioral domains, ultrasonic vocalization recordings in pups, grooming and social interaction tests, were conducted in adult mutant and control groups. By quantifying the laminar distribution of CUX-1 positive cells in cortical areas of this genetic model of ASD, we found more ectopic CUX-1 positive cells in lower layers (V and VI) of cortical areas as compared to the control animals. Some changes were observed in co-localized CUX-1-positive and fluorogold retrogradely labelled cells in lower layer 5 of primary cortical areas in the Cntnap2-/- mice compared to the WT mice. Furthermore, our results indicate reduced ultrasonic vocalizations in mutant mouse pups as compared to controls. Also, the mutant group exhibited a decrease in sociability and increased grooming in comparison to controls. Presence of ectopic neurons in the lower layer 5 of primary cortical areas may form normal (corticocortical connections) or altered connections (corticothalamic connections) with their respective targets. These results suggest that neuroanatomical alterations in cortical areas could account for some core autistic behaviors.

Title: Characterization of the effects of autism risk gene chd8 mutation on zebrafish neurodevelopment

Authors: *S. E. FITZPATRICK[1], H. WEINSCHUTZ MENDES[2], T. CHEN[2], J. RIHEL[3], E. J. HOFFMAN[2];
[1]MD-PhD Program, Interdepartmental Neurosci. Program, [2]Child Study Center, Dept. of Neurosci., Yale Sch. of Med., New Haven, CT; [3]Cell & Developmental Biology, Div. of Biosci., Univ. Col. London, London, United Kingdom

Abstract: Idiopathic autism spectrum disorder (ASD) is remarkably prevalent (1-2% of the population) and clinically complex. Despite decades of research, an understanding of the specific mechanisms underlying the abnormal neurodevelopment of ASD remains elusive. Whole genome and exome sequencing studies implicate over 100 genes as “autism risk genes” - genes in which de novo rare variants in offspring are sufficient to cause ASD. The majority of risk genes identified by these studies play a role in either regulation of gene expression or neuronal communication. Within the broad category of gene expression regulators are chromatin modifiers - genes that produce proteins involved in chromatin modification to affect the expression of downstream genes involved in neurodevelopment. One such chromatin modifier gene repeatedly identified by sequencing studies and highly associated with ASD is chromodomain-helicase DNA-binding protein 8 (*CHD8*). To study the effects of *chd8* mutation on early neurodevelopment, we generated a zebrafish line with a frameshift deletion in an early exon of *chd8* and performed behavioral, immunohistochemical, molecular, and gene expression analyses of 6 days post-fertilization (dpf) larvae to characterize the line. All experiments were performed using sibling homozygous, heterozygous, and wild-type mutants to avoid potential genetic background effects. Heterozygous and homozygous mutants survive to adulthood,

although homozygous mutants have decreased fertility and are grossly smaller as adults. Behavioral analyses show homozygous *chd8* mutants have decreased daytime activity and decreased total sleep at night despite an increased number of sleep bouts compared to wild-type siblings. Brain activity mapping using phosphorylated extracellular signal-related kinase (pERK) and total ERK staining shows differences in baseline neural activity. RNA sequencing suggests homozygous *chd8* mutants have alterations in several key neurodevelopmental pathways. This work suggests disrupting mutations in a master regulator gene have significant effects on zebrafish behavior and neurodevelopment. The *chd8* mutant zebrafish line will be useful for dissecting the molecular mechanisms that underlie these changes and provide insight into the altered neurodevelopment of autism.

Title: Development and description of Kcnq2 and Kcnq3 gain-of-function mice

Authors: *N. VARGHESE, K. SPRINGER, H. SOH, D. K. MULKEY, A. TZINGOUNIS; Physiol. and Neurobio., Univ. of Connecticut, Storrs, CT

Abstract: A major development over the last few years is the recognition that gain-of-function (GOF) pathogenic variants in potassium channels could lead to neurological and neuropsychiatric disorders. This is particularly striking with KCNQ2 and KCNQ3 channels, where *KCNQ2* and *KCNQ3* GOF variants have been identified in patients with Developmental and Epileptic Encephalopathy (DEE) and more recently with Autism Spectrum Disorders (ASD) with or without epilepsy. Currently, the mechanisms by which *KCNQ2 and KCNQ3* GOF pathogenic variants lead to the various disorders is not fully known. This is partly due to the scarcity of mouse animal models carrying KCNQ2 and KCNQ3 GOF variants preventing a detail analysis of their impact in brain excitability. To fill this gap, we have developed constitutive $Kcnq3^{R231C}$ and conditional $Kcnq2^{R201C}$ knock-in mice to act as a foundation of our work and a resource to the neuroscience community. $Kcnq2^{R201C}$ and $Kcnq3^{R231C}$ are recurrent GOF human variants that stabilize the open state leading to constitutively open KCNQ2 and KCNQ3 channels at the physiological voltage range. Unlike

constitutive *Kcnq2*$^{R201C/+}$ heterozygous mice, constitutive heterozygous *Kcnq3*$^{R231C/+}$ mice survive to adulthood. To bypass the very early lethality of constitutive *Kcnq2*$^{R201C/+}$ mice, we developed conditional mice using a cre-mediated genetic switch approach (Kcnq2$^{fR201C/+}$), that is *Kcnq2*^{R201C} is expressed only in cells expressing cre-recombinase. In the absence of cre-recombinase *Kcnq2*$^{fR201C/+}$ animals survive to adulthood and no apparent behavioral abnormalities are seen. Crossing the Kcnq2$^{fR201C/+}$ mice with Emx1-cre mice allowed for expression of the *Kcnq2*^{R201C} to forebrain excitatory cells starting at ~E10-E11. These mice die starting at ~P40, suggesting that expression of *Kcnq2*^{R201C} in forebrain excitatory cells leads to premature lethality. We also found that expression of *Kcnq2*^{R201C} leads to hypoexcitable CA1 pyramidal neurons, whereas expression of *Kcnq3*$^{R231C/+}$ reduced excitability in only a subset of pyramidal neurons, segregated based on the radial axis. In summary, we have developed two new mouse KCNQ GOF mouse lines that could act as tools to understand how potassium channel GOF variants could alter network excitability in general.

Title: The Role of Foxp1 and Foxp2 in Striatal D1 Spiny Projection Neurons

Authors: *N. AHMED, A. ANDERSON, K. SIVAPRAKASAM, G. KONOPKA;
Univ. of Texas Southwestern Med. Ctr., Dallas, TX

Abstract: Autism spectrum disorder (ASD) is diagnosed by impaired social communication and restrictive or repetitive behavior. Variants in the transcription factors FOXP1 and FOXP2 are amongst the most significant genes implicated in the development of ASD. Mutations in these genes have also been linked to expressive language impairments in patients, while mutations or knockout of either gene in mice has been implicated in ASD-like behavior. Both genes are co-expressed in the striatum, where they may work together to regulate gene expression. More specifically, both genes are expressed in the dopamine receptor expressing spiny projection neurons (SPNs) of the striatum, cell types that have enriched expression for ASD candidate

genes. Reduction or knockout of Foxp1 from the dopamine 2 receptor (D2) SPNs in mice results in behavioral, morphological, and physiological impairments with fewer changes upon deletion of Foxp1 from the dopamine 1 receptor (D1) SPNs. This difference may be due to the differential expression of Foxp1 and Foxp2 in the SPNs; Foxp1 is highly expressed in both D1 and D2 SPNs whereas Foxp2 is more highly expressed in the D1 SPNs relative to D2 SPNs. Taken together, we hypothesize that Foxp1 and Foxp2 have compensatory functions in the D1 SPNs. Utilizing mice that have a Drd1 specific knockout of Foxp1, Foxp2, or both, we have found that loss of both genes results in impaired motor learning, hypoactivity, and social behavior. Differential gene expression analysis from single nuclei RNA-sequencing implicates genes involved in ASD risk, locomotive behavior, and neuronal development and function. These data support the hypothesis that Foxp1 and Foxp2 functionally compensate for each other in D1 striatal neurons.

Title: The role of Pten during primary sensory neuron development

Authors: *A. FERNANDEZ, K. M. WRIGHT;
Vollum Inst., Oregon Hlth. and Sci. Univ., Portland, OR

Abstract: <Altered sensory processing is a common feature of autism spectrum disorders (ASD). The contribution of sensory processing centers in the brain to abnormal somatosensation in models of ASD is well established. Recent studies have also found that primary sensory neurons in the dorsal root ganglia (DRG) show abnormal function in *Mecp2* and *Gabrb3* animal models of ASD. Phosphatase and tensin homolog (*Pten*) is a known ASD susceptibility gene that functions as a key regulator of neuronal proliferation and differentiation pathways. We therefore examined how altered *Pten* signaling in primary sensory neurons affects peripheral nervous system circuit development. Using *Pten*hemizygous mice as a model for syndromic ASD, we determined that altered *Pten* signaling during development compromises primary sensory neuron population diversification. Loss of a single copy of *Pten* disrupts neuronal cell cycle regulation and primary sensory neuron progenitor differentiation, ultimately leading to altered proportions

of nociceptors and proprioceptors in adult mice. Using primary sensory neuron-specific *Cre* lines (*Isl1*^{Cre} and *Avil*^{CreERT2}) in combination with a conditional allele of *Pten* (*Pten*^{Flox}), we found that defects in population diversity result from cell-intrinsic alterations in *Pten* signaling during an early developmental window. Altogether, we have identified a critical role for *Pten* signaling in primary sensory neuron population diversification during development, and established the relationship between specific cell-intrinsic signaling mechanisms and peripheral nervous system organization. These findings offer insight into the contribution of the peripheral nervous system to a key clinical feature of ASD.>

Title: Disruption of mTORC1 rescues PTEN loss mediated neuronal hypertrophy

Authors: *K. TARIQ[1], A. CONCHING[1], E. CULLEN[2], S. A. GETZ[4], W. WANG[1], M. LI[1], M. C. WESTON[3], B. W. LUIKART[5];
[1]Dartmouth Col., Hanover, NH; [3]Neurolog. Sci., [2]Univ. of Vermont, Burlington, VT; [4]Geisel Sch. of Med. At Dartmouth, Lebanon, NH; [5]Mol. and Systems Biol., Dartmouth Col. Geisel Sch. of Med., Lebanon, NH

Abstract: Phosphatase and tensin homolog deleted on chromosome 10 (PTEN) is a lipid phosphatase that negatively regulates AKT/mTOR signaling pathway and serves as a brake on unregulated cellular growth. In a non-dividing neuronal cell population, PTEN inactivation leads to hypertrophy, and such neuropathology has been observed in individuals with Autism Spectrum Disorder (ASD). In mouse models of autism, conditional Pten knockout (KO) in hippocampus leads to larger soma size, dendritic hypertrophy, ectopic neuronal migration, and increased spine densities. The underlying molecular mechanisms producing such alterations in neuronal architecture remain incompletely understood. Using well-defined mouse genetic alleles and retroviral systems to specifically target developing granule neurons, we aimed to determine the role of mTORC1 (mammalian target of rapamycin complex 1) in the development of Pten-KO-mediated autism-associated hypertrophy. mTOR kinase regulates cell growth, proliferation, and survival by operating in two multi-protein complexes, one of them being mTORC1. For genetic disruption, we knocked out Raptor, which is a unique and obligatory component of

mTORC1. We found that disruption of mTORC1 completely rescued Pten-KO-mediated effects on soma size, migration, spine density, and dendritic arborization. Similarly for pharmacological inhibition of mTORC1, acute treatment with rapamycin was able to completely rescue Pten-KO-mediated effects on soma size, migration, spine density, and dendritic arborization. These results suggest Raptor as a potential therapeutic target for treatment of ASD.

Abstract: Postmortem studies have revealed increased density of excitatory synapses in the brains of individuals with autism, with a putative link to aberrant mTOR-dependent synaptic pruning. Autism is also characterized by atypical macroscale functional connectivity as measured with resting-state fMRI (rsfMRI). These observations raise the question of whether excess of synapses cause aberrant functional connectivity in autism. Using rsfMRI, electrophysiology and in silico modelling in Tsc2 haploinsufficient mice, we show that mTOR-dependent increased

spine density is associated with autism-like stereotypies and cortico-striatal hyperconnectivity. These deficits are completely rescued by pharmacological inhibition of mTOR. Notably, we further demonstrate that children with idiopathic autism exhibit analogous cortical-striatal hyperconnectivity, and document that this connectivity fingerprint is enriched for autism-dysregulated genes interacting with mTOR or TSC2. Finally, we show that the identified transcriptomic signature is predominantly expressed in a subset of children with autism, thereby defining a segregable autism subtype. Our findings causally link mTOR-related synaptic pathology to large-scale network aberrations, revealing a unifying multi-scale framework that mechanistically reconciles developmental synaptopathy and functional hyperconnectivity in autism.

Title: Analysis of iba1 microglia activation in the hippocampus of adolescent NS-Pten knockout mice

Authors: *P. D. WOMBLE, K. BLANDIN, J. PILCHER, E. KWOK, G. SULLENS, D. S. COELHO, D. NGUYEN, J. N. LUGO, JR;
Psychology and Neurosci., Baylor Univ., Waco, TX

Abstract: The NS-*Pten* (neuron subset-specific) KO mouse model develops spontaneous seizures beginning as early as 6wks. PTEN is a negative regulator of the mTOR pathway and deletion results in hyper activation of the pathway. NS-*Pten* KO mice have morphological abnormalities, specifically to the granule layer of the dentate gyrus (dysplasia), an increase in soma size of neurons, and increases in neuroinflammation found through western blot assay. KO animals have shown deficits in behavioral tasks involved in sociability and learning and memory. This finding is not surprising given that there is a high comorbidity between epilepsy and other cognitive disorders such as Autism Spectrum Disorder (ASD). This current study utilized 4, 10, and 15-week-old wildtype (WT) and knockout (KO) mice. For immunofluorescence protocol, mice were perfused with 50mls of 1x PBS followed by 50mls of 4% PFA in PBS. Dorsal

hippocampus was located, and tissue was randomly sampled to obtain a total of 6 slices per animal. Slices were stained for Iba1 (microglia) and mounted using a mounting medium containing Dapi. For each animal, 3 of the 6 stained slices were imaged on either the left or right hemisphere then total number of microglia was averaged between them. Total number of Iba1 cells was counted in the CA1 region, CA2/3 region, dentate gyrus, and total hippocampus using a custom semi-automated counting system made by creating a program using macros from ImageJ (NIH). Preliminary findings show that across all groups there is a genotype difference that KO animals have an increased total number or Iba1 positive cells in their hippocampus. For 4-week-old mice, all regions of the hippocampus (CA1, CA2/3, dentate gyrus) of KO animals were found to have an increase in the number of microglia. For 10-week-old mice, KO animals had more microglia in the CA1, dentate gyrus compared to WT mice. For 15-week-old mice, only the dentate gyrus had an increase in the number of microglia. These data suggest an increase in immune reactivity in KO mice with hyperactive mTOR signaling in the hippocampus in an age-dependent manner. We found that Pten KO mice had an increase in the microglia marker Iba1 in all three time points. Additionally, we found that this increase was in all regions for the 4-week time point, only the CA1 and dentate gyrus for the 10-week time point, and only the dentate gyrus for the 15-week time point, suggesting that the dentate gyrus may play a critical role in the inflammatory response of the Pten KO mice. Further research is needed to look at other brain areas, as well as characterizing the different stages of microglia in Pten WT and KO mice.

Title: Rapamycin Corrects Stereotypic and Social Behavior Deficits in NS-Pten Knockout Mice

Authors: *D. A. NARVAIZ, S. O. NOLAN-STRLE, G. SMITH, A. HOLLEY, M. VOLQUARDSEN, C. REYNOLDS, J. LUGO;
Baylor Univ., Waco, TX

Abstract: Genetic mutations to phosphatase and tensin homolog deleted on chromosome ten (*PTEN*) produces hyperactive mTOR signaling followed by neuronal hypertrophy and a progressive development of seizures. *PTEN* mutations are also thought to contribute to the development of intellectual disabilities and autistic behaviors. Rapamycin, an mTOR inhibitor,

has been shown to reverse neuronal hypertrophy and reduce seizures in neuronal subset specific *Pten* knockout (NS-*Pten* KO) mice. Although NS-*Pten* KO mice exhibit cognitive, social, and motor deficits, the impact of mTOR inhibition on the development of these behavioral impairments has not been determined in this model. NS-*Pten* KO and wild type (WT) male and female mice were administered 10 mg/kg of rapamycin for 10 days beginning at postnatal day 28. Treatment and control groups were then subjected to the following behavioral test battery to determine the impact of rapamycin on behavior: open field, elevated plus maze, marble burying, social chamber, and trace fear conditioning. Rapamycin improved social behavior, *p* < .05, and stereotypic behaviors during marble burying, *p* < .05, in all mice, as well as stereotypic behavior in the open field, *p* < .05 in KO mice. Across all mice, rapamycin impaired contextual fear memory, *p* < .05. There were no sex differences in either the behavioral phenotype or impact of rapamycin on behavior in NS-*Pten* KO mice. Contrary to previous analyses, we found NS-Pten KO mice displayed less exploratory behavior, *p* < .05, and more stereotypic behavior, *p* < .05, in the open field compared to WT mice, as well as increased freezing to baseline, *p* < .001, a marginal increase to freezing to contextual cues, and no differences in freezing to an auditory cue or during the intertrial interval during a trace fear conditioning task. These data show that administration of rapamycin reduces the impairment of stereotypic and social behavior deficits in NS-*Pten* KO mice but impairs contextual fear memory.

Title: Early developmental impact of flurothyl seizures in FMR1 knockout mice

Authors: *K. BLANDIN[1], D. NARVAIZ[1], G. SULLENS[2], M. BINDER[4], A. FAUST[1], J. N. LUGO, JR[3];
[1]Psychology & Neurosci., Baylor Univ., WACO, TX; [2]Psychology & Neurosci., [3]Psychology and Neurosci., Baylor Univ., Waco, TX; [4]Yale Sch. of Med., Waco, TX

Abstract: Autism Spectrum Disorder (ASD) is characterized by changes in repetitive behaviors, social, and communication deficits. One of the leading causes of inherited intellectual disability and a significant genetic contributor to ASD is fragile x syndrome, which occurs through the

silencing of the FMR1 gene. There is also a strong relationship between the presence of seizures during early life and the development of autistic-like behaviors. In this study, we investigated the impact of superimposing several seizures on a genetic condition, to determine the impact of seizures, the impact of the genetic condition and the combined impact of both. In the present study we investigated the effects of several seizures over many days on the FMR1 knockout (KO) mice. On Postnatal days 7 to 11, we presented flurothyl-induced seizures to wildtype (WT) and FMR1 KO mice. The seizures occurred 3 times a day with two-hour interval between seizures, while the control group received no treatment. A battery of behavioral tests was performed in adult mice (postnatal day 90) to assess the effects of seizures early in life: nose poke, social partition and open field-tested hyperactivity, sociability, anxiety, repetitive and restrictive behavior. A two-way ANOVA test of our nose poke behavior task revealed that KO mice exhibited both increased consecutive nose pokes, $p<.05$ and a longer latency to first nose poke, $p<.05$. Seizure induction increased latency to first nose poke in KO mice, $p<.05$ compared to KO mice without seizures. In our social behavior task, we found that the mice with early-life seizures had a social behavior deficit compared to controls, $p<.05$. A two-way ANOVA of the open field task showed that seizures resulted in a decrease in vertical episode count, $p<.01$, stereotypy time, $p<.05$ and stereotypic episode count, $p<.01$. The KO mice displayed an increased number of clockwise revolutions compared to WT, $p<.05$. We replicated prior findings that FMR1 KO mice display deficits in repetitive behavior and a reduction in exploratory behavior. Early life seizures decreased sociability and stereotypy in WT and FMR1 KO mice. We did find that seizures superimposed on a genetic condition exacerbated the exploratory behavioral deficits. These results aid in understanding how we can use double-hit models to understand the relationship between a genetic condition and seizures during early life.

Title: Temporal response of hippocampal microglia to status epilepticus during the neonatal period in mice.

Authors: *D. SANTANA-COELHO, D. NARVAIZ, S. CHILUKURI, J. LUGO;
Baylor Univ., Waco, TX

Abstract: The developing brain is uniquely susceptible to seizures. Studies have demonstrated that seizures during the early postnatal period can have deleterious consequences to brain development leading to behavioral outcomes such as deficits in communication, cognition, and increased anxiety. However, the mechanisms by which neonatal seizures disrupt neurodevelopment are unclear. Microglia are resident brain immune cells that respond to insults and exhibit important roles in development such as synapse pruning, maturation, and function. Considering the detrimental roles of microglia during development, we aimed to assess microglial response to status epilepticus, seizures characterized by lasting longer than 30 minutes that commonly occur during the neonatal period in humans. To investigate the temporal response of microglia to status epilepticus, we treated mice with 2 mg/kg kainic acid (i.p.) at postnatal day 10. Following seizures, hippocampal microglia activation was assessed at 1, 2, 3, 4, and 5 days post seizures. Analysis of microglial activation was done using flow cytometry to quantify MHCII+ myeloid cells. Preliminary data demonstrated that microglial activation was significantly increased by status epilepticus ($p=0.0012$) with the highest activation at 1 and 2 days post-seizure. Full characterization of microglial response will enable us to identify a critical window where the use of therapeutic interventions might prevent the deleterious consequences that status epilepticus during early life can have on neurodevelopment.

Title: Aggression and reward processing in Autism Spectrum Disorder

Authors: *A. HERTZ, N. BLACKWOOD, M. M. PETRINOVIC, G. MCALONAN; Forensic and Neurodevelopmental Sci., King's Col. London, Inst. of Psychiatry, Psychology, and Neurosci., London, United Kingdom

Abstract: Aggression is a common form of challenging behavior among individuals with autism spectrum disorder (ASD). Affecting as many as 2-out-of-3 individuals with ASD, aggression has serious detrimental effects. Aggression often exacerbates core ASD symptoms and is the strongest predictor of parental stress, yet we lack effective treatments. Thus, a neurobiologically informed approach to the understanding and treatment of aggression in ASD is needed. Therefore, this project is built upon 2 key pieces of evidence: i) aggression may have rewarding

properties, and ii) the reward system shows aberrant activity following social stimuli in individuals with ASD. We aim to investigate whether aggression associated with ASD may be a rewarding experience.
To this end, we used the *Neurexin1α* (*Nrxn1α*) knock-out (KO) mouse model as i) *Nrxn1α* is a category-1 classified ASD-linked gene and ii) because mutations in *Nrxn1α* were associated with aggression both in humans and animal models of ASD. Male *Nrxn1α* KO (n=15) mice and their Wild-Type (WT) (n=15) littermates were tested for sociability, aggression, and conditioned place preference (CPP) for aggression (where 1-out-of-2 contexts are paired with an aggressive encounter). Furthermore, activity of the brain reward circuitry following aggression was investigated by c-Fos immunohistochemistry and correlated with behavior.
Our results show that *Nrxn1α* KO mice exhibit increased aggression compared to their WT littermates. In contrast to WTs, *Nrxn1α* KO mice acquired a robust CPP to the aggression paired context, which was correlated with activity levels of several brain regions involved in reward processing.
Our study suggests that aggressive behavior in the *Nrxn1α* KO mice is associated with aberrant recruitment of the reward system.

Title: The Differential Contribution of Excitatory and Inhibitory Neurons to Cortical Pathology in a Mouse Model of Autism Spectrum Disorder

Authors: *D. BOYLE[1], M. HANSON[1], D. NAGARAJAN[2], J. FITZGERALD[3], O. KOKIKO-COCHRAN[3], J. C. WESTER[2];
[1]The Ohio State Univ. Neurosci. Grad. Program, Columbus, OH; [2]Dept. of Neurosci., [3]Dept. of Neuroscience, Animal Behavior Core, The Ohio State Univ., Columbus, OH

Abstract: The Differential Contributions of Excitatory and Inhibitory Neurons to Cortical Pathology in a Mouse Model of Autism Spectrum Disorder Danielle Boyle, Meretta Hanson, Devipriyanka Nagarajan, Julie Fitzgerald, Olga Kokiko-Cochran and Jason Wester Autism Spectrum Disorder (ASD) is a neurodevelopmental disease considered among the most impactful in the United States. A primary hypothesis of the mechanism underlying ASD etiology is that the

ratio of excitation to inhibition (E/I) is imbalanced in the cortex, leading to disrupted information processing. E/I balance depends on the proper development of synaptic connections among subtypes of excitatory projection neurons (PNs) and inhibitory interneuron (INs). Thus, an imbalance in E/I may result from abnormal development of neurons from either population. *ARID1B* is a high confidence ASD risk gene that is initially expressed during early embryonic development in both excitatory PNs and inhibitory INs. Here, we used transgenic strategies in mice to conditionally knock out (cKO) one copy of *Arid1b* from either excitatory PNs or a subset of inhibitory INs (Parvalbumin+, PV+ and Somatostatin+, SST+). We used paired whole-cell patch clamp recording in acute cortical slices to investigate intrinsic membrane properties and synaptic physiology among mutant and control neurons. Our data show that cKO of *Arid1b* from PNs increases both their excitability and their rate of forming recurrent excitatory synaptic connections, which may contribute to E/I imbalance. In behavioral tests, conditional *Arid1b* haploinsufficiency in PNs led to disruptions in social novelty selectively in males. In contrast, cKO of *Arid1b* from INs does not alter the intrinsic membrane properties of either PV+ or SST+ INs, the rates at which they target neighboring PNs for synaptic connections, or the physiology of inhibitory synapses. However, the physiology of excitatory connections from non-mutant PNs to mutant PV+ and SST+ INs is altered. Specifically, the potency and success rate of excitatory postsynaptic currents (EPSCs) onto PV+ INs are enhanced. Furthermore, EPSCs recorded in SST+ mutant INs do not display synaptic facilitation in response to excitation from non-mutant PNs, which likely disrupts disynaptic inhibition and gating of PN dendritic plasticity. Collectively, our work demonstrates novel disruptions to synaptic physiology that could alter E/I balance in the cortex of *Arid1b* haploinsufficient mice.

Title: Neurodevelopmental disorder risk factors ADNP and POGZ affect convergent neuroinflammatory pathways

Authors: *M. E. CONROW-GRAHAM, J. B. WILLIAMS, J. A. MARTIN, P. ZHONG, B. A. REIN, Q. CAO, Z. YAN;
State Univ. of New York at Buffalo, Buffalo, NY

Abstract: ADNP and POGZ are two high-confidence risk factors for autism spectrum disorder (ASD) and intellectual disability (ID), but how haploinsufficiency of each gene is linked to these

neurodevelopmental disorders (NDD) is largely unknown. Using postmortem tissue from patients with ASD, we found diminished protein levels of ADNP and POGZ in the prefrontal cortex (PFC), a region highly implicated in NDD. To understand the functional role of these important risk factors, we investigated how Adnp or Pogz deficiency in PFC affects behavioral, transcriptomic, and synaptic function by using viral-based gene transfer to knock down *Adnp* and *Pogz* in PFC of male and female wild-type mice. Behavioral testing revealed impaired NDD-linked cognitive task performance with *Adnp*- or *Pogz*-deficiency. Patch-clamp recording showed impaired NMDA- and AMPA-mediated glutamatergic signaling in PFC pyramidal neurons from *Adnp*- or *Pogz*-deficient mice. Both ADNP and POGZ are chromatin remodelers, which could profoundly affect gene transcription in the brain. To determine whether their roles in gene transcription are linked to the behavioral and synaptic findings, we performed RNA-sequencing analysis. We found predominant transcriptional upregulation induced by *Adnp*- or *Pogz*-deficiency, with significant overlap in upregulated gene targets. Strikingly, 48% of commonly upregulated genes are involved in inflammation, as demonstrated by gene ontology and HUB gene analyses. In particular, many of these genes are part of the complement system, which is thought to affect synapse function and removal. Furthermore, immunohistochemistry reveals significant microgliosis and astrocytosis in PFC with ADNP or POGZ deficiency. These findings are reminiscent of multiple human findings of increased gliosis and pro-microglial signaling in NDD. Taken together, these data suggest that ADNP or POGZ deficiency leads to the elevation of inflammatory genes in the PFC, causing increased microglial activation and impaired synaptic transmission, which could contribute to the impairment of PFC-mediated cognitive behaviors. This study has provided novel insights into the convergent actions of two top risk factors for NDD and potential intervention targets.

Title: In utero exposure to maternal Anti-Caspr2 antibodies leads to sustained microglial activation and impedes normal microglial maturation in male offspring

Authors: *B. SPIELMAN, D. CAMPBELL, C. BAGNALL-MOREAU, L. BRIMBERG; Feinstein Inst. for Med. Res., Manhasset, NY

Abstract: Exposure in utero to maternal anti-brain antibodies (IgG) has been associated with an increased risk of having a child with Autism Spectrum Disorder (ASD). Caspr2 protein (Contactin-associated protein-like 2, encoded by the ASD risk gene, CNTNAP2) is one of the most common targets of these maternal antibodies. We have shown that male, but not female mice born to dams immunized with the extracellular portion of Caspr2 show an ASD-like phenotype. Here, we examine the role of microglia in mediating the ASD-like phenotype in mice exposed in utero to anti-Caspr2 ("Anti-Caspr2") IgG or to adjuvants alone ("Control"). We observed increased microglial activation in E18.5 and adult Anti-Caspr2 male mice, corresponding to decreased dendritic arborization and reduced spines in the CA1 region of the hippocampus. Single nucleus (sn) RNA-seq of adult hippocampus from Anti-Caspr2 and Control male mice demonstrates that microglia may be halted in an immature, pruning stage in these mice. In adulthood, depletion and subsequent reconstitution of microglia using PLX3397, an inhibitor of colony stimulating factor 1 receptor, does not restore normal dendritic arborization nor does it change the activated phenotype of microglia. This suggests that in utero exposure to maternal anti-Caspr2 IgG affects microglial programming in males but not females, with male microglia arrested in an immature/pre-microglia stage, leading to sustained pruning. We hypothesized that early suppression of microglial activation using captopril, an FDA approved drug for hypertension and heart failure that has previously been shown to suppress microglial activation, will prevent the decreased dendritic arborization and reduced spines in the hippocampus that have been noted in Anti-Caspr2 male mice. This study is currently ongoing. Altogether, our model can be utilized to examine early sex differences in microglial activation in ASD and to assess microglia as targets for potential therapeutic strategies.

Title: Enhancing potassium-chloride co-transporter-2 (KCC2) function in neurons by targeting protein-protein interactions

Authors: *V. A. RAVEENDRAN[1], J. C. PRESSEY[1], S. NIM[2], C. CORBI-VERGE[2], P. M. KIM[2], M. A. WOODIN[1];
[1]Cell and Systems Biol., [2]Terrence Donnelly Ctr. for Cell. & Biomolecular Res., Univ. of Toronto, Toronto, ON, Canada

Abstract: Fast synaptic inhibition in the adult brain is mediated by the neurotransmitter γ-aminobutyric acid (GABA). The hyperpolarizing action of GABA requires low intracellular chloride (Cl^-) which is maintained by the potassium-chloride co-transporter 2 (KCC2) in mature neurons. KCC2 protein expression and/or function can be regulated by its interactome, which can affect its ability to extrude Cl^- ions. Altered Cl^- homeostasis is associated with various neurological disorders including schizophrenia and autism spectrum disorder (ASD). Using two different approaches, we are investigating strategies to promote KCC2 function by targeting its interaction with novel interacting partners, namely Protein kinase C and casein kinase substrate in neurons protein 1 (PACSIN1) and 14-3-3. Our first approach used computational methods to develop peptide-based protein-protein interaction inhibitors (PPI inhibitors) which prevent KCC2-PACSIN1 interaction. PACSIN1 is a neuron-specific protein involved in vesicle transport and clathrin-mediated endocytosis, and has been identified as a negative regulator of KCC2. Therefore, inhibiting KCC2-PACSIN1 interaction using PPI inhibitors can provide a neuron-specific therapeutic strategy to rescue KCC2. I have identified and validated two PPI inhibitors that result in hyperpolarized E_{GABA} in primary neurons, indicating enhanced KCC2 function in the presence of these inhibitors. The second approach used genetic manipulation of the ε, γ, and θ isoforms of 14-3-3 which interact with KCC2 in co-immunoprecipitation assay. Overexpression of 14-3-3 γ isoform resulted in reduced KCC2 expression in primary neurons, revealing potential targets for the development of new PPI inhibitors. The remainder of this study will examine the mechanisms underlying regulation of KCC2 by these interacting partners and further development of PPI inhibitors to treat disrupted KCC2 function in neurological disorders such as ASD.

Abstract: Defective neuritogenesis has been strongly implicated in the etiology of many neurodevelopmental disorders, but a mechanistic understanding as to how and why neurite formation goes awry in disease states is yet to be understood. Single gene mutations in activity-dependent neuroprotective protein (ADNP) are among the most frequent among autism spectrum disorders (ASDs) and intellectual disability (ID), leading to the neurodevelopmental disorder ADNP syndrome. Symptoms of ADNP syndrome include ID, ASD, delayed speech and motor development, sleep disorder, and seizures. However, there are currently no approved treatment options for patients with mutations in ADNP, rendering a greater understanding of ADNP's functions during development and mutational etiology of high importance. Previous studies showed that during neuritogenesis, Adnp localizes to the cytoplasm/neurites, and *Adnp* knockdown inhibits neuritogenesis in culture. Here, we hypothesized that Adnp is shuttled from the nucleus to the cytoplasm during neurite formation and that this process is mediated by the known nuclear-cytoplasm protein re-localizer, 14-3-3. Indeed, applying the 14-3-3 inhibitor, difopein, blocked Adnp cytoplasmic localization. Furthermore, pull-down showed that Adnp bound the nuclear-cytoplasmic shuttle 14-3-3 and we identified phospho-dependent 14-3-3/Adnp binding sites mediated by PKC. Here, we discovered that knockdown of Adnp using *in utero* electroporation of mouse layer 2/3 pyramidal neurons in the developing somatosensory cortex led to previously unreported changes in neurite formation beginning at P0. Defects in pyramidal neurons were sustained throughout development, the most notable including increased basal dendrite number, increased axon length, and increased excitatory axon innervation to different cortical areas. Paralleling the observed morphological aberrations, *ex vivo* calcium imaging revealed that Adnp deficient neurons had greater and more frequent spontaneous calcium influx in female mice. GRAPHIC, a novel synaptic tracing technology, substantiated this finding, revealing increased interhemispheric connectivity between female Adnp deficient layer 2/3 pyramidal neurons in the somatosensory cortex. Furthermore, in the Adnp syndrome mouse model we found markers of excitotoxicity in the female cortex. We conclude that Adnp is shuttled to the cytoplasm by 14-3-3, where it regulates neurite formation, maturation, and functional cortical connectivity significantly building on our current understanding of Adnp function and the etiology of ADNP syndrome.

Title: Top2a promotes the development of social behavior via PRC2 and H3K27me3

Authors: *Y. GENG[1], T. ZHANG[1], S. GODAR[1], B. PLUIMER[2], D. HARRISON[3], A. NATH[4], J.-R. YEH[5], I. DRUMMOND[6], M. BORTOLATO[1], R. PETERSON[1];

Abstract: Human infants exhibit innate social behaviors at birth, a trait that is closely associated with neurodevelopmental disorders such as autism spectrum disorder, yet little is understood about the embryonic development of sociality. Using an automated high-throughput behavioral analysis system which we created and named Fishbook, we screened 1120 known drugs and found that embryonic inhibition of topoisomerase IIα (Top2a) resulted in lasting social deficits in zebrafish. In mice, prenatal Top2 inhibition caused behavioral defects related to core symptoms of autism, including social communication impairments and increased perseveration. Several known or suspected environmental risk factors of autism are Top2 inhibitors, indicating that Top2 inhibition may be a common mechanism through which environmental insults contribute to the development of autism. Mutation of Top2a in zebrafish caused downregulation of a set of genes highly enriched for genes associated with autism in humans. Both the Top2a-regulated genes and known autism-associated gene possess binding sites for polycomb repressive complex 2 (PRC2), a regulatory complex responsible for H3K27 trimethylation. Moreover, both gene sets are highly enriched for H3K27me3. Strikingly, inhibition of PRC2 component Ezh2 rescued the social deficit caused by Top2 inhibition. Therefore, Top2a is a key component of an evolutionarily conserved pathway that promotes the development of social behavior through PRC2 and H3K27me3. For future studies, the Fishbook platform enables systematic evaluation of environmental chemicals to identify those affecting social behavior development.

Title: The aperiodic 1/f signal as a proxy marker of excitation- inhibition flux in the brain: evidence from individuals with and without autism

Abstract: Efficient brain function is governed by coordination of Excitatory (E) glutamate and Inhibitory (I) GABA signalling. E-I regulation is thought to be disrupted in neurodevelopmental conditions such as autism. However, in living humans, investigation of E-I is constrained by the methods available which lack temporal resolution (Magnetic Resonance Spectroscopy) or are invasive (Positron Emission Tomography). Hence, as E-I signalling is dynamic, complementary metrics are needed to track its flux in real time. Electroencephalography (EEG) has good temporal resolution suited to this goal. Computational modelling and animal studies suggest the aperiodic exponent of the EEG power spectrum may be a proxy of E-I, where more inhibition is associated with larger exponents. However, whether this relationship translates to typical humans is unknown, let alone in autism. In this Proof of Concept (PoC) study we hypothesised that the aperiodic exponent is sensitive to E-I pharmacological challenge using a GABAergic agonist, arbaclofen, in autistic and non-autistic individuals. Participants were 33 adults, 18 with autism.

EEG was recorded during an auditory odd-ball paradigm after placebo and after 30mg of arbaclofen. Data were segmented into 2.4 seconds of 4 standard tones. Power Spectral Densities were extracted and parameterised using the FOOOF model to separate periodic (oscillatory) from aperiodic activity. A 2 x 2 mixed ANOVA was performed with dose as the within subjects' factor (placebo or 30mg), group as the between subjects' factor (autism or no-autism) and aperiodic exponent as the dependent variable. On average, aperiodic exponents from autistic individuals (M = 1.27, SD = 0.25) were smaller than those from non-autistic individuals (M = 1.41, SD = 0.23); but, this did not reach statistical significance ($F(1, 31) = 3.23$, $p = 0.082$). However, there was a significant main effect of drug dose $F(1, 31) = 4.44$, $p = 0.043$, whereby aperiodic exponents after 30mg of arbaclofen (M = 1.37, SD = 0.27) were larger than those at placebo (M = 1.30, SD = 0.24) across both groups. There was no significant interaction between dose and group on aperiodic exponent; $F(1, 31) = 1.77$, $p = .194$. We provide the first PoC evidence that, in humans, the aperiodic exponent is sensitive to GABAergic drug challenge and so may be a proxy marker of E-I. Although not statistically significant, the lower aperiodic exponent in the autism group compared to neurotypicals at placebo was increased by arbaclofen. The next steps will be to determine if shift in E-I (as captured by aperiodic shift) predicts a clinical response to a potential pharmacological intervention (with arbaclofen) in autism at an individual level.

Title: Implications of FMRP Control of Ribosome Translocation

Authors: *M. A. NASRALLAH, S. JUNG, S. SHAH, O. AYDEMIR, J. D. RICHTER;
Mol. Med., Univ. of Massachusetts Med. Sch., Worcester, MA

Abstract: Fragile X Syndrome (FXS) is a neurodevelopmental disorder (NDD) lying on the autism spectrum whereby afflicted individuals display developmental delays, learning impairment, hyperexcitability, epilepsy, and non-neurological maladies. FXS is caused by a triplet repeat expansion in the *FMR1* gene, which leads to its DNA methylation and transcriptional inactivation. *FMR1* encodes Fragile X Mental Retardation Protein (FMRP), an RNA binding protein (RBP) that regulates mRNA translation. In the mouse brain, one mechanism by which FMRP inhibits protein synthesis is by stalling ribosome translocation along mRNA, thereby slowing polypeptide elongation. In the FMRP knockout (KO) brain, ribosome translocation is rapid, thereby leading to elevated translation of specific mRNAs, many of which are implicated in autism. Our lab recently reported that FMRP stalls ribosome translocation on specific mRNAs in the mouse hippocampus, particularly on those that establish epigenetic marks on chromatin (Shah/Molinaro et al 2020). However, how FMRP controls ribosome translocation on specific mRNAs remains elusive. Here, we used CRISPR-Cas 9 edited murine neuroblastoma (mN2a) cells to generate a deletion in *Fmr1* exon 3 that prevents FMRP expression. We probed the dynamics of ribosome translocation through run-off polysome sequencing from WT and FMRP-deficient mN2a cells. Our preliminary results confirm that FMRP associates with stalled polysomes in mN2a cells and reveal, on a whole transcriptome level, that FMRP stalls ribosome translocation on specific mRNAs in this cell type. We aim to perform further mechanistic analyses such as run-off ribosome profiling and genetic loss-of-function experiments in various RNA-binding domains in FMRP to define the region governing its function of ribosome stalling. Additionally, we aim to perform similar analyses in WT and *Fmr1* KO mouse hippocampal slices. These studies will improve our understanding of the molecular basis of FXS and other autism spectrum disorders (ASDs). Shah, S., Molinaro, G., Liu, B., Wang, R., Huber, K.M., and Richter, J.D. Title: Comparing of the Effects of Two Kappa Opioid Receptor Antagonists in male and female Fragile X transgenic mice

Authors: D. M. MCCARTHY, A. J. CANEKERATNE, O. G. MOORE, N. E. GILLEN, P. G. BHIDE;
Biomed. Sci., Florida State Univ. Col. of Med., Tallahassee, FL

Abstract: Fragile X syndrome (FXS) is the number one inherited cause of intellectual disabilities, and the most common genetic cause of autism spectrum disorder. Neuro-behavioral symptoms of FXS include anxiety, attention deficit, hyperactivity, and changes in social interactions consistent with autistic behavior. FXS is caused by inactivation of the X-linked fragile-X mental retardation -1 (*FMR1*) gene. Despite intensive preclinical and clinical research, effective treatment for FXS is not available at this time. The *Fmr1* knockout (KO) mouse, in which the *Fmr1* gene is deleted is an excellent model to evaluate potential novel treatments for FXS. The mouse model displays behavioral impairments that are consistent with the behavioral symptoms reported in FXS. We showed that *Fmr1* KO male and female mice have significant impairment in nest building behavior, which is an excellent proxy for compulsive behavior and social behavior. Since activation of the kappa opioid receptor (KOR) disrupts nest building in wild type mice, we hypothesized that KOR antagonists improve nest building in the *Fmr1* KO mouse. To test our hypothesis, we examined the effects of two kappa opioid receptor antagonists, norbinaltorphimine (NorBNI) and aticaprant (LY245630) on nest building behavior in *Fmr1* KO male and female mice. Although both the compounds are selective KOR antagonists, the effects of norBNI last significantly longer than those of LY245630, likely because each compound activates a distinct intracellular signaling cascades. A single intraperitoneal administration of norBNI (20mg/kg) or LY245630 (10mg/kg) to *Fmr1* KO male mice improved nest building. However, the effects of norBNI lasted for up to 3 weeks whereas those of LY245630 lasted only up to 24 hours. No significant improvement was seen in female *Fmr1* KO mice with either compound at the doses used here, suggesting sex-differences in the response to KOR antagonists. We are examining the potential cellular and molecular mechanisms underlying the sex differences. Collectively, our data suggest that the KOR plays a role in nest building behavior in the *Fmr1* KO mouse and that FXS drug development efforts could target the KOR.

Title: Identification of FMR1 regulated molecular networks in human neurodevelopment

Authors: M. LI, J. SHIN, R. RISGAARD, M. PARRIES, J. WANG, D. CHASMAN, S. LIU, S. ROY, X. ZHAO, ***A. BHATTACHARYYA**;
Univ. of Wisconsin-Madison, Madison, WI

Abstract: RNA binding proteins (RNA-BPs) play critical roles in development and disease to regulate gene expression. However, genome-wide identification of their targets in primary human cells has been challenging. Here, we applied a modified CLIP-seq strategy to identify genome-wide targets of the FMRP translational regulator 1 (FMR1), a brain-enriched RNA-BP, whose deficiency leads to Fragile X Syndrome (FXS), the most prevalent inherited intellectual disability. We identified FMR1 targets in human dorsal and ventral forebrain neural progenitors and excitatory and inhibitory neurons differentiated from human pluripotent stem cells. In parallel, we measured the transcriptomes of the same four cell types upon FMR1 gene deletion. We discovered that FMR1 preferentially binds long transcripts in human neural cells. FMR1 targets include genes unique to human neural cells and associated with clinical phenotypes of FXS and autism. Integrative network analysis using graph diffusion and multi-task clustering of FMR1 CLIP-seq and transcriptional targets reveals critical pathways regulated by FMR1 in human neural development. Our results demonstrate that FMR1 regulates a common set of targets among different neural cell types, but also operates in a cell type-specific manner targeting distinct sets of genes in human excitatory and inhibitory neural progenitors and neurons. By defining molecular subnetworks and validating specific high priority genes, we identify novel components of the FMR1 regulation program. Our results provide new insights into gene regulation by a critical neuronal RNA-BP in human neurodevelopment.

Title: Astrocytic contribution to audiogenic seizures in a mouse model of fragile X syndrome

Authors: *L. BERGDOLT[1], P. RAGUNATHAN[2], M. DOUCHEY[2], A. REID[2], E. ELDRIDGE[2], O. TARASCHENKO[2], A. DUNAEVSKY[2];
[2]Dept. of Neurolog. Sci., [1]Univ. of Nebraska Med. Ctr., Omaha, NE

Abstract: Fragile X syndrome (FXS) is caused by the silencing of the fragile X mental retardation protein (FMRP). Patients with FXS are often also diagnosed with autism spectrum disorder and exhibit additional symptoms which may include intellectual disability, seizures, anxiety, and sensory hypersensitivity. FMRP, encoded by the *Fmr1* gene, is known to regulate protein expression via interactions with mRNA or protein. Despite extensive characterization of FMRP function, particularly in neurons, the effects of FMRP deletion on astrocyte physiology and the contribution of astrocytes to FXS symptoms, particularly sensory hypersensitivity, remain understudied. A robust phenotype in *Fmr1* knockout (KO) mice is susceptibility to audiogenic seizures, manifested as wild running and tonic-clonic seizures following exposure to a 120 dB siren. Using the inducible cre line Aldh1l1-cre/ERT2, we have found that astrocyte-specific deletion of *Fmr1* (*Fmr1* conditional KO) during the first postnatal week confers susceptibility to audiogenic seizures in three-week-old male mice. Moreover, selective restoration of *Fmr1* expression in astrocytes decreases the propensity for audiogenic seizures. Six-week-old *Fmr1* conditional KO mice do not exhibit observable seizure behavior in response to the auditory stimulus, but we have found a higher propensity for seizure activity detected by electroencephalogram recordings. Taken together, these data suggest that astrocytes play a role in auditory hypersensitivity and hyperexcitability in *Fmr1* KO mice. A key way astrocytes could contribute to altered neuronal signaling is through alterations in intracellular calcium signaling. Indeed, in acute brain slices from mice expressing the genetically encoded calcium indicator GCaMP6f, we have found enhanced spontaneous and ATP-induced somatic calcium signaling in cortical astrocytes in *Fmr1* KO mice. Overexpression of the purinergic receptor P2Y1R may contribute to this phenotype, as we have found a significant increase in P2Y1R expression in the cortex of *Fmr1* KO mice. Furthermore, enhanced calcium signaling is normalized by pretreatment with a P2Y1R antagonist. *Fmr1* knockout mice also exhibit enhanced calcium signaling in astrocytic processes *in vivo*. We also observed a smaller enhancement of ATP-induced calcium signaling in acute brain slices from *Fmr1* conditional KO mice Together, these data suggest that the mechanisms underlying elevated calcium signaling in *Fmr1* knockout mice

are both intrinsic and extrinsic. Ongoing experiments examine if altered astrocytic calcium signaling contributes to sensory hypersensitivity in FXS.

Title: Abnormal spine development alters visual responses in a zebrafish model of Fragile X syndrome

Authors: *I. S. Y. WONG, E. C. DEMARCO, A. LAMARCA DELA PLATA, E. ROBLES; Dept. of Biol. Sci., Purdue Univ., West Lafayette, IN

Abstract: Fragile X syndrome is caused by loss-of-function mutations in the *fmr1* gene, which encodes Fragile-X Mental Retardation protein, a translational regulator highly expressed in the brain. At the level of individual neurons, loss of *fmr1* results in abnormal development of dendritic spines, the principal postsynaptic site of excitatory synaptic transmission in mammalian cortex. To non-invasively monitor spine development in vivo, we combined an *id2b:gal4* transgenic zebrafish line with mosaic genetic labeling to specifically label single pyramidal neurons (PyrNs) in the optic tectum. Live imaging of PyrN dendritic morphology during larval development revealed rapid formation of dendritic spines between 4- and 8-days postfertilization (dpf). At 4 dpf, PyrN dendrites have long filopodia-like protrusions with high turnover rates, whereas stable spine-like protrusions with enlarged heads predominate at 8 dpf. To determine if PyrN spine development is affected by the loss of *fmr1*, we examined PyrN morphology in homozygous *fmr1* mutants. Live imaging of single neurons in *fmr1* mutants revealed a reduction in dendritic area and length. At the level of spines, loss of *fmr1* caused a significant decrease in spine number and spine stability. These findings support a synaptotrophic model of dendrite growth in which *fmr1* normally functions to promote synapse formation and spine stabilization, which in turn positively influences dendritic growth. Next, we sought to determine if the reduction in spines caused by loss of *fmr1* leads to altered visual responses in PyrNs. Response properties in WT and *fmr1* larvae were assessed by monitoring GCaMP6s fluorescence in PyrNs during presentation of a luminance ramp stimulus. These experiments revealed altered response kinetics in PyrNs lacking *fmr1* during early larval development (3 and 4 days), although these changes were not evident in older larvae (6 or 8 dpf). This suggest that loss of *fmr1* may cause a delay in the formation of synaptic inputs that shape PyrN responses to luminance ramps. Experiments are currently underway to determine if the receptive fields (RFs) of PyrNs are

altered in *fmr1* mutants. Preliminary data indicate that WT PyrNs have large RFs that span a large portion of the retinal hemifield, whereas PyrNs in *fmr1*-/- larvae exhibit significantly reduced RF sizes. Together these data suggest that the formation of stable spines on PyrN dendrites is necessary for the generation of large visual RFs. Overall, these findings establish the zebrafish PyrN system as a valuable model system to quantify spine defects in vivo and to assess the functional consequences.

Title: Protein synthesis-dependent hyperexcitability of Fmr1-KO visual cortex layer 5 pyramidal cells offers path to identify novel therapeutic targets for the treatment of fragile X syndrome

Authors: *M. J. HEINRICH, D. C. STOPPEL, F.-J. WENG, P. K. MCCAMPHILL, R. K. SENTER, M. F. BEAR;
The Picower Inst. for Learning & Memory, MIT, Cambridge, MA

Abstract: Caused by the silencing of the *FMR1* gene encoding fragile X mental retardation protein (FMRP), fragile X syndrome (FXS) in humans has been modeled in *Fmr1*-knockout (KO) mice. It is now recognized that there are different classes of pathophysiological mechanisms in the *Fmr1*-KO, one of which is altered regulation of neuronal protein synthesis. Within this class, a subset of FXS phenotypes respond immediately to inhibition of protein synthesis, suggesting involvement of pathogenic proteins that are rapidly turned over. Identifying these proteins, and linking them directly to altered neuronal physiology that could be used as biomarkers, is the goal of this project. To achieve this objective, one must identify an accessible population of neurons that display a functional and cell-autonomous phenotype which responds rapidly to manipulations that target protein synthesis. We have shown that a genetically accessible subset of layer (L) 5 cortical neurons fulfills these criteria. In acutely prepared slices of visual cortex, L5 pyramidal neurons exhibit increased neuronal spiking in *Fmr1*-KO mice that is corrected by bath application of various drugs known to normalize enhanced protein synthesis by targeting key nodes of the metabotropic glutamate receptor 5 (mGluR5) signaling cascade.

Importantly, we demonstrate that this cortical hyperexcitability is corrected within 30 minutes of protein synthesis inhibition by cycloheximide (CHX), providing the mechanistic insight that the proteins involved in maintaining cortical hyperexcitability are dynamically regulated. Furthermore, whole-cell patch-clamp recordings in the presence of synaptic blockers reveal *Fmr1*-KO L5 pyramidal cells exhibit increased input resistance and decreased rheobase current and that this cell-intrinsic hyperexcitability, like increased L5 spiking activity, is ameliorated within 30 minutes of CHX treatment. We further investigated this cell-autonomous phenotype by generating current-voltage (IV) curves that demonstrate a voltage-dependent increase in membrane resistance, suggesting deficient activity of inward-rectifying potassium channels. Current experiments are focused on identifying the proteins involved in altering this potassium channel activity, potentially uncovering novel therapeutic targets for the treatment of FXS, as well as the mechanisms for development of tolerance to treatment with mGluR5 inhibitors (See abstract by Heynen et al.).

Title: Mglur5 negative modulators for Fragile X: resistance and persistence

Authors: *A. J. HEYNEN, **D. C. STOPPEL**, P. K. MCCAMPHILL, R. K. SENTER, M. F. BEAR;
The Picower Inst. for Learning & Memory, Cambridge, MA

Abstract: Fragile X syndrome (FXS) is caused by silencing of the human *FMR1* gene and is the leading monogenic cause of intellectual disability and autism spectrum disorder. Abundant preclinical data has indicated that negative allosteric modulators (NAMs) of metabotropic glutamate receptor 5 (mGluR5) or inhibitors of key downstream signaling nodes might be

efficacious in treating FXS in humans. Initial attempts to translate these findings in clinical trials have failed. The emergence of acquired treatment resistance ("tolerance") after chronic administration of mGluR5 NAMs is a potential factor in the lack of translational success. Here we provide evidence confirming that the mouse model of FXS (*Fmr1*-KO) displays acquired treatment resistance after chronic treatment with the mGluR5 NAM CTEP (2-chloro-4-((2,5-dimethyl-1-(4-(trifluoromethoxy)phenyl)-1H-imidazol-4-yl)ethynyl)pyridine) in three assays that respond to acute mGluR5 inhibition: (1) audiogenic seizure susceptibility, (2) sensory cortex hyperexcitability, and (3) hippocampal protein synthesis. As compared to the ameliorative effect of a single acute dose of CTEP (I.P., 2 mg/kg) prior to experimental testing, chronic CTEP (I.P., 3 doses over 5 days) failed to reverse deficits in these three assays. Treatment resistance does not appear to be due to increased mGluR5 expression or sensitivity as it was not overcome by additional treatment with structurally distinct mGluR5 NAMs in the cortical hyperexcitability and hippocampal protein synthesis assays. Furthermore, a selective inhibitor of glycogen synthase kinase 3α (GSK3α) was unable to overcome acquired treatment resistance, but the protein synthesis inhibitor cycloheximide was still effective, positioning the mechanism of acquired treatment resistance downstream of GSK3α, but upstream of protein synthesis. The rapid emergence of tolerance to CTEP treatment begged the question of how previous studies showed an improvement in inhibitory avoidance (IA) cognitive performance after chronic treatment. We show that this observation is likely explained by timely inhibition of mGluR5 during a critical period of development as brief CTEP treatment (I.P. 2 mg/kg, 3 doses over 5 days) in juvenile mice (P28) is sufficient to provide a persistent improvement of IA behavior measured many weeks later ($\geq$ P58). These data will be important to consider when designing future fragile X clinical trials using compounds that target the mGluR5-to-protein synthesis signaling cascade.

Title: Fxr1 knockout alters electrophysiological properties of parvalbumin-positive interneurons in somatosensory cortex

Authors: *K. SCHEUER[1], M. SHEN[2], X. ZHAO[1], M. B. JACKSON[1];
[1]Neurosci., [2]Waisman Ctr., Univ. of Wisconsin-Madison, Madison, WI

Abstract: Parvalbumin-positive interneurons (PVIs) are a class of fast-spiking GABAergic interneuron defined by the expression of the calcium-binding protein parvalbumin. Their short membrane time constant and capacity to fire at frequencies of more than 80 Hz enable PVIs to exert tight control over the temporal integration window of their targeted excitatory neurons. Their strong, precisely timed inhibition enables PVIs to drive and entrain gamma oscillations, rhythmic brain waves between 30-80 Hz that have been linked to numerous functions including working memory, social cognition, and perceptual binding. PVI dysfunction and gamma oscillation impairment have been implicated in psychiatric disorders such as autism spectrum disorder (ASD) and schizophrenia which are marked by social impairment, altered sensory processing, and deficits in executive functions such as working memory. Knockout of the FMR1 autosomal homolog 1 gene (FXR1) in PVIs results in some similar deficits, including impairments in gamma oscillations, social behavior, sensory processing, and spatial learning. Because the role of FXR1 in PVI electrophysiology in the somatosensory cortex has not been investigated, we used a genetically-encoded hybrid voltage optical sensor (hVOS) to image electrical behavior in somatosensory cortex and evaluate the impact of PVI-specific FXR1 knockout (KO). We crossed an hVOS Cre reporter mouse with a parvalbumin Cre driver to generate PV::hVOS mice with hVOS probe targeted to PVIs. Electrical stimulation of somatosensory cortex in slices from these mice elicited fluorescence changes in up to 75 PVIs in a single field of view spanning multiple cortical layers. PVI::hVOS mice were bred with FXR1-floxed mice to obtain animals in which PVIs expressed the hVOS probe and also lacked FXR1. Stimulation of somatosensory cortex layer IV evoked responses that had significantly larger amplitudes in FXR1-KO PVIs than in control PVIs. In response to layer IV stimulation, FXR1-KO PVIs in layer II/III had significantly longer latencies than control PVIs. Thus, PVIs lacking FXR1 in somatosensory cortex have altered electrophysiological properties. The FXR1-related changes in PVI functional activity may be relevant to cognitive, behavioral, and psychiatric impairments reported in FXR1 KO animals.

Natl. de la Recherche Scientifique (CNRS), Commissariat à l'Énergie Atomique et aux Énergies Alternatives (CEA), Fontenay-aux-Roses, France; [6]Kennedy Krieger Inst., Baltimore, MD; [7]Rush Univ., Chicago, IL; [8]Washington Univ. St. Louis, St. Louis, MO

Abstract: Background: Convergent evidence indicates that deficits of Fragile X Mental Retardation Protein (FMRP) cause dysfunctional regulation pathways of metabotropic glutamate receptor subtype 5 ($mGluR_5$). This results in the neurobehavioral phenotype of fragile X syndrome (FXS); however, in several clinical trials with $mGluR_5$ negative allosteric modulators, behavioral symptoms were not improved in patients with FXS (Budimirovic, et al., 2017).
Methods: Adult men with FXS (N = 7, age 27.67 $\pm$ 4.28, range (22.3, 33.6) with the full mutation of the fragile X mental retardation 1 (*FMR1)* gene underwent quantitative measurements of FMRP by PCR/Southern Blot testing and $mGluR_5$ by positron emission tomography (PET) with 3-[^{18}F]fluoro-5-(2-pyridinylethynyl)benzonitrile ([^{18}F]FPEB).
Results: The $mGluR_5$ uptake in all brain regions (caudate nucleus, occipital cortex, parietal cortex, posterior cingulate cortex, putamen, thalamus, and temporal lobe) of men with FXS as a regression against FMFP concentration represented in the Figure suggests a trend towards significance ($p = 0.0773$).
Limitations: FXS affects a small portion of the population, and so recruiting participants presents financial and logistical constrictions. The small sample size provides a basis from which future studies may build; however, external validity is limited for the findings of this study.
Conclusions: The reductions of $mGluR_5$ in key brain regions may contribute to the neurobehavioral phenotype of FXS. Understanding this relationship between FMRP and $mGluR_5$ expression could provide the basis for the development of novel interventions for FXS.

Title: Daddy's drinking matters: The transgenerational impact of paternal alcohol consumption on brain and behavioral development of progeny

Authors: *K. E. CONNER[1], R. F. PEREZ[2], M. NABATANZI[2], K. J. HUFFMAN[3]; [1]Neurosci., [2]Psychology, [3]Psychology/Neuroscience, Univ. of California, Riverside, Riverside, CA

Abstract: Fetal alcohol spectrum disorders (FASD) describe the wide array of long-lasting developmental abnormalities in offspring due to prenatal alcohol (ethanol [EtOH]) exposure via maternal gestational drinking. Although the teratogenic consequences of prenatal EtOH exposure are apparent, the effects of preconception paternal EtOH exposure (PatEE) are still unclear. In previous rodent models, PatEE has been shown to disturb gene expression in the brain (Finegersh and Homanics, 2014; Kim et al., 2014; Liang et al., 2014; Przybycien-Szymanska et al., 2014; Rompala et al., 2017) and liver (Chang et al., 2017, 2019) of offspring. Our previous research suggests that PatEE can induce molecular changes and abnormal behavior in the offspring in the first filial generation (F1) (Conner et al., 2020). However, it is not known whether the effects of PatEE can be passed transgenerationally. In this study, we utilized a novel mouse model of PatEE where male mice self-administered 25% EtOH for an extended period prior to conception, generating indirect exposure to the offspring (F1) through the paternal germline. PatEE (F1) males were paired with EtOH naïve females to generate offspring for the second generation (F2). The impact of paternal ethanol exposure on newborn offspring neocortical development was evaluated using neuroanatomical and molecular techniques, as well as a battery of behavioral assays in pre- and peri-pubescent mice. We observed no differences between control and PatEE (F1 and F2) mice in measures of brain weight or neocortical length. *In situ* RNA hybridization was used to investigate gene expression in the neocortex of newborn control and PatEE brains. Specifically, *Id2* and *RZRβ* expression patterns were examined; these genes play critical roles in neocortical patterning. Laminar-specific patterns of gene expression were found, where *Id2* was expressed rostromedially and *RZRβ* rostrolaterally, and expression boundaries were shifted laterally in *Id2* and medially *RZRβ* in PatEE F1 mice. Finally, two subsets of pups per filial generation were raised to ages postnatal day (P) 20 and P30 when performance was evaluated on various behavioral assays. PatEE F1 mice exhibited increased motor deficits and PatEE (F1 and F2) male mice exhibited hyperactivity compared to controls, as assessed by the Suok bar test. PatEE (F1 and F2) male mice displayed significantly reduced sensory motor integration and motor learning compared to controls, as assessed by the accelerating rotarod test. Overall, these findings suggest that ethanol exposure in males prior to conception may induce long-lasting, transgenerational changes in the brain and behavior of offspring.

Title: Drinking while breastfeeding: Impacts on brain and behavioral development in a mouse model

Authors: *R. F. PEREZ[1], K. E. CONNER[2], M. NABATANZI[1], K. J. HUFFMAN[3]; [1]Psychology, [2]Neurosci., [3]Psychology/Neuroscience, Univ. of California, Riverside, Riverside, CA

Abstract: Maternal consumption of alcohol during pregnancy can lead to fetal alcohol spectrum disorders (FASD) in offspring. Prenatal ethanol exposure disrupts several aspects of normal brain development; however, little is known about how early exposure of ethanol contaminated breast milk may impact development. Infants exposed to ethanol via breastmilk often present with reduced body mass, verbal IQ scores, and altered sleeping patterns (Tay et al., 2017; May et al., 2016). In the U.S., approximately 36% of breastfeeding mothers consume alcohol (May et al., 2016); incidence rates are even higher in Australia (60%; Tay et al., 2017). To examine these effects, we designed a novel murine lactational ethanol exposure (LEE) model, where offspring were administered ethanol via nursing from postnatal day (P) 6 through P20. Dam and pup blood ethanol concentration (BEC) and plasma osmolality (pOsm, a measure of hydration) were measured at weaning (P20). As expected, experimental dams had significantly higher BEC levels when compared to controls, as did LEE pups at P20. Also, pOsm was unaffected by treatment. To examine sex specific impacts of our model, we analyzed data from our neuroanatomical and behavioral assays at P20 and P30 separately for males and females. Offspring body weights were significantly lower for male and female LEE offspring. Brain weights were significantly lower for male LEE offspring at P20 and P30; however, females displayed significantly lower brain weights only at P20. At P30, LEE Males displayed significantly shorter cortical lengths. Nissl staining revealed a significant decrease in size of the frontal cortex of P20 LEE mice compared to controls. However, there were no differences in prelimbic, somatosensory, auditory, and visual cortices. Additionally, spine densities were recorded for all groups via Golgi-Cox staining. Our behavioral results indicate main effects of treatment for LEE mice, with increased time spent in the open arms of the elevated plus maze and a decreased time spent immobile in the forced swim test. However, there were no significant effects observed in the accelerated rotarod, three-chambered sociability task, and Suok bar test. Our data describe potential adverse outcomes due to LEE and suggest that women refrain from drinking during breastfeeding. As there is a paucity of research examining the effects of alcohol consumption during breastfeeding, we need more studies using animal models of lactational exposure to advance our understanding and recommendations of safe maternal practices in early infancy.

Title: Next-generation phenotyping of craniofacial abnormalities in 22q11.2 deletion syndrome and in patients along the psychosis-spectrum.

Authors: *J. JEE[1], M. KRALL[1], D. MCDONALD-MCGINN[3], A. BAILEY[3], E. CHEN[3], K. CLARK[1], A. CROW[1], T. B. CROWLEY[3], K. GAISER[1], R. S. GALLAGHER[1], V. GONZENBACH[1], R. C. GUR[4], C. KOHLER[1], E. J. MCCLELLAN[1], D. MCGINN[1], P. J. MOBERG[1], K. RUPAREL[1], R. T. SHINOHARA[1], B. I. TURETSKY[1], L. K. WHITE[3], R. E. GUR[1], D. R. ROALF[2];
[2]Neuropsychiatry, [1]Univ. of Pennsylvania, Philadelphia, PA; [3]Children's Hosp. of Philadelphia, Philadelphia, PA; [4]Univ. Pennsylvania, Philadelphia, PA

Abstract: **Background**: Minor physical anomalies (MPAs) of aberrant facial development are common in 22q11.2 deletion syndrome (22q11DS) and in psychosis-spectrum patients (PS). Given the embryological basis of facial development comparing discrete measurements of facial MPAs in individuals with and without specific genetic abnormalities may help elucidate risk for overlapping features such as psychosis. Here we use 2D photographs and the Facial Dysmorphology Novel Analysis (Face2Gene (FDNA Inc.) technology, which combines facial recognition software with clinical knowledge enabling detection of dysmorphic features and recognizable patterns of human malformations.**Methods**: 2D photographs from patients with 22q11DS (n=171), schizophrenia (SZ; n=37), clinical high risk for psychosis (CHR; n=16) and healthy individuals (HC; n=94) were collected and submitted to FDNA. The top 30 syndromes to which an individual's photograph resembled were reported along with a "gestalt" score as measurement of similarity. A series of Receiver Operating Curve (ROC) analysis, Principal Component Analysis (PCA), and follow-up t-tests were performed.**Results**: In 22q11DS, 98.2% of facial images submitted to FNDA had positive hits for 22q11DS with an average mean gestalt score (0.51). ROC analysis correctly classified 22q11DS individuals 88% of the time using only the 22q11DS gestalt score. In SZ, 65.5% of images submitted to F2G were positive hits for 22q11DS but with a lower gestalt score (0.21), but, unsurprisingly, no one syndrome could correctly identify SZ, CHR, or HC. Analysis of the whole sample found that 22q11DS could be distinguished from other groups using FNDA analysis with an AUC of 90% and psychosis-spectrum (CHR + SZ) could be distinguished from HC, but with less accuracy (AUC=68%). Average gestalt scores were significantly different between non-deleted groups: HC > SZ $t(83.67)=3.75$, $p=0.0003$ and HC > CHR $t(33.03)=3.87$, $p=0.0005$.Specifically, FNDA gestalt scores for 22q11DS explained the most variance for 22q11DS patients while gestalt scores for Fragile X Syndrome explained the most variance for psychosis-spectrum (CHR + SZ), with other syndromes contributing in both cases. **Conclusions:** These preliminary results suggest overlap in

facial dysmorphogenesis between 22q11DS and SZ patients. Future work linking measures of facial dysmorphology to clinical and neurobiological phenotypes will help identify those features most directly linked to psychosis risk. Also, to the extent that these developmental markers are evident before sub-psychotic symptoms are evident, they may allow more reliable identification of psychosis risk.

Title: Ube3a transcript and protein levels in a novel mouse model for 15q11.2-q13.3 duplication syndrome

Authors: *J. C. GODINEZ[1], D. H. YASUI[2], J. M. LASALLE[2];
[2]Med. Microbiology and Immunol., [1]Univ. of California, Davis, Davis, CA

Abstract: The duplication of human chromosomal region 15q11.2-13.3 (Dup15q syndrome) is one of the most common copy number variants in individuals with Autism Spectrum Disorder (ASD). Dup15q syndrome can result from either an intrachromosomal interstitial duplication or an extra isodicentric 15 chromosome. 15q11.2-13.3 duplications inherited from maternal, but not the paternal, chromosome result in ASD. *UBE3A*, encoding a ubiquitin E3 ligase, is the only gene within the 15q11-13 duplicated region that is expressed solely from the maternal allele in neurons. *UBE3A* is therefore thought to be the prominent molecular cause of Dup15q syndrome phenotypes. Previous mouse models studying the overexpression of *Ube3a* displayed the core behavioral traits of autism but were difficult to replicate because of unstable genetic lines. These mice were genotyped only by *Ube3a* copy number and were not bred for maintaining a single allele. Therefore, to test the hypothesis that transgenic mice with stable, extra *Ube3a* gene copies will have elevated levels of *Ube3a* transcript and protein compared to wild-type littermates, a mouse model was created by insertion of extra copies of *Ube3a* into the mouse genome using the PiggyBac-on-BAC transgenic method. We chose to focus our analysis on mice with a

chromosome 6 insert because the transgene was inserted between genes and thus less likely to affect endogenous gene expression. We genotyped transgenic and wild type mice tail DNA samples by PCR and checked for the presence of extra copies of*Ube3a*. Western blot analysis was performed, with Gapdh as the control, to quantify Ube3a protein levels in brain samples. We also isolated total RNA from brains using a QIAGEN kit and manufacturer's protocol, and performed qRT-PCR to assess the RNA transcript levels of*Ube3a*. The sample size was n=10. Sex differences were not assessed but are pending with a larger sample size. Preliminarily we found that *Ube3a* transgenic mice display higher levels of *Ube3a* transcript compared to wild-type littermates. *Ube3a* transgenic brain did trend toward higher levels of Ube3a protein compared to wild-type mice, but the results were not significant. Further tests will determine if Ube3a protein level is elevated in transgenic mice. In the future, behavioral analysis will be performed to confirm if *Ube3a* transgenic mice display phenotypes relevant to Dup15q. This novel mouse model will serve as a tool to further understand the role of UBE3A in Dup15q syndrome and to develop effective treatments.

Title: Phenotyping mouse models of Angelman syndrome using multidimensional behavioral analysis

Authors: *J. K. TANAS[1], J. M. WOLTER[2], I. WALLAARD[3], Y. ELGERSMA[3], M. S. SIDOROV[1];
[1]Ctr. for Neurosci. Res., Children's Natl. Med. Ctr., Washington, DC; [2]UNC Neurosci. Ctr., The Univ. of North Carolina at Chapel Hill, Chapel Hill, NC; [3]Dept. of Neurosci., Erasmus Med. Ctr., Rotterdam, Netherlands

Abstract: Angelman syndrome (AS) is a single-gene neurodevelopmental disorder caused by loss of function mutations in the maternal copy of the paternally imprinted UBE3A gene. Individuals with AS have a multifaceted behavioral phenotype consisting of deficits in motor function, epilepsy, cognitive impairments, sleep abnormalities, as well as other comorbidities. Effectively modeling this behavioral profile and measuring behavioral improvement will be crucial for the success of ongoing and future clinical trials. Foundational studies have defined an array of robust and reliable behavioral phenotypes in the AS mouse model. However, no single

behavioral test is able to fully capture the complex nature of AS - in mice, or in children. Here, we use a multidimensional analysis approach comprised of principal component analysis (PCA) and k-means clustering to quantify the combined performance across eight behavioral domains in a mouse model of AS (Ube3am-/p+). This approach can successfully predict the genotype of mice based on their behavioral profile with approximately 95% accuracy, and typically achieves >90% accuracy with an "n" of ~10 to 15 mice per genotype. We confirmed that multidimensional analysis has the necessary sensitivity to detect behavioral improvement following treatment to increase Ube3a expression in Ube3am-/p+ mice. This approach can be applied to related neurodevelopmental disorders, and may be particularly valuable for disorders where individual behavioral tests are less reliable than in AS and a combinatorial approach is required to determine a phenotype.

Title: Enhanced activation of $Na_V1.1$ rescues synaptic properties of CA1 interneurons, but not pyramidal neurons, in a mouse model of Dravet syndrome

Authors: *Y. ALMOG[1], M. RUBINSTEIN[2];
[2]Sackler Sch. of Med., [1]Tel Aviv Univ., Tel Aviv, Israel

Abstract: Dravet syndrome is severe childhood-onset epilepsy, caused by mutations in the *SCN1A* gene, encoding for the voltage-gated sodium channel $Na_V1.1$. $Na_V1.1$ channels govern the firing and synaptic functions of inhibitory neurons, with several lines of evidence also indicating their importance to the activity of excitatory neurons. Here, we focused on synaptic evoked activity within the hippocampal CA1 microcircuit in Dravet syndrome (DS, $Scn1a^{WT/A1783V}$) and wild-type (WT) mice, assessing the contribution of $Na_V1.1$ to synaptic responses using Hm1a (50 nM), a selective $Na_V1.1$ opener. Specifically, we stimulated CA3 Schaffer collaterals while simultaneously probing the activity of excitatory CA1 pyramidal neurons (extracellular field potential or whole-cell recordings) and their postsynaptic horizontal stratum-oriens (SO) interneurons (whole-cell recordings). Stimulation of the Schaffer collaterals elicited smaller CA1 field responses in DS mice, indicating impaired synaptic activation. Interestingly, Hm1a augmented the CA1 field response in WT, but had no effect in DS.

Additionally, whole-cell recordings of CA1 pyramidal neurons demonstrated that the threshold for synaptically evoked action potential (sAP) is more depolarized in DS. Finally, while Hm1a hyperpolarized this threshold in WT neurons, it had no effect in DS. Together, these data indicate that $Na_V1.1$ channels contribute to synaptic functions and firing in WT CA1 excitatory neurons, whereas the lack of DS excitatory neurons response to Hm1a suggests that $Na_V1.1$ expression is hampered in these cells. SO interneurons presented an elevated sAP threshold, as expected. However, in contrast to the differential effect of Hm1a on CA1 pyramidal neurons, SO interneurons of WT and DS responded similarly, with reduced threshold for sAP and increased firing probability. Thus, although SO interneurons demonstrate lower excitability in DS, their $Na_V1.1$ expression level is sufficient to elicit a comparable response to Hm1a. Unexpectedly, the firing of SO interneurons per the same strength of CA3 Schaffer collaterals stimulation, was similar between WT and DS, despite the described deficits in CA1 excitatory and SO inhibitory neurons. This observation may be related to increased release probability in CA1-SO synapses, as suggested by reduced paired-pulse ratio in DS. Together, the differential effects of Hm1a on CA1 pyramidal neurons and SO interneurons indicate that DS pathophysiology is governed by complex mechanisms, with multiple neuronal and synaptic alterations occurring in both excitatory and inhibitory neurons.

Medicine, Genome Center, MIND Inst., Univ. of California Davis, Davis, CA

Abstract: Angelman Syndrome (AS) is a neurodevelopmental disorder caused by mutations in the maternal allele of UBE3A. Due to neuronal specific imprinting the paternal allele is silenced

via a long non-coding RNA antisense. The loss of UBE3A in neuorns presents exciting therapeutic avenues for gene replacement via AAV or cross-correction via engineered cells or reactivation of the silent paternal allele via antisense oligonucleotides (ASO) or other genetic targeting strategies. The goal of this project was to identify, validate and test a sensitive biomarker assay to be used for any AS translational effort. Previous efforts on biomarker discovery has been performed for over a decade utilizing a variety of approaches. While clinical readouts such as EEG and sleep provide robust and reproducible phenotypes in rodent models and children with AS, the need for a molecular biomarker that can be assessed repeatedly, pre and post therapeutic intervention and non-invasively is needed. Due to the wealth of existing and published data sets we assembled a group of conserved proteins that demonstrated a significant difference between neurotypic and AS samples. These 30 candidate proteins were be assessed in multiple brain regions, cerebral spinal fluid (CSF), and plasma in a recently developed rat mpdel of AS. Additional biomarkers implicated in aging disorders but directly linked to the activity of UBE3A were also assessed. Several canididate biomarkers were identified across multiple brain regions and in the CSF of the AS rats suggestive of a potential biomarker. Future studies will evaluate the responsiveness of these measures following intrathecal administration of ASO in samples from the brain and periphery. We are also establishing a sensitive biomarker panel utilizing the Quanterix Ultra-Sensitive Biomarker Detection System. The results of this study may provide a reliable and sensitive biomarker assay to accurately predict therapeutic efficacy and could serve as a therapeutic endpoint in either translational studies using preclinical models or in clinical trials of AS.

Abstract: Angelman's syndrome (AS) is a severe neurodevelopmental disease caused by a lack of function of a segment of chromosome 15. Most of the time it is related to a deletion or mutation of the UBE3A gene on that chromosome. The electroencephalogram (EEG) in AS is usually abnormal and may be used as a quantitative biomarker for differential diagnosis, to track progression, and as clinical outcome estimate. Here we investigate the effect of UBE3A deletion on the spontaneous activity and auditory-evoked responses by using a UBE3A knock-out rat model of AS. To do that, we explored the ongoing activity (qEEG), the auditory steady state responses (ASSR, oscillatory responses to rhythmic auditory stimuli) and the chirp-EP responses (responses related to a tone modulated in amplitude at increasing frequencies) under open-field, freely-moving conditions. Spectral analyses suggest a decrease in gamma oscillatory activity at the frontal cortex in knock-out rats when compared to wild-type. Interestingly, robust changes in the ASSR and chirp-EP were found. The 40-Hz ASSR evoked activity and intertrial coherence were increased for transgenic animals. Similarly, the chirp-EP evoked activity and intertrial coherence were increased in a region at around 60 Hz. These differences are found bilaterally in the frontal cortex but not in the parietal cortex, suggesting a region specific disruption of neuronal synchronization mechanisms in the UBE3A knock-out rats. If replicated in patients, the ASSR and chirp-EP could constitute a useful biomarker for AS, guiding pharmacological development of therapies that target aberrant neuronal function.

Title: Intracellular Ca2+ stores are required for synaptic tag and capture in mouse hippocampal slices

Authors: *L. A. KOEK[1,2], T. M. SANDERSON[1], J. GEORGIOU[1], G. L. COLLINGRIDGE[1,2,3]; [1]Lunenfeld-Tanenbaum Res. Inst., Toronto, ON, Canada; [2]Physiol., Univ. of Toronto, Toronto, ON, Canada; [3]TANZ Ctr. for Res. in Neurodegenerative Diseases, Univ. of Toronto, Toronto, ON, Canada

Abstract: Long term potentiation (LTP) is a form of synaptic plasticity vital for learning and memory and can be differentiated mechanistically into two distinct forms based on independence of (LTP1) or requirement of (LTP2) de novo protein synthesis. In addition, LTP induced by a

weak stimulus can be enhanced if it is preceded by LTP induced by a strong stimulus at neighbouring synapses due to a process known as synaptic tagging and capture (STC). The role of intracellular Ca^{2+} stores in LTP1, LTP2 and STC are not well understood.
We induced LTP using two induction protocols, a compressed theta burst protocol (cTBS) that induces LTP1, and a spaced TBS protocol (sTBS) that additionally induces LTP2. The theta bursts in these two protocols were identical (5 pulses at 100Hz repeated 5 times at 5 Hz) as were the total number of pulses (75). The only difference was the inter theta burst interval: in cTBS this was 10 seconds, in sTBS this was 10 minutes. In some experiments we followed the sTBS protocol with a weak TBS (wTBS; one round of theta burst, 25 pulses) applied to an independent pathway 30 mins later, to study STC. We recorded fEPSPs from stratum radiatum in response to stimulation of the Schaffer Collateral -Commissural pathway of 10-12 week old C57BL/6J mice in the presence of cyclopiazonic acid (CPA, 30 uM), Ryanodine (Ry, 10uM) and vehicle.
We found that sTBS induced LTP that was inhibited by both CPA and Ryanodine. In interleaved vehicle and CPA treated slices LTP, quantified 120 min after delivery of sTBS was 174.3±7.9% and 141.6±7.5% respectively, (n=5, p<0.05). In a second set of interleaved vehicle- and Ry-treated slices, LTP was 160.3±3.7 % and 136.6±2.8 % respectively (n=6, p<0.01). In contrast, LTP induced by cTBS was not affected by either compound. LTP levels were 145.1±2.7, and 147.2±3.2, respectively, in control and CPA treated slices (n=5, $p > 0.05$) and 146.3±2.8, and 137.4±2.6, respectively in control- and Ry- treated slices (n=6, $p > 0.05$). To study STC, we delivered a weak TBS after delivery of the sTBS to an independent input, as determined by lack of heterosynaptic paired-pulse facilitation. The wTBS alone induced an LTP of 103.3±7.2 %, (n=5) whereas the wTBS induced an LTP of 137.9±5.7 %, n=8 when preceded by the sTBS. However, when Ry was present during the sTBS, the level of LTP induced by the wTBS was reduced to 112.7±5.94% (n=6, p<0.05).
These results demonstrate that Ca^{2+} stores are required for the protein synthesis-dependent form of LTP (LTP2) and are also involved in STC.

Title: Determining the neuronal substrates of the RhoGEF, Ephexin5

Authors: *S. PETSHOW[1], K. M. ZITO[2];
[1]Univ. of California, Davis, Davis, CA; [2]Univ. of California Davis, Davis, CA

Abstract: The activity-dependent structural plasticity of dendritic spines is a necessary component of learning and memory. Spine plasticity requires the local rearrangement of the actin cytoskeleton. Crucial for this is the activation of the Rho GTPases RhoA, Cdc42, and Rac1, whose activity control cytoskeleton dynamics, and their activators, RhoGEFs. Ephexin5 (E5) is a RhoGEF important for regulating synapse development. Previous work from the Zito lab demonstrated a role for E5 in regulating activity-dependent spine plasticity; however, the molecular pathways involved are unknown. While E5 has been shown to activate RhoA in neuronal tissue, evidence from somatic cells show E5 activates Cdc42 and Rac1. Notably, RhoA and Cdc42/Rac1 have been shown to play opposing roles in regulating dendritic spine structure, with RhoA activation inducing spine collapse and Cdc42/Rac1 activation inducing spine outgrowth and stabilization. Therefore, uncovering the full range of neuronal GTPase substrates of E5 is critical for understanding its role in spine plasticity. Crucially, the E5 homolog, Ephexin1, undergoes a phosphorylation-dependent switch in substrate preference from Cdc42/Rac1 to RhoA. It is our hypothesis that E5 undergoes a neuronal activity-dependent shift in substrate specificity from RhoA to Rac1/Cdc42, relevant to its role in regulating spine plasticity. To test this, we used 2-photon fluorescence lifetime imaging of genetically-encoded FRET biosensors for Rho GTPase activity in hippocampal CA1 neurons of E5 knockout (E5 KO) and wildtype (WT) mice. We found that, in response to glutamatergic stimulation, E5 KO neurons displayed lower Cdc42 activation compared to WT, while RhoA activation was unaltered. Intriguingly, E5 has previously been shown only to activate RhoA in neurons. Our results provide evidence that E5 activates Cdc42 during glutamatergic signaling in neurons.

Title: Inhibitor-2 positively regulates PP1-neurabin synaptic activity

Authors: *K. FOLEY[1,2], T. COUCH[2], H. HOU[2], M. M. PAPASERGI-SCOTT[2], D. M. MACLEAN[2], H. XIA[1,2];

Abstract: Protein phosphatase 1 (PP1) is a classic molecule of forgetfulness and potent regulator of post-synaptic plasticity. PP1 dephosphorylates a broad array of proteins, but requires targeting proteins to achieve substrate specificity: each function of PP1 is mediated by a PP1 holoenzyme, consisting of the PP1 catalytic subunit and a targeting protein. At the synapse, the neurabin-PP1 holoenzyme is a well-established regulator of AMPA receptor trafficking under basal and activity-dependent conditions. However, additional PP1-interacting proteins are present at the synapse, and little is known about the functional roles of the associated PP1 holoenzymes. Here we study inhibitor-2 (*PPP1R2*) and its interactions with PP1 and neurabin, as well as its functional role in synaptic transmission. Inhibitor-2 is so named by its inhibitory effect on PP1 *in vitro*, although we recently discovered that, paradoxically, inhibitor-2 positively regulates PP1 function *in vivo*. These opposing roles of inhibitor-2 on PP1 regulation may depend on the presence of, and interaction with, other PP1 targeting proteins. Using Förster resonance energy transfer (FRET)-fluorescent lifetime imaging microscopy (FLIM), we demonstrate direct interactions of inhibitor-2 with PP1 and neurabin, and key residues affecting interaction. Additionally, by performing field recordings in acute hippocampal slices, we show that knockout of inhibitor-2 replicates PP1 inhibition in CA1 synaptic function. Finally, we present a model by which inhibitor-2 could act as a positive regulator of PP1 function in the brain.

Title: ELAV-mediated mRNA translocation to the synapse: a candidate molecular mechanism for savings memory

Authors: *A. A. MIRISIS, A. SERRANO LUGO, J. Y. ZHAO, T. J. CAREW;
Ctr. for Neural Sci., New York Univ., New York, NY

Abstract: Savings memory is a phenomenon in which the molecular remnants of a “forgotten” memory are able to prime a neural system to re-express the memory following a reminder event

(which alone is insufficient to induce a *de novo* memory). In the marine mollusk *Aplysia californica*, behavioral long-term memory (LTM) for the tail-elicited siphon withdrawal reflex requires: (i) ERK activation, (ii) protein synthesis, and (iii) *de novo* transcription in the pleural sensory neurons (SNs) that mediate the reflex. Following the natural decay of LTM (forgetting), savings LTM can be established by a reminder stimulus which alone does not establish LTM in naïve animals. This process is dependent on protein synthesis but is unaffected by ERK inhibition (Menges et al., 2015). In our current work we have studied the *Aplysia* sensory neuron-motor neuron (SN-MN) system in both culture and *ex vivo* pleural-pedal ganglia. We found that, following LTM training (4 5HT pulses separated by 15 min), the RNA-binding protein ApELAV1 translocates in a microtubule-dependent manner from the SN nucleus into synaptic/dendritic processes. We have further determined that the mRNA encoding the transcription factor ApC/EBP, an ELAV-target RNA (Mirisis et al., 2021), is localized to distal SN compartments (including SN-MN synapses) after LTM training. Translation of this mRNA by subsequent savings training could provide a molecular mechanism for the re-establishment of LTM following its natural decay. In support of this hypothesis, we have found that savings training induces expression of ApC/EBP protein in previously trained, but not in naïve animals. The mechanisms underlying this expression of savings memory are distinct from the mechanisms underlying its expression in initial LTM training. Our findings thus identify a set of novel molecular mechanisms which can facilitate relearning, and interestingly, are distinct from those mechanisms that are required to establish original LTM.

Title: Progression of granule cell dispersion occurs along with in vivo LTP reinstatement and contextual fear memory recovery

Authors: *K. HERNÁNDEZ MERCADO[1], A. MARTÍNEZ MORENO[2], L. RODRÍGUEZ DURAN[2], M. L. ESCOBAR[2], A. ZEPEDA[1];
[1]Inst. de Investigaciones Biomédicas, [2]Facultad de Psicología, UNAM, Mexico City, Mexico

Abstract: The dentate gyrus (DG) is a structure through which multiple sensory information coming from the perforant pathway (PP) enters the hippocampus. The adequate integration of such information in the DG is critically important for the execution of hippocampal-dependent cognitive functions. Granular cell dispersion (GCD) is a pathological widening of the DG granular cell layer frequently observed in humans with mesial temporal lobe epilepsy (MTLE). Until now, it is unclear whether synaptic plasticity and hippocampal-mediated cognitive behaviors are affected by the presence and severity of GCD in MTLE. To evaluate the latter, we used the intrahippocampal injection of kainic acid (KA) mouse model of MTLE and analyzed in the temporal development of GCD: 1) the establishment of in vivo long-term potentiation (LTP) in the PP-DG pathway, and 2) the performance in learning and memory through contextual fear conditioning. Our results show that the gradual increase in GCD severity along time was accompanied by a synaptic reorganization and functional cognitive recovery. Impairment in LTP induction along deficits in learning and memory were observed as GCD subtly developed at 10 days-post-lesion (dpl). However, at 30 dpl a severe increase in GCD occurred which was surprisingly accompanied by the restoration of LTP induction and memory recovery. These findings support the hypothesis that GCD emerges as a local homeostatic change that maintains the physiological function of the DG network.

Title: Proteolytic processing of growth factor TGFβ provides a mechanism for precise temporal orchestration in long term memory formation

Authors: *P. MIRANDA, N. KUKUSHKIN, A. A. MIRISIS, M. SCHREIBMAN, T. J. CAREW;
Ctr. for Neural Sci., New York Univ., New York, NY

Abstract: While typically viewed as hormone-like molecules operating with little temporal resolution, growth factors can also play key roles in orchestrating the timing of molecular events required to form a long-term memory (LTM). In a two-trial training paradigm that induces LTM for sensitization in the marine mollusk *Aplysia californica*, growth factor TGFβ is critically

required during Trial 2 but not Trial 1 (Kopec et al, 2015). This finding suggests a temporally specific inter-trial regulation of TGFβ's signaling cascade, either upstream or downstream of TGFβ release. Since TGFβ is necessary and sufficient to promote LTM, we hypothesized that it contributes to the inter-trial interactions that determine the temporally restricted requirement of repeated trial learning (Miranda et al 2021). However, the precise mechanisms that determine the differential requirement for TGFβ during two trial training remain unknown.To examine whether interactions between trials alter the magnitude of TGFβ signaling, we have developed a bioassay based on the nuclear translocation of Smad, a downstream target of the TGFβ cascade. Cultured *Aplysia* sensory neurons were treated with either one or two pulses of 5HT to mimic two-trial sensitization training in the intact animal. We found that the rate of Smad nuclear translocation is indeed significantly increased after Trial 2 compared to Trail 1, suggesting differential activation of the TGFβ cascade during two trial training. To investigate the mechanism underlying this effect, we monitored Smad translocation in the presence of BMP-1, a protease known to convert secreted TGFβ from a latent to an active state. While BMP-1 alone had no effect on Smad translocation, when combined with a single pulse of 5HT, it significantly enhanced Smad's redistribution. Finally, in a gain of function experiment, we found that a single pulse of 5HT, when paired with BMP-1, induces long-term synaptic facilitation (LTF) in cultured sensory-motor neurons, whereas a single 5HT pulse alone does not induce LTF. These data support a model in which the interaction between the two trials involves both temporally segregated stages of TGFβ release and its proteolytic activation, the combination of which is required for the precise temporal processing during LTM formation.

Title: Loss of MicroRNA-324-5p alters cytoskeletal protein expression, modifies dendritic spine morphology, reduces dendritic spine density, and impairs long-term potentiation in the hippocampus

Authors: *E. V. PARKINS[1,3], D. H. BRAGER[7], J. K. RYMER[3], J. M. BURWINKEL[3], D. ROJAS[3], Y.-C. HU[4,5], D. TIWARI[3,6], C. GROSS[3,2];

Abstract: MicroRNAs are small noncoding RNAs that post-transcriptionally regulate gene expression. Their ability to rapidly alter gene expression and target multiple pathways makes them interesting candidates in the study of synapses, which are both dynamic and highly regulated. Here, we demonstrate that miRNA-324-5p regulates dendritic spines, small protrusions along the dendrite that comprise the majority of excitatory synapses in the brain. Using intracerebroventricularly (ICV) administered antagomir (inhibitor) of miR-324-5p in Thy1-eGFPhemi mice, we demonstrate that acute loss of miR-324-5p leads to a reduction in dendritic spine density and altered spine morphology in the hippocampus, with fewer thin and more stubby spines. To investigate the effect of chronic loss of miR-324-5p, we generated a CRISPR-Cas9-mediated Mir324 knockout (miR324 KO) mouse model and completed Golgi-cox staining to assess spine density. We also crossbred miR-324 KO mice with Thy1- $eGFP^{hemi}$ mice to assess spine density and morphology. Interestingly, we found reduced spine density and the same changes in morphology with both acute and chronic miR-324-5p loss. RNA-sequencing identified altered biological pathways in the miR-324 KO hippocampus that may contribute to the mechanism of miR-324-5p-mediated spine regulation, including cytoskeletal organization. Western-blot and quantitative Real-Time PCR also revealed changes in protein and mRNA levels for potassium channels, cytoskeletal components, and synaptic markers, including MAP2, a cytoskeletal protein that is essential for long-term potentiation (LTP). Intriguingly, slice electrophysiology revealed that LTP is severely impaired in miR-324 KO mice, while baseline excitatory activity remained unchanged. Altogether, our findings suggest that miR-324-5p is an important regulator of dendritic spines, and that its loss has brain functional consequences. Future studies will explore the mechanism by which miR-324-5p regulates dendritic spines and the role it plays in LTP, for example its role in dendritic spine dynamics during potentiation. We will also explore miR-324-5p antagomir's potential to reduce aberrant dendritic spine density in mouse models of autism. Both male and female mice were used in these studies, and no sex differences were detected. Experimenters and analyzers were blind to conditions, and studies were fully powered (power≥0.8) or indicated as preliminary.

Title: Frontal cortical microglia respond to dopaminergic signals in the adolescent mesofrontal circuit

Authors: *R. D. STOWELL, K. H. WANG;
Neurosci., Univ. of Rochester, Rochester, NY

Abstract: Psychiatric disorders such as schizophrenia are recognized as developmental disorders with complex disruptions in neuronal circuitry. Research in both psychiatric patients and animal models indicate that mesofrontal dopaminergic circuit abnormalities are involved in cognitive deficits. Furthermore, mesofrontal dopaminergic projections have a unique capacity for activity-dependent plasticity not found in adult animals. However, the mechanisms behind this adolescent plasticity process remain unclear. Microglia, the resident immune cell of the central nervous system, are integral participants in numerous developmental synaptic pruning and synaptic plasticity processes. Recent evidence has shown that microglia also respond *in vivo* to specific neurotransmitter signals including norepinephrine. Here utilizing a combination of transgenic, chemogenetic, and viral transduction strategies, we investigated if microglia are key participants in adolescent plasticity of mesofrontal dopaminergic circuit in mice. Utilizing chronic *in vivo* two-photon microscopy we were able to track fluorescently labelled microglia and dopaminergic axons in the M2 frontal cortical region pre- and post- stimulation of ventral tegmental area (VTA) dopaminergic neurons. We found that microglia respond to increased dopaminergic release from both chemogenetic stimulation of the VTA and wheel-running driven VTA activity. The morphology of microglial arbors changed after both chemogenetic and behavior stimulation. Microglial processes also made putative contacts with axonal elements of mesofrontal dopaminergic projections. Pharmacological manipulations further suggest that the microglial responses may be partially mediated by D2-type dopaminergic receptor signaling. Together, our results reveal an interaction between dopaminergic input and microglial activity in the adolescent frontal cortex. Further experiments will address if these microglial responses to dopaminergic signaling are essential for the adolescent development and plasticity of dopaminergic circuits in the frontal cortex. An improved understanding of these mechanisms will facilitate the identification of therapeutic targets for neurodevelopmental disorders.

Title: Neuronal ADAM17 mediated shedding of CX3CL1 contributes to microglial activation and inflammation

Authors: *N. LAKKAPPA[1,2], E. D. LAZARTIGUES[4,3];
[1]Louisiana State Univ. of Hlth. Sci., New Orleans, LA; [2]Southeast Louisiana Veterans Hlth. Care Syst., New orleans, LA; [3]Southeast Louisiana Veterans Hlth. Care Syst., Neworleans, LA; [4]LSU Hlth. Sci. Center-NO, New Orleans, LA

Abstract: Microglia is the principal immune cell in the brain and, once activated, releases cytokines contributing to neuroinflammation and sympathetic over-activation. Proinflammatory cytokines-mediated activation of microglia in the hypothalamus contributes to neurogenic hypertension.
Mouse Neuro-2a (N2A) cells were treated with DPC333 (ADAM17 inhibitor, 100 nM) for 24 h, followed by Ang-II (100 nM) stimulation. After 4 h, cells and media were harvested. The N2A conditioned media was added to human (HMC3) (ATCC® CRL-3304™) or Primary Microglia cells and incubated for 24 h. HMC3 cells and media were then harvested for estimation of ACE2 enzyme activity, protein expression of ACE2 and Iba1 and estimation of cytokines such TNFα, IL-6 and CX3CL1. A subset of cells were also used for IHC. CX3CL1 was identified as one of the inflammatory cytokines released from neurons after Ang-II stimulation, contributing to microglia activation and inflammation. Ang-II stimulation induced a 4-fold increase in CX3CL1 levels in N2A cells media (n=3: one-way ANOVA, $P<0.001$), implying ADAM17-mediated shedding of CX3CL1. When the Ang-II-treated N2A cells conditioned media was added to microglial cells, it resulted in a 4-fold increase in ACE2 activity and a 2-fold increase in Iba1 expression compared to untreated microglial cells (n=3: one-way ANOVA, $P<0.01$, $P<0.001$). However, microglial cells treated with N2A conditioned media exposed to DPC33 alone and DPC33+Ang-II, exhibited significantly attenuated ACE2 shedding and Iba1 levels. These data suggest that Ang-II-induced activation of neuronal ADAM17 and CX3CL1 shedding contribute to ACE2 shedding and the increase in Iba1 levels in microglia cells, respectively, promoting microglia activation and inflammation. In addition, histology data show that untreated microglial cells maintain a triangular shape with few branches, whereas cells exposed to Ang-II-treated N2A conditioned media form a network with many ramifications, which is the morphological presentation of activated microglia.
Together, we show that neuronal ADAM17-mediated shedding of CX3CL1 contributes to ACE2

shedding and activation of microglia. Therefore, inhibition of neuronal ADAM17 mediated shedding of CX3CL1 may prevent microglia activation and inflammation.

Title: IdentificaciÓN de la isoforma vegfc y su receptor transmembrana vegfr2 en células gliales de müller

Authors: *Z. CARRANZA JIMENEZ[1], L. OCHOA DE LA PAZ[2];
[1]Univ. Nacional Autónoma De México, Coyoacan, Mexico; [2]Univ. Nacional Autónoma de México, COYOACAN, Mexico

Abstract: Identification of the VEGF-C isoform and its transmembrane RECEPTOR VEGFR2 in Müller's glial cells. Authors * Carranza Jiménez Zoe Pamela[1,2], Ochoa-de la Paz Lenin David[1,2]. Laboratory of Molecular and Cellular Neurobiology of Glia, Department of Biochemistry, Faculty of Medicine, UNAM, Mexico City, Mexico[1.] Research Department, Association to Prevent Blindness in Mexico IAP Hospital "Dr. Luis Sánchez Bulnes" APEC, Mexico City, Mexico[2]. Summary Müller's glial cells are the main macroglia of the retina. They extend from the layer of ganglion cells to the inner segments of the photoreceptors, facilitating physical contact with many types of retinal cells. So it plays an important role in various physiological processes of the retina. In pathological conditions such as diabetic retinopathy induce the synthesis and release of inflammatory and angiogenic factors from Müller's glial cells that contribute to the processes of neurovascular dysfunction in these pathologies. Several observations in recent years indicate that Müller's glial cells are an important source of VEGFA under pathological conditions. The VEGF family consists of five members, structurally related to three different tyrosine kinase receptors (VEGFR1, VEGFR2 and VEGFR3). VEGFC is structurally related to VEGFA, induces lymphangiogenesis, increases vascular permeability and the release of inflammatory factors (IL). This VEGF isoform is attached to VEGFR2 and VEGFR3. Considering that Müller's glial cells are in contact with the blood retina, the dysfunction of Müller's glial cells can contribute to the angiogenic processes of the retina and also to the release of inflammatory factors. In this work, we characterize the presence of the

VEGF-C isoform and VEGFR-2 in Müller's glial cell culture. Müller's glia cell culture was obtained from retinas of dissociated postnatal mice. For control, we use ARPE-19 cell lines. The results indicate the presence of VEGF-C transcription in Müller's glial cells and the ARPE 19 cell line, however, transcription is more important than the ARPE-19 cell line. This result was confirmed by immunomarking assays, in which the VEGF-C isoform is expressed in the Müller glial cell soma. VEGFR-2 showed an expression of this receptor along with Müller's glial cells. So far, these results indicate the presence of VEGF-C and its receptor in Müller's glial cells, suggesting that these glial cells are the main source of VEGF-C. On the other hand, the presence of VEGFR-2 could imply a mechanism of self-regulation in the process of release of VEGF-C under pathological conditions.

Title: The expression of Angiotensin-Converting Enzyme type 2 (ACE2) in rat brain: a circuit analysis and possible implications for COVID-19 neurological manifestations

Authors: V. S. HERNANDEZ[1], ***M. A. ZETTER**[1], I. HERNÁNDEZ-ARAIZA[3], E. CAMPOS[2], L. ZHANG[1];
[1]Dept. of Physiology, Fac. of Med., [2]Physiol., Natl. Autonomous Univ. of Mexico, Mexico City, Mexico; [3]Sch. of Med., Univ. of Maryland, Baltimore, MD

Abstract: The angiotensin-converting enzyme type 2 (ACE2) has gained attention as it acts as the receptor for the SARS-CoV-2, and because its dysregulation is associated with COVID-19 pathophysiology. The frequent neurological manifestations during and after the acute infection have raised the interest in its expression at nervous tissue and despite it has been detected at the single-cell level, its anatomical distribution at the level of neuronal circuits has not been yet addressed. We examined the neuronal and glial expression of ACE2 and its distribution in the rat brain. ACE2 was detected in astrocytes and its endfeet processes, at pericytes, and endothelial cells, key components of the blood-brain barrier, suggesting its possible participation in the viral

entrance to nervous tissue. ACE2 was found ubiquitously present in brain vasculature, with the highest density of capillaries expressing the enzyme in the olfactory bulb; the hypothalamic paraventricular, supraoptic, and mammillary nuclei; the midbrain substantia nigra and ventral tegmental area; and hindbrain pontine nucleus, pre-Bötzinger complex, and the nucleus of *tractus solitarius*. Furthermore, we found discrete neuronal groups immunopositive for ACE2 in brainstem respiratory rhythm generating centers, including the pontine nucleus, the parafascicular/retrotrapezoid nucleus, parabrachial nucleus, Bötzinger, and pre-Bötzinger complexes and in the nucleus of *tractus solitarius*; in the arousal-related pontine reticular nucleus and *gigantocellular* reticular nuclei. In brainstem aminergic nuclei, mainly related to reward, as the substantia nigra, ventral tegmental area, dorsal raphe, and locus coeruleus, ACE2 was expressed in tyrosine-hydroxylase positive neurons. In the epithalamic habenula, thalamic paraventricular and supramammillary nuclei positive neurons were found. At the hippocampus, pyramidal neurons were positive in all CA regions, as well as abundant ACE2 positive astrocytes. The identification of these ACE2-expressing hubs in the rat brain within well-established functional circuits facilitates the prediction of possible neurological manifestations derived from the dysregulation of brain ACE2 in humans and could serve as a reference for future translational investigation.

Title: Long-term effects of adolescent THC exposure: role of prenatal environment

Authors: *K. MURLANOVA, Y. JOUROUKHIN, M. PLETNIKOV;
State Univ. of New York at Buffalo, Buffalo, NY

Abstract: The two-hit hypothesis of adult psychopathology predicts that a combination of prenatal and postnatal environmental insults increases risks for major psychiatric disorders. We generated a mouse model of environment x environment (E x E) interaction based on maternal immune activation (MIA) as a “first hit” and adolescent Δ^9-tetrahydrocannabinol (THC) exposure as a “second hit”. Both environmental factors were associated with psychiatric conditions, hence we hypothesized that MIA would interact with adolescent THC, to synergistically produce neurobehavioral abnormalities in adulthood. MIA was induced by administration of a viral mimetic, polyriboinosinic-polyribocytidilic acid [Poly (I:C), 5 mg/kg; IP] to gestating dams (CD1 mice, GD 12.5) and was validated by detecting increased levels of

IFN-γ, IL-1β, IL-6 and TNF- α in maternal serum. Male and female offspring received THC (8 mg/kg; SC) or vehicle during adolescence (PND 30-51) and were evaluated in a series of behavioral tests as adults (PND 72-90). We found that E x E interaction increased exploratory behaviors in the Hole Board Test (increased head dipping), the Open Field (increased rearing), Elevated Plus Maze (increased open space exploration) and elevated sensitivity to amphetamine (2 mg/kg, IP) in female but not male mice. Our data indicate that E x E interaction synergistically produces neurobehavioral alterations (hyperdopaminergic state) in adult mice in a sex-dependent manner. On-going studies aim at identifying the cell type-specific molecular mechanisms underlying E x E interaction in this model.

Title: Parkinson's disease relevant stressors induce neutral lipid changes in primary rodent astrocytes and microglia

Authors: *R. THOMAS, P. ROWICKA, O. ISACSON, P. J. HALLETT;
McLean Hospital/ Harvard Med. Sch., Belmont, MA

Abstract: Dysregulation of lipid metabolism has been identified to be a central pathway perturbed in Parkinson’s disease (PD) and related dementias. Elevated glycosphingolipid levels, reduction in the activity of the lysosomal hydrolase, glucocerebrosidase, and cell type-specific changes in the distribution of neutral lipids in neurons and glia are observed in PD mouse models and human PD cells and tissues (Rocha EM et al., 2015; Huebecker M et al., 2019; Thomas R et al., 2021; Brekk O et al., 2020). Furthermore, high resolution microscopic analysis of Lewy bodies from post-mortem human PD brains shows that they are composed of abundant lipid membranous structures along with other dystrophic organelles such as mitochondria and lysosomes (Shahmoradian S et al., 2019). Taken together, these studies suggest a potential pathological role for lipid dyshomeostasis in the etiology of neurodegenerative disorders. To

investigate the effect of PD relevant cellular insults on intracellular neutral lipid levels, primary rodent-derived astrocytes and microglia were treated with varying concentrations of mitochondrial depolarizing agents valinomycin and rotenone, and toll-like receptor (TLR) -3 and -4-dependent inducers of inflammation, Poly(I:C) and LPS. The cell cultures were microscopically analyzed using the neutral lipid probe BODIPY. Elevated BODIPY signals were observed in both astrocytes and microglial cells upon rotenone and valinomycin treatments. Murine macrophage cells co-treated with rotenone and the acyl CoA synthetase inhibitor TriacsinC showed reduced BODIPY signal intensity from lipid droplets (LDs), confirming that LD induction in response to rotenone is the result of *de novo* synthesis of triacylglycerols. BODIPY induced changes were also seen in LD analysis of astrocytes and microglia following exposure to Poly(I:C) and LPS. These data show that cellular stressors relevant to PD induce neutral lipids in astrocytes and microglial cells. Current work is investigating how cellular stressors and lipid changes are altered in neuron-glia co-cultures and the mechanisms that lead to these changes, which will help to identify cell-cell interactions between neurons and glia in PD and related disorders.

Title: Roles of programmed cell death protein-1 (PD-1) in spinal cord microglia activation and mechanical pain in mice of different sexes

Authors: *S. RAHMAN[1], O. CHEN[2], Z. WANG[1], R.-R. JI[2];
[1]Ctr. for Translational Pain Medicine, Dept. of Anesthesiol., [2]Ctr. for Translational Pain Medicine, Dept. of Anesthesiology, Dept. of Cell Biol., Duke Univ., Durham, NC

Abstract: The blockade of programmed cell death protein-1 (PD-1) with antibodies such as nivolumab has been proven to be an effective treatment for various cancers by immunotherapy. Nivolumab is capable of reaching the brain in patients with a compromised nervous system, and PD-1 could modulate pain and cognitive function in these cases. However, the relationship between the nervous and immune systems and the effect of PD-1 inhibition on the nervous system are not yet fully understood. We recently reported that PD-1 activation in primary sensory neurons inhibits neuronal excitability and pain[1]. PD-1 also mediates opioid receptor signaling in nociceptive neurons, leading to altered opioid analgesia in rodents and nonhuman primates[2]. To explore the role of PD-1 in microglial signaling, we generated Pdcd1-Cre-reporter mice. Nerve injury induced profound PD-1 expression in a subset of microglial cells in the spinal

cord of Pdcd1-reporter mice. We also analyzed the size and number of microglia in mouse spinal cords sections before and after treatment with the PD-1 antibody nivolumab using confocal microscopy imaging. IBA1 immunohistochemistry staining was performed to label microglia in the spinal cord dorsal horn. We found that the intrathecal (spinal) injection of nivolumab (5 μg) not only induced mechanical allodynia, but also caused a robust microglial reaction with increased cell numbers and enlarged cell bodies. Furthermore, nivolumab-induced mechanical allodynia was blocked by the intrathecal injection of minocycline, a microglial activation inhibitor, in male, but not female, mice. Our findings suggest that PD-1 serves as a negative regulator of microglial activation and neuropathic pain. Furthermore, this data supports sex dimorphism in the microglial regulation of neuropathic pain. These results align with previous studies, which have shown that PD-1 inhibition induces hyperalgesia and the blockage of antinociception, and future studies can further elucidate this relationship to improve and expand on current immunotherapy strategies for chronic pain and cancer patients.

Title: Combining single cell chromatin landscape and gene expression with FFPE spatial transcriptomic approaches to characterize Alzheimer’s disease (AD) progression in TgCRND8 APP transgenic mice

Authors: *L. J. ALVARADO[1], S. WILLIAMS[1], V. GIANGARRA[1], A. PULEO[1], K. MILLER[1], Y. LEVITES[2], K. DILLON[2], S. PROKOP[2], S. TAYLOR[1];

Abstract: Alzheimer’s Disease (AD) currently impacts 6 million Americans who are living with the disease and 1 in 3 seniors die with a diagnosis of AD or dementia. Given the epidemiological state and impact of AD, a better understanding of the biology of the disease is needed to develop effective preventative and curative therapies. Here, we demonstrate the benefits of combining both single cell and spatial information in TgCRND8 APP transgenic mice to further understand

the progression of AD. Using the Chromium Single Cell Multiome ATAC + Gene Expression and Visium Spatial Gene Expression with FFPE assays, the open chromatin landscape and gene expression profiles of Tg APP-overexpressing and wild-type mice brains from 2 to 20 months old mice were evaluated. In addition, Aβ production and Aβ-associated neuroinflammation across several anatomical regions of the brain were analyzed and correlated with regulatory programs identified based on multiomic data. Results showed multi-cellular gene co-expression networks at both the single nucleus and spatial levels as well as distinct open chromatin sites during the course of evolution of AD pathology. These findings were noteworthy in brain regions containing Aβ plaques accompanied by a neuro-immune response from distinct cell populations as a function of disease progression. Together, the data showcases the utility of combining open chromatin and gene expression analysis at the single cell level with spatial transcriptomics of FFPE tissues to fully characterize cellular networks and responses in the time-sensitive context of AD.

Abstract: Identifying individual cells and their genetic makeup is critical for understanding their roles in how the central nervous system (CNS) functions in both healthy and diseased states. Here we demonstrate characterization of spatial transcriptomic patterns in the APPSWE [Tg2576] mouse model of familial Alzheimer's Disease (Taconic) using the Visium Spatial Gene Expression Solution. The assay involves placing serial coronally sectioned fresh-frozen tissue samples onto Visium Spatial Gene Expression slides. The slides consist of ~5,000 spot arrays with uniquely barcoded probes enabling the capture of native mRNA. From the captured molecules, cDNA were generated and libraries constructed and sequenced on an Illumina NovaSeq. Using the Space Ranger analysis pipeline and the Loupe Browser desktop software, the RNA-seq data were merged with H&E and immunostained images of the same tissue to align reads and to perform clustering and gene expression analysis. With the generated data, we demonstrated an improved version of the spotted oligo array technology that increases tissue coverage and spatial resolution with reduced spot size, and increased spot number and packing density. We captured spatial patterns of gene expression and mapped the information back to H&E and immunostained images with regional annotations. Correlation analysis demonstrated differential spatial gene expression between the control and APPSWE [Tg2576] mouse model. Together, this confluence of imaging and sequencing is a valuable tool for understanding the relationships between CNS cell types in healthy and diseased samples with an unbiased anatomical and gene expression-driven method.

Title: Profiling gene expression in single cell populations within the frontal cortex of postmortem human tissue in Alzheimer's disease and control subjects

Authors: *A. LABUZA[1,2,3], *M. J. ALLDRED[1,2], A. SALTZMAN[1], S. D. GINSBERG[1,2,3,4]; [1]Ctr. for Dementia Res., Nathan Kline Inst., Orangeburg, NY; [2]Psychiatry, [3]NYU Neurosci. Inst., [4]Neurosci. & Physiol., NYU Grossman Sch. of Med., New York, NY

Abstract: Alzheimer's disease (AD) is a neurodegenerative disease that accounts for the majority of dementia cases affecting an estimated 6.2 million Americans. Currently, there is no single test for AD and diagnosis can only be confirmed by postmortem neuropathological assessment. None of the current pharmacological treatments available significantly slow or stop the damage or destruction of neurons that cause AD, providing only symptomatic relief without treating the source of disease onset or progression. While the hallmark of AD pathology is defined as the presence of amyloid-beta plaques and neurofibrillary tangles, it is still not well understood how they contribute to neurodegeneration. It is critical we understand mechanisms underlying AD to develop early biomarkers and therapies. Recent 'omics platforms (e.g., transcriptomics, proteomics, metabolomics) technical advancements enable assessment of numerous genes, proteins, metabolites, and impacted pathways through bioinformatic inquiry, which may allow a better unbiased assessment of disease mechanism(s) and potential therapeutic interventions. Currently, AD pathophysiology at the single population and circuit levels may be best dissected by examining transcriptomic analyses, since rigorous proteomic and metabolomic assessments are technically challenging using postmortem brain tissues at the present time. Accordingly, RNA sequencing (RNA-seq) provides a profile of expressed genes as well as noncoding RNAs (ncRNAs) within a given population. However, a limitation is that bulk-tissue resolution masks complex alterations occurring across cell types. Therefore, we are performing RNA-seq on single-cell populations isolated using laser capture microdissection (LCM). Using LCM, we isolate Nissl-stained pyramidal neurons from Layer III or Layer V within the frontal cortex (Brodmann area 9) utilizing postmortem human brain tissue obtained from clinically and pathologically characterized AD and age-matched nondemented control patients. RNA species from these neurons are isolated, converted to cDNA library preparations, and then analyzed via RNA-seq with subsequent bioinformatic pathway analyses (e.g., IPA, KEGG, and GO) to identify changes between control and AD patients. By studying the molecular fingerprints of selected cells known to be vulnerable to AD, we can gain insight into mechanistic changes that will enable unbiased pathway analyses through bioinformatics approaches that we expect to help explain circuit degeneration and inform novel therapeutic strategies.

Title: Deep and superficial CA1 pyramidal neurons show distinct expression profiles via single population RNA-seq in a mouse model of Down syndrome (DS) and Alzheimer's disease (AD)

Authors: *M. J. ALLDRED[1,3], S. C. PENIKALAPATI[1], S. LEE[2,4], A. HEGUY[5], S. D. GINSBERG[1,3,6,7];
[1]Ctr. for Dementia Res., [2]Ctr. for Biomed. Imaging and Neuromodulation, Nathan Kline Inst., Orangeburg, NY; [3]Psychiatry, [4]Child & Adolescent Psychiatry, [5]Genome Technol. Ctr., [6]Neurosci. & Physiol., [7]NYU Neurosci. Inst., NYU Grossman Sch. of Med., New York, NY

Abstract: Individuals with Down syndrome (DS) have intellectual disability and develop hallmark Alzheimer’s disease (AD) pathology during midlife. Several circuits underlying memory and executive function in the DS and AD brain are vulnerable to neurodegeneration, notably the interconnected basal forebrain cholinergic system and the hippocampus. Murine studies demonstrate CA1 pyramidal neurons have distinct sublayers along the radial axis, namely deep and superficial neurons, that also differ along the transverse axis with regard to innervation and function. The mediolateral innervation pattern of these neuronal subpopulations is postulated to impact both spatial and non-spatial learning and memory. We performed laser capture microdissection to isolate medial deep and superficial CA1 pyramidal neuron populations in concert with single population RNA-seq and subsequent bioinformatic inquiry to determine if transcriptomic differences exist within these CA1 pyramidal neuron subpopulations. Gene expression profiles were accrued from the Ts2 trisomic mouse model of DS and AD, which presents phenotypic and pathological features similar to the human condition including age-related synaptic loss and degeneration of basal forebrain cholinergic neurons. Importantly, trisomic mice have deficits in spatial and non-spatial learning and memory linked to the septohippocampal connectome including CA1 pyramidal neurons. RNA-seq results in 11 month old Ts2 mice compared to normal disomic (2N) littermates indicate medial deep and superficial CA1 neurons exhibit unique gene expression profiles, which also differ from pooled CA1 pyramidal neurons collected along the medial-lateral axis. Classes of transcripts with significant differences in Ts2 compared to 2N CA1 pyramidal neurons that were unique to deep or superficial expression included apoptotic genes and cell signaling factors. By examining these distinct transcriptomic differences, we can potentially link innervation differences to gene expression and changes in canonical pathway expression. Preliminary RNA-seq profiling results support the hypothesis both deep and superficial CA1 pyramidal neurons have dysregulated gene

expression in Ts2 mice. We are undertaking bioinformatic inquiry (e.g., IPA, KEGG, and GO) to examine mechanistic pathways and biological functions that may be relevant towards deciphering the pathogenesis of DS and AD. Understanding expression profiles of distinct cell populations involved in a key vulnerable learning and memory circuit may translate into novel treatment options for DS and possibly lead to therapeutics for arresting cognitive decline associated with AD.

Title: Shared and disparate genotype contributions to TDP-43 related phenotypes

Authors: *B. SPENCER[1], D. IRWIN[2], V. M. VAN DEERLIN[3], C. MCMILLAN[1]; [1]Neurol., [2]Univ. of Pennsylvania, Philadelphia, PA; [3]Dept Pathol & Lab. Med., Univ. Pennsylvania, Philadelphia, PA

Abstract: Case-control genome wide association studies (GWAS) have identified single nucleotide polymorphisms (SNPs) associated with risk of neurodegenerative diseases related to TAR DNA-binding protein (TDP-43) proteinopathies, including amyotrophic lateral sclerosis (ALS), frontotemporal lobar degeneration (FTLD), and hippocampal sclerosis of aging (HS-Aging). However, it is unclear the extent to which risk SNPs are shared or disparate across TDP-43 proteinopathies and whether these genotypes contribute to distinct phenotype presentations. We selected 69,360 SNPs that were common across prior case-control GWAS summary statistics for ALS, FTLD with TDP-43 inclusions (FTLD-TDP), and HS-Aging risk and exceeded a minimum threshold of risk ($p<0.05$) for at least one phenotype. We then performed a weighted correlation analysis to identify modules of highly correlated SNPs. This revealed 6 distinct modules including 3 modules strongly associated with either ALS (containing 19,912 SNPs), FTLD-TDP (containing 19,717 SNPs), or HS-Aging (containing 16,424 SNPs) and 3 that were strongly associated with phenotypic pairs, ALS-FTLD (containing 3,717 SNPs), ALS-HS-Aging (containing 4,888 SNPs), and FTLD-HS-Aging (containing 4,702 SNPs). To establish whether these modules confer biological meaning, we evaluated the associations between module SNPs

and gene expression quantitative trait loci (eQTL) from the public Genotype-Tissue Expression project for vulnerable brain regions associated with these phenotypes: spinal cord, frontal cortex, and hippocampus. To test whether modules contained a significant proportion of eQTLs we compared actual SNP-gene pairs within a region relative to 1000 bootstrap samples of pseudo-module assignments for each SNP-gene pair. Several biologically plausible regional differences were observed. Within the frontal cortex and spinal cord, but not the hippocampus, there were more SNP-gene pairs in the module representing the overlap between ALS and FTLD-TDP than in the pseudo-module (p= 0.04 and 0.04, respectively). In hippocampus, but not frontal cortex or spinal cord, there were more SNP-gene pairs in the module representing the overlap between HS-Aging and FTLD-TDP (p= 0.02). Examining genotypes revealed modules of both shared and disparate correlated SNPs across phenotypes associated with TDP-43 proteinopathies which have biologically plausible regional eQTL associations. We suggest that genetic variation across TDP-43 proteinopathies may contribute to the phenotypic heterogeneity across these neurodegenerative diseases related in part to transcriptomic signatures of selective vulnerability in the brain.

Title: ApoE2 reverses glycolytic deficit in ApoE4 models

Authors: *X. ZHANG[1], *X. ZHANG[2], H.-J. MOON[2], T. SIAHAAN[3], L. ZHAO[2,4];
[2]Dept. of Pharmacol. & Toxicology, [3]Dept. of Pharmaceut. Chem., [4]Neurosci. Grad. Program, [1]Univ. of Kansas, Lawrence, KS

Abstract: Continued clinical failures in the search for treating Alzheimer's disease (AD) raise questions about the validity of currently focused therapeutic targets, underscoring the importance of an alternative concept that emphasizes on the neuroprotective mechanism to promote brain resilience against AD. We recently demonstrated that human ApoE genetic isoforms (ApoE2, ApoE3, ApoE4) differentially modulate neuronal glycolytic metabolism with the ApoE2-expressing cells exhibiting the most robust while the ApoE4-expressing cells display the most deficient profile. Our follow-up study revealed that these ApoE isoforms-mediated glycolytic differences directly correlated to cellular overall health status, as indicated by both morphological phenotype and metabolic activity of the cells. In the present study, we investigated glycolytic changes in cells stably expressing hApoE4 upon a transient transfection of pCMV-hApoE2. Results show that 48hr post-transfection of hApoE2 induced a significant increase in both the expression and enzymatic activity of hexokinase (HK) when compared to the vehicle-treated group. Furthermore, we treated human ApoE4 knock in (hApoE4-KI) mouse primary cortical neurons with recombinant human ApoE2 (rhApoE2) protein for 4 days and found that exposure to rhApoE2 protein led to a considerable upregulation of HK2 and synaptic markers in hApoE4-KI primary neurons. Interestingly, a significant decrease of endogenous hApoE4 protein level was also observed in rhApoE2 protein treated primary neurons. We next examined the ability of rhApoE2 protein to improve the survival of hApoE4KI primary cortical neurons exposed to H_2O_2 for 30mins. Data indicate that rhApoE2 treatment effectively protected primary neurons against H_2O_2 insult assessed by less released LDH, potentially via the upregulation of HK. In our further *in vivo* study, we delivered rhApoE2 protein using ADTC5 peptide as a blood brain barrier modulator into the brains of hApoE4KI mice via tail vein injection. Results showed a remarkable higher deposition of rhApoE2 protein compared to vehicle treated groups, indicating an enhanced delivery of rhApoE2 protein into the brain. In addition, a significant increase of HK was observed in the brains treated with rhApoE2 protein and ADTC5, with no significant change of GFAP level, indicating that introduction of rhApoE2 via ADTC5 can potentially reverse the glycolytic deficit in ApoE4 brains without inducing neurotoxicity. These data provide a proof of concept for the potential of translating ApoE2-mediated neuroprotective mechanisms into a novel therapeutic approach in the prevention and early intervention of AD.

Title: Brain mitochondrial clusterin (mitoCLU) and its potential role in the regulation of F1Fo-ATP synthase

Authors: *H.-J. MOON[1], S. K. HERRING[1], P. RAWAL[1], L. ZHAO[1,2];
[1]Pharmacol. and Toxicology, Sch. of Pharm., [2]Neurosci. Grad. Program, Univ. of Kansas, Lawrence, US-KS, KS

Abstract: Clusterin (CLU), or apolipoprotein J (ApoJ), is currently assessed as the third most predominant genetic risk factor for the development of late-onset Alzheimer's disease (LOAD). A number of single nucleotide polymorphisms (SNPs) in CLU, with the majority being intronic, have been linked to significantly altered LOAD risk; however, it is unclear how these SNPs affect CLU mRNA and protein isoform expression and function in the brain. We have discovered that the unglycosylated, non-secreted mitochondrial isoform of CLU protein (mitoCLU) is localized to the mitochondrial matrix and expressed in both rodent and human neurons and astrocytes. To understand the neural function of mitoCLU, we performed mitoCLU coimmunoprecipitation and proteomic analysis using mitochondrial fractions isolated from human neuronal cell lines. We identified several potential mitoCLU-interacting proteins, including two crucial subunits of mitochondrial F1Fo-ATP synthase, a key enzyme for mitochondrial oxidative phosphorylation and ATP synthesis. In addition, we evaluated the impact of mitoCLU on mitochondrial respiration by performing a mito stress test. MitoCLU significantly increased the mitochondrial spare respiratory capacity and total ATP production. Taken together, these findings suggest that mitoCLU may play an important role in the regulation of the activity of mitochondrial F1Fo-ATP synthase, and which may be negatively affected by CLU variants leading to the development of risk phenotype for LOAD.

Title: Regulation of astrocyte-microglia crosstalk and neuroinflammation by clusterin

Authors: P. RAWAL[1], H.-J. MOON[1], L. ZHAO[1,2];
[1]Pharmacol. and Toxicology, Sch. of Pharm., [2]Neurosci. Grad. Program, Univ. of Kansas, Lawrence, US-KS, KS

Abstract: Clusterin (CLU), also known as apolipoprotein J, is one of the top three genetic risk factors for the development of late-onset Alzheimer's disease (LOAD); however, how its genetic variants influence the risk of LOAD is unknown. Apart from the well-characterized amyloid and tau pathologies, the presence of extensive neuroinflammation mediated by microglia, the brain-resident immune cells, has been emerging as a major contributor in the pathogenesis of LOAD. Therefore, modulation of microglial activation is crucial for retaining microglial homeostasis and maintaining overall brain health. In this study, using mouse primary astrocytic and microglial cultures as well as a microglial cell line, we analyzed the expression profile of CLU and the role of CLU on microglial response to inflammatory challenge induced by lipopolysaccharide (LPS). We found that CLU is abundantly expressed in and secreted from astrocytes, however, it is neither expressed in nor secreted from microglia. Furthermore, both astrocyte-secreted and recombinant CLU glycoprotein interacted with microglia and reduced the level of LPS-induced microglial inflammation. We have also identified a crosstalk between astrocytes and microglia in which LPS induces microglial inflammation, which further induces astrocytic activation that results in increased synthesis and secretion of CLU. In addition to the immunomodulatory role of CLU in vitro, we found that the loss of CLU can lead to a chronic neuroinflammatory state indicative of AD risk in vivo. Neuroinflammation induced by intraperitoneal injection of LPS was also found to be exacerbated in CLU knockout mice when compared to wild type mice. Furthermore, consistent with our in vitro studies, LPS induced neuroinflammation resulted in an increased expression of CLU in the brain in WT mice. Overall, these findings indicate that CLU may play an important immunomodulatory and anti-inflammatory role in the brain.

Abstract: Excitatory neurons of the layer II of lateral entorhinal cortex (ECII) are the first neurons to degenerate in Alzheimer's disease (AD). They develop neurofibrillary tangles (NFT, intracellular aggregates of hyperphosphorylated tau protein) at prodromal AD stages, and their degeneration correlates with the clinical symptoms observed with the disease progression. To identify potential drivers of AD pathology in ECII neurons, we reprioritized GWAS data for NFT formation by performing Network-Wide association study (NetWAS 2.0). This analysis identified DEK proto-oncogene as a potential driver of tau pathology in ECII neurons. Our results show that downregulation of *Dek* in ECII neurons *in vitro* and *in vivo* and leads to alterations in synaptic transmission, neuronal plasticity and learning and memory associated pathways. Interestingly, while *Dek* silencing leads to increased chromatin accessibility in the promoter and proximal enhancer region of the immediate early gene *Egr1*, its expression levels are overall decreased in *Dek*-silenced neurons. Induction of neuronal depolarization by KCl leads to a higher induction of *Egr1* in *Dek*-silenced neurons compared to control, supporting the notion that *Egr1* downregulation is associated with changes in neuronal excitability. Furthermore, these alterations are accompanied by deregulation in Tau exon 10 splicing, leading to an imbalance in the 4R/3R Tau ratio, Tau accumulation in ECII neurons *in vivo*, microglia activation and ECII neuron loss. Together, our results identify *Dek* proto-oncogene as a novel regulator of neuronal plasticity and synaptic transmission which deficiency leads to AD-associated pathological alterations.

Title: Molecular Atlas of Alzheimer's Disease Vulnerable Entorhinal Cortex

Authors: W. WANG[1], P. RODRIGUEZ-RODRIGUEZ[1,2], I. SALAS-ALLENDE[1], M. FLAJOLET[3], ***J.-P. ROUSSARIE**[4,1];
[1]Rockefeller Univ., New York, NY; [2]Karolinska Institutet, Stockholm, Sweden; [3]Mol. and Cell. Neurosci., The Rockefeller Univ., New York, NY; [4]Boston Univ., Boston, MA

Abstract: A major obstacle in our understanding of early stages of Alzheimer's disease (AD), is our limited knowledge of the very first neurons to die in the disease, and of their surrounding cellular environment. In most patients with amnestic AD, neurons from the layer II of the entorhinal cortex (ECII) are the first neurons to form neurofibrillary tangles and degenerate. We previously profiled neurons from the entire ECII in the mouse using cell-type specific ribosomal profiling and demonstrated that a gene module involved in axonal plasticity underlies their vulnerability to neurofibrillary degeneration (Roussarie et al., Neuron, 2020). This proved that molecular characteristics of ECII neurons could predispose them to the formation of pathological lesions in AD. A large literature describes the heterogeneity in connectivity, cytoarchitectonics and function of this region in mice and primates. In addition, the transentorhinal subdivision of the EC shows strikingly higher vulnerability than the rest of the ECII. We now propose to more precisely identify the molecular subtypes that compose this layer. Using single-nucleus RNA-sequencing and *in situ* hybridization in the mouse, we 1) delineate molecular subpopulations of EC - some discrete, some in transcriptional gradients, in a data-driven way, 2) identify markers for these anatomically distinct populations of ECII neurons, as well as for specific cell states within these populations, 3) identify subpopulation-specific signal in our whole ECII ribosomal profiling data. Overall this study is an indispensable first step in the characterization of transentorhinal neurons, and in the precise molecular dissection of the neuronal pathological cascade taking place during prodromal AD.

Title: Identifying Cellular and Molecular Mechanisms Underlying Selective Regional Degeneration in Spinocerebellar Ataxia Type 2

Authors: *A. B. ROBBINS[1,3], P. T. RANUM[3], B. L. DAVIDSON[3,2];
[1]Neurosci. Grad. Program, [2]Dept. of Pathology and Lab. Med., Univ. of Pennsylvania, Philadelphia, PA; [3]Raymond G. Perelman Ctr. for Cell. and Mol. Therapeut., Children's Hosp. of Philadelphia, Philadelphia, PA

Abstract: Many genes implicated in neurodegenerative disorders are widely expressed yet trigger dysfunction in specific brain regions and cell populations. Here we investigate the molecular underpinnings of selective degeneration in a fatal, late-onset disorder, Spinocerebellar Ataxia Type 2 (SCA2). SCA2 is caused by an abnormal CAG repeat expansion in the *ATXN2* gene, conferring a toxic gain of function. Clinical manifestations of SCA2 are linked to cerebellar dysfunction, including speech difficulties and loss of motor coordination. Although *ATXN2* is ubiquitously expressed, cerebellar Purkinje cells are most vulnerable to degeneration and cell death. Clinical case studies of SCA2 neuropathology demonstrate a distinct anterior to posterior atrophy pattern and sparing of the most posterior cerebellum. The mechanisms underlying both the variable cerebellar loss and Purkinje cell-specific vulnerability have not yet been investigated**.** Recent transcriptional profiling of individual cerebellar lobules has identified variation in specialized neuronal and glial subtypes across the adult wild-type murine cerebellum. Here we sought to identify differential expression of disease-relevant pathways contributing to regional and cell type-specific cerebellar vulnerability in the context of SCA2 and normal cerebellar aging. Utilizing a well-characterized mouse model of SCA2, we profiled the cerebellar transcriptome at tissue and single-cell level while retaining spatial information across the anterior to posterior cerebellum via fine microdissection. Tissue for single nuclei RNA-sequencing (snRNA-Seq) was collected at pre-symptomatic, early, and late-stage disease time points, capturing transcriptional alterations across the spatiotemporal landscape of SCA2 pathogenesis. To overcome the cost and sample size limitations of prevailing droplet-based snRNA-seq methodologies, we implemented SPLiT-Seq. This barcode-based single cell RNA-Seq workflow facilitates the creation of highly multiplexed snRNA-Seq datasets. By encoding spatiotemporal and sample ID information within three rounds of combinatorial barcoding, we indexed 96 biological samples per sequencing library, simultaneously assessing samples from distinct cerebellar regions, genotypes, and timepoints. This study is the first to characterize SCA2 degeneration and disease progression at a single-cell spatiotemporal resolution, alongside cerebellar aging in normal and disease brain. Our results offer new insights into the cell-type-specific contributions to regional disease vulnerability and the spatial regulation of genes and pathways for future therapeutic validation.

Title: Translational profiling of striatal spiny projection neurons in a mouse model of dystonia reveals distinct adaptations in D1 dopamine receptor- versus D2 dopamine receptor-expressing cells

Authors: *K. M. ROMAN, E. J. HESS;
Emory Univ., Atlanta, GA

Abstract: Striatal dysfunction is implicated in many forms of dystonia with diverse etiologies. The striatum is primarily composed of spiny projection neurons (SPNs), which generally express either D1 or D2 dopamine receptors (D1Rs; D2Rs). D1R- and D2R-expressing SPNs act in concert to regulate motor activity by modulating basal ganglia output. Although both D1R- and D2R-expressing SPNs are implicated in dystonia, our knowledge of the cell type-specific molecular abnormalities underlying dystonia is extremely limited. We have previously demonstrated that the striatum is central to the dystonia in a mouse model of DOPA-responsive dystonia (DRD). Further, both D1R and D2R signaling mediates dystonia in DRD mice. Thus, this novel mouse model provides an opportunity to understand striatal cell-type specific molecular adaptations in dystonia. We used translating ribosome affinity purification (TRAP) to purify cell-type specific mRNA from either D1R- or D2R-expressing SPNs from DRD and control littermates and used RNA-seq to obtain an extensive profile of the actively translating genes. In D1R-expressing SPNs, we detected 31,549 unique transcripts, and 806 transcripts were differentially expressed (451 upregulated; 355 downregulated) in DRD compared to control mice (Benjamini-Hochberg padj<0.05; |FC|≥1.5; n=3F/5M mice/genotype). In D2R-expressing SPNs, we detected 28,530 unique transcripts and 932 transcripts were differentially expressed (496 upregulated; 436 downregulated) in DRD compared to control mice (Benjamini-Hochberg padj<0.05; |FC|≥1.5; n=5F/3M mice/genotype). In DRD mice, a higher percentage of genes were differentially expressed in D2R-SPNs (3.27%) than in D1R-SPNs (2.55%). Only 121 transcripts were differentially expressed in both SPN subtypes (38 commonly upregulated; 15 commonly downregulated; 68 oppositely regulated). We used Gene Set Enrichment Analysis to identify dysregulated biological pathways that may play an important role in the pathomechanisms of dystonia and found that MAPK signaling pathway genes are abnormally regulated in D1R-SPNs. In contrast, calcium signaling pathway genes are abnormally regulated in D2R-SPNs. Interestingly, several differentially expressed genes from D1R-SPNs (6 genes) and D2R-SPNs (5 genes) are already implicated in dystonia. Identifying dysregulated pathways in D1R- and D2R-expressing SPNs may provide a foundation for the development of desperately needed therapeutics for the many dystonias associated with striatal dysfunction.

Title: Loss of the ataxia protein sacsin perturbs trafficking, formation of cell adhesions, and disrupts synaptic organization of Purkinje neurons

Authors: L. E. ROMANO[1], W. AW[2], K. M. HIXSON[2], T. HAVENER[2], S. HOWELL[2], T. NOVOSELOVA[1], C. HALL[1], P. CHAPPLE[1], ***J. WOLTER**[2];

Abstract: Autosomal recessive spastic ataxia of Charlevoix-Saguenay (ARSACS) is a childhood-onset cerebellar ataxia that is caused by mutations in the gene *SACS*. The ARSACS mouse model and patient derived cell lines display mitochondrial dysfunction and abnormal neurofilament structure, yet the large size of the SACS protein (520 kDa) has hampered standard biochemical characterization. Thus, it is unclear how the loss of SACS causes these deficits, or why they manifest as a cerebellar ataxia. To address this critical gap in knowledge, we employ a multi-omics approach to characterize molecular deficiencies in *SACS* knockout (KO) cells, including phosphoproteomics, kinome profiling, cell surface proteomics, RNA-seq, and co-IP mass spectrometry. We identified overabundance and hyperphosphorylation of the protein Tau in *SACS* KO cells, as well as deficits in microtubule structure, dynamics, and protein trafficking. We also identified altered membrane localization of multiple synaptic adhesion proteins, including ITGA1, NRCAM, NFASC, and CNTN1. Mutations in several of these genes cause various cerebellar ataxias with overlapping phenotypic manifestations with ARSACS. We also identified striking synaptic deficits in the deep cerebellar nucleus of the ARSACS mouse, prior to the onset of Purkinje cell death or motor deficits. In all, our data suggests that deficits in synaptic adhesion protein trafficking is a causal molecular deficiency in ARSACS.

Title: Differential effects of enhanced Wnt-β-catenin signaling in Purkinje cells and glial cells in SCA1

Authors: *K. LUTTIK[1], L. TEJWANI[1], H. JU[2], T. DRIESSEN[2], C. SMEETS[2], J. LIM[2]; [1]Yale Univ., New Haven, CT; [2]Yale Univ., Not Hispanic or Latino or Spanish Origin, CT

Abstract: Spinocerebellar ataxia type 1 (SCA1) is a dominantly inherited neurodegenerative disorder characterized by progressive ataxia and degeneration of specific neuronal populations, including Purkinje cells (PCs) in the cerebellum. SCA1 is caused by a nucleotide expansion of a glutamine-encoding (CAG) repeat tract in *ATXN1*, and can be characterized by progressive ataxia, mild cognitive impairments, and ultimately, respiratory failure, etc. Previous studies have demonstrated a critical role for various evolutionarily conserved signaling pathways in cerebellar patterning, such as the Wnt-β-catenin pathway; however, the roles of these pathways in adult cerebellar function and cerebellar neurodegeneration are largely unknown. In this study, we found that Wnt-β-catenin activity was progressively enhanced in several cell types in the adult SCA1 mouse cerebellum, and that activation of this signaling occurs in an Ataxin-1 polyglutamine (polyQ) expansion-dependent manner. Genetic manipulation of the Wnt-β-catenin signaling pathway in specific cerebellar cell populations revealed that activation of Wnt-β-catenin signaling in PCs alone was not sufficient to induce SCA1-like phenotypes, while its activation in astrocytes including Bergmann glia (BG) resulted in gliosis and disrupted BG localization, which was replicated in SCA1 mouse models. The role of BG in degeneration of PCs in SCA1 is currently under further investigation, as well as the necessity of Wnt-β-catenin signaling activation in BG towards SCA1 pathology. Our studies identify a novel mechanism in which polyQ-expanded Ataxin-1 positively regulates Wnt-β-catenin signaling, and demonstrate that different cell types have distinct responses to the enhanced Wnt-β-catenin signaling in the SCA1 cerebellum, underscoring an important role of astrocytes, specifically BG, in SCA1 pathogenesis.

Title: Genetically altering mitochondrial morphology does not modify the progression of symptoms in a mouse model of ARSACS

Authors: *C. CHEN[1], R. A. MERRILL[2], Y. KONG[1], G. HEALEY[3], S. STRACK[4]; [1]Neurosci. and Pharmacol., Univ. of Iowa, IOWA CITY, IA; [2]Dept. of Pharmacol., Univ. of Iowa, Iowa City, IA; [3]Neurosci. and Pharmacol., Univ. of Iowa, Iowa, IA; [4]Neurosci. and Pharmacol., Univ. Iowa Col. Med., Iowa City, IA

Abstract: BACKGROUND: Autosomal recessive spastic ataxia of Charlevoix-Saguenay (ARSACS) is an early-onset neurodegenerative disease caused by a loss-of-function mutations in the SACS gene. ARSACS is characterized by cerebellar dysfunction and atrophy resulting from Purkinje cell death. Mice lacking the sacsin protein, encoded by SACS gene, recapitulate the human disease with age-dependent neurodegeneration of cerebellar Purkinje cells. Additionally, loss of sacsin function may lead to hyperfused mitochondria that accumulate in the soma and leads to the Purkinje neuron loss.**METHODS:** Since mitochondrial morphology may underlie disease progression, we have crossed the sacsin knockout mouse with two additional knockout mice that either increase or decrease mitochondrial fission. A Kinase Anchoring Protein 1 (AKAP1) loss is known to induce mitochondrial fission while loss of the protein phosphatase 2A (PP2A) regulator Bbeta2 is known to decrease mitochondrial fission. These knockout mice elicit their effects through modifying the mitochondrial fission mediator dynamin-related protein 1 (Drp1). **RESULTS:** Preliminary results show no change in the age-related progression of the sacsin KO mice phenotypes associated with cerebellar neurodegeneration following crosses with either AKAP1 KO mice or Bbeta2 KO mice. Behavioral tests utilized include rotorod and balance beam. **CONCLUSION:** Dysfunctional mitochondrial fission may underlie the neurodegeneration of cerebellar Purkinje cells. By modifying the fission mediator Drp1 through genetic intervention, we were not able to alter the progression of a mouse model of the disease. Additional work will include defining the mitochondrial morphology and function in these new mouse crosses.

Title: Deficits in oligodendrocyte differentiation foundearlyin SCA3 disease pathogenesis

Authors: K. H. SCHUSTER[1], A. J. ZALON[1], D. DIFRANCO[1], N. STEC[1], H. ZHANG[1], S. JARRAH[1], Y. GUAN[1], H. L. PAULSON[2], *H. MCLOUGHLIN[1];
[1]Univ. of Michigan, Ann Arbor, MI; [2]Prof, Neurol, Univ. of Michigan Dept. of Neurol., Ann Arbor, MI

Abstract: Spinocerebellar Ataxia Type 3 (SCA3) is the most common dominantly inherited ataxia. This progressive, neurodegenerative disease is caused by a CAG repeat expansion in the *ATXN3* disease gene, which produces an enlarged poly-glutamine repeat in the ATXN3 protein. Research of the pathogenic mechanisms underlying SCA3 has mainly focused on the gain-of-toxic functions of mutant ATXN3 (mutATXN3) that lead to neuronal impairment and death. Consistent with evidence across other neurodegenerative diseases, our studies demonstrate that oligodendrocytes (OLs) play a major role in SCA3 pathogenesis. By mapping transcriptional changes in the most vulnerable SCA3 brain regions across disease states in transgenic mice, we revealed an explicit dysfunction in OL maturation. This phenomenon was seen earliest and most prominently in the brainstem relative to the cerebellum. These differentially expressed genes were verified by biochemical analysis, revealing a decrease in immature OL genes and an increase in mature OL genes. We also utilized SCA3 mice crossed with Mobp-eGFP reporter mice to evaluate mature OL counts in the brain regions of interest. We confirmed a significant loss of mature OLs by 16 weeks in the pons and deep cerebellar nuclei. However, mature OL counts in the corpus callosum, a white matter tract that expresses mutATXN3 but is not affected in SCA3, displayed no difference between diseased mice and WT littermates. This indicates OL maturation deficits reflect the regional specificity of degeneration in SCA3. Notably, we found no changes in OL lineage cell counts from SCA3 vulnerable brain regions using a pan-OL antibody. With these data, we hypothesize a stalling of OL maturation in disease due to mutATXN3 expression in SCA3 vulnerable brain regions. Importantly, we confirmed that ATXN3 knockout mice show no biochemical or histological changes in OL expression at

analogous timepoints. In summary, our data suggest a severe deficit in OL maturation caused by the gain-of-toxic function of mutATXN3 early in SCA3 disease progression.

Title: Transient changes in choroid plexus function during asymptomatic period in CLN2 mouse model

Authors: *M. S. DOMOWICZ, N. A. PEREZ CATALAN, P. CLAUDIO-VAZQUEZ, T. GONZALEZ, Y. MARTINEZ-CASTILLO, N. B. SCHWARTZ;
Dept. of Pediatrics, Univ. of Chicago, Chicago, IL

Abstract: Neuronal ceroid lipofuscinosis type 2 (CLN2 disease) is a neurodegenerative disease that results in progressive visual deterioration resulting in blindness, intellectual and motor decline, epilepsy, ataxia, spasticity, and premature death. Here we are using a well characterized mouse model of CLN2, in which the tripeptidyl peptidase 1 (*Tpp1*) gene is disrupted by gene targeting resulting in loss of detectable *TPP1* activity leading to progressive neurological phenotypes including; ataxia, decrease motor function and early death (median survival of 19 weeks) (Sleat D.E. et al., 2004). Global RNAseq analysis of 1- to 4-month-old *Tpp1-/-* mouse forebrain/midbrain and cerebellum show a transient increase in transcripts expressed almost exclusively in the choroid plexus (ChP) during asymptomatic stages of the disease (1- to 2-month-old). These initial transcriptional changes in the ChP include genes for structural extracellular matrix proteins, secreted proteins, transporters, tight junction components, receptors, integral components of secretory epithelium membrane, cilia components and enzymes, all of which indicate a global functional activation of the ChP. To confirm that these changes were associated with the ChP, we assessed expression levels in ChP isolated from the lateral and fourth ventricle by qPCR, and verified increased transcriptional expression of *Aqp1, Clic6, Kl, Prlr, Ttr*, and the ciliary dynein *Dnah1 and Dnah11* in the *Tpp1-/-* mouse ChP. Also, immunohistochemical analysis using the ciliary marker, acetylated tubulin, indicated an increase in the number of cilia per cell in ChP epithelium. Transcriptional upregulation of *Fzd4* and downregulation of *Axin2*, as well as redistribution of beta-catenin to the apical surface of the ChP epithelium were also observed in the *Tpp1-/-* ChP, indicating that the Wnt/beta-catenin pathway

may be an important regulatory driver of the ChP response in affected brains. Together, our results provide novel insights into early events in the onset of CLN2 disease that involve functional and structural changes in ChP, a highly critical brain structure for metabolite recycling.

Title: Characterizing the binding of bupropion and ibogaine to the dopamine transporter

Authors: *E. WILLIAMS[1], A. SALAHPOUR[1], M. SHAPIRA[1,2];
[1]Univ. of Toronto, Toronto, ON, Canada; [2]Structural Genomics Consortium, Toronto, ON, Canada

Abstract: Individuals afflicted with Dopamine Transporter Deficiency Syndrome (DTDS) have minimal to no dopamine transporter (DAT) proteins at plasma membranes. Pharmacological chaperones selectively binding the DAT present a unique and viable path for treatment of select DTDS disease-causing variants. Two such compounds have been previously identified: bupropion and ibogaine, both atypical DAT inhibitors. However, it is not well understood how these drugs bind to the orthosteric binding site of DAT. Characterizing the binding of bupropion and ibogaine to DAT will provide critical information about the nature of the DAT orthosteric binding site and will aid in identifying more efficacious and potent pharmacological chaperones for treatment of DTDS. We used molecular homology modeling of the human DAT to model and investigate the binding of bupropion and ibogaine to DAT. Currently, the predicted binding site and key residues involved in the binding of bupropion and ibogaine are being explored using site-directed mutagenesis followed by assessment of inhibition of binding and chaperone activity of the compounds. Our studies will provide key information as to which residues are necessary for bupropion and ibogaine binding and pharmacological chaperone activity.

Title: Nr1d1 down-regulation in astrocytes is detrimental to co-cultured motor neurons

Authors: K. M. KILLOY[1], B. A. HARLAN[3], M. PEHAR[2], ***M. R. VARGAS**[1];
[1]Dept. of Neurol., [2]Div. of Geriatrics and Gerontology, Dept. of Med., Univ. of Wisconsin, Madison, Madison, WI; [3]Biomed. Sci. Training Program, Med. Univ. of South Carolina, Charleston, SC

Abstract: Nuclear receptor subfamily 1 group D member 1 (Nr1d1, also known as Rev-erbα) is a nuclear transcription factor part of the molecular clock that encodes circadian rhythms and may link daily rhythms with metabolism and inflammation. Nr1d1, unlike most nuclear receptors, lacks a ligand-dependent activation function domain 2 and is a constitutive transcriptional repressor. We have previously shown dysregulated clock and clock-controlled genes expression in multiple tissues from amyotrophic lateral sclerosis (ALS) mouse models. ALS is the most common adult-onset motor neuron disease, caused by the progressive degeneration of motor neurons in the spinal cord, brain stem, and motor cortex. Approximately 10-20% of familial ALS is caused by a toxic gain-of-function induced by mutations of the Cu/Zn-superoxide dismutase (SOD1). Here we explore Nr1d1 dysregulation in the spinal cord of mutant hSOD1-linked ALS-mouse models and its consequences on astrocyte-motor neuron interaction. Nr1d1 protein and mRNA expression is significantly downregulated in the spinal cord of symptomatic mice expressing mutant hSOD1, while no changes were observed in age-matched animals over-expressing wild-type hSOD1. In addition, Nr1d1 down-regulation in primary astrocytes causes a pro-inflammatory phenotype and decreases the survival of co-cultured motor neurons. Nr1d1 orchestrates the crosstalk between physiologically pathways identified to be disrupted in ALS (e.g. metabolism, inflammation, redox homeostasis, and circadian rhythms) and we observed that down-regulation of Nr1d1 alters astrocyte-motor neuron interaction. Our results suggest that Nr1d1 could be a potential therapeutic target to prevent astrocyte-mediated motor neuron toxicity in ALS.

Title: Jnk promotes stress granule assembly by epigenetically regulating g3bp1

Authors: *T. SAHANA, K. ZHANG;
Mayo Clin., Jacksonville, FL

Abstract: Stress granules (SGs), RNA/protein condensates assembled in cells upon stress, can trigger the aggregation of their component proteins TAR DNA-binding protein-43 (TDP-43), fused in sarcoma (FUS), etc. Since aggregation of these proteins is a pathological hallmark of Amyotrophic Lateral Sclerosis (ALS) and Frontotemporal dementia (FTD), two related neurodegenerative diseases, SGs are considered the crucible of these diseases. Given this critical role, SGs have been actively studied in the ALS/FTD research field. Biochemical studies have revealed the molecular mechanism by which they assemble, and drug screens have identified their inhibitors. However, how SG assembly is regulated at the cellular level is unclear—an important question to both fundamental cell biology and disease pathophysiology.
In a genetic screen, we identified that an RNAi against the *basket*, the fly homolog of c-Jun N-terminal kinase (JNK), suppresses neurodegeneration in a *Drosophila* model of *C9ORF72*-mediated ALS and FTD (c9ALS/FTD), the most common familial ALS/FTD. Consistent with these data, JNK activity is upregulated in both c9ALS/FTD *Drosophila* and U-2 OS cell models. Furthermore, this upregulation is caused by ER stress activating inositol requiring enzyme 1 (IRE1). Interestingly, we found that JNK activation induces SG assembly via phosphorylation of histone 3 protein at serine 10 (H3S10), an epigenetic modification that transactivates a key SG protein, G3BP1. Consistent with these data, we showed that IRE1 or JNK inhibitors suppress H3S10 and G3BP1 levels, SG assembly, and neurodegeneration in c9ALS/FTD U-2 OS models or patient neurons derived from induced pluripotent stem cells (iPSNs). Together, our findings connected ER stress, JNK activation, epigenetic modulation, and SG assembly in a unified pathogenic pathway in c9ALS/FTD, thereby allowing us to better understand how cells respond to stress and how this process is implicated in neurodegeneration.

Title: In vitro modeling of Charcot-Marie-Tooth Type 2D using engineered human induced pluripotent stem cells

Authors: *T. J. HINES[1], E. L. SPAULDING[2], J. LI[1,3], P. BAIS[1], D. E. CORTES[1], R. W. BURGESS[1];
[1]The Jackson Lab., Bar Harbor, ME; [2]Mount Desert Island Biol. Lab., Bar Harbor, ME; [3]Tufts Univ., Boston, MA

Abstract: Charcot-Marie-Tooth type 2D (CMT2D) is a dominant axonal neuropathy caused by mutations in glycyl tRNA-synthetase (GARS). The GARS enzyme charges glycine onto its cognate tRNAs for translation, but like many neurodegenerative diseases, this "housekeeping gene" causes a very specific disease phenotype when mutated. We previously performed gene expression analysis using ribotagging and RNAseq to specifically examine the motor neuron transcriptome of 3 different Gars/CMT2D mouse models. This revealed signatures consistent with activation of the integrated stress response (ISR). This was confirmed by immunofluorescence for phosphorylated eIF2α, a canonical marker of the ISR, and by RNAscope ISH for upregulated ATF4 targets. Both phospho-eIF2α and ATF4 targets were restricted to alpha-motor neurons in the spinal cord. These gene expression changes, as well as the neuropathy phenotype, were abrogated by crossing Gars mutant mice with mice lacking the cell stress sensing kinase, Gcn2. This indicates that the ISR is initiated by GCN2, which itself is activated by ribosome stalling and amino acid deprivation. Additionally, Gars mutants lacking the ribosome rescue factor, Gtpbp2, had an exacerbated neuropathy phenotype. This further supports our hypothesis of ribosome stalling inducing the integrated stress response in Gars mutant mice. In order to confirm these findings in a human system, as well as further interrogating the mechanism(s) underlying ISR activation and cell-type specificity, we have used CRISPR/Cas9 genome editing in a well-characterized "healthy control" human induced pluriopotent stem cell (hIPSC) line, KOLF2-C1, to develop cell-based models of CMT2D. These engineered cells express only WT Gars, or one of two dominant Gars mutations - G240R, a common mutation in North American CMT2D patients, and ΔETAQ, a severe, early onset allele for which we also have a mouse model. Since motor neurons are such a small fraction of the total cells in the spinal cord, it is difficult to measure changes in gene expression and protein levels by conventional methods. After differentiation, these cell-based models provide a relatively pure population of motor neurons, which enables bulk analysis of the affected cell population and high throughput screening of potential therapeutics. We are currently analyzing gene expression data and markers such as phospho-eIF2α levels to confirm ISR activation in these cells. We will

then compare changes seen in motor neurons to other terminally differentiated cell types, which are unaffected in CMT2D.

Title: Ligand-free mutant AR promotes motor neuron-related mitochondrial dysfunction in spinal and bulbar muscular atrophy

Authors: *X. FENG[1,2,3], X.-T. CHENG[4], P. ZHENG[2], Y. LI[5], J. HAKIM[3], S. Q. ZHANG[6], S. M. ANDERSON[7], K. LINASK[8], J. ZOU[8], Z.-H. SHENG[4], C. BLACKSTONE[2,9];

Abstract: As the first uncovered CAG-repeat expansion disease, spinal and bulbar muscular atrophy (SBMA) is an adult-onset X-linked neuromuscular disorder. Its genetic cause is a CAG repeat expansion in the androgen receptor (AR) gene. The mutant AR protein with an expanded polyglutamine (polyQ) tract, encoded by pathological CAG repeats, is prone to aggregation and induces cytotoxicity upon ligand binding, leading to progressive motor neuron degeneration and muscle atrophy. SBMA exhibits mitochondrial abnormalities. Utilizing a newly developed isogenic human induced pluripotent stem cell model, we show that mitochondrial impairments, including aberrant mitochondrial depolarization, increased mitochondrial oxidative stress, and altered cristae architecture, occurred in the neurites of the differentiated motor neuron-like cells by introducing a pathological polyQ length into the wildtype AR, while these aberrations were rescued by correcting the expanded repeats in the mutant AR. Interestingly, compared with the isogenic control cells, the AR knockout motor neurons showed no significant changes in the maintenance of membrane potential, reactive oxygen species levels, and cristae architecture in

the mitochondria, suggesting that the mitochondrial damage observed in the neurites of the disease motor neurons are possibly due to a gain of function of the mutant AR. Although androgen is widely believed to play an essential role in the mutant AR-induced cytotoxicity in SBMA, here we found that, surprisingly, the mutant protein was sufficient to lead to mitochondrial dysfunction in the disease motor neurons without ligand binding, whereas the ligand treatment only aggravated such impairments. Our data indicate that different molecular mechanisms underpin the pathological polyQ-dependent, mitochondrial-targeted cytotoxicity in SBMA motor neurons, which involve both ligand-free and ligand-bound forms of the mutant AR.

Title: Mechanistic investigation of aberrant neurite outgrowth and androgen receptor transcriptional activity in spinal and bulbar muscular atrophy

Authors: *J. KARLINER, D. MERRY;
Thomas Jefferson Univ., Philadelphia, PA

Abstract: Spinal and bulbar muscular atrophy (SBMA) is a slowly progressing X-linked neuromuscular disease characterized by the degeneration of spinal cord and brainstem lower motor neurons and muscle atrophy. It is caused by a polyglutamine (polyQ) expansion in the androgen receptor (AR), a transcription factor that promotes neurite outgrowth and regeneration in neurons. In SBMA, androgen binding to polyQ-expanded AR causes its misfolding and intranuclear aggregation, resulting in reduced AR transcriptional activity and aberrant neurite outgrowth. However, the contribution of these processes to SBMA pathogenesis is unknown. This study aims to fill these gaps by studying neurite outgrowth in the presence of DNA-binding-competent and -incompetent (V581F) polyQ-expanded AR and investigating mechanisms underlying aberrant neurite outgrowth in SBMA. Based on previous findings suggesting that reduced activity of the E3 ligase anaphase promoting complex/cyclosome-CDC20 homolog 1 (APC/C^{Cdh1}) underlies aberrant neurite outgrowth in SBMA, we will investigate the role of Cdh1 by studying its metabolism, which regulates APC/C activity. Experiments were conducted using

a PC12 cell model of SBMA in which full-length AR with pathological (AR112Q/AR111Q V581F) or nonpathological (AR10Q) polyQ-repeats is expressed under the control of a tetracycline-inducible promoter. Cells were differentiated through treatment with nerve growth factor (NGF) for 6 days, induced to express AR (+Dox) and treated with the androgen dihydrotestosterone (DHT) for 96 hours, and analyzed for the number of neurite-positive cells and Cdh1 protein expression. Through the use of live-cell imaging, preliminary results demonstrate a significant decrease in the number of neurite-positive cells upon polyQ-expanded AR expression in the presence of DHT. This is true for both DNA-binding-competent and -incompetent polyQ-expanded AR, but not for normal polyQ-length AR, demonstrating a pathological phenotype independent of AR transcriptional activity. Some cells expressing polyQ-expanded AR were observed to retract their neurites during this 96-hour period. Results also show a decrease in Cdh1 protein expression following 96 hours of Dox and DHT treatment in the presence of polyQ-expanded AR, suggesting that reduced Cdh1 expression could underly aberrant neurite outgrowth in SBMA. Ongoing studies will investigate whether altered Cdh1 phosphorylation leads to its reduced protein expression. Overall, this work helps elucidate mechanisms underlying aberrant neurite outgrowth in SBMA and determine if therapeutics should preserve or inhibit normal AR functions to be most efficacious.

Title: Ataxin-2 polyQ expansions aberrantly sequester TDP-43, impair anterograde transport of neuronal RNP granules along the axon and suppress translation

Authors: *D. WIJEGUNAWARDANA, S. S. VISHAL, P. P. GOPAL;
Dept. of Pathology, Yale Sch. of Med., New Haven, CT

Abstract: Amyotrophic lateral sclerosis (ALS), a debilitating and fatal neurodegenerative disease, is characterized by aggregates of TDP-43, an RNA-binding protein (RBP) with multiple roles in post-transcriptional RNA processing. Mutations in TDP-43 and other RBPs cause familial and sporadic ALS, highlighting altered RNA metabolism as a common pathogenic mechanism. Recent studies have identified genetic interactions between TDP-43 and Ataxin-2, a RBP with a polyglutamine (polyQ) tract normally 22-23Q in length. Intermediate-length

expansions of the Ataxin-2 polyQ tract (27-33Q) confer increased risk for ALS. However, the underlying molecular mechanisms by which Ataxin-2/TDP-43 interactions increase ALS risk are unclear. We hypothesized that Ataxin-2 polyQ expansions aberrantly scaffold TDP-43, stabilize TDP-43/Ataxin-2 interactions within ribonucleoprotein (RNP) granules and disrupt their dynamic properties, increasing the propensity for pathologic transformation of TDP-43. We used live-cell confocal imaging, photobleaching and immunofluorescence experiments to study the localization, motility and interactions of TDP-43 and Ataxin-2 in rodent primary cortical neurons. Our data show that endogenous wild type Ataxin-2 colocalizes with a subset of TDP-43 positive RNP granules, which are dynamic liquid-like biomolecular condensates. While TDP-43 positive granules exhibit oscillatory or long-range motility in the mid axon, Ataxin-2 Q22 RNP granules are predominantly stationary and localize within the proximal axon. Kymographs were used to analyze the motility of RNP granules containing TDP-43 with or without Ataxin-2 of varying polyQ lengths. We found that TDP-43 granules positive for Ataxin-2 Q30 or Q39 exhibit reduced anterograde run lengths and sequester TDP-43. In addition, our photobleaching experiments show that Ataxin-2 Q30 and Q39 expansions impair TDP-43 dynamics and FRAP recovery. These data suggest that TDP-43 RNP granule transport and intramolecular motility is perturbed in neurons with Ataxin-2 polyQ expansions. Finally, we used puromycinylation assays to show that translation is suppressed in primary cortical neurons expressing Ataxin-2 polyQ expansions, compared to those expressing Ataxin-2 Q22 or RFP. Our data suggest that Ataxin-2 polyQ expansions perturb TDP-43 anterograde transport and its spatial localization, and impair translation as well. Overall, these results indicate Ataxin-2 polyQ expansions aberrantly sequester TDP-43 and may have detrimental effects on stability, localization, and translation of transcripts critical for axonal and cytoskeletal integrity, particularly in motor neuron axons.

Title: Investigation of TDP-43 phosphorylation and cleavage on TDP-43 localization and nucleocytoplasmic transport using iPSC motor neurons

Authors: *M. J. ADLER[1], A. HELD[1], A. KAVUTURU[1], C. MARQUES[1], M. E. WARD[2], B. J. WAINGER[1];

[1]Massachusetts Gen. Hosp., Boston, MA; [2]Inherited Neurodegenerative Dis., Natl. Inst. of Neurolog. Disorders and Stroke, Bethesda, MD

Abstract: Aggregation of the RNA binding protein TDP-43 is the major molecular hallmark of amyotrophic lateral sclerosis (ALS), a rapidly-progressing fatal disease of the motor nervous system. Cytoplasmic TDP-43 may result in loss of normal nuclear TDP-43 function as well as gain of cytoplasmic function, potentially upon aggregate formation. Aggregates typically contain phosphorylated, truncated C-terminal fragments (CTFs), but the effects of these modifications on the compartmentalization of TDP-43 are not well characterized. Overexpression of tagged TDP-43 CTF in neuroblastoma cells shows a predominantly cytoplasmic location, association with nucleoporins, and disruption of global nucleocytoplasmic transport. It is less clear whether this disruption results specifically from TDP-43 phosphorylation, mislocalization, truncation, or expression level, and to what extent other causes of nucleocytoplasmic transport impairment are sufficient to mislocalize endogenous TDP-43. While many studies correlate TDP-43 aggregation with neuronal toxicity, a recent investigation found that TDP-43 hyperphosphorylation reduced aggregate accumulation. Our study aims to examine how TDP-43 phosphorylation and the generation of CTFs affect subcellular localization and nucleocytoplasminc transport.
We have generated mCherry-tagged TDP-43 expression constructs with point mutations in the CTF converting serines to either glutamate or alanine to mimic or block phosphorylation, respectively. We have also made 25kDa truncated TDP-43 CTFs with these same modifications. We will express these constructs in human iPSC-derived motor neurons. Using previously validated shuttling proteins as reporters of nucleocytoplasmic transport integrity, we will measure how TDP-43 phosphorylation and truncation affect nucleocytoplasmic transport function and TDP-43 location. Further, casein kinases (CK) have been recognized to phosphorylate TDP-43, CK1E colocalizing with TDP-43 in sporadic ALS postmortem tissue. In addition to phosphomimetic mutations, we will assess the effects of expressing these kinases versus applying inhibitors of the kinases, thus allowing us to evaluate over-expressed versus endogenous TDP-43. These experiments will provide insight into the interactions of TDP-43 function, nucleocytoplasmic transport, and TDP-43 modifications by phosphorylation and cleavage.

Title: Input specific intrinsic excitability differences in thalamocortical cells after cerebellar stroke

Authors: *M. MORENO GARCIA[1], N. QUILLINAN[2];
[1]Univ. of Colorado Anschutz Med. Campus, Aurora, CO; [2]Anesthesiol., Univ. of Colorado, AMC, Aurora, CO

Abstract: There are approximately 20,000 cerebellar stroke (CbS) cases annually in the United States. Symptoms in these patients can range from ataxia to impaired cognitive function. Stroke therapies are extremely limited and mechanistic studies in animal models at molecular, cellular and systems levels after CbS, are needed to advance the development of better treatments. The cerebellum (Cb) communicates with the rest of the brain via the cerebello-thalamo-cortical pathway. Damage starting at the Cb might carry altered signaling through the pathway via the ventrolateral (VL) thalamus, a major target of cerebellar (Cbr) efferents. Interestingly, evidence has shown that damage to thalamic afferents (cortical or spinal) can lead to increased excitability in the thalamus. Our goal is to investigate if intrinsic excitability of thalamocortical cells (TCCs) would be significantly altered after CbS. To investigate this, TCCs with Cbr afferents, we injected AAV-hSyn-Chief-mRuby in the cerebellar nuclei (CbN) and in SNr nuclei of naïve mice, 3 weeks prior to performing whole-cell slice electrophysiology in the VL thalamus (contralateral to viral injection). A dual step protocol in current clamp was run in naïve and CbS animals. CbS were induced with photo-thrombosis in the artery that supplies the cerebellar cortex 7 days prior to recordings and 2 weeks after viral injections in CbN. Cbr fibers were opto-genetically stimulated with 470nM LED illumination to test for a synaptic response in the analyzed cell. TCCs with cerebellar afferents (Cb-thalamic, n=13) showed significantly higher tonic (2.4 fold) and rebound firing (2.14 fold) rates than TCCs with no Cbr afferents (n=16). Thalamic cells that showed no synaptic response were suspected to receive input from the basal ganglia, specifically from SNr. To corroborate this, tonic and rebound firing rates of TCCs with SNr input (SNr-thalamic) matched the non-responding rates from experiments with Cbr afferent stimulation. We next assessed changes in intrinsic excitability in TCCs following CbS. No significant changes in tonic or rebound firing were observed in Cb-thalamic cells, however, SNr-thalamic cells showed a significant increase in rebound firing compared to control. Our data suggest that TCCs in the VL with Cbr or SNr inputs exhibit distinct excitability properties. Cb-thalamic neurons exhibit high tonic and rebound excitability that is not altered by CbS. The increased excitability in SNr-thalamic neurons is surprising, but perhaps suggests global maladaptive changes in the VL. Future studies will investigate molecular underpinnings in TCCs heterogeneity and stroke-induced excitability changes.

Title: Infratentorial contributions to post-stroke aphasia: insights from transcranial direct current stimulation and diffusion tensor imaging

Authors: *Z. ZHENG[1,2], K. WANG[2], S. LEE[1], J. WANG[1], M. HOWARD[1], E. ROSARIO[1], C. SCHNAKERS[1];
[1]Res., Casa Colina Hosp. and Centers for Healthcare, Pomona, CA; [2]UCLA, Los Angeles, CA

Abstract: Transcranial direct current stimulation (tDCS) has emerged as a popular adjunct therapy to traditional speech and language therapy (SLT) in post-stroke aphasics to facilitate language recovery. While promising, studies investigating the efficacy of tDCS have yielded variable responses, likely, in part, due to the substantial stroke heterogeneity, especially in lesion location and size. Thus, determining the most optimal stimulation site remains difficult. Here, we aim to evaluate the efficacy of tDCS applied over two different sites, left inferior frontal gyrus (Broca's area) and right posterolateral cerebellum (a novel target), with sham tDCS as the control. Because variable and extensive cortical lesions introduce major methodological limitations that hinder automation and feasibility in a clinical environment, we additionally aim to identify microstructural correlates of post-stroke aphasia that are relatively spared from macrostructural damage. Following a double-blind controlled design, patients received either anodal frontal tDCS (f-tDCS; n=17), anodal cerebellar tDCS (c-tDCS; n=12), or sham stimulation (n=18), concurrent with 20 minutes of SLT over five consecutive days. Behavioral and diffusion-weighted data (64 directions) were collected within one week before and after intervention. The Western Aphasia Battery-Revised (WAB-R), which consisted of four subscales addressing spontaneous speech, name and word finding, repetition, and auditory verbal comprehension, was used to assess aphasia severity (aphasia quotient [AQ]). Mixed ANOVA was used to compare the efficacy of f-tDCS, c-tDCS, and sham. The average fractional anisotropy (FA) and mean diffusivity (MD) values were extracted from selected white matter regions from the JHU White Matter Atlas that were macrostructurally intact across all patients. Correlations were performed between WAB-R scores and diffusion metrics at baseline across all participants. After controlling for age and time since injury, we found the greatest improvements in the f-tDCS group, followed by c-tDCS, and then sham. Moreover, f-tDCS improved spontaneous speech and c-tDCS improved repetition scores in non-fluent patients, while sham did not. Furthermore, we identified significant correlations between various WAB-R scores and white matter integrity in predominantly brainstem and cerebellar tracts, especially the cerebral peduncle and middle cerebellar peduncle. These findings highlight the therapeutic potential of different tDCS targets for post-stroke aphasia and suggest that the integrity of infratentorial white matter tracts may serve as novel biomarkers of aphasia severity.

Title: Assessment of motor deficits after experimental stroke using staircase reaching test

Authors: *A. KIM[1], Z. CAO[2], G. K. STEINBERG[1], T. C. CHIANG[2], M. Y. CHENG[2]; [2]Neurosurg., [1]Stanford Univ., Stanford, CA

Abstract: Keywords: Stroke recovery, side-specific deficit, motor skill, reaching, paw use, behavior test, staircase test
Background: Assessment of rodent neurological functions after experimental stroke has translational applications, as accurate and objective measurements of functional recovery are crucial for evaluating the effectiveness of various treatment strategies. Some of the existing behavior tests assess only motor coordination and general locomotor activity and lack side-specific motor impairments that occur after unilateral lesion such as focal ischemic stroke. Furthermore, effective behavior tests that can evaluate neurological deficits long-term are necessary for focal ischemic stroke models, as these mice recover quickly.
Methods: Adult male C57BL/6J mice (12-14 weeks of age) were subjected to permanent distal middle cerebral artery occlusion (dMCAO, n=10). Naïve mice (n=5) were prepared as no stroke control. Staircase reaching tests were performed using staircase chambers from Lafayette Instruments (30-min sessions). Mice were subjected to a 14-day training period where they were kept on a 21-hour food deprivation regime. The number of steps reached and pellets grasped/eaten were evaluated at pre-stroke baseline and at post-stroke days (PD) 7, 8, 14, and 15. Mice were maintained at 85%–90% of their original body weight. Brains were collected at post-stroke day (PD) 16 and sections were processed for immunostaining using antibodies targeting neurons (MAP2) and/or activated microglia/macrophage (CD68).
Results: After a 14-day training period, mice reached a stable baseline for both reaching and pellets consumed. At PD7 and PD8, stroked mice performed only 88% and 89% of their left and right maximum step reached when compared to pre-stroke baseline, respectively. At PD14 and PD15, stroked mice exhibited a further decline in performance and only reached 65% of their baseline performance on the affected side (right limb) while reaching 92% of their baseline performance on the non-affected side (left limb).
Conclusions: Our results show that the staircase reaching test can detect side-specific motor

deficits at up to post-stroke day15 in a dMCAO model. Ongoing studies are evaluating long-term deficits up to one month post-stroke and assessing the effects of optogenetic circuit stimulations on grasping behavior using staircase test.

Title: Changes in neural population dynamics during stroke recovery in non-human primates

Authors: *H. CHOI[1], P. KHANNA[1], L. NOVIK[2], J. ROBERTS[2], R. J. MORECRAFT[3], K. GANGULY[1];
[1]Dept. of Neurol., UCSF, San Francisco, CA; [2]California Natl. Primate Res. Ctr., UC Davis, Davis, CA; [3]Univ. South Dakota Schl Med., Vermillion, SD

Abstract: Stroke is a leading cause of serious long-term motor disability; while there have been significant advances in rehabilitation, a large number of stroke survivors are still left with long-term disability due to upper limb dysfunction. The goal of this study was to fully delineate how neural population dynamics change with motor recovery. Here we specifically focused on spiking activity and local field potentials (LFP). Population spiking activity and LFP have been found to be predictors of motor recovery from stroke in rodents, but this is less clear in non-human primates (NHP) performing a dexterous motor task. Understanding this relationship can help drive the development of novel clinical therapies. In this study, we tracked spiking activity and LFPs in a NHP cortical stroke model along with motor behavior during long-term recovery. During the hand movement task, we recorded neural signals and analyzed how they change with recovery. Spike population dynamics, low-frequency oscillations (LFOs), mu, and beta band powers were calculated. In general, LFOs are known to be linked to movement execution, and mu and beta band powers are known to be involved in movement preparation, e.g. show event-related desynchronization (ERD) at movement onset. We found that movement-related population spiking was increased with the recovery of motor function. LFOs also appeared to follow this population spiking metric. In contrast, mu and beta band power appeared to be most linked to processing prior to movement onset and had a negative correlation with population spiking activity. Our results thus provide additional evidence that changes in spiking and LFP coupling are present with dexterous motor recovery, in general, and in NHPs, in specific. These

findings also suggest precisely how neural dynamics correlate with motor recovery. In addition to providing possible clinical biomarkers to track motor recovery, they also suggest targets for neuromodulation to improve motor function after stroke.

Title: Intrinsic plasticity following in vitro ischemia in the adult rat hippocampus

Authors: *B. NATWORA[1], M. MASSMAN[1], I. MORLEY[1], J. R. MOYER, JR.[1,2];
[1]Psychology, [2]Biol. Sci., Univ. of Wisconsin-Milwaukee, Milwaukee, WI

Abstract: Stroke is the fifth leading cause of death in the United States, killing nearly 150,000 of the 860,000 Americans who die of cardiovascular disease each year. Approximately 87% of those cases are the result of an ischemic stroke (Virani, *Circulation*, 2020), characterized by the occlusion of an artery that supplies oxygen-rich blood to the brain. Neurons within the territory of the blocked vessel exhibit increased excitability due to the accumulation of extracellular glutamate, causing an overload of Ca^{2+} and ultimately delayed neuronal death (Choi, *Neurosci Lett*, 1985). The present study tested the hypothesis that exposure of brain slices to *in vitro* ischemia alters neuronal membrane properties, excitability and structural integrity of hippocampal CA1 pyramidal neurons. Brain slices prepared from adult Fisher 344 rats were subjected to 5 min of oxygen-glucose deprivation (OGD) after which slices were placed back in oxygenated aCSF (control slices remained in oxygenated aCSF). Within a subset of control and OGD-treated slices from each rat, cell death was assayed by trypan blue exclusion (Detert, *PLoS One*, 2013). For the remaining slices, whole-cell recordings were obtained from CA1 neurons to study basic membrane properties and intrinsic excitability. Preliminary data suggest that neurons from OGD-treated slices exhibit significantly reduced intrinsic excitability, as evidenced by a decrease in the number of action potentials following a stepwise current injection as well as a reduced neuronal input resistance (R_N). Neurons from OGD-treated slices also displayed a reduction in spike threshold and hyperpolarization-activated current (I_h) relative to those from control-treated slices. Interestingly, confocal images from biocytin-filled neurons suggest that some neurons from OGD-treated slices displayed dendritic beading, a morphological change commonly seen in neurons following a stroke. Additionally, OGD-treated slices had a

significantly greater number of trypan blue-labeled neurons compared to control-treated slices, confirming the effectiveness of our OGD protocol. While preliminary, these results suggest that *in vitro* ischemia leads to changes in neuronal membrane excitability, which may impact susceptibility to cell death and recovery of function. Understanding the nature of these changes may also shed light on mechanisms that underlie intrinsic plasticity within hippocampal CA1 pyramidal neurons and provide an avenue to study neurotherapeutics that could reverse the damage inflicted by ischemic stroke.

Title: Deep-learning based behavioral profiling of rodent stroke recovery

Authors: R. WEBER[1], G. MULDERS[1], J. KAISER[3], C. TACKENBERG[2], ***R. RUST**[1]; [1]Inst. for Regenerative Med., Univ. of Zurich, Schlieren, Switzerland; [2]Inst. for Regenerative Med., Univ. of Zurich, Schlieren, ZH, Switzerland; [3]Novago, Schlieren, Switzerland

Abstract: Patients suffering from ischemic strokes have limited therapeutic options and are often left with considerable disabilities. To promote neurological recovery, a variety of experimental strategies have evolved to enhance regeneration of damaged neuronal circuits. These preclinical studies heavily rely on behavioral improvements to evaluate the treatment's efficacy. Although behavior evaluation is considered important, tests in rodents are still often poorly reproducible and often not suitable to unravel the complex behavior after stroke. Here, we present a comprehensive 3D gait analysis of mice after focal cerebral ischemia based on the new deep-learning based software that requires only basic behavioral equipment. We developed an experimental set-up to perform high-precision tracking up to 10 body parts of several mouse strains. This approach enables to identify new biologically relevant differences in locomotor profiles following stroke across a time course of three weeks. We further directly compare the performance of deep-learning based motion tracking to conventional assessments including horizontal rung walk, cylinder test and single-pallet grasping with regard to sensitivity, accuracy and time consumption. Overall, we conclude that deep learning based motion tracking with

comprehensive post-analysis provides accurate and sensitive data to describe complex recovery of rodents following a stroke. The experimental set-up and analysis may also be applied to a range of other neurological injuries that affect motor function.

Title: Local field potentials identify features of hippocampal activity and cortico-hippocampal communication which are impacted by stroke and environmental enrichment therapy

Authors: *Z. IP[1], G. RABILLER[3], J.-W. HE[3], S. CHAVAN[1], Y. NISHIJIMA[4], Y. AKAMATSU[3], J. LIU[5], A. YAZDAN-SHAHMORAD[2];

Abstract: Stroke is a leading cause of disability with more than 15 million people affected by stroke every year. Impaired cognition is a common consequence following stroke, though how middle cerebral artery (MCA) stroke affects the neural activity of the hippocampus, an area critical for memory is not well understood. Environmental enrichment (EE) is a therapy that has consistently been shown to improve cognition following stroke, yet the electrophysiology that underlies this improvement is not well understood. To gain a deeper understanding of EE in the context of stroke we induced ischemic stroke in the rats. After recovery and subsequent EE therapy, we used urethane anesthesia and recorded local field potentials simultaneously from sensorimotor cortex & hippocampus. We analyzed the stability of sleep like brain states in the hippocampus, characteristics of sharp wave associated ripples (SPW-Rs) and the current source density surrounding SPW-Rs, and phase amplitude coupling within the hippocampus and between the cortex and the hippocampus. Our results show that MCA stroke impacts the electrophysiology in the hippocampus, disrupting the stability of brain states, characteristics of

SPW-Rs, and PAC both within the hippocampus and between hippocampus and cortex. Subsequent EE therapy mitigated changes to SPW-R characteristics, however, interestingly, EE further disrupted brain state and coupling both in controls and following stroke. These results show that despite having no direct lesion to the hippocampus, stroke strongly affects the electrophysiology within the hippocampus, and communication between the hippocampus and the cortex. These results provide a valuable set of neural features to take into consideration when developing therapeutic strategies for stroke.

Title: CLIP antagonism improves neurobehavioral outcomes after Traumatic Brain Injury

Authors: *L. VENKATASAMY[1], S. BEEVERS[1], J. IANNUCCI[1], V. ARISMENDI[1], K. MONTGOMERY[1], K. NEWELL ROGERS[2], L. A. SHAPIRO[1];
[1]Texas A&M Univ. Syst. Hlth. Scien Neurosci. and Exptl. Therapeut., Bryan, TX; [2]Med. Physiol., Texas A&M Hlth. Med. Physiol., Bryan, TX

Abstract: Background:Traumatic Brain Injury (TBI) can cause permanent damage to the brain, life-long disability and is animportant worldwide health problem. Millions of people each year suffer a TBI and post-traumaticsymptoms are often highly debilitating. In addition to neurodegeneration, those who suffered a TBI candevelop cognitive, affective and behavioral impairments, and are at a higher risk of developing addiction,alcoholism, post-traumatic epilepsy and Alzheimer's disease. However, the underlying mechanisms arenot fully understood, and therapeutic options are limited. Innate and adaptive immune responses playimportant roles in the inflammatory response following a TBI. The full-length CD74 molecule contributesto several mechanisms of the innate immune response, and MHC II-associated invariant peptide (CLIP), acleavage product of CD74, is involved in the transition from an innate to an adaptive immune response.Depletion of CD74, or CLIP antagonism, was previously shown to prevent the secondaryneurodegeneration in a fluid percussion injury (FPI) model of TBI. However, the role of CLIP antagonismin improving functional post-traumatic outcomes has not been previously examined.Hypothesis:CLIP antagonism after TBI will improve neurobehavioral impairment.Methods:The Fluid Percussion Injury (FPI) model was induced in male and female

C57BL/6 mice, as previouslydescribed. Mice were injected (1 mg/kg, i.p.) with our CLIP antagonist peptide (CAP) at 30 mins after FPIor sham FPI. Vehicle animals (VEH) received DMSO in place of CAP. We performed the followingneurobehavioral tests beginning 32 days after FPI: Object location test (OLT), Novel object recognitiontest (NORT) and pattern separation test (PST).Results:We observed behavioral deficits after FPI and observed improvements in behavioral outcomes in thosemice treated with CAP. In OLT, a significant number of the FPI+CAP mice visited the novel place objectfirst, whereas FPI+VEH mice showed no significant preference between the novel and familiar placeobject. In NORT, FPI+CAP mice spent significantly more time exploring the novel object than the familiarobject, whereas FPI+VEH mice showed no preference for the novel object compared to the familiarobject. These results suggest an impaired object recognition memory after TBI that is rescued byantagonizing CLIP with CAP. Follow-up studies are planned to test the immune response profiles andtheir influence on these behavioral outcomes.

Title: Intranasal Treatment of Human MSC-derived EVs Enriched with Microglia Modulating miRNAs after TBI Prevents Cognitive and Mood Dysfunction with Inhibition of NLRP3 Inflammasomes

Authors: *M. KODALI[1], R. REGER[1], M. BOJANA[1], L. N. MADHU[1], R. UPADHYA[1], J. GONZALEZ[1], S. ATTALURI[1], B. SHUAI[1], D. GITAI[2], J. M. CHOI[3,4], S. Y. JUNG[4], A. K. SHETTY[1];

Abstract: Cognitive and mood impairments allied with chronic neuroinflammation and diminished neurogenesis are among the most conspicuous features in the chronic phase after traumatic brain injury (TBI). One approach to mitigating these chronic alterations is administering extracellular vesicles (EVs) secreted by human mesenchymal stem cells (hMSCs)

due to their well-known antiinflammatory, neuroprotective, and neurogenic properties. Our previous study showed that intravenous delivery of hMSC-EVs could reduce acute neuroinflammation and improve cognitive function in the early post-injury period (Kim et al., PNAS, 2016). This study investigated the dose-response effects of a single intranasal (IN) administration of hMSC-EVs enriched with microglia modulating microRNAs (miRs) early after a moderate TBI. The antiinflammatory property of EVs employed in the study was validated through an LPS-stimulated in vitro macrophage assay. A small RNA-seq study also confirmed that the EVs were enriched with miRs capable of modulating microglia and inhibiting NLRP3 inflammasomes. Nine-week-old male mice were subjected to unilateral controlled cortical impact injury (impactor diameter-3mm, velocity-5m/s, dwell time-300ms, and injury depth-0.8 mm). Ninety minutes later, mice received an IN administration of EVs (6.4, 12.8, or 25.6 billion doses) or the vehicle (TBI-VEH). Three months later, a series of behavioral tests examined cognitive and mood function. TBI-VEH mice displayed recognition memory problems, pattern separation deficits, anhedonia, and anxiety. However, TBI mice that received higher doses of EVs (12.8 and 25.6 billion) displayed preserved cognitive, memory, and mood function. These functional benefits were linked with reduced astrocyte hypertrophy and microglial density, an enhanced ratio of noninflammatory M2 microglia vis-à-vis the proinflammatory M1 microglia in the hippocampus, and somatosensory cortex, ipsilateral (IL) to injury. Remarkably, EV treatment also inhibited the activation of NLRP3 inflammasomes, with downregulation of NF-kB, caspase-1, IL-1β, and IL-18 in the somatosensory cortex. Proteomic analysis revealed that hMSC-EV treatment inhibited the inflammatory proteome in the hippocampus IL to the injury. TBI-EV mice also showed a higher level of neurogenesis and reduced synapse loss in the hippocampus IL to the injury. Thus, IN hMSC-EV treatment after a moderate TBI is efficacious for preventing long-term cognitive and mood dysfunction. Inhibition of NLRP3 inflammasomes and inflammatory proteome and preservation of neurogenesis in the hippocampus likely underlie such beneficial effects.

Title: Anti-Nogo-A antibody therapy improves functional recovery from traumatic brain injury in rats

Authors: *B. POWERS[1], S.-Y. TSAI[1], S. TON[1], R. FARRER[1], G. KARTJE[1,2];
[1]Edward Hines Jr. Veteran's Affairs Hosp., Hines, IL; [2]Loyola Univ. Chicago, Maywood, IL

Abstract: Traumatic brain injury (TBI) results in debilitating outcomes including deficits in sensory and motor function, and recovery is often slow and incomplete. In addition to brain tissue damage from the immediate trauma, head injuries may have long-term effects that increase the risk for development of mood and dementia disorders. Unfortunately, there are no effective pharmacological treatments for recovery from TBI, but research suggests great potential demonstrated by anti-Nogo-A antibody therapy. This therapy is designed to neutralize Nogo-A, an endogenous protein that inhibits neuronal plasticity. In the current study, we modeled TBI in adult male, Long Evans rats, using the controlled cortical impact (CCI) method, which results in focal brain damage and induces motor deficits very similar to the effects of TBI in humans. We hypothesized that treatment with anti-Nogo-A neutralizing antibodies following TBI would result in disinhibited axonal and dendritic growth, the establishment of new compensatory synaptic connections, and improvement in functional outcome. Prior to TBI, subjects were trained to a high level of proficiency on the skilled forelimb reaching task, and we assessed baseline performance on the skilled ladder rung walking task as well as two ethological measures of anxiety in rodents, the elevated zero maze and the light/dark apparatus. Subjects were given a TBI, and one week later were randomly divided into 3 groups: TBI only (n=7), TBI + anti-Nogo-A antibody (n=8), and TBI + control antibody (n=8). Testing on the skilled forelimb reaching task and skilled ladder rung walking task resumed 3 days after TBI and continued until 8 weeks after TBI. The tests for anxiety were repeated at 8 weeks after TBI. At the conclusion of behavioral testing, subjects received an injection of the neuronal tracer biotinylated dextran amine (BDA) into the motor cortex contralateral to the injury. Our behavioral results indicate significant improvement in motor functional recovery in rats that received anti-Nogo-A antibody therapy. Results for measures of anxiety as well as anatomical evidence of new neuronal pathways are still under investigation. This study indicates that anti-Nogo-A antibody therapy may be a promising treatment to improve functional recovery in humans who have suffered a TBI.

Title: Amplified cognitive deficits, gliosis, and interferon-associated neuroinflammation in aged mice after diffuse brain injury

Authors: *L. WANGLER[1], C. BRAY[1], J. PACKER[1], S. M. O'NEIL[2], M. OUVINA[3], M. WITZEL[3], K. BAETZ[3], E. HANS[3], J. GODBOUT[1];
[1]The Ohio State Univ. Neurosci. Grad. Program, Columus, OH; [2]The Neurosci. Grad. Program, The Ohio State Univ., Columbus, OH; [3]The Ohio State Univ., Columus, OH

Abstract: Traumatic brain injury (TBI) can lead to significant neuropsychiatric complications and neurodegenerative pathologies. Moreover, aged individuals are particularly susceptible to fall-related diffuse brain injuries and subsequently exhibit worse functional impairment. Although the vulnerability of older individuals to complications following brain injury is well-recognized, the mechanisms by which this occur are unclear. There is evidence of increased neuroinflammation and microglial priming in aging, and these factors may underlie the increased neuropathology and impaired functional recovery in aged individuals after TBI. Therefore, we aimed to determine the degree to which neuroinflammation, neuropathology, and cognitive decline were increased following TBI as a function of age. In these experiments, adult and aged C57Bl/6 mice received a TBI using a midline fluid percussive injury (mFPI). Several cognitive and biochemical parameters were assessed at subacute (7 days post injury, dpi) and chronic (30 dpi) time-points. Aged mice had increased time to right after mFPI compared to adults. While both adult and aged mice showed impairment in Novel Object Recognition (NOR) and Novel Object Location (NOL) memory, Aged-TBI mice showed exacerbated deficits at 7 and 30 dpi. Moreover, histological analysis of microglia and astrocytes showed Aged-TBI mice had augmented cortical gliosis, and mRNA analysis showed an enhanced neuroinflammatory profile with evidence of microglial priming (Clec7a, H2-Eb1, Itgax) at 7 dpi. In addition, cortical mRNA analysis revealed a robust inflammatory signature associated with type 1 interferons in the Aged-TBI mice. For instance, at 7 and 30 dpi there was exacerbated expression of Tmem173, Irf7, and Ifi27l2a in the Aged-TBI mice compared to Adult-TBI. Collectively, these studies indicate that aged mice have enhanced cognitive decline, neuroinflammation, and neuropathology after TBI that is associated with pronounced type 1 interferon signaling.

Title: A retinoic acid dose response study: evaluating therapeutic effects on hippocampal synaptic protein expression and cognitive function after traumatic brain injury.

Authors: *S. SVIRSKY[1], J. HENCHIR[1], Y. LI[1], M. PARRY[1], E. HOLETS[1], S. W. CARLSON[1], C. DIXON[1,2];
[1]Neurolog. Surgery, Univ. of Pittsburgh, Pittsburgh, PA; [2]Pittsburgh VA, Pittsburgh, PA

Abstract: Traumatic brain injury (TBI) is known to impair synaptic function, and subsequently contributes to observed cognitive deficits. Retinoic acid (RA), a metabolite of Vitamin A, has been identified as a potential pharmacotherapeutic for experimental ischemic injury and other neurological disorders, partially due to increased expression of synaptic signaling and plasticity proteins. This study aims to understand the effect of various doses of RA on improving hippocampal synaptic protein expression and learning and memory behaviors after TBI. Adult, male Sprague Dawley rats (275-300g, 9-10 per group) received either controlled cortical impact (CCI, 2.5mm deformation, 4m/s) or control/sham surgery. Animals received daily intraperitoneal injection of 0.5, 1, 5, or 10 mg/kg body weight of RA or DMSO-vehicle for 2-weeks. Animals underwent Morris Water Maze (MWM) testing days 9-14 post-injury. Neurogranin (Ng), Ca^{2+}/calmodulin-dependent protein kinase II (CaMKII), post-synaptic density protein 95 (PSD-95) and synaptophysin expression was measured in hippocampal synaptosomal lysates by western blot at 2-weeks post-injury. A repeated measures ANOVA showed an overall group effect in MWM latency to reach submerged platform (p=0.001). *Post-hoc* analysis revealed a significant injury effect between Sham and CCI vehicle groups (p=0.004). No significant differences between Sham-vehicle and CCI-0.5, 1 and 5mg dose groups were observed. A one-way ANOVA of synaptosomal Ng and CaMKII expression showed an overall group effect (p=0.002, p&lt0.0001). *Post-hoc* analysis showed a significant injury effect between Sham and CCI-vehicle groups (p=0.0025, p=0.0027), but no significant difference between Sham-vehicle and CCI-1 and 5mg doses. Furthermore CCI-1mg dose showed a trending increase in Ng expression from the CCI-vehicle group (p=0.0583). No significant group effect was observed in PSD-95 and synaptophysin expression. In conclusion, RA had a modestly positive effect on both behavior and hippocampal synaptic protein expression, with doses demonstrating similar effects across behavioral and biochemical outcomes. Further work is needed to investigate mechanisms of RA signaling in TBI-induced cognitive dysfunction, given the pleiotropic effects of RA.

Title: The effects of 7,8-Dihydroxyflavone and exercise on brain atrophy, functional connectivity, and behavior following mild to moderate TBI

Authors: *G. SMITH[1,2], A. PAYDAR[1,2], L. ZHE YING[3], G. KRISHNA[3], N. HARRIS[1,2], F. GOMEZ-PINILLA[1,2,3];
[1]Neurosurg., UCLA David Geffen Sch. of Med., Los Angeles, CA; [2]UCLA BIRC, Los Angeles, CA; [3]Dept. Integrative Biol. and Physiol., UCLA, Los Angeles, CA

Abstract: 7,8-Dihydroxyflavone (DHF) an agonist of the Brain-derived neurotrophic factor (BDNF)/tropomyosin-related kinase B (TrkB) receptor has been shown to be neuroprotective. The ability of DHF alone and in combination with exercise to normalize brain structure and function following mild to moderate traumatic brain injury (TBI) was assessed using adult Sprague Dawley rats (n=55) in a fluid percussion injury (FPI) model. Some of the long-term effects of TBI are chronically altered MRI based metrics such as increased mean diffusivity (MD) and decreased fractional anisotropy (FA), as well as increases in local tissue atrophy within the brain. These indicators of micro and macro-structural damage in the brain following TBI occur commensurate with a loss of function connectivity that may underlie persistent deficits in multiple behavioral processes. We tested the effects of DHF, either administered alone or in combination with exercise starting at post injury day (PID) 1 to PID 14, to normalize the degree of structural changes after TBI that will result in improved functional connectivity. This improvement in connectivity will help improve cognitive function and reduce anxiety-like behaviors.
Following injury rats were assessed for anxiety-like behaviors using open field and elevated plus maze, and cognitive function was measured using a Barnes maze which the rats had been previously trained on. Functional and structural MRI data were also acquired at 2 wks post-injury using a standard resting state acquisition protocol with dexmedetomidine sedation followed by an anatomical scan to assess tissue atrophy.
Preliminary analysis of these data indicates that administration of DHF either alone or in combination with exercise help normalize local tissue atrophy resulting in improved functional connectivity in the rat brain following FPI.

Title: Epigenetics, neuroinflammation:Possible targets for therapy following traumatic brain injury (TBI)

Authors: *D. P. CROCKETT[1], V. L. DIBONA[2], H. CAIOLA[1], E. C. KELLY-CASTRO[1], M. VOGLEWEDE[1], N. BADADE[1], N. MALLALIEU[1], H. ZHANG[1];
[1]Neurosci. and Cell Biol., Rutgers-Robert Wod Johnson Med. Sch., Piscataway, NJ; [2]Pathology, Rutgers-Robert Wood Jonsnon Med. Sch., New Brunswick, NJ

Abstract: Each year, traumatic injury to the brain or to the spinal cord will afflict millions of people around the world. At present, there is no effective cure. An effective treatment will have to addresses a wide range of issues. One factor that will need to be addressed is the ongoing neuroinflammation triggered by injury. Prolonged inflammation can lead to continued loss of neurons and oligodendrocytes and consequently loss of function. Major players in the inflammatory response include the microglia and the astrocytes. Both cell types undergo major morphological changes as part of their response to injury which requires transcriptional regulation. Microglia are highly ramified at “rest” but change into rounded phagocytic cells following injury. The mechanism associated with this activation and morphological change is not completely understood. Likewise, the injury response of astrocytes includes numerous biochemical, morphological, metabolic, and physiological remodeling (Escartin et al 2021). We have recently demonstrated that the polarity protein Par1b/MARK2 may be instrumental in the inflammatory response to TBI (DiBona et al 2019). The loss of Par1b/MARK2 facilitates the microglial inflammatory response in both primary microglia *in vitro* and following traumatic brain injury (TBI) in mice. Par1b/MARK2 is a serine/thionine kinase and is a member of Par1/MARK (microtubule affinity regulating kinase) family of polarity proteins. One possible pathway that Par1b/MARK2 may influence microglial activation may include the class IIa histone deacetylase, HDAC7. Previously, HDAC7 has been shown to play an important role in macrophage immune responses (Shakespeare et al 2013 and Gupta et al 2020). Par1b/MARK2 has been shown to regulate cellular localization, and function of the class IIa HDACs through N-terminal phosphorylation (Dequiedt et al 2006). Interestingly, we have observed an increase in HDAC7 immunostaining in both activated microglia and reactive GFAP+ astrocytes within cortex following traumatic injury. We are currently examining the link between Par1b/MARK2

and the class IIa HDACs following TBI in both juvenile and adult mice and are examining other epigenetic factors that may play an important role in the inflammatory response to injury.

Title: Brief oxygen exposure following blunt head trauma improves survival and reduces pathologic signs of traumatic optic neuropathy with variable, time-dependent ER stress responses in the retina.

Authors: *S. M. HETZER[1], N. K. EVANSON[2];
[1]Univ. of Cincinnati, Cincinnati, OH; [2]Div. of Pediatric Rehabil. Med., Cincinnati Children's Hosp. Med. Ctr., Cincinnati, OH

Abstract: Visual deficits after traumatic brain injury (TBI) develop in 50-60% of patients with 5% occurring because of injury to the optic nerve (ON). Symptoms of this traumatic optic neuropathy vary and can worsen for up to 35 years after TBI. Current literature predominantly follows adult subjects, despite a significant incidence of visual deficits in 20% of pediatric TBIs. We previously reported that adolescent mice experience higher mortality and worse histological outcomes following blunt head injury, compared to adult mice. We also found that Endoplasmic Reticulum (ER) stress and ER-mediated reactive oxygen species (ROS) proteins are elevated following ON injury in the retina. Because elevated adolescent mortality appeared to be due to post-impact apnea, we hypothesized that a brief exposure to oxygen (O_2) after injury would improve survival but that increased O_2 would be toxic to retinal cells by increasing ER stress and ROS production. To test this, we utilized a single weight-drop injury in adolescent male mice who were either exposed to 100% O_2 by hood until normal breathing returned (~3 min) or allowed to recover in room air. We followed mice 7- and 30-days post injury (DPI) and examined (a) behavioral measures of visual function, (b) histological measures in retina and brain tissue for retinal ganglion cell loss, axonal degeneration, and glial reactivity, and (c) molecular changes in the retina involving markers of ROS and ER stress via western blot. We found that O_2 reduces adolescent mortality by 40%, improves post-injury visual acuity, and reduces axonal degeneration and gliosis in central ON projection targets 7- and 30-DPI. ER

stress marker expression was altered in injured mice overall, and mice given O_2 appear to utilize different ER-stress pathways in a time dependent manner, compared to other experimental groups. O_2 exposed mice had increased expression of IRE-1α pathway markers 7 DPI and increased PERK pathway expression 30 DPI. Room air exposed mice showed the opposite pattern of expression at 7 and 30 DPI. O_2 exposed mice did not have significantly elevated ER-mediated apoptosis markers (i.e., CHOP) 30 DPI, while room air mice did. Finally, brief O_2 exposure reduced ER-mediated ROS production, as seen through significantly reduced PDI and ERO1α expression, compared to room air and uninjured mice. Taken together these results suggest that a single, short exposure to O_2 immediately following head trauma is beneficial to survival and ON injury outcomes, potentially by altering ER stress response pathways. Our results suggest that changing the oxygen/redox balance immediately following TBI has significant effects on ER stress responses to optic nerve trauma.

Title: Glymphatic transport and drainage to the deep cervical lymph nodes is sustained in ciliopathy with hydrocephalus

Authors: *Z. H. GURSKY[1], Y. XUE[1], B. MONTE[1], S. CONSTANTINOU[1], X. LIU[1], S. KOUNDAL[1], H. LEE[1], A. NEMAJEROVA[2], T. MICHURINA[3], K. MELLANSON[3], K.-I. TAKEMARU[4], G. ENIKOLOPOV[3], N. PEUNOVA[3], H. BENVENISTE[1];

Abstract: Multiciliated cells (MCC) serve many functions in the developing and mature brain, lining the ventricles of the brain, the airways, and the ducts of reproductive organs. The contribution of MCC to CSF motion and central nervous system (CNS) fluid homeostasis is poorly understood. In two separate experiments, we utilized two adult mouse models of ciliopathy with hydrocephalus — knockout of global p73 (i.e., missing both TAp73 and DeltaNp73 isoforms) [Yang et al., 2000, *Nature*] or FOXJ1-conditional knockout of CEP164 [Siller et al., 2017, *PLoS Genetics*]— to examine glymphatic system function and waste drainage

patterns from the CNS. Both ciliopathic mouse models presented with the communicating form of hydrocephalus. Brain tissue volume was normal in the FOXJ1-Cre;CEP164$^{fl/fl}$ compared to CEP164$^{fl/fl}$ control mice, but reduced by 25% in p73$^{-/-}$ compared to p73$^{+/+}$. Hippocampal anatomy was substantially altered in p73$^{-/-}$ (but not CEP164) mutant mice, manifested as visible folding of pyramidal cell layers, an 'underdeveloped' lower granular cell layer with an abnormal shape of the dentate gyrus, and atypical expression of mature neuronal marker NeuN. Glymphatic transport at 1 hour after infusion of a Gd-based contrast agent (Gd-DOTA) and quantified using T1 mapping was similar across the FOXJ1-Cre;CEP164$^{fl/fl}$ and CEP164$^{fl/fl}$ groups. However, when correcting for differences in total intracranial volume, glymphatic transport in p73$^{-/-}$ was increased by 20% compared to p73$^{+/+}$ mice. Supporting these observations, there were no significant alterations in AQP4 water channel expression along capillaries or small vessels in the ventral hippocampus of FOXJ1-Cre;CEP164$^{fl/fl}$ mice. However, p73$^{-/-}$ mice exhibited a significant increase in AQP4 polarization around capillaries in the ventral hippocampus. Glymphatic transport function is dependent on egress of interstitial fluid and CSF along meningeal lymphatics and cervical lymphatic vessels. Drainage of Gd-DOTA to the nasal conchae was significantly reduced in both ciliopathic mouse models likely due to impaired lymphatic drainage to the submucosa covering the spiral lamellae, secondary to inflammation caused by purulent sinusitis. Notably, drainage of Gd-DOTA to the deep cervical lymph nodes in the ciliopathic mice strains was within normal ranges. The relationship between intracranial pressure and glymphatic-lymphatic transport in the two ciliopathic mouse strains remains a topic for future study.

Title: Unexpected source and function of brain perivascular macrophages in health and diseases.

Authors: *A. DRIEU, J. RUSTENHOVEN, S. STORCK, T. MAMULADZE, Z. PAPADOPOULOS, I. SMIRNOV, J. KIPNIS;

Abstract: Unexpected source and function of brain perivascular macrophages in health and diseases.

Abstract:
Microglial cells are the resident macrophages of the brain. Perivascular macrophages (PVM) are also myeloid resident cells that are located at the interface between blood, CSF and brain in the perivascular space. Previous studies showed that PVM and microglia are coming from early erythro-myeloid progenitors from the yolk sac, but how they repopulate throughout life remained unknown. We now demonstrate that upon depletion, PVM are provided by the skull bone marrow source. Intrigued by this result, we decided to study the role of PVM in the homeostatic brain. Due to their strategic location and their ability to sample CSF content, we hypothesized that PVM might play a role in CSF flow. Using different fluorescent tracers injected either into the CSF (influx) or the brain parenchyma (efflux) we assessed their spatio-temporal distribution and found that ablation (using clodronate liposomes) or dysfunction (using genetic tools) of PVM alters CSF dynamics and patterns. Interestingly, aging results in altered PVM phenotype. Reversing this phenotype using macrophage specific grown factors, reversed some of aging-associated dysfunctions of CSF flow.In summary, our results identify a new role of PVM in CSF flow and open new avenues for therapeutical applications targeting PVM in neurodegenerative diseases such as Alzheimer's disease.

Abstract: Downregulation of a Dorsal Root Ganglion-SpecificallyEnriched Long Noncoding RNA is Required for NeuropathicPain by Negatively Regulating RALY-Triggered Ehmt□ExpressionDownregulation of a Dorsal Root Ganglion-SpecificallyEnriched Long Noncoding RNA is Required for NeuropathicPain by Negatively Regulating RALY-Triggered Ehmt□ExpressionDownregulation of a Dorsal Root Ganglion-SpecificallyEnriched Long Noncoding RNA is Required for NeuropathicPain by Negatively Regulating RALY-Triggered

Ehmt□ExpressionDownregulation of Dorsal Root Ganglion-Specifically Enriched Long Noncoding RNA (*DS-lncRNA*) negatively regulated RALY-Triggered Ehmt2 Expression after peripheral nerve injury

Xiaozhou Feng, Zhiqiang Pan, Shibin Du, Kun Wang, Huijuan Hu, Yuan-Xiang TaoDepartment of Anesthesiology, New Jersey Medical School, Rutgers, The State University of New Jersey, Newark, NJ07103, USA. Nerve injury-induced changes in gene expression in the dorsal root ganglion (DRG) contribute to neuropathic pain genesis. Recent evidence revealed the dysregulated expression of long non-coding RNAs (lncRNAs) in the damaged nerve, dorsal root ganglion (DRG), and spinal cord dorsal horn following peripheral nerve injury. However, the role of the majority of lncRNAs in neuropathic pain is still elusive. We recently identified a unique and native lncRNA highly expressed in mammalian DRG, named DRG-specifically enriched lncRNA (*DS-lncRNA*). Our pilot data demonstrated that nerve injury-induced downregulated of the *DS-lncRNA* in injured DRG contributed to neuropathic pain genesis. However, the mechanism underlying this phenomenon is still unclear. Here, we show that rescuing *DS-lncRNA* downregulation blocks nerve injury-induced increases in the transcriptional cofactor RALY-triggered DRG *Ehmt2* mRNA and its encoding G9a protein, reverses the G9a-controlled downregulation of opioid receptors and Kcna2 in injured DRG, and attenuates nerve injury-induced pain hypersensitivities. Conversely, *DS-lncRNA* downregulation increases RALY-triggered Ehmt2/G9a expression and correspondingly decreases opioid receptor and Kcna2 expression in DRG, leading to neuropathic pain symptoms in mice in the absence of nerve injury. *DS-lncRNA* contributes to neuropathic pain through participation in negatively regulated RALY-Triggered *Ehmt2*/G9a expression in injured DRG.

Abstract: Downregulation of DS-lncRNA in DRG contributes to neuropathic pain
Gokulapriya Govindarajalu, Zhiqiang Pan, Shibin Du, Kun Wang, Huijuan Hu, Yuan-Xiang Tao

Department of Anesthesiology, New Jersey Medical School, Rutgers, The State University of New Jersey, Newark, NJ07103, USA.
Neuropathic pain affects the quality of life of 7-10% of the world's population. Current treatments for this debilitating disorder have limited effectiveness and/or produce severe adverse effects. Understanding the mechanisms by which nerve injury causes pain hypersensitivity may provide a new avenue for neuropathic pain management. Nerve injury-induced alterations in gene expression in the dorsal root ganglion (DRG) are considered to be critical in neuropathic pain genesis. Long non-coding RNAs (lncRNAs) are emerging as potent and multifunctional regulators of gene expression. Here, we reported a unique and native lncRNA highly expressed in mammalian DRG, named DRG-specifically enriched lncRNA (*DS-lncRNA*). *DS-lncRNA* contains a long and highly expressed splice isoform transcript I (SIT1) and a short and weakly expressed splice isoform transcript II (SIT2) in mouse DRG. *DS-lncRNA* was expressed highly in DRG neuronal nuclei, but not in adjacent satellite cells. Peripheral nerve injury down-regulated the expression of *DS-lncRNA* and its two transcripts in injured DRG neurons. Rescuing this down-regulation attenuated the development and maintenance of neuropathic pain. Mimicking this down-regulation led to neuropathic pain-like behaviours in mice with the absence of peripheral nerve injury. Our findings suggest that DRG *DS-lncRNA* downregulation is required for neuropathic pain induction and maintenance.

Title: Sex specific role of RNA-binding protein, AUF1, on somatosensory responses from muscle after repetitive ischemia with reperfusion injury

Authors: *M. QUIJAS[1], A. A. WEYLER[1], L. F. QUEME COBAR[1,2], D. P. JOSHI[1], M. P. JANKOWSKI[1,2,3];
[1]Dept. of Anesthesia, [2]Pediatric Pain Res. Ctr., Cincinnati Children's Hosp. Med. Ctr., Cincinnati, OH; [3]Dept. of Pediatrics, Univ. of Cincinnati Col. of Med., Cincinnati, OH

Abstract: Musculoskeletal pain is experienced worldwide more than any other type of pain. Currently, few effective measures are available that help prevent acute pain from developing into

chronic pain. A major cause of disease-based myalgia is equated with repetitive ischemia with reperfusion (IR) injury. IR injury occurs in many disorders such as fibromyalgia or complex regional pain syndrome (CRPS) which are reported in significantly greater numbers in females than males. Pain tolerance is also lessened in females compared to males in these conditions. Mechanisms of sensitization that generate sex differences have been linked to distinctions in cytokine signaling. We recently identified an association between sensitization in group III and IV muscle afferents and an increase in acid sensing ion channel (ASIC) expression in male dorsal root ganglia (DRG) and an increase in TRPV1 expression in female DRGs that each correlated with behavioral hypersensitivity to IR. Both male and female DRGs displayed upregulation of the interleukin 1β (IL1β) receptor, IL1r1, in the DRGs after a single IR injury, but females specifically upregulated IL1r1 after double IR. To determine possible mechanisms by which distinct sex specific gene expression patterns modulated IR-related hypersensitivity in mice, we performed unbiased and targeted screening strategies in male and female DRGs with or without IR. Several distinct proteins were found to be differentially expressed between male and female DRGs including phosphorylated AU-rich element RNA binding protein 1 (AUF1), which was specifically upregulated in females DRGs when compared to males. AUF1 can stabilize or degrade RNA depending on cell type. Since AUF1 is known to have a high number (7) of IL1R1 binding sites in its 3'UTR, we hypothesized that AUF1 can promote the continued expression of IL1R1 and lead to prolonged hypersensitivity in females with repeated IR. To test this, we performed nerve targeted AUF1 knockdown in males and females with repeated IR injury and assessed behavioral responsiveness and gene expression with experimenters blinded to the conditions. No effect of AUF1 knockdown was observed on male DRG gene expression, or behavior post-repeated IR injury. AUF1 knockdown in females however, reduced the injury related paw guarding behaviors and prevented the upregulation of IL1r1 and TRPV1 in the DRGs. Data suggests that RNA binding proteins like AUF1 may underlie the sex specific effects on DRG gene expression that modulate behavioral hypersensitivity after repeated IR injury. This study may aid in finding distinct receptor differences related to the evolution of acute to chronic pain development between sexes.

Title: Early life neuroimmune interactions modulate neonatal nociceptive priming.

Authors: *A. J. DOURSON[1], A. M. WARSHAK[1], M. C. HOFMANN[1], M. P. JANKOWSKI[1,2,3];
[1]Dept. of Anesthesia, [2]Pediatric Pain Res. Ctr., Cincinnati Children's Hosp. Med. Ctr., Cincinnati, OH; [3]Dept. of Pediatrics, Univ. of Cincinnati, Col. of Med., Cincinnati, OH

Abstract: Peripheral injury evokes responses from a number of cellular systems including the nervous system and the immune system which alerts the body of damage and modulates repair of the affected area, respectively. Despite evidence that the pediatric population is unique compared to adults and requires specialized care following a painful insult, we do not have a full understanding of how the immune and nervous systems change during development to distinctly modulate injury responses in children. Clinical and rodent data indicate that early life aversive events alter the development of the somatosensory system, predisposing subjects to persistent pain following a repeated injury later in life. This “priming” effect is at least partially maintained by the central nervous and immune systems, but the peripheral component is unknown. We aimed to fill this gap in knowledge by investigating how peripheral immune cells may affect responses to repeated injury. Evidence suggests that macrophages are important mediators for acute pain, and can become “trained” by a previous stimulus. We hypothesized that developing macrophages uniquely drive neonatal nociceptive priming.
Neonatal hindpaw muscle incision induces pain-like behaviors and an inflamed microenvironment which includes damage-associated molecular patterns (DAMPs) that act on immune cells. Similar to previous work, we demonstrated that a postnatal day 7 (P7) incision “primes” the animals to an injury later in life indicated by exaggerated paw guarding and mechanical hypersensitivity compared to sham surgery controls. Macrophage depletion using macrophage fas-induced apoptosis (MaFIA) animals, blocked acute neonatal mechanical hypersensitivity and increased pro- and anti-inflammatory factors including nerve growth factor (NGF), interleukin 6 (IL-6) and IL-10. Further, the neonatal depletion of macrophages rescued the priming effect of early life injury. Using ATAC-seq, we found differences in chromatin accessibility in immature macrophages, an effect that may be modulated by early life incision and underlie how early life neuroimmune interactions modulate neonatal priming effects. Finally, adult bone marrow derived macrophages from neonatal incised animals were found to have enhanced production of pro-inflammatory cytokines upon stimulation with LPS/IFN-γ, indicating that the stem cell pool may be affected by early life injury. Together, these data suggest that early life injury alters how peripheral macrophages respond to repeated injury. Results may provide new information on how acute neonatal pain transitions to chronic pain after surgical injury.

Title: Expression of neuronal injury markers after chemoradiation treatment in a rat model of radiation-induced swallowing dysfunction

Authors: *S. N. KING[1], N. KAISSIEH[1], A. DESHMUKH[2], E. GREENWELL[1], J. FOX[3], M. SHOJAEI[3], M. BLACKBURN[3], J. PETRUSKA[4];
[1]Otolaryngology Head and Neck Surgery and Communicative Disorders, [2]Sch. of Med., [3]Radiation Oncology, [4]Anatom. Sci. and Neurobiology, KY Spinal Cord Injury Res. Center, Neurolog. Surgery, Univ. of Louisville, Louisville, KY

Abstract: Concurrent radiation and chemotherapy is the standard of care for the management of locally advanced oropharyngeal cancers. Impairments in swallowing function (dysphagia) is a dose-limiting toxicity of these radiation-based treatments that leads to negative effects in quality of life and oral intake. To develop targeted therapies to improve swallowing outcomes relies on understanding of the mechanisms that impact motor function after chemoradiation. The purpose of this study was to determine if chemoradiation damages axons/nerves that innervate the swallowing muscles, which could lead to impairments in sensorimotor control. We hypothesized that radiation given in combination with cisplatin chemotherapy will induce injury/stress-like markers i.e. activating transcription factor 3 (ATF-3) in swallow-related cranial nerves located within or outside the field of radiation. Twelve rats underwent 48Gy of fractionated radiation to the submental muscles using a clinical linear accelerator given in 12 fractions of 4Gy. Irradiated rats received either cisplatin 1mg/kg or saline IP once per week for four weeks during radiation treatment. One-month post treatment, the branch of the hypoglossal nerve, vagal ganglia, dorsal root ganglia, and trigeminal ganglia tissues were harvested. RNA was isolated and expression of injury markers were analyzed via RT-PCR. Alterations in ATF3 mRNA expression were observed. Results demonstrate that chemoradiation, which can induce functional deficits in swallowing, also provokes neuronal injury/stress markers.

Title: Identifying the molecular mechanism for the pain caused by lionfish venom

Authors: *S. MOUCHBAHANI-CONSTANCE, R. SHARIF-NAEINI;
Dept. of Physiol. and Cell Information Systems Group, McGill Univ., Montreal, QC, Canada

Abstract: The lionfish (Pterois volitans) is a venomous species endemic to the Indo-Pacific, but that has now invaded the Northwestern Atlantic as well as the Caribbean and Mediterranean Seas. It poses a growing health problem due to the increase in frequency of painful stings that it delivers, for which no treatment or antidote exists. A prior collaborative study by our group characterized the pain and inflammation caused by the lionfish venom and provided the first insight into the venom's cellular target in the peripheral nervous system - nonpeptidergic nociceptors. The aim of this research project is to isolate the algogenic toxin in the venom and identify its receptor target to understand the molecular mechanism for the pain caused by lionfish venom. The toxin will be isolated using High Pressure Liquid Chromatography (HPLC) to fractionate the venom, fractions will then be screened for their ability to elicit a rise in intracellular calcium in iPSC-derived sensory neurons using a high throughput screening system (FLIPR). Active fractions will be sub-fractionated and further screened until a single active fraction remains, this will then subject to mass spectrometry in order to identify the sequence of the algogenic toxin. Preliminary results point to the venom's receptor target, which has been verified using calcium imaging, behaviour and patch-clamp electrophysiology experiments. We have cloned the venom's target from Gymnothorax favagineus (Honeycomb moray eel), a predator of the lionfish, as well as from the lionfish itself to evaluate these targets' sensitivity to lionfish venom using calcium imaging and electrophysiology. Sequences of the human, G. favagineus and P. volitans genes have been aligned to identify divergent domains with an aim to generate chimera of this receptor to demonstrate whether insensitivity to lionfish venom can be conveyed to the human receptor by simply swapping domains with those from G. favagineus' or P. volitans' sequence. These results will 1) identify novel modulators of the pain pathway, 2) provide insights into the parallel evolution of the algogenic toxin in lionfish venom and its target in predators and 3) potentially produce novel analgesics by using low-dose toxin peptides in therapeutic agents to produce analgesic effects.

Title: Experience-dependent plasticity of cold nociception in Drosophila larvae

Authors: *K. J. DONALDSON, J. T. PAPANIA, D. N. COX;
Neurosci. Inst., Georgia State Univ., Atlanta, GA

Abstract: Organisms encounter constantly changing sensory stimuli requiring timescale-specific processing to ensure proper growth, development, and survival. The predictive qualities of many stimuli are encoded via inherent neuronal circuitry, but some are modified through exposure. While experience-dependent plasticity has been previously studied in a variety of modalities and sensory systems, little is known about thermal sensation, specifically cold. *Drosophila* larvae predominantly respond to acute noxious cold (≤10°C) with a full body contraction (CT) behavior requiring activation of Class III multidendritic neurons (CIIIs) by cold stimuli. Injury-induced cold sensitization via UV damage leads to behavioral plasticity such that CT responses are diminished, while body rolling behavior, which is normally associated with noxious heat, mechanical or chemical stimulation mediated by Class IV neurons (CIVs), begins to emerge. These data reveal that cold nociceptive circuitry exhibits injury-induced behavioral plasticity, however, whether this plasticity holds true in a non-injury model involving activity-dependent plasticity through accumulated cold experience remains unknown. Here, we sought to determine the existence and extent of cold-evoked behavioral plasticity as a result of prior cold experience under non-damage conditions and to explore the potential cellular mechanisms underlying changes in behavior. *Drosophila* larvae were reared under noxious cold temperature (10° C) for various durations prior to being selected at the 3rd instar stage for behavioral testing during acute cold challenge at noxious and innocuous temperatures. In a set of parallel experiments, chronic "fictive cold" was achieved by targeted optogenetic stimulation of CIII neurons using the GAL4/UAS system to selectively express the light-gated cation channel, ChETA. In this condition, larvae were reared *sans* cold at room temperature (23°C) while being exposed to repeated blue light stimulation in a custom built, high-throughput device. We find that prior cold experience causes cold-evoked behavioral plasticity, exhibited by increased magnitude of CT behavior as well as the appearance of additional CIV-related behaviors such as C-bending, a precursor to rolling. These changes in behavioral responses were mirrored in "fictive" cold reared larvae, indicating that chronic activation of primary nociceptors is sufficient to induce behavioral sensitization and shifts. Together, these data demonstrate that the cold nociceptive system is capable of experience-dependent plasticity in non-injury conditions and that this change is neuronally driven.

The parabrachial nuclear complex (PB) is a key nexus for aversive behavior, including that related to pain perception. We have previously shown that, during chronic pain, PB activity is amplified, and its neurons respond to noxious stimuli with prolonged after-discharges, defined as responses that far outlast the stimulus. The activity of PB neurons in pain conditions has been studied almost exclusively in anesthetized animals. Because pain and aversion have important affective components, and because they are readily modulated by behavioral states, we seek to study PB in awake animals. We developed a method to investigate PB in awake, behaving mice by obtaining single unit *in vivo* electrophysiological recordings from head restrained mice. This allows us to record for extended periods of time, up to 2 hours, responses to different stimuli, under different conditions. This approach also allows us to compare, in the same animals, PB activity before the induction of chronic pain, while chronic pain develops, and after it has been established. Here, we compare single-unit PB data from naïve mice, both males and females, with activity during chronic pain.

Title: Sting activation in microglia attenuates nerve injury-induced neuropathic pain

Authors: A. S. ANDRIESSEN[1], A. S. PRUDENTE[2], J. ZHAO[1], A. MCGINNIS[1], R.-R. JI[1], A. G. NACKLEY[1], T. BERTA[2], ***C. R. DONNELLY**[1];

Abstract: Interactions between central glial cells and neurons are critical to the pathogenesis of neuropathic pain. Peripheral nerve injuries, such as chronic constriction injury (CCI) of the sciatic nerve, induce profound changes in the morphological, molecular, and functional properties of spinal microglia, which act to promote sensitization of neurons in pain circuitry, thereby driving the initiation and maintenance of chronic pain. We recently demonstrated that activation of stimulator of interferon genes (STING) in peripheral sensory neurons could attenuate pain in naïve mice and in a variety of murine models, including CCI-induced neuropathic pain. However, the prolonged antinociceptive effects of STING agonists were only partially mediated by STING signaling in sensory neurons, suggesting an important role of STING signaling in additional cell types. In naïve mice, we found that the majority of cells expressing STING in the spinal dorsal horn (SDH) were Iba1+ cells (~90%), likely microglia. Based on these data, we sought to determine the contribution of STING signaling in microglia to CCI-induced neuropathic pain using *Sting1*$^{fx/fx}$; *Cx3cr1*-Cre/ER^{T2} conditional knockout (STING-cKO^{MG}) mice. Notably, we observed that repeated intrathecal (e.g. spinal) administration of small molecule STING agonists immediately after CCI (days 3-5) produced a robust, but transient reduction in neuropathic pain behaviors, whereas administration at later timepoints (days 11-13) led to sustained antinociception and early resolution of pain. Although the acute antinociceptive effects of STING agonists were maintained in STING-cKO^{MG} mice, the long-term analgesic effects were abolished. Moreover, genetic and pharmacologic ablation of microglia could also abolish the prolonged antinociceptive effects of STING agonists in naïve and CCI mice. Finally, adoptive transfer of microglia from STING-WT, but not STING-cKO^{MG}, mice following incubation with STING agonists produced long-lasting antinociceptive effects in multiple models of neuropathic pain. Ongoing work is aimed at understanding the mechanisms by which STING activation in microglia attenuates pain by altering the neuroinflammatory microenvironment induced by peripheral nerve injury.

Title: Hyperexcitation of prodynorphin neurons in the prelimbic cortex in a mouse model of surgical pain

Authors: *S. ZHOU, P. L. SHEETS;
Dept. of Pharmacol. & Toxicology, Stark Neurosciences Res. Institute, Indiana U, Indianapolis, IN

Abstract: Incomplete understanding of how surgical incision elicits maladaptive changes to endogenous opioid circuits in the central nervous system remains a significant hurdle in developing new therapeutics for alleviating surgical pain. **Objective**: Determine how surgical incision alters endogenous opioid circuits in the medial prefrontal cortex (mPFC). **Rationale:** Prodynorphin (Pdyn) is the precursor peptide for the endogenous opioid dynorphin and is expressed in brain areas implicated in pain regulation. Increased expression of Pdyn mRNA is observed in the mPFC in a mouse model of chronic pain. One important subdivision of mPFC is the prelimbic cortex (PL). While maladaptive changes to the PL have been reported in multiple chronic pain models, intrinsic and synaptic alterations to PL Pdyn neurons following surgical incision are not known. **Methods:** Female Pdyn-IRES-Cre (B6;129S-$^{Pdyntm1.1(cre)Mjkr}$/LowIJ; stock #027958; Jackson labs) mice were mated with male Ai14 (B6;129S6-Gt(ROSA)$^{26SORtm14(CAG-tdTomato)Hze}$/J; stock #007914; Jackson Labs) mice to label Pdyn neurons with tdTomato. Coronal brain slices from offspring showed that Pdyn neurons are predominantly expressed in PL laminae 2/3 (L2/3). Here, we performed whole-cell patch clamp recordings in acute brain slices to study changes to L2/3 Pdyn neurons elicited by the plantar incision model of surgical pain (PIM). **Results:** Both male (n = 10) and female (n = 10) mice displayed mechanical allodynia compared to sham controls (male, n=11; female, n=9) one day after plantar incision. Electrophysiology data show that L2/3 PL Pdyn neurons are an intrinsically heterogenous population consisting of pyramidal and inhibitory-like neurons, which we confirmed morphologically. Interestingly, only pyramidal L2/3 PL Pdyn neurons display hyperexcitability

one day after plantar incision ($p < 0.05$). There is also a decrease in the frequency of spontaneous inhibitory post-synaptic currents in pyramidal Pdyn neurons in male PIM mice. We are currently exploring the role of PL Pdyn neurons in regulating surgical pain behaviors by using *in vivo* optogenetics. By manipulating the activity of PL Pdyn neurons, we will study the role of PL Pdyn neurons in regulating surgical pain behaviors. **Conclusion:** PL Pdyn neurons are a heterogenous population, and the excitability of only pyramidal Pdyn neurons is increased after plantar incision in both male and female. Data from male mice suggest that increased excitability is a result of reduced inhibitory synaptic inputs. We are currently studying the functional role of Pdyn neurons in surgical pain regulation, and the origin of the decrease in inhibitory inputs to Pdyn neurons in PIM mice.

Title: Behavioral and functional neural correlates of visual hypersensitivity in chronic nociplastic pain

Authors: *N. C. WALLER, I. MAWLA, E. ICHESCO, A. SCHREPF, S. E. HARTE, R. E. HARRIS;
Anesthesiol., Univ. of Michigan, Ann Arbor, MI

Abstract: Fibromyalgia (FM) is a nociplastic pain condition with amplified central nervous system responses to external stimuli resulting in symptoms of sensory hypersensitivity and hyperalgesia. This hypersensitivity extends to non-painful stimuli including lights, which suggests multimodal central sensory amplification. The present study sought to understand behavioral and neural responses to aversive visual stimulation in individuals with FM compared to healthy controls (HC) using quantitative sensory testing (QST) and neuroimaging. Female participants (Total N = 26; FM: N=13) underwent aversive visual stimuli presentations of black/white checkerboard patterns. Visual stimuli were presented pseudo-randomly in 6 brightness levels. Participants rated each stimulus on Gracely-Box Scales for sensory intensity and unpleasantness. Sensory sensitivity to visual stimuli were analyzed with repeated measures ANOVA. Functional images were preprocessed in fMRIPrep and analyzed via FSL Local Analysis of Mixed Effects contrasting visual and rest conditions ($Z = 2.3$, $p < 0.05$). Whole-brain linear regression analyses assessed the associations between the images and various clinical

measures. Individuals with FM and HCs reported greater perceived sensory unpleasantness and intensity in a step-wise manner with increasing brightness intensity levels (HC: unpleasantness, $F(5) = 9.945$, $p < 0.001$; intensity, $F(5) = 9.465$, $p < 0.001$; FM: unpleasantness, $F(5) = 20.152$, $p < 0.001$; intensity, $F(5) = 16.357$, $p < 0.001$). Compared to HCs, individuals with FM rated visual stimuli as more unpleasant and intense compared to HCs (unpleasantness, $F(1, 21) = 6.690$, $p = 0.017$; intensity, $F(1, 21) = 5.212$, $p = 0.033$). fMRI contrast analyses between visual stimulation and rest revealed increased activity in visual and pain processing regions in individuals with FM to HCs, including bilateral dlPFC and V1. This difference was driven primarily by increased regional activation during rest. Whole-brain regression analyses in individuals with FM revealed positive correlations between visual-rest comparisons of pain severity and IFG, among others. (all $r > 0.69$, $p = 0.05$). Consistent with previous findings, individuals with FM reported significantly increased unpleasantness and intensity ratings to aversive visual stimulation compared to HCs. FM participants also showed increased brain activation during visual stimulation in core visual and pain network regions, including the dlPFC which is implicated in antinociceptive processing. These findings suggest increased antinociceptive network reactivity in patients with nociplastic pain occurs in nonpainful sensory contexts.

Title: Transcriptome analysis of repopulated spinal cord microglia identifies potential therapeutic targets in a mouse model of complex regional pain syndrome

Authors: *L. J. DONOVAN, C. M. BRIDGES, N. A. HUCK, S. WU, T. E. FORMAN, C. E. JORDAN, A. S. GARDNER, E. S. HAIGHT, V. L. TAWFIK;
Anesthesiol., Stanford Univ., Stanford, CA

Abstract: Complex regional pain syndrome (CRPS) is a form of chronic pain, occurring after limb fracture and immobilization, that affects 50,000 new patients per year in the United States alone. CRPS exhibits a clear acute-to-chronic transition and as a result rodent models of CRPS

can be utilized to understand mechanisms underlying the development of chronic pain. In particular, we have found prolonged microglial activation in the spinal cord dorsal horn in a rodent tibial fracture/casting model of CRPS which peaks at the time of acute-to-chronic pain transition. A more detailed understanding of the contribution of microglial activation to CRPS progression would enable the development of successful glial-targeted therapeutics. We hypothesized that diphtheria toxin-mediated transient depletion of microglia (and not macrophages) at 3 weeks post-fracture in *Cx3CR1*^{CreER}; *R26*^{iDTR} mice would resolve existing pain in males but not females after tibial fracture/casting. We further hypothesized that the transcriptome of newly repopulated microglia would reveal key genes that contribute to the resolution of pain. We performed unilateral tibial fracture followed by 3 weeks of casting in male and female *Cx3CR1*^{CreER}; *R26*^{iDTR} mice. To deplete microglia, diphtheria toxin was injected at the time of cast removal, at the time of acute-to-chronic transition. Mouse behavioral tests were performed after cast removal. Microglial cells from the spinal cord were isolated 2 weeks after depletion/repopulation (5 weeks post-fracture) by fluorescence-activated cell sorting (FACS) and the transcriptome was profiled using RNA sequencing (RNA-seq). Microglial depletion reversed existing mechanical allodynia and thermal hyperalgesia in both males and females. RNA-seq performed on FACS-isolated lumbar spinal cord microglia showed that the microglial transcriptome profiles clustered by group, with microglia depletion/repopulation having the greatest effect. DESeq2 analysis uncovered a shared set of differentially expressed genes (DEGs) in males and females after microglial depletion. Further, weighted gene correlation network analysis (WGCNA) of the DEGs was used to identify modules most significantly associated with a pain state vs no-pain state using module-trait correlations. Overall, transcriptome analysis of repopulated microglia identified a number of microglial genes and pathways that may contribute to the transition from acute-to-chronic pain in a CRPS model. Future studies will focus on analyzing lead genes as potential therapeutic targets.

Title: Theta-burst stimulation induces spinal cord long-term potentiation and pain hypersensitivity via α2δ-1-bound NMDARs

Authors: *Y. HUANG, S.-R. CHEN, H. CHEN, J.-J. ZHOU, D. JIN, H.-L. PAN;
MD Anderson Cancer Ctr., Houston, TX

Abstract: Activity-dependent long-term potentiation (LTP) is a fundamental feature of synaptic plasticity, and spinal cord LTP represents a state of central sensitization in chronic pain. Tetanic high-frequency stimulation (HFS) has been used to induce LTP in the spinal cord. However, many painful conditions generate theta rhythm bursting activity in primary afferent nerves. In this study, we determined how theta-burst stimulation (TBS) impacts LTP in the spinal dorsal horn and pain hypersensitivity. TBS induced LTP in 50% of excitatory neurons expressing vesicular glutamate transporter 2 (VGluT2) but only in 16% of inhibitory neurons expressing vesicular GABA transporter (VGAT). Nerve injury significantly increased the ratio of VGluT2-expressing, but not VGAT-expressing, neurons that showed TBS-induced LTP. TBS-induced LTP in VGluT2-expressing neurons was diminished by the NMDAR antagonist AP5, and was partially reduced in mice with conditional knockout of GluN1 in primary sensory neurons. Also, TBS failed to induce LTP in VGluT2-expressing neurons in the presence of α2δ-1 inhibition with gabapentin, genetic α2δ-1 knockout, or disruption of the α2δ-1-NMDAR interaction with α2δ-1Tat peptide. Furthermore, TBS of the sciatic nerve induced long-lasting allodynia and hyperalgesia in wild-type, but not in α2δ-1 knockout mice. In addition, treatment with the NMDAR antagonist memantine or AP5, gabapentin, or α2δ-1Tat peptide diminished TBS-induced allodynia and hyperalgesia. These findings indicate that TBS induces pain hypersensitivity and LTP predominantly in spinal excitatory dorsal horn neurons via activation of α2δ-1-bound NMDARs.

Title: Glun2d subunit-containing nmda receptors mediate cisplatin-induced neuropathic pain

Authors: *D. GAWANDE[1], R. PAVULURI[2], S. G. GAKARE[2], L. JENSON[2], S. DRAVID[1];
[2]Pharmacol. and Neurosci., [1]Creighton Univ., Omaha, NE

Abstract: Augmented N-methyl-D-aspartate receptor (NMDAR)-dependent synaptic plasticity at spinal as well as cortical levels is believed to contribute to enhanced sensory responses after chronic pain, but subunit specific NMDAR involvement in chronic pain is still unclear. Interestingly GluN2D subunit-containing NMDARs could be a potential target for chronic pain, because of their unique biophysical and pharmacological properties (less sensitivity to Mg^{2+}-block, prolong deactivation kinetics and higher glutamate/glycine affinity). Therefore, in the present study we used the global GluN2D knockout mouse model to characterize its potential role in inflammation and cisplatin induced neuropathic pain. We used three different mouse models to assess the pain (acute pain induced by 5% formalin, chronic pain induced by Complete Freund's adjuvant (CFA), neuropathic pain induced by the cisplatin), We found that formalin and CFA injected wildtype and global GluN2D KO mice showed similar pain sensitivity. In contrast, cisplatin injected global GluN2D KO mice had attenuated mechanical hypersensitivity compared to wildtype mice. Additional results using pharmacological tools further supported these findings. Overall, these results suggest that GluN2D subunit-containing NMDARs are involved in neuropathic pain.

Title: Ampakines relieves persistent neuropathic pain through the restoration of anti-nociceptive response in the prefrontal cortex in rats

Authors: *Y. LIU, R. TALAY, M. MICHAEL, I. FRIESNER, F. ZENG, H. XU, G. SUN, Z. CHEN, Q. ZHANG, J. WANG;
New York Univ., New York, NY

Abstract: While the prelimbic prefrontal cortex (PL-PFC) has been shown to play a key role in the top-down regulation of sensory pain, few studies have examined pharmacological agents that target maladaptive changes in the region for chronic pain regulation. AMPAkines, compounds that enhance glutamate transmission by binding to the AMPA (Amino-3-hydroxy-5-methyl-4-isoxazolepropionic acid) receptor, have been shown to relieve acute incisional and inflammatory pain symptoms in animals. However, the cortical mechanisms for their anti-nociceptive effects remain unknown. Here, we studied the impact of AMPAkines on the anti-nociceptive function of

neurons in the PL-PFC in a well-known neuropathic pain model. Silicon probes were implanted in the PL-PFC for *in vivo* recording of neuronal spike activities in response to peripheral noxious (pin prick) or non-noxious (von Frey (VF) filaments) stimuli from freely moving Sprague-Dawley rats. The impact of chronic neuropathic pain induced by spared nerve injury (SNI) was evaluated by basal and peak firing rates extracted from each individual neuron's perievent time histograms. We then studied how the PL-PFC neuronal abnormality in the chronic pain state was rescued by systemic delivery of a well-established AMPAkine (CX546). The chronic pain relief effects from systemic and intracranial administration of CX546 were compared using both mechanical and cold allodynia tests. We used optogenetic and pharmacological modulations of the PL-PFC neurons to verify whether CX546 could target PL-PFC AMPA receptors to relieve pain. In both allodynia tests, we interfered PL-PFC through either shining yellow light on halorhodopsin-expressing pyramidal neurons or injecting AMPA receptor antagonist (NBQX) intracranially. We found that neurons in the PL-PFC increase their firing rates in response to noxious stimulations. While chronic pain suppresses this pain response, CX546 restores the anti-nociceptive response in PL-PFC neurons to reduce chronic pain. Furthermore, we found that both systemic and direct delivery of CX546 into the PL-PFC inhibited chronic pain symptoms, whereas optogenetic and pharmacological inhibitions of PL-PFC neurons blocked the anti-nociceptive effects of CX546. The analgesic and respiratory-stimulating properties of AMPAkines make them an intriguing treatment choice for persistent neuropathic pain. More generally, our results indicate that drugs targeting the endogenous cortical pain-regulatory system are likely to have important roles in the treatment of chronic pain.

Title: Antibody receptor signaling from spinal cord astrocytes promotes neuropathic pain

Authors: *M. J. LACAGNINA, K. WILLCOX, J. LI, A. G. ALFARO, S. LORCA, P. M. GRACE;
Labs. of Neuroimmunology, Dept. of Symptom Res., Univ. of Texas MD Anderson Cancer Ctr., Houston, TX

Abstract: Background: Injury to somatosensory nerves can lead to mechanical allodynia, in which normally innocuous touch is perceived as painful. The cellular and molecular mechanisms responsible for mechanical allodynia are not fully understood, and therefore therapeutic options remain inadequate. Inflammatory signaling arising from spinal cord glial cells are thought to promote pain hypersensitivity, but it remains unclear what mechanisms control spinal glia activation after injury. Previous transcriptional datasets identified Fc gamma receptors (FcγR), the antibody receptors for immunoglobulin G (IgG), as a potential signaling axis associated with mechanical allodynia. Here, we demonstrate a role for Fc gamma receptor subtype IIa (FcγRIIa) on spinal cord astrocytes as contributing to neuropathic pain.
Methods: To model neuropathic pain, adult male and female Sprague Dawley rats received unilateral chronic constriction injury (CCI) of the sciatic nerve. To determine the role of spinal FcγRs signaling on pain behaviors, we used intrathecal (i.t.) injections of IgG immune complex (IgG-IC). To determine the functional role of FcγRIIa$^+$ astrocytes *in vivo*, we used a CRISPR-Cas9 approach to edit *Fcgr2a* function by i.t. injection of viral constructs co-expressing GFAP-driven Cas9 (or eGFP as control) and single guide RNA (sgRNA) against *Fcgr2a*. Pain-related behaviors were assessed by measuring reflexive withdrawal responses to innocuous punctate stimuli (von Frey filaments) and dynamic light touch (paintbrush assay). Gene and protein expression were measured by *in situ* hybridization, qRT-PCR, and immunohistochemistry. For *in vitro* experiments, astrocytes were purified by immunopanning and treated with IgG-IC.
Results: Activating FcγRs by spinal administration of IgG-IC is pro-nociceptive. *Fcgr2a* expression increases in ipsilateral spinal dorsal horn after CCI, and FcγRIIa co-localizes primarily with GFAP$^+$ astrocytes. Astrocytes respond to IgG-IC by increasing production of pro-inflammatory mediators, including TNF and IL-1β, which are known to influence nociceptor activity. Genetic disruption of *Fcgr2a* in spinal GFAP$^+$ astrocytes attenuates mechanical allodynia after CCI.
Conclusion: These data suggest FcγRIIa on spinal astrocytes may be activated following peripheral nerve injury and directly contribute to injury-induced tactile pain. These findings expand our understanding of how glial neuroimmune signaling contributes to mechanical allodynia and suggest that autoantibody IgG signaling at glial FcγRs could be a novel therapeutic target to alleviate suffering from neuropathic pain.

Title: Examining the role of inflammation in a zebrafish model of sensory hair cell aging

Authors: E. DALE[1], O. MOLANO[1], A. B. COFFIN[2];
[1]Neurosci. Program, Washington State Univ. Vancouver, Vancouver, WA; [2]Integrative Physiol. and Neurosci., Washington State University-Vancouver, Vancouver, WA

Abstract: Thirty-six million Americans suffer from hearing impairment, resulting in significant decreases in quality of life for those affected. Over 50% of individuals above the age of 75 experience age-related hearing loss (ARHL), and as the Baby Boomer cohort ages an increasing portion of the population will require assistive listening devices. While assistive technologies improve hearing capabilities in some, it is of great interest to prevent ARHL and preserve hearing. We proposed that two likely primary causes of ARHL are localized inflammation and mitochondrial dysfunction; here we focus on the role of inflammation in a zebrafish model. Zebrafish are an excellent model for auditory research, particularly studies of sensory hair cell development and physiology, due in part to the presence of exterior lateral line hair cells which are homologous to the hair cells in the human inner ear. Additionally, zebrafish development occurs rapidly and lateral line hair cells are in a constant state of turnover, resulting in lateral line organs containing cells of different ages. Lateral line hair cells are relatively mature in five days-post fertilization (dpf) animals, allowing us to study hair cell aging in a period of days, rather than waiting years for an animal to age. We hypothesize that inhibiting inflammation will prolong the functional lifespan of lateral line hair cells, and thus we would expect reduced hair cell addition and decreased longevity under inflammatory conditions. Using transgenic zebrafish that express green fluorescent protein (GFP) in hair cells, we pharmacologically manipulated a key inflammatory cytokine TNF-alpha and global inflammation using dexamethasone and lipopolysaccharide to investigate hair cell longevity *in vivo*. Fish were incubated in 4',6-diamidino-2-phenylindole (DAPI) at 4 dpf to label existing hair cells, then incubated in one of our inflammatory modulators. We can discriminate between cells that were present during at 4 dpf and newly added cells, as older cells are GFP+ and DAPI+, while newer cells are only GFP+. Our preliminary data demonstrates that inhibiting TNF-alpha increases hair cell longevity, consistent with our hypothesis. Future work will include genetic manipulation of inflammatory signaling and examine the role of mitochondria in the hair cell aging process. This work will increase understanding of inflammatory signaling in ARHL and may yield molecular targets for therapeutic development.

Title: Effects of high fat diet on aminoglycoside-induced hearing damage, regeneration, and gut microbiome composition in zebrafish

Authors: *S. SCHLOSS[1], I. HINCHLIFF[2,4], K. J. LAWTON[3], C. A. GAULKE[5], A. B. COFFIN[6];
[1]Washington State University, Vancouver, Vancouver, WA; [3]Neurosci., [2]Washington State Univ. Vancouver, Vancouver, WA; [4]Camas High Sch., Camas, WA; [5]Pathobiology, The Univ. of Illinois Urbana-Champaign, Champaign, IL; [6]Washington State Univ., Vancouver, WA

Abstract: Obesity is an extremely prevalent health issue that affects almost half of all people in the United States, according to the CDC. The consumption of a high fat diet (HFD) and large amounts of processed foods not only results in weight gain but can lead to a host of other comorbid conditions, including diabetes and heart disease. One relatively unrecognized comorbid condition that can present alongside obesity is hearing loss. Hearing loss is often caused by damage to sensory hair cells in the inner ear but it's not known how obesity influences hair cell survival. Here we examine the correlation between diet-induced obesity and hair cell damage in a zebrafish model. Zebrafish have hair cells located on a sensory system called the lateral line and are a well-established model for hearing research, in part because fish can robustly regenerate hair cells. Similarly, zebrafish are an excellent model for diet-induced obesity. We fed zebrafish for one month using either a control diet of dry food, dry food mixed with 20% lard, or dry food mixed with 20% egg yolk powder. We used an aminoglycoside antibiotic to damage hair cells and compared counts between groups. We also examined hair cell regeneration 48 hours after aminoglycoside treatment. Obesity has been linked with an overproduction of reactive oxygen species (ROS) which may contribute to hair cell death via apoptosis. ROS could also damage hair cell precursors and result in decreased hair cell regeneration for the HFD groups. A link exists between diet and gut microbiome composition, so we also assessed whether differences in gut microbiome composition can be related to hearing loss. We tested this hypothesis by 16S sequencing fecal samples and quantifying microbial populations based on taxon-specific DNA signatures. The mechanism behind the relationship of diet-induced obesity and hearing loss is not understood. Our work establishes a model for future mechanistic studies.

Title: Identification and characterization of OTO-510 as a novel approach to the prevention of cisplatin-induced hearing loss

Authors: *P. D. MATHUR, C. FERNANDEZ, P. URIBE, R. FERNANDEZ, S. SZOBOTA, N. TSIVKOVSKAIA, X. WANG, A. JONES, S. SIEGEL, G. PETTUS, K. HALDERMAN, R. FONG, J. HOU, A. STEPHANEKO, E. ALLSOPP, B. JACQUES, F. PIU, A. FOSTER; Otonomy Inc., San Diego, CA

Abstract: Among the effective chemotherapeutics used in oncology, cisplatin remains the first line of treatment for various cancer types, despite its deleterious effects on the peripheral auditory system. Several human and animal studies have demonstrated that cisplatin causes damage to the sensory hair cells (HCs), spiral ganglion neurons (SGNs) and cells of the stria vascularis (SV) in the inner ear, leading to permanent and bilateral sensorineural hearing loss. Local administration of drugs to the inner ear is an attractive means for preventing cisplatin-induced ototoxicity and ensuring low systemic exposure that does not compromise the anti-tumor efficacy of intravenously administered cisplatin. Here we report local administration of OTO-510 as an effective otoprotection strategy against cisplatin-induced hearing loss (CIHL). Approximately 100 molecules from different potentially otoprotective classes were screened at multiple concentrations in cochlear explant assays utilizing tissues from neonatal rat pups to evaluate otoprotection in HCs, SGNs and SV cells against cisplatin-induced damage. This led to the identification of a novel therapeutic class of molecules with consistently greater effects in preventing cisplatin-induced damage to HCs, SGNs and SV cells than other otoprotective molecules reported in the literature and in clinical studies, such as STS. Selected molecules from this novel class were tested for their cisplatin binding ability at equimolar concentrations in vitro using HPLC. Top performing candidates were then formulated to optimize local delivery and their pharmacokinetic properties were evaluated. Intratympanic delivery of the lead molecule OMY-150 in an optimized formulation (OTO-510) provided therapeutic levels of OMY-150 to the inner ear compartment with minimal systemic exposure. To evaluate its *in vivo* efficacy, OTO-510 was delivered locally via intratympanic administration to rats prior to cisplatin dosing, and the degree of otoprotection was assessed by recording auditory brainstem responses (ABRs) across several frequencies and by histological assessment of inner ear cells. OTO-510 prevented deleterious hearing threshold shifts and preserved all inner ear structures *in vivo*. Thus, OTO-510 represents a novel approach for protection against cisplatin-induced damage by optimizing an effective otoprotectant for local delivery to the inner. These results support the continued development of OTO-510 for the prevention of hearing loss caused by cisplatin administration in cancer patients.

Title: Novel Fab fragments derived from trk-selective agonist monoclonal antibodies are potent and selective antagonists of the trkb and trkc receptors

Authors: *S. SIEGEL[1], P. MATHUR[1], S. SZOBOTA[2], A. C. FOSTER[3];
[1]Otonomy, San Diego, CA; [3]Res., [2]Otonomy, Inc., San Diego, CA

Abstract: The neurotrophin receptors, TrkA, TrkB, and TrkC are expressed in neurons throughout the nervous system and mediate trophic signaling such as neuron survival, neurite outgrowth, and synaptogenesis. We previously demonstrated that agonistic monoclonal antibodies (mAbs) raised against TrkB or TrkC produced potent neurotrophic effects in cultured cochlear neurons (Szobota et al., PLoSOne 2019). Here, we examined the function of the Fab fragments of these mAbs. Surprisingly, we found that the Fab fragments blocked neurotrophic signaling at their respective receptors, functioning as highly-selective and potent antagonists. In a cell line overexpressing human TrkB, the TrkB-selective Fab had no agonist activity by itself, but at nanomolar concentrations inhibited phosphorylation of TrkB by BDNF and blocked its downstream effects on ERK phosphorylation. Similarly, in a cell line overexpressing human TrkC, the TrkC-selective Fab had no agonist activity by itself, but at nanomolar concentrations inhibited phosphorylation of TrkC by NT-3 and blocked downstream phosphorylation of ERK. The Fab fragments were highly selective for their respective Trk receptor and did not activate or inhibit other Trk subtypes. To date, inhibitors of neurotrophin receptors have demonstrated poor selectivity for Trk subtypes. For example, anti-cancer agents that target the intracellular kinase domains of Trk receptors have demonstrated potent inhibition but little selectivity between subtypes due to the conserved nature of the kinase domains. Subtype-selective Fabs, which bind to targeted extracellular epitopes, provide a unique opportunity to dissect the physiological roles of TrkB and TrkC in cellular systems that present both of these receptors, such as cochlear neurons. Previously, we found that survival of dissociated rat cochlear neurons was greatly augmented by treatment with BDNF, NT-3, or mAb Trk agonists. Application of exogenous BDNF or a TrkB-selective mAb greatly enhanced survival. In order to directly assess the significance of both endogenous and exogenous BDNF signaling in cochlear neurons, we treated these cultures with the TrkB-selective Fab, which produced a dose-dependent inhibition of neuron survival both in the absence and presence of exogenous BDNF, indicating that TrkB signaling is critical in this model of cochlear neuron survival. The Fabs described here represent novel tools for understanding the role of TrkB and TrkC in the development, maintenance, and

restoration of neuronal systems in physiology and disease. Additional studies with these Fab antagonists will examine the specific roles of TrkB and TrkC in cochlear function and repair.

Title: Local delivery of BDNF (OTO-413) and a selective TrkB agonist (M3) restores hearing function in models of cochlear synaptopathy

Authors: C. FERNANDEZ, N. TSIVKOVSKAIA, X. WANG, R. FERNANDEZ, T. ALTMANN, P. URIBE, P. D. MATHUR, Y. TSABUR, S. SIEGEL, *S. SZOBOTA, A. STEPANENKO, B. JACQUES, A. C. FOSTER, F. PIU;
Otonomy, Inc., San Diego, CA

Abstract: Evidence from preclinical and clinical studies indicates that loss of the synapses that connect inner hair cells of the cochlea with spiral ganglion neurons (SGNs), whose axons form the cochlear nerve, contributes to hearing impairment. This synaptopathy is proposed as an underlying pathology in age-related and noise-induced hearing deficits and has been hypothesized to explain speech-in-noise hearing difficulties that can occur despite normal audiometric thresholds. The application of Trk receptor agonists, in the form of neurotrophins such as Brain Derived Neurotrophic Factor (BDNF), Neurotrophin-3 (NT-3), or high affinity monoclonal antibodies (mAbs), has been investigated as a therapeutic approach for hearing loss based on their ability to provide trophic support to SGNs in the cochlea. In recent studies, BDNF, NT-3 and several Trk agonist mAbs were found to promote survival, neurite extension and synapse restoration in ex vivo cochlear cultures, with the strongest effects observed using the TrkB agonists BDNF and a TrkB-selective mAb, M3.
We developed sustained-exposure formulations of both BDNF (known as OTO-413) and M3 for

intratympanic delivery to the inner ear. Pharmacokinetic studies in rats demonstrated significant and dose-dependent inner ear drug levels for several weeks. Following noise exposure, administration of either BDNF or M3 one day post-trauma, improved functional (ABR, wave 1 amplitude) and histological (ribbon synapse counts) measures of hearing and cochlear synaptopathy. We further characterized the effects of OTO-413 when delivered up to 7 days post-noise insult and found that OTO-413 administration again improved these functional and histological readouts. In addition, biomarker studies revealed that elevated levels of proteins important for neuronal survival and synaptogenesis are present for several days in cochlear tissues following a single injection of OTO-413.
The present studies using sustained-exposure formulations of BDNF and M3 demonstrate the effectiveness of TrkB agonists in alleviating noise-induced cochlear synaptopathy in vivo. The pharmacokinetic and pharmacodynamic profiles, along with the practical benefits of delayed administration, create an attractive therapeutic approach for the treatment of cochlear synaptopathy-associated hearing loss and the preservation of cochlear neurons. Correspondingly, OTO-413 has demonstrated benefit in a Phase 1/2 clinical trial in subjects with speech-in-noise hearing impairment across various intelligibility metrics.

Title: Aav-mediated gene therapy with oto-825 rescues hearing loss and cochlear degeneration in two mouse models of gjb2 congenital hearing loss

Authors: *P. URIBE[1], P. D. MATHUR[1], X. WANG[1], S. SZOBOTA[1], J. BARDEN[1], S. SIEGEL[1], C. L. BARTOLOME[2], D. JARAMILLO[2], A. HARROP-JONES[1], R. FERNANDEZ[1],

Abstract: Congenital hearing loss is the most common inherited sensory disorder. Of the >100 genes associated with hereditary deafness, most are expressed by mechanosensitive hair cells or their neighboring support cells. The *GJB2* gene encodes the protein connexin26 (CX26) which forms gap junctions across multiple cell types within the cochlea, and mutations in this gene represent the most common cause of genetic hearing loss. Results from mouse and human studies have shown that *GJB2* mutations lead to degeneration of cochlear structures within the organ of Corti. We previously reported a class of novel AAV capsids that efficiently transduce cochlear cell types that natively express CX26 in rodents and nonhuman primates. We then further optimized the AAV construct by packaging the novel capsid, a broad spectrum promoter, and human GJB2 gene elements with and without a Flag tag (OTO-825-Flag and OTO-825, respectively). To test the efficacy of OTO-825 we utilized *in vitro* assays and two different conditional *Gjb2* knockout mouse models (*Cx26* cKO) to assess *in vivo* rescue of *Gjb2* deficiency. In cell-based assays, utilizing HeLa cells that do not natively express CX26, OTO-825 induced expression of CX26 that was correctly trafficked to the cell membrane, evidenced by typical gap junction plaque-like expression. In the same cells, OTO-825 enhanced uptake and intercellular transfer of gap junction-permeant dyes suggesting that the AAV-delivered CX26 forms functional gap junctions. Intracochlear injection of OTO-825-Flag into rodents or nonhuman primates labeled cell types that natively express CX26 in a plaque-like manner consistent with endogenous CX26. To assess the potential for in vivo rescue using OTO-825, two *Cx26* cKO mouse models were generated by crossing $Cx26^{loxp/loxp}$ mice with either a tamoxifen inducible cre mouse line (*Rosa*) or an inner ear-specific constitutive cre mouse line (*P0*). In both models, cre induction caused severe to profound hearing loss. *Cx26* cKO mice also exhibited severe loss of hair cells, a phenotype that is characteristic of *GJB2* mutations in humans. We then performed postnatal intracochlear injection of OTO-825 or vehicle into *Cx26* cKO mice. Compared with vehicle, administration of OTO-825 to *Cx26* cKO mice substantially restored CX26 expression, rescued hair cell and support cell loss, and more importantly demonstrated functional improvement in hearing across multiple frequencies as measured using auditory brainstem responses (ABR). These encouraging results support the further development of OTO-825 as a clinical candidate for the treatment of congenital hearing loss caused by *GJB2* mutations.

Title: Asymmetry in vestibular afferent responses to transmastoid galvanic vestibular stimulation

Authors: *P. A. FORBES[1], A. KWAN[2], D. E. MITCHELL[3], J.-S. BLOUIN[4], K. E. CULLEN[5]; [1]Erasmus Med. Ctr., Rotterdam, Netherlands; [2]McGill Univ., Montreal, QC, Canada; [3]Dept. de neurosciences, Univ. De Montréal, Montreal, QC, Canada; [4]Univ. of British Columbia, Vancouver, BC, Canada; [5]Dept. of Biomed. Engin., The Johns Hopkins Univ., Baltimore, MD

Abstract: Vestibular afferent activity, which encodes head movement and orientation, can be modulated by delivering galvanic vestibular stimulation (GVS) through electrodes placed on the mastoids. This virtual signal of head motion has grown as a unique technique to investigate and manage vestibular disorders, and provide artificial sensations of motion for virtual reality applications. Establishing a direct relationship between GVS- and motion-evoked vestibular responses is critical for developing methods that mimic natural motion. Indeed, dynamic models (i.e. transfer functions) of GVS-evoked afferent responses are used to estimate and generate motion equivalent activation of vestibular afferents using GVS. The underlying assumption, however, is that GVS-evoked activity has symmetric effects on afferent firing rates across stimulus polarity. Here we directly investigated whether vestibular semicircular and otolith afferents symmetrically encode opposing polarities of transmastoid GVS. We recorded responses from individual vestibular afferents in macaque monkeys during prolonged (40 s) constant current stimulation using a bilateral bipolar configuration. We found that the onset and offset of constant current GVS evoked significant asymmetries in irregular but not regular afferent responses. While significant asymmetries were seen in both semicircular canal and otolith systems, they were most pronounced for irregular otolith afferents. Similar asymmetries were observed when comparing afferent responses to cathodal and anodal stimulation; the offset of a cathodal stimulus was comparable to the onset of an anodal stimulus, and vice versa. Likewise, afferent response dynamics differed for stochastic GVS stimulation that spanned the physiologically relevant range of the vestibular system (0-25 Hz) and the application of single sinusoidal GVS stimulation over the same range. Using computational methods, we establish that a nonlinear model that separately combines the dynamics of afferent responses to anodal and cathodal stimuli can explain the changes in firing rate evoked by both constant current and stochastic GVS. Finally, and surprisingly, using established models of neural activity to natural motion, we found that in both stimulus directions the sustained firing rate throughout stimulation is encoded as constant rotational and linear acceleration signals for the canals and otoliths, respectively. Taken together, our results reveal the neural substrate underlying asymmetries in

GVS-evoked perceptual and responses, thereby providing new insights in developing physiologically relevant models and advancing the application of GVS.

Title: Galvanic stimulation of the vestibular afferent reveals novel ability to produce naturalistic firing patterns via pre-synaptic and axonal modulation

Authors: *C. STEINHARDT[1], G. FRIDMAN[2];
[1]Biomed. Engin., [2]Otolaryngology, Johns Hopkins Univ., Baltimore, MD

Abstract: Galvanic vestibular stimulation (GVS) is a common tool for probing computations of the vestibular system and regularly used in the clinic to diagnosis eye movement conditions without requiring physical displacement. An on-going debate surrounds how GVS activates neurons to induce these eye motions, including to what extent it affects afferents of different regularity and via which mechanism it drives changes in firing rate. In previous work, cathodic and anodic direct current (DC) and sinusoidal stimulation were introduced to irregular afferents *in vitro*, revealing afferents are highly sensitive to GVS, smoothly modulate firing rate proportional to GVS amplitude while preserving CV*, and show high pass filtering effects in response to sinusoidal modulation. In this study, we form a cohesive explanation for these effects by systematically refining the Hight and Kalluri (2016) model until a single simulation neuron could replicate the results of all experiments. The original Hight and Kalluri model of the vestibular hair cell-axon complex simulates an axon with realistic channel dynamics receiving stochastic EPSC input. Using this model, we find that when GVS directly affects the axon, it raises or lowers the membrane potential in turn increasing or decreasing the probabilities of EPSCs becoming action potentials. Because the spike timing derives from the timing of EPSCs, GVS preserves firing statistics (CV*) while modulating the firing rate. The other effects can only be explained if GVS triggers two additional natural effects of mechanical perturbation of the hair bundle: hair cell adaptation pathways and the non-quantal effect. When the simulation includes equations so that GVS produces these effects as well, it replicates all experimental findings from

the *in vitro* study. These findings corroborate previous evidence that GVS affects the hair cell and put forward a wholistic model with testable predictions to resolve this debate. More generally, our findings indicate that GVS it has a unique ability to produce axonal, synaptic, and pre-synaptic effects and activate natural pathways. These capabilities position galvanic stimulation as an exciting tool for scientific exploration and clinical interventions in the brain and peripheral nervous system.

Title: The effect of activating a vestibular prosthesis on the activity of units recorded in 8th nerve of monkey.

Authors: L. LING[1], Y. KOJIMA[1], A. NOWACK[1], S. D. NEWLANDS[3], J. O. PHILLIPS[2]; [2]Otolaryngology - HNS, [1]Univ. of Washington, Seattle, WA; [3]Otolaryngology, Univ. of Rochester Med. Ctr., Rochester, NY

Abstract: Introduction: Vestibular loss is often caused by damage to the sensory periphery. A vestibular prosthesis can theoretically restore function by bypassing the damaged region and activating vestibular afferents directly. This study evaluated how vestibular afferent fibers respond to prosthetic activation.
Methods: We simulated natural vestibular loss in rhesus monkeys by repeated bilateral injection of gentamicin into the middle ear, causing reduction of the passive rotational VOR gain. We recorded from fibers in the 8th nerve to examine how activation of the vestibular prosthesis is reflected in the pattern of discharge. We extracted unit activity from the field potential that follows the stimulus artifact. We estimated the pure field potential for each stimulus condition to be subtracted from the raw signal to reveal the underlying single unit activity.
Results: Many units with regular tonic discharge show no change in activation from any electrode of the vestibular prosthesis at maximal safe currents (without overt spread to facial nerve). Some regular units are driven in a canal specific manner. Many spikes following the stimulus pulse are shifted to be aligned at short latency (0.6-0.8 ms) whereas the rest of the spike train remains unaffected. Typically, spikes are consistently elicited by stimulation from a single canal site, and then less consistently elicited from another canal. Units with irregular tonic discharge display added spikes which are elicited at short latency (0.5-0.9 ms) following

stimulus pulses generated by the implanted device. The stimulus-triggered histogram shows a clear gap following the stimulus artifact. However, the added spikes are not exclusively elicited by electrical stimulation of the canal in the plane of the passive rotational response of the afferent fiber. In addition, we encountered 8th nerve fibers driven inconsistently at short latency, but consistently at synaptic latencies of 1.5-2.0 ms, and which pause during saccades. We hypothesize that these are vestibular efferents.
Conclusion: Multiple types of response are seen in 8th nerve fibers in response to stimulation with a vestibular prosthesis. This variety of discharge may provide a clue to the mechanism underlying afferent activation with such devices.

Title: Sex differences and the influence of auditory experience on premotor HVC neurons of juvenile zebra finches

Authors: *A. BRUNICK[1], R. BERTRAM[2], F. JOHNSON[3], R. L. HYSON[3];
[1]Program in Neurosci., [2]Dept. of Mathematics, [3]Dept. of Psychology, Florida State Univ., Tallahassee, FL

Abstract: Juvenile zebra finches undergo auditory learning when exposed to an adult tutor's song during development, though only males will go on to produce a song as adults. The network that modulates vocal output is largely conserved between males and females, though the nuclei tend to be much smaller in females. The cortical premotor nucleus HVC (proper name) projects to two motor regions (robust nucleus of the arcopallium [RA] & Area X), allowing for direct and indirect modulation of vocal motor output, respectively. The influence of these pathways on vocal motor output changes throughout development, in males. HVC is critical for timing of adult song production and is sensitive to auditory experience. The function of HVC in females, particularly during development, is poorly understood. To better understand the differences between male and female HVC, whole cell recordings were obtained from sections of HVC to compare the electrophysiological features of HVC neurons in juvenile males and females raised with or without a tutor, at the time males begin sensorimotor learning (~40 days post hatch). Recorded neurons were filled with biocytin for later confirmation of their location within HVC

and to confirm cell identity when possible. Preliminary results demonstrate that there are sex differences in the spike width and spike accommodation of HVC_X neurons, and these effects seem to be sensitive to auditory experience. Potential group differences in putative HVC_{RA} neurons have also emerged including, but not limited to, changes in spike latencies and voltage sag. The effect of auditory experience on physiology differs between males and females, suggesting that different mechanisms mediate these changes. However, there is more overlap in the features than there are differences, which suggests that HVC neurons have "default" physiological states. These differences due to auditory experience expand upon prior investigation of HVC neuron physiology and demonstrate that there is considerably more heterogeneity within cell groups than expected. This means that any effects of auditory experience are more nuanced than previously thought. These subtle physiological changes could have large impacts on activity propagation within HVC, particularly when examining HVC's microcircuitry.

Title: Vocal-motor network in the female zebra finch

Authors: *D. SHAUGHNESSY[1], R. BERTRAM[1], F. JOHNSON[1], R. L. HYSON[2];
[2]Dept Psychology, [1]Florida State Univ., Tallahassee, FL

Abstract: The zebra finch (Taeniopygia guttata) is a songbird whose expertise in vocal learning is studied for insight into how brain & behavior contribute to the learning, encoding, and production of a vocal-motor skill — singing. Zebra finch song production is sexually dimorphic, where only male zebra finches learn to produce song although both sexes form an auditory memory of adult tutor song during a developmental critical period. This offers a within-species contrast between subjects who experience auditory learning + motor learning (males) and subjects who experience only auditory learning (females) in the song-learning context. One hypothesis for why only males sing is that only males possess the requisite neural circuitry for song production. This hypothesis is supported by a handful of early zebra finch neuroanatomy papers which reported that the network of discrete brain regions linked to song in male brains were mostly absent in females. Previously we used a novel surgical visualization technique to target tracer injections into female vocal-premotor cortex (**HVC**, proper name) - demonstrating

formerly uncharted male-typical connections to a range of other song network nodes. Notably, adult female HVC robustly innervates female vocal-motor cortex (**RA**, robust nucleus of the arcopallium), a connection which is integral to learned song production in male zebra finches. In males, RA integrates cortical pre-motor input from HVC and LMAN (lateral magnocellular nucleus of the anterior nidopallium), and projects to vocal-motor control regions of the brainstem. In the present study we continue mapping female vocal-motor circuitry by examining the anterograde and retrograde connectivity of female RA. Here we inject bidirectional fluorescent dye into female RA and verify injection sites histologically. In RA-injected female brains we find male-typical retrograde connectivity to HVC and LMAN and male-similar anterograde projection in the vocal brainstem. Our findings demonstrate the potential of the female zebra finch brain to advance our understanding of the division of sensory & sensorimotor learning within the song network.

Title: Automated classification of neurons based on electrophysiological features

Authors: *P. EASTHAM, A. BRUNICK, R. HYSON, F. JOHNSON, R. BERTRAM; Florida State Univ. Program In Neurosci., Tallahassee, FL

Abstract: Electrophysiology experiments are often conducted in an effort to categorize neurons into different classes based on exhibited features. A primary difficulty in categorizing neurons is the subjective choices of the experimenter which, to the detriment of experimental rigor, makes reproducing or comparing classifications across labs difficult. Additionally, there is no measure for choosing a representative neuron from a given class which, for example, can be used in a data visualization in a manuscript. We describe a novel method for the automated classification of neuronal phenotypes based on electrophysiological data. This method relies on generating network graphs whose nodes are biological neurons and weighted edges represent the “degree of similarity” between neurons. Using existing graph theory and optimization algorithms leads to the automatic classification of neuronal phenotype based on features and, furthermore, allows selection of a representative neuron for each class. As a demonstration, we apply this method to classify physiological properties of Zebra Finch HVC neurons. This method is accessible for

neuroscience researchers and will aid in the reproducibility of neuronal phenotype classification. In particular, it provides a rigorous and objective method for investigators to define the representative case when presenting physiological data.

Title: Just around the corner: Acoustic mirroring enables echolocating bats to detect hidden targets

Authors: *K. M. ALLEN, C. FARID, M. FU, C. F. MOSS;
Dept. of Psychological and Brain Sci., Johns Hopkins Univ., Baltimore, MD

Abstract: The ability to detect salient targets and segregate them from background clutter is a key function of sensory systems. The presence of clutter stimuli typically degrades sensory performance in a variety of detection tasks. The echolocating bat Eptesicus fuscus is an ideal model for investigating the influence of clutter on target detection, as they must navigate through dense foliage at high speed, while simultaneously tracking small moving prey. This difficult task requires bats to reliably detect and track objects in the environment despite changes in distance, angle of view, and interference from background clutter echoes, which obscure targets from sonar “view” and creates physical barriers bats must navigate around. However, recent studies reveal that environmental clutter echoes may improve performance under some conditions. Previous neurophysiological recordings in the bat inferior colliculus indicate that acoustic scattering caused by physical clutter from foliage can improve target discrimination when the separation between target and clutter is ~20 cm. These findings suggest the possibility that acoustic reflections from environmental clutter may provide additional “glimpses” of targets, and under the correct conditions, improve target discrimination. Here, we test the ability of echolocating bats to make use of acoustic mirrors from clutter objects for target detection using a yes/no behavioral assay inspired by Non-Line of Sight Imaging experiments. Much like technology employed by machine imaging, robotics, and self-driving automobiles, we test the

potential for bats to “see around corners” using only echoes reflected from objects in the environment to locate a target hidden behind an occluder.

Title: Two-photon calcium imaging reveals functional microarchitecture for auditory processing in the inferior colliculus of the awake bat

Authors: *J. LAWLOR BLONDEL[1], Y. SUEOKA[2], P. GUTRUF[3], M. J. WOHLGEMUTH[4], C. F. MOSS[1], K. KUCHIBHOTLA[1];
[1]Psychological and Brain Sci., Johns Hopkins Univ., Baltimore, MD; [2]The Solomon Snyder Dept. of Neurosci., Johns Hopkins Univ. Sch. of Medecine, Baltimore, MD; [3]Dept. of Biomed. Engin., [4]Dept. of Neurosci., Univ. of Arizona, Tucson, AZ

Abstract: Navigating our everyday world requires parsing relevant information from constantly evolving sensory flows. How the brain processes and sorts sensory inputs is a central ongoing question in systems neuroscience. Here, we take advantage of a model long-studied for its expert auditory sensing of the world: the echolocating bat. The echolocating bat produces ultrasonic vocalizations and listens to returning echoes to determine the identity and location of objects in the environment. As such, the bat constructs a rich representation of the external environment primarily using the auditory modality, making it a powerful model to study how the brain represents natural acoustic signals. While traditional multi-channel electrophysiology techniques have provided key insights into network-level activity, they are limited in their ability to reveal micro-functional architecture and cell-type specific activity. We developed two-photon calcium imaging in the awake big brown bat, *Eptesicus fuscus*, to assay the activity of a population of neurons with cellular and sub-cellular resolution. We expressed GCaMP6f in the excitatory population of the Inferior Colliculus, a central auditory hub, while using a head-fixation and thinned-skull surgical approach to longitudinally monitor the same local population over days to weeks. We assessed functional auditory properties of thousands of neurons in awake, passively listening bats (n=3) by presenting pure tones, white noise, frequency sweeps, echolocation and social calls, and other stimuli. We parametrically controlled features including the duration and delay of relevant stimuli. In preliminary analyses, we observe a novel, fine-scaled tonopy in the superficial layers of the IC. In addition, presentation of ‘prey capture’ echolocation sequences

varying in their spectral content (‘natural’ vs ‘artificial’) elicited a population rotational dynamic reflecting the temporal structure of the call sequence, while manifolds separate the spectral information. In the longer-term, we will use these studies as an entry point to understand the neural basis of active sensing in the context of ethologically-relevant behaviors by combining cell-type specific calcium imaging with wireless optogenetics.

Title: Vocal perceptual category boundaries are modified by maternal experience in female mice

Authors: *L. SHEN, S. D. SHEA;
Cold Spring Harbor Lab., Cold Spring Harbor, NY

Abstract: Only a fraction of sounds an organism encounters are behaviorally significant. One example is vocalizations, which occur against a backdrop of sounds with overlapping features, while exhibiting substantial variability. This presents two competing challenges: detection must be selective enough to minimize false alarms while also being tolerant to natural variation. Here we use a vocally-motivated pup retrieval behavior to reveal how the brain adjusts and enforces perceptual boundaries between vocal signals and other sounds. When pups are separated from their nest, they emit an ultrasonic vocalization (USV) that maternally-experienced mice can use to locate and retrieve the pups back to the nest. We have developed a high-throughput, quantitative behavioral paradigm where nulliparous female mice are water-deprived and trained in a probabilistic go/no-go task. They are conditioned to lick a water spout in response to playback of a USV, and to withhold licking in response to a synthetic tone. Once stable performance (>80%) is achieved, the mice are separated into two groups: mice that are exposed to pups and gain maternal experience (‘surrogates’), and mice that have never been exposed to pups (‘naïves’). We next present a set of novel sounds to the mouse as infrequent and unrewarded catch trials (including bandwidth-limited noise and pitch-shifted USVs), and we use licks to the novel stimuli as a measure of perceived similarity to natural USVs. These infrequent stimuli are not rewarded, and USVs are rewarded on 80% of trials. The catch trials demonstrate that mice response rates vary systematically with the catch trials stimuli similarity to natural USVs, a result supported by a freely moving behavioral task where mothers are timed in how quickly they approach a speaker playing the catch trial sounds. Furthermore, we find that responses to the synthetic sounds show evidence of learning between initial and late trials that

differs in naïves and surrogates. Initial responses of surrogates towards broadband sounds in the range of USVs are similar to those of the Go-Cue, while naïve mice tend to initially have lower response rates to those same sounds. Late responses of surrogate mice toward those same sounds were generally lower than those of the naïve mice. Finally, electrophysiological data in the primary auditory cortex done before and after behavioral training suggests that those neurons adjust their firing rate following both pup exposure and task learning. Taken together, our results suggest that vocal perceptual filters are optimized during maternal experience, and will provide insight into how categorical perception contributes to speech processing and learning.

Title: Inferior colliculus neurons respond to individual syllables of mouse ultrasonic vocalizations with high specificity

Authors: *B. J. SLATER, R. D. MOONEY;
Dept. of Neurobio., Duke Univ., Durham, NC

Abstract: The fidelity of auditory stimulus representation varies markedly from the periphery to the cortex. The coding behavior of earlier nuclei is characterized by neuronal responses statistically similar to a given stimulus progressing to higher order nuclei with sparse representation for even complex stimuli, such as vocalizations. The transformation of high to low statistical fidelity in the auditory system is most often characterized in reference to pure tone stimuli. However, it is unclear how these pure tone responses relate to the neural coding of vocalizations, which are by spectrotemporally more complex and dynamic than tones. Neurons in the inferior colliculus (IC) can exhibit complex and specific responses to acoustic signals as a function of their timing, intensity, and frequency, but how this complexity relates to natural sound stimuli remains unclear. Using extracellular recordings in the IC of awake head-fixed mice, we examined neural responses to both pure tones as well as playback of ultrasonic vocalizations (USVs) previously recorded during courtship behavior. As expected, most IC neurons responded to pure tones in a frequency-dependent manner, the greatest response being

referred to as a neuron's best frequency. We also found a majority of IC neurons responded to playback of USVs with high temporal precision, and often only to a single syllable in the USV bout. Curiously, we did not find a good correlation between an IC neuron's best frequency and mean frequency of the USV syllable(s) that it responded to. We also found that while some neurons responded to a number of different syllables, there were no units that were responsive to all syllables within bout. This indicates that there is particular specificity of IC neurons to individual syllables within the animal's vocal repertoire.

Title: Cell type specific short-term plasticity of sound offset responses in the auditory cortex

Authors: *T. R. OLSEN, A. R. HASENSTAUB;
Otolaryngology / Ctr. for Integrative Neurosci., UCSF, San Francisco, CA

Abstract: The neural response to sound is dependent on stimulus history, with sound-evoked responses subject to various forms of short-term plasticity (STP). In addition to spiking in response to sound onsets, many neurons in the central auditory system fire action potentials in response to the cessation of a sound (so-called "offset responses"). Sound offset responses are essential for aspects of sound processing including the encoding of sound duration and the discrimination of up versus down frequency-modulated sweeps, which in turn are essential for the understanding of continuous sounds such as speech. Whether offset responses are also subject to STP is currently unknown. We here study the history-dependence of sound offset responses among units in the primary auditory cortex (A1). Inhibitory interneurons in A1 are also subject to STP, and their activity in turn shapes the temporal response profile of excitatory neurons. We therefore also measured offset STP in PV- and SST-tagged inhibitory neurons. We presented awake mice with a series of repeating noise bursts, recorded through the layers of

cortex with a silicon probe, and measured dynamics of spiking response magnitudes. Single units responded to sound onsets, offsets, and/or both, with purely offset responsive neurons far less common than purely onset responsive neurons. Onset responses mainly adapted over repeated sound stimuli, with a smaller proportion of units showing either no change or facilitation. In contrast, sound offset responses were less likely to adapt and more likely to either remain stable or facilitate. Among units which showed both onset and offset responses, onset response plasticity was not predictive of offset response plasticity, and vice versa. PV-tagged interneurons typically showed both onset and offset responses, with their onset responses predominantly adaptive and their offset responses more likely to be either stable or facilitating. SST-tagged neurons typically showed onset responses but not offset responses, with their onset responses more likely to facilitate than those of broad-spiking and PV-tagged units. This study reveals that offset responses in A1 are subject to short-term plasticity, with different cell types in A1 showing varying amounts of onset and offset adaptation and facilitation. The discovery of offset STP presented in this study increases our understanding of the auditory system's response to continuous sound, and provides a foundation for future research into the function of offset responses in a brain where response magnitudes are infrequently static over time.

Title: Cortical efficient coding dynamics shape behavioral performance

Authors: *C. F. ANGELONI[1], W. F. MLYNARSKI[2], E. PIASINI[1], A. M. WILLIAMS[1], K. C. WOOD[1], L. GARAMI[1], A. M. HERMUNDSTAD[3], M. N. GEFFEN[1];
[1]Univ. of Pennsylvania, Philadelphia, PA; [2]Brain and Cognitive Sci., Inst. of Sci. and Technol. Austria, Klosterneuburg, Austria; [3]Janelia Res. Campus, Ashburn, VA

Abstract: The efficient coding hypothesis postulates that neurons shape their response properties to match their dynamic range to the statistics of incoming signals. However, whether and how the dynamics of efficient neuronal adaptation inform behavior has not been directly shown. Here, we trained mice to detect a target presented in noise shortly after a change in the noise contrast.

The observed changes in cortical gain and detection behavior followed the predictions of a normative model of efficient cortical sound processing; specifically, target detection and sensitivity improved in low contrast relative to high contrast noise. Furthermore, the time course of cortical gain and target detectability varied depending on contrast, decreasing rapidly after a transition to high contrast, and increasing at a slower rate after a transition to low contrast. We found that the auditory cortex was required for detection of targets in noise and neuronal responses exhibited the predicted patterns of target detectability. Furthermore, the magnitude of gain modulation in cortical neurons predicted individual differences in behavioral performance. Combined, our results demonstrate that efficient neural codes in auditory cortex directly influence perceptual behavior.

Title: Function of cortical NDNF interneurons in sound frequency discrimination

Authors: *M. E. THOMAS[1], C. G. SWEENEY[1], E. Y. YU[2], K. SMITH[1], W. REID[3], A. E. TAKESIAN[1];
[1]Mass Eye and Ear, Harvard Med. Sch., Boston, MA; [2]Harvard Col., Cambridge, MA; [3]Harvard Univ., Cambridge, MA

Abstract: Sound frequency discrimination, the ability to distinguish between pure tones of different frequencies, underlies both speech and music perception. A growing understanding of auditory cortical interneuron circuits has highlighted the role of specific inhibitory interneurons in shaping frequency tuning and discrimination acuity. Here, we focus on a recently identified class of interneurons that express neuron-derived neurotrophic factor (NDNF) and reside primarily within neocortical layer 1. In auditory cortex, NDNF interneurons integrate direct sensory inputs from the auditory thalamus and long-range neuromodulatory signals from diverse

brain regions. In turn, these interneurons powerfully inhibit the distal dendrites of excitatory neurons while simultaneously disinhibiting their somata via deeper projections to parvalbumin-positive interneurons. While this circuitry suggests that NDNF interneurons are poised to shape excitatory neuron tuning, little is known about their function in sound processing. Thus, the present research aims to investigate the function of NDNF interneurons in frequency tuning of neurons in primary auditory cortex and behavioral frequency discrimination in mice. Using in vivo two-photon calcium imaging, we first characterized the tuning properties of NDNF interneurons in response to pure tones of varying frequencies and intensities. We found that a subset of NDNF interneurons exhibit robust frequency and intensity tuning comparable to excitatory neurons in layer 2/3. We next developed a behavioral frequency discrimination paradigm in which mice distinguished trains of repeating pure tones of a single frequency from trains of two alternating tones of different frequencies. Mice readily learned this task within two weeks, allowing us to establish reliable frequency discrimination thresholds by varying the frequency of the alternating tone. We subsequently recorded the responses of both NDNF interneurons and layer 2/3 excitatory neurons to the training stimuli under both passive and behaving contexts. We identified individual neurons in both neuron classes capable of discriminating between repeating or alternating tones, and future analyses will assess the population dynamics associated with behavioral discrimination. Finally, ongoing experiments using chemogenetic silencing of NDNF interneurons will demonstrate the necessity of their activity for task performance. This work will help establish the function of NDNF interneurons in frequency discrimination and further elucidate the contribution of specific inhibitory cortical circuits to sound processing.

Title: Olfactory modulation of auditory cortical responses to sound

Authors: *N. W. VOGLER, T. LING, A. C. VIRKLER, V. Y. TU, J. A. GOTTFRIED, M. N. GEFFEN;
Univ. of Pennsylvania, Philadelphia, PA

Abstract: In complex environments, the brain must integrate information from multiple sensory modalities, including the auditory and olfactory systems, for perception and behavior. However, despite the importance of multisensory integration, there is a critical gap in our understanding of how the brain integrates auditory and olfactory stimuli. Here, we investigated the mechanisms underlying auditory-olfactory integration using electrophysiology, anatomy, and behavior. First, we tested whether and how odor stimuli modulate auditory cortical neurons' responses to sound in awake mice. We developed an experimental system for delivering combinations of auditory and olfactory stimuli, and we collected *in vivo* electrophysiological recordings from the auditory cortex (ACx) in response to sounds, in the presence or absence of an odor. Our results demonstrate that ACx neurons exhibit greater firing rates in response to an odor stimulus (odor+air) compared to air alone. Furthermore, the presence of odor changes the gain of sound responses. Together, these results demonstrate that ACx neurons are odor-responsive, and that odors modulate sound responses in awake mice. Next, we used viral tracing strategies to investigate the anatomical circuits underlying auditory-olfactory integration. Our results demonstrate direct inputs to the ACx from the piriform cortex (PCx), suggesting a possible substrate for olfactory integration in ACx. Finally, behavioral experiments are investigating how odor stimuli influence sound detection. Combined, our results point to ACx as an important area for auditory-olfactory integration.

Title: Recurrent network activity in layer 1 interneurons of the mouse primary auditory cortex

Authors: *L. G. VATTINO[1], M. E. THOMAS[1], C. G. SWEENEY[1], R. BRITO[2], C. P. MACGREGOR[3], A. E. TAKESIAN[1];
[1]Massachusetts Eye and Ear - Harvard Med. Sch., Boston, MA; [2]Massachusetts Eye and Ear - Speech and Hearing Biosci. and Technology, Div. of Med. Sciences, Harvard Med. Sch., Boston, MA; [3]Massachusetts Eye and Ear, Boston, MA

Abstract: Inhibitory interneurons in neocortical layer 1 (L1) convey behaviorally relevant information by integrating sensory-driven inputs with neuromodulatory signals. Their activity is known to regulate moment-to-moment encoding of the sensory environment in a context-dependent manner and can drive cortical plasticity mechanisms, both during postnatal development and adulthood. We and others have shown that these interneurons are heterogenous and can be subdivided into two major classes defined by the expression of either neuron-derived neurotrophic factor (NDNF) or vasoactive intestinal peptide (VIP). It has been previously demonstrated that L1 interneurons make recurrent synaptic contacts and are also connected electrically through gap junctions, suggesting that they might form coordinated inhibitory networks. However, the connectivity patterns of specific L1 interneuron subtypes and the *in vivo* functional implications remain unclear. We performed fluorescence-guided whole-cell electrophysiology in slices of the mouse primary auditory cortex (A1) while optogenetically activating VIP or NDNF interneurons. We found that $GABA_A$-mediated synaptic connections between NDNF interneurons were significantly stronger than those between VIP interneurons or other L1 interneurons, suggesting a robust NDNF recurrent inhibitory network. Next, we performed two-photon calcium imaging in A1 of awake, behaving mice to monitor the spontaneous and sound-driven activity of networks of VIP and NDNF interneurons. These results will reveal how behavioral context impacts the *in vivo* coordinated activity of these L1 inhibitory networks. Together, our findings suggest that distinct connectivity patterns among NDNF and VIP interneurons may underlie specialized functions in sensory encoding and cortical plasticity.

Abstract: Sensory cues are differentially encoded depending on the contextual stream in which they are embedded. This adaptation can be understood through a predictive coding framework, in which responses to predictable stimuli become attenuated, in a process known as repetition suppression, while unexpected cues elicit a prediction error response. In the auditory system, prediction error first appears at the level of the auditory midbrain, or inferior colliculus (IC), and is most prominent in the auditory cortex (AC), suggesting that these regions engage in hierarchical predictive coding. To determine whether descending connections from AC to IC carry top-down predictions, we selectively suppressed the cortico-collicular (CC) pathway while recording responses to predictable and unpredictable stimuli in IC.
To selectively target auditory CC cells, we made bilateral injections of a retro AAV-Cre construct in IC, while injecting an AAV-Flex-ArchT construct in AC. We performed extracellular recordings in IC in awake mice while oddball stimuli, consisting of 90% repeated, or "standard" tones, and 10% deviant tones, were played to the contralateral ear. An additional control sequence that was free of repetition effects and contained no statistical deviants was used to compute prediction error and repetition suppression metrics. We suppressed CC cells on a fraction of trials, and quantified differences in predictive coding metrics for laser on and off conditions.
We found that suppression of the CC pathway led to a decrease in prediction error but did not affect repetition suppression, suggesting that this metric may reflect fatigue of bottom-up sensory inputs. We also discovered populations of IC neurons that exhibit repetition enhancement, an increase in firing with stimulus repetition, and error suppression, a stronger response to a tone in a predictable rather than unpredictable context. CC suppression led to a decrease in repetition enhancement and a reduction in error suppression. Neurons in IC responded more similarly to each context in the absence of cortical input, suggesting that AC provides cues about the statistical context of sound to subcortical brain regions.

Title: Differential function of distinct inhibitory neuronal types in cortical networks

Authors: *M. TOBIN[1], J. SHETH[1], K. WOOD[2], M. N. GEFFEN[1];
[2]Dept. of Otorhinolaryngology, [1]Univ. of Pennsylvania, Philadelphia, PA

Abstract: Cortical neuronal networks are comprised of multiple types of excitatory and inhibitory neurons, which perform specific computations. In the auditory cortex (AC), excitatory neurons receive the sound input and transmit the processed signal to other areas, whereas the inhibitory neurons dynamically help shape the response of the excitatory neurons. Different inhibitory neurons differentially affect sound processing in excitatory neurons, yet how they affect network dynamics remains poorly understood. To establish the role of different interneurons within the cortical network, we stimulated specific interneuron subpopulations, while imaging the network responses to sounds in AC of awake, head-fixed mice. We monitored the activity of populations of hundreds of neurons using two-photon calcium imaging and simultaneously increased the activity of an interneuron subpopulation using optogenetic stimulation. We focused on vasoactive intestinal peptide-positive (VIP) and somatostatin-positive (SST) inhibitory neurons, which have been found to shape cortical responses in a context-dependent fashion (Natan et al, 2015; Pi et al, 2013). Responses of cells activated by sound were enhanced when VIPs were activated, but reduced upon activation of SSTs. The timing of the responses of sound-activated cells did not change with VIP activation, whereas SST activation slowed down their responses. Sound elicited an increase in response in different populations of neurons at different levels of interneuron activation, with more overlap between these populations with VIP than with SST activation. By fitting rate-level functions of single neurons by either a sigmoid (monotonic) or Gaussian (non-monotonic) function, we observed that SST activation displaced the rate-level functions of monotonic cells to higher sound amplitudes and reduced the maximum response in non-monotonic cells. VIP activation led to an upward shift of the rate-level functions to higher responses for monotonic cells and to an increase in the mean and variance for non-monotonic cells. At the population level, we computed measures of detectability and discrimination across neural populations. SST activation decreased population detectability of sounds and increased discriminability between sounds. By contrast, VIP activation increased population sound detectability and decreased discriminability between sounds. We conclude that the activation of VIP or SST interneurons leads to opposite effects on the response of the neural networks to sounds in AC. Our results suggest that the VIP and SST neurons are likely differentially recruited in discrimination and detection behaviors.

Title: High call repetition rate enhances objects representation in the bat primary auditory cortex

Authors: *S. MACIAS, K. BAKSHI, M. SMOTHERMAN;
Dept. of Biol., Texas A&M Univ., College Station, TX

Abstract: The temporal order and proximity of sounds influence both their perception and neuronal responses. Here, we investigated how internal representation of target's surface in the primary auditory cortex (A1) of bats is affected by the high pulse repetition rates used during echolocation. We recorded the responses of 165 neurons from the A1 of four passive listening Mexican free-tailed bats, *Tadarida brasiliensis*, while stimulating with sequences of pulses and echoes at different repetition rates recorded from surfaces with different roughness. Pulse-echo combinations repeated at 12 and 15 Hz produced a significant reduction in the neuronal response. This decrease in the neurons number of spikes came along with an increase in the response temporal precision and the amount of information carried by spike times across time. In addition, it contributed to neuronal synchronization patterns with a higher signal to noise ratio. We propose that the primary auditory cortex in the bat uses this reduction in the neuronal response as leverage to improve the ability of discriminate objects with different shape and structure.

Title: Teasing apart the influences of neural fluctuations and off-CF inhibition in the inferior colliculus using wideband tone-in-noise stimuli

Authors: *J. FRITZINGER, L. H. CARNEY;
Univ. of Rochester, Rochester, NY

Abstract: There are many proposed mechanisms in the auditory periphery and midbrain for encoding of complex sounds. We hypothesize that comparison of responses to diotic and contralateral wideband tone-in-noise (WB-TIN) stimuli in the inferior colliculus (IC) can differentiate between mechanisms. Two mechanisms of interest are capture and off-characteristic frequency (CF) inhibition. Capture occurs when a tone near the CF of an inner hair cell (IHC) saturates its response, reducing the amplitude of neural fluctuations, the low-frequency changes in auditory-nerve firing rate that arise from nonlinear peripheral filtering of complex sounds. IC neurons are sensitive to amplitude modulation and are hypothesized to respond to neural fluctuations with enhanced or suppressed rates. Other studies have suggested a need for off-CF inhibitory inputs to IC cells to explain sensitivity to frequency sweep direction and psychophysical forward masking. Often the ipsilateral projection to the IC is inhibitory, whereas the contralateral projection is excitatory. We hypothesize that off-CF inhibition will be stronger in response to diotic WB-TIN and that the effect of capture will be similar for diotic and contralateral stimuli. Extracellular single-unit responses were recorded in the IC of two female Dutch-belted rabbits using tetrodes. The WB-TIN stimuli were four-octave noise bands centered on CF with an added tone that varied in frequency across three octaves centered on CF. Diotic or contralateral stimuli were used to investigate peripheral and brainstem contributions to IC responses. In preliminary results, diotic responses to WB-TIN often had inhibitory regions flanking an excitatory region near CF, consistent with off-CF inhibition. Contralateral WB-TIN responses had less sideband inhibition compared to diotic responses, consistent with off-CF inhibitory inputs that arise from ipsilaterally driven inputs to the IC. A current computational IC model for amplitude-modulation tuning, based on same-frequency inhibition and excitation, does not predict the responses to WB-TIN. We are testing an updated model framework with off-CF inhibition. The role of capture in IC responses to WB-TIN can also be investigated using inputs arising from our peripheral model, which features IHC saturation. Responses to diotic WB-TIN indicate the presence of off-CF inhibitory inputs to the IC. Contralateral results show weaker off-CF inhibition in some neurons, indicating ipsilateral inputs to the IC may contain off-CF inhibition. Models that feature different encoding mechanisms will be used to further explore the differences between diotic and contralateral WB-TIN results.

Title: The effects of aging on the cortical representation of continuous speech

Authors: *I. M. D. KARUNATHILAKE[1], J. L. DUNLAP[2], J. PERERA[2], A. PRESACCO[4], L. DECRUY[3], S. ANDERSON[2], S. E. KUCHINSKY[5], J. Z. SIMON[3];

Abstract: Selectively attending to speech in noisy environment is crucial in day-to-day interactions, and this becomes more challenging with aging. Neural mechanisms utilized in selective attention and speech perception with age-related differences are not well understood. In this study using magnetoencephalography (MEG), we investigate how continuous speech is perceived and represented in the cortex while attending to one speaker and ignoring the other, at different signal-to-noise ratios. We recorded MEG data from 35 subjects (18 younger, 17 older) with clinically normal hearing. The low frequency (1-10 Hz) neural responses that track the low frequency speech stimulus envelope, both attended and unattended, were investigated using temporal response functions (TRFs) and envelope reconstruction. Consistent with previous findings, older adults exhibit exaggerated speech envelope representation in all SNR conditions and systematic differences between stimulus reconstruction accuracies in attended vs unattended as well as in different SNR conditions. Integration window analysis shows that over-representation starts as early as ~70 ms and older adults' responses need a much longer integration time window (~200 ms) for better reconstruction of the speech envelope. TRF analysis produces three prominent peaks, $M50_{TRF}$, $M100_{TRF}$ and $M200_{TRF,}$ representing distinct auditory processing stages, at corresponding early, middle and late latencies respectively. Older adults exhibit stronger TRF peak amplitudes at all three latencies compared to younger, possibly due to several mechanisms. The $M50_{TRF}$ peak is relatively early in older adults, suggesting speech perception is altered even at early processing stages. In contrast, in older adults the $M200_{TRF}$ is delayed, and its amplitude negatively correlates with its latency, suggesting there are other neural mechanisms contributing to $M200_{TRF}$ modulation. Furthermore, only in older adults, the $M100_{TRF}$ and $M200_{TRF}$ peak amplitude increase and decrease respectively with task difficulty. In both groups all TRF peaks are delayed as the task becomes harder and this effect is larger for older adults, suggesting additional cortical processing is utilized with the task difficulty. Together these results suggest a possible temporal processing deficit and partial compensation in older adults' cortex, and highlights the importance of cortical processing around 200 ms that may compensate for the impaired speech perception.

Title: Evaluating the sensitivity of Functional Ultrasound Imaging for 3D retinotopy in ferret primary visual cortex

Authors: *W. HU[1], M. DOYLEY[1], F. BRIGGS[2];
[1]Electrical and Computer Engin., [2]Neurosci., Univ. of Rochester, Rochester, NY

Abstract: Functional Ultrasound Imaging (fUS), developed in 2011 [1], has quickly become an important tool in neuroscience research. Compared to traditional imaging methods like functional Magnetic Resonance Imaging (fMRI), fUS provides high spatial and temporal resolution (<0.1mm, >10Hz) with good penetration depth (>15mm). The utility of fUS in measuring the activity of small populations of neurons has not yet been fully determined, however. Here, we examine the ability of fUS to localize and differentiate the representations of visual stimuli placed at different locations within the visual field. Importantly, we reconstruct the retinotopy of the primary visual cortex (V1) of ferrets in a three-dimensional (3D) view. fUS was performed through a craniotomy, allowing imaging access to both V1 and the LGN, with a Vantage 256 scanner (Verasonics, Inc., Kirkland, WA, USA) with an 18 MHz L22-14vX transducer. Responses to drifting gratings placed at distinct positions throughout the field of view were acquired in a series of parallel para-sagittal imaging planes. To generate a ground truth retinotopic map of ferret V1, we combined retinotopic information from electrophysiological recordings [2] with an MRI-based ferret brain atlas template [3] to form a 3D retinotopic model of V1. We then stacked our fUS images to form an fUS volume and registered the fUS volume to the brain atlas template. We find good agreement between the fUS data and the 3D retinotopic model. Our objective is to further quantify the spatial resolution of fUS using an intersectional approach combining optogenetics with fUS imaging and the same 3D reconstruction and modeling pipeline.

Title: A new mesoscope for deep tissue three-photon imaging in vivo

Authors: H. JAYAKUMAR[1], C.-H. YU[2], D. FARINELLA[1], E. TILSETH[1], S. L. SMITH[2], *P. KARA[1];

Abstract: Different layers of the mammalian neocortex have very different functions and thus a complete functional architecture of the neocortex necessarily requires a description of functional maps and receptive field properties across all cortical laminae. Here we present a fully customized mesoscope with a field of view 5 × 5 mm, a Dual Independent Enhanced Scan Engines for Large Field-of-view 3-Photon imaging (Diesel3p) designed for large volume imaging of neurons and other structures across all layers of the neocortex. Based on our Diesel2p system developed for 2-photon microscopy (Yu et al. 2020 bioRxiv), the Diesel3p can be used in a variety of modalities. The two independent scan engines allow simultaneous two-region imaging with acquisition parameters independently configured for each region (see attached figure, panels a-b). Each arm can accommodate 920nm and 1300nm, so dual-region 2-photon or 3-photon imaging is feasible. The system is thus not only ideal for imaging GCaMP and various fluorescent dyes, but also may be used for third harmonic generation (THG) imaging. Our mesoscope has custom-designed relay lenses, scan lenses, a tube lens and an objective that provides a large field of view with diffraction-limited excitation to imaging depths > 1 mm. Based on the optical design model, the system has a Strehl ratio > 0.8 for 1300 nm light across a region of 5 × 5 mm, at a depth of 1 mm (see attached figure, panel c). Simultaneous imaging is implemented by temporal multiplexing of the excitation laser pulses from the two independent scan engines. We use a Vidrio Technologies DAQ and ScanImage software for demultiplexing the signals across the two scan engines. This mesoscope will help identify laminar-specific and regional-specific neural computations along with hemodynamic responses in a variety of model

systems. Thus, in addition to advances in neural circuit mapping and functional architecture, this system may help determine the neural and vascular underpinnings of signals that contribute to functional magnetic resonance imaging (fMRI).

Title: Advancing laser standards for three-photon microscopy

Authors: *D. FARINELLA, A. ROY, C. J. LIU, P. KARA;
Neurosci., Univ. of Minnesota, Twin Cities, Minneapolis, MN

Abstract: Three-photon excitation microscopy has double-to-triple the penetration depth in biological tissue over two-photon imaging and thus has the potential to revolutionize the visualization of biological processes in vivo. However, unlike the plug-and-play operation and performance of lasers used in two-photon imaging, lasers used in three-photon microscopy present new technological challenges that require a closer look at the fidelity of laser pulses. We built a second harmonic generation frequency-resolved optical gating (SHG-FROG) device (Fig. 1a), and developed and implemented a new technique called deep-memory diode imaging (DMDI) (Fig. 1d) to more fully characterize the pulse shape and pulse-to-pulse intensity stability of our commercial laser source, respectively. SHG-FROG revealed a large pulse distortion called third-order dispersion (TOD), which poses significant challenges to three-photon imaging by preventing effective compression of laser pulses and thereby decreasing the efficiency of nonlinear excitation (Fig. 1b,c). Additionally, DMDI demonstrated its ability to detect pulse-to-pulse intensity fluctuations in the laser source itself that were shown to be the cause of brightness artifacts in microscope images and were not captured using conventional diagnostics and statistics (Fig. 1e,f). If three-photon imaging is to become mainstream, these tools may be used by laser manufacturers to improve system design and by end-users to validate the performance of their current and future three-photon imaging systems.

Title: Strategies to determine the functional micro-architecture in non-rodent cortical layer 4

Authors: *A. LEIKVOLL, A. ROY, C. J. LIU, P. KARA;
Neurosci., Univ. of Minnesota, Minneapolis, MN

Abstract: In V1 of non-rodents (cats, ferrets and monkeys) receptive field properties such as orientation selectivity and binocular disparity emerge *de novo* in cortical layer 4. To date, these receptive field properties have only been determined with single-unit electrophysiological recordings. Thus, the functional micro-architecture of orientation, disparity and other maps in layer 4 remains unknown. Here we take advantage of the well-known neural and vascular functional architecture in layer 2/3 of cat V1 to determine if an equivalent architecture is present in layer 4. Moreover, because hemodynamic signals are often used a proxy for neural activity, we also determine the response selectivity of blood flow in individual layer 4 vessels. Critically, there are two major technical hurdles that need to be overcome in order to examine the functional architecture in layer 4. First, the laminar thickness of non-rodent V1 is at least twice that of mouse V1. In cat V1, we found that layer 4 is 650-1150 μm below the pial surface. This depth is inaccessible for two-photon GCaMP and iGluSnFr imaging. Also, typical AAVs with synapsin promoters do not lead to robust expression in layer 4 neurons (see Liu et al. 2020 Scientific Reports). We therefore developed three-photon microscopy for imaging in layer 4 and tested a variety of AAVs that optimally express in layer 4. As shown in the attached figure, we can successfully image in cat layer 4 with high signal-to-noise in both blood vessels (panels A-B) and neurons (panel C, green GCaMP6 neurons and blue THG). Our histology shows good expression in layer 4 (panel D, green GCaMP6 neurons and red VGLUT2 labeling LGN terminals). We will present data to compare neural and vascular responses across layers 2/3 and 4. The changes in selectivity across cortical layers for individual blood vessels appear to have a clear underpinning in neural circuitry. We expect that our three-photon imaging approach will facilitate the development of neural-to-vascular coupling models that map features of neural activity into predictions of activity observed for individual fMRI voxels.

Title: Visually-evoked responses from individual blood vessels in the white matter below V1

Authors: *A. BHALERAO, C. J. LIU, P. KARA;
Neurosci., Univ. of Minnesota, Minneapolis, MN

Abstract: Neural activity causes localized changes in blood flow. This neurovascular coupling is the basis for blood-oxygen-level-dependent functional magnetic resonance imaging (BOLD fMRI). Historically, fMRI studies on the neocortex have focused on the gray matter and undervalued BOLD signals in the white matter, whether that be ignoring them or using them for noise correction (Grajauskas et al., 2019 Front. Neurosci.). We have obtained optical imaging data from individual blood vessels which suggest that the past approach may need to be revised. We first used two-photon imaging to examine whether there were visually-evoked blood flow

responses (measured as red blood cell velocity) in the white matter below the primary visual cortex in mice. We also collected visually-evoked responses from pial and intra-cortical blood vessels. All vessels were imaged using Alexa 680 Dextran. We presented drifting square-wave grating stimuli in either a 3 × 3 or 4 × 4 grid of positions on the visual display monitor. Stimuli were presented for 5 s with 20 s of blank in between presentations and repeated 4-6 times. In a subset of experiments, we also obtained three-photon third harmonic generation (THG, 1300 nm) signals to verify that the vessels were indeed in the white matter based on the strong intrinsic THG signal of axons (Liu et al., 2020 Sci. Rep.). We recorded blood velocity responses from white matter vessels at depths ranging from 729-920 μm below the pial surface. The diameter of these vessels ranged from 4-35 μm. We show for the first time that many white matter vessels demonstrate significant increases in blood flow in response to visual stimulation. Furthermore, several of these white matter vessels had clear retinotopically-selective responses such that a spatial receptive field could be mapped. The parent collaterals of the imaged white matter vessels may be principal cortical veins that dive in through the visual cortex gray matter or white matter vessels that bypass the imaged cortical region. To determine such anatomical categories of white matter vessels, we collected anatomical Z-stacks of the pial to white matter vessel volumes and we are currently performing quantitative reconstructions on these volumes. The functional significance of our new findings of visually-evoked and retinotopic responses in white matter vessels remains to be determined. However, they do suggest that white matter BOLD responses should not be treated as a proxy for physiological or machine noise. Assuming sufficient voxel resolution/magnetic field strength and an appropriate hemodynamic response function, the response properties of white matter voxels need to be thoroughly investigated in fMRI.

Title: Sex and estrous cycle have minimal effects on physiology or experience-dependent plasticity in mouse primary visual cortex

Authors: *C. JENSEN[1], R. W. SCHECTER[2], J. GAVORNIK[1];
[1]Boston Univ., Boston, MA; [2]Sage Therapeut., Cambridge, MA

Abstract: It's been said that men are from Mars and women are from Venus (John Gray, PhD), but does this translate to the neurobiology of male and female mice? Most experimental neuroscience has been conducted using male animals. Various neuromodulators, including the hormone estrogen, can fundamentally alter plasticity induction. A report (Jeong et al. 2011) showing that V1 produces, and is sensitive to, estrogen suggests that functional physiological processing and learning from visual information may be sexually dimorphic. It is not clear from existing literature the extent to which sex chromosomes and the estrous cycles introduces variability in female mice that is not found in males. The recent NIH directive to include sex as a factor in vertebrate research also raises practical issues about how to properly control for variations and apply existing knowledge to sexually heterogeneous populations. For these reasons, we performed a series of in vivo electrophysiological experiments to characterize baseline visual function and several forms of experience-dependent plasticity in the primary visual cortex of male and female mice. We find a high degree of estrous cycle variability that is difficult to effectively control for in multi-day yoked experimental designs. However, while the literature suggests that underlying plasticity mechanisms are likely influenced by estrogen levels, we find no statistical difference in baseline function or functional experience-dependent plasticity relative to sex or estrous cycle in any of our assays. Though more investigation is necessary to explain why specific cellular-level sexual dimorphisms reported in previous studies are not obviously responsive to natural estrous cycles in vivo, we conclude that the cumulative endpoint of these plasticity processes is minimally influenced by gonadal hormones. Our findings suggest that female mice can be included alongside males in experiments focused on early visual processing or adult visual plasticity with no additional controls required.

Title: M2 receptors are required for spatiotemporal sequence learning in mouse primary visual cortex

Authors: S. SARKAR, G. FERRON, C. MARTINEZ-REYEZ, C. JENSEN, *J. GAVORNIK; Boston Univ., Boston, MA

Abstract: Acetylcholine is a neurotransmitter that plays a variety of roles in both the central and peripheral nervous systems. In the CNS, ACh can act as a neuromodulator and and is known to

be involved in both visual perception and visuocortical plasticity (Kang et al., 2015). Our lab has previously shown that spatiotemporal sequence learning, defined here as the ability to encode and predict the spatiotemporal content of visual information, requires muscarinic signaling in the mouse primary visual cortex (V1, Gavornik and Bear, 2014). Muscarinic signaling is a complex process involving the combined activities of five different G-protein coupled receptors, M1-M5, all of which are expressed in the brain but differ from each other functionally and in anatomical localization (Groleau et al., 2015). Here we present electrophysiological evidence that M2, but not M1, receptors are critical for spatiotemporal sequence learning in mouse V1. We show that M2 is highly expressed in the neuropil in V1, especially in thalamorecipient layer IV, also is co-localized to the soma of a subset of somatostatin expressing neurons in both deep and superficial layers. We also show that expression of M2 receptors is relatively higher in the monocular region of V1 than than it is in the binocular region, but that paradoxically the amount of experience-dependent sequence potentiation that occurs in the monocular cortex is less than that seen in the binocular cortex. This work demonstrates that monocular circuits encode the same types of information as do binocular circuits and raises interesting questions about the functional role of M2-type receptors in processing temporal information with potential relevance to understanding how degradation of cholinergic neurons impacts cognitive function.

Title: Statistics of Temporally Ordered Stimuli Modify Activity in the Primary Visual Cortex

Authors: *S. KNUDSTRUP[1], J. P. GAVORNIK[2];
[2]Biol., [1]Boston Univ., Boston, MA

Abstract: Learning neural representations of regularities in the environment is critical for behavior (Ma and Jazayeri 2014). Temporal regularities are particularly important as they can infer causation and allow predictions about future events, and predictive coding may be a mechanism used by cortical circuits to detect and respond when the external environment violates learned expectations (Keller and Mrsic-Flogel 2018). The work from multiple labs suggests that V1 circuits are capable of building local predictive models of visual experience,

though the degree to which statistical predictability in the environment shapes these models is unclear (Bear, Buonomano, Carandini, Fiser, Gavornik, Hawkins, Keller, Shouval). To address this issue, we investigated how neurons in the mouse primary visual cortex (V1) respond during exposure to sequences of visual stimuli with a non-deterministic order governed by a set of transition probabilities. Using two-photon microscopy, we analyzed visually evoked neural activity at the population level as a function of transition probability, comparing responses elicited by higher and lower probability transitions. Here we will report how neural firing is modified and scales with transition probability and the time course of these modifications as the mouse accumulates exposure to various image sequences.

Title: Unsupervised Predictive Learning in Mouse Primary Visual Cortex: Experimental Data and Statistical Modeling

Authors: *B. PRICE, C. JENSEN, A. KHOUDARY, J. GAVORNIK;
Boston Univ., Boston, MA

Abstract: Predictive processing is a general term for various theories of cortical function, which describe the ability of the nervous system to predict future sensory inputs and the sensory consequences of action (Keller & Mrsic-Flogel, 2018). Such predictive processing is useful for the efficient coordination of movement (Körding & Wolpert, 2004; McNamee & Wolpert, 2019; Wolpert, Ghahramani, & Jordan, 1995), extrapolation of trajectories (Montague & Sejnowski, 1994; Palmer et al., 2015), and information compression (H. Barlow, 2001; Srinivasan, Laughlin, & Dubs, 1982), among others. In the present study, we investigate predictive processing in the context of sequence learning. Sequence learning is an unsupervised learning protocol in which repeated exposure to a visual stimulus induces a novel from of acetylcholine-dependent plasticity in V1 (Gavornik & Bear, 2014). In particular, for several days mice passively observe a sequence of rapidly-flashed sinusoidal gratings at about 7 Hz. Based on the principles of predictive processing and previous research within our lab, we hypothesized the visual system would learn a representation of the trained sequence that allows it to predict the order and timing of sequence elements. Under this framework, when an unexpected stimulus is presented or an expected

stimulus omitted, the mismatch between expectation and reality generates a so-called prediction error. Using sequence learning to induce expectations, we present spiking data from a cohort of about 50 adult mice suggesting that both positive and negative prediction errors are present in layer 4 of binocular V1. In addition, we use a statistical model (model-based targeted dimensionality reduction, Aoi & Pillow, 2018) to analyze how neural dynamics change with learning and the extent to which prediction errors are tuned to the precise spatiotemporal structure of the learned sequence.

Title: Nucleus accumbens D1-positive neurons show escalating, reward-expectation-dependent spiking during motivated approach

Authors: *T. FAUST[1], A. MOHEBI[2], M. DUHNE[3], J. D. BERKE[1];
[2]Neurol., [1]UCSF, San Francisco, CA; [3]Neurociencia Cognitiva, Inst. De Fisiologia Celular UNAM, Mexico DF, Mexico

Abstract: A fundamental feature of basal ganglia circuitry is the distinction between two major subtypes of striatal projection neurons. About half express dopamine D1 receptors (D1+) while the other half express D2 receptors and adenosine A2a receptors (A2a+). Many studies manipulating these neuron subtypes have demonstrated distinct, opposite effects on behavior, yet their specific functional roles remain less than clear. Attempts to reveal these distinct functions by measuring their activity in behaving animals have described unexpectedly-similar patterns, with both subtypes increasing activity during action initiation.Using knock-in rat Cre driver lines (Pettibone *et al.* 2019), we recorded from optogenetically-identified D1+ cells (n=146, from 4 rats) and A2a+ cells (n=74, from 3 rats) in the nucleus accumbens during unrestrained performance of a reinforcement learning task (Hamid *et al.* 2016). In this task, rats dynamically adjust their action selection and willingness to work based on recent choice and reward history. In particular, when rats have recently received more rewards they are more motivated to begin a trial by approaching an illuminated port.As rats approached the trial initiation port, the D1+ neuron population progressively increased their firing, with greater initial firing rates corresponding to faster approach latencies. This ramping activity scaled with recent reward history, as quantified either by reward rate, or by state value in an actor-critic reinforcement

learning model. The timing of this ramp coincided with increased accumbens dopamine release, which also scales with reward history (Mohebi *et al.* 2019). By contrast, A2a+ neurons showed neither ramping during approach nor scaling with reward history. Neither D1+ nor A2+ neurons in accumbens showed substantial coding of left vs right choices, or the values of those actions.Our findings are consistent with accumbens D1+ neurons helping drive motivated approach behaviors, with this drive being promoted by dopamine release that scales with reward expectation.

Title: Coincident dopamine and acetylcholine ramps in the nucleus accumbens during motivated approach

Authors: *A. MOHEBI, J. D. BERKE;
Neurol., UCSF, San Francisco, CA

Abstract: Dopamine (DA) is a crucial regulator of both learning and motivation. Learning involves reward prediction errors, encoded by bursts of DA cell firing in the midbrain (including the ventral tegmental area, VTA). How exactly DA contributes to motivated behavior is less clear. Numerous studies have observed ramps in nucleus accumbens (NAc) DA release during motivated approach behaviors, that scale with reward expectation (value). Surprisingly, these value-related changes in the NAc DA release occur without any change in VTA DA cell spiking (Mohebi *et al.* Nature 2019). The specific mechanism(s) producing these DA ramps, and whether they are specific to NAc, is yet unknown. We used the DA biosensor dLight1.3b to measure DA dynamics across multiple subregions of the rat striatum: NAc (n=9 fiber placements), dorsomedial striatum (DMS, n=10), and dorsolateral striatum (DLS, n=10). We find that DA pulses to reward predictive cues covary with RPE in each subregion. However, ramps were only present in NAc, and not DLS or DMS - demonstrating a clear dissociation between ramps and RPE coding.In brain slices and anesthetized animals, striatal cholinergic interneurons (CINs) have been shown to locally regulate DA release. We therefore hypothesized that NAc DA ramps are driven by CINs, and recorded CIN activity using the calcium indicator GCaMP6f and fiber photometry (n=8 ChAT-Cre rats). We observed fast ramps in CIN activity, that mirrored the DA

ramps unaccounted for by VTA dopamine cell firing. Furthermore, we established that cholinergic modulation of DA release operates in freely-moving rats. We expressed ChR2 in NAc CINs and stimulated these neurons while monitoring dopamine DA through the same optic fiber using the red-shifted dopamine sensor RdLight. We observed a robust increase in dopamine that scaled with the duration and intensity of stimulation (n=4 rats). Finally, simultaneous monitoring of CIN GCaMP and DA using RdLight showed rapid, bidirectional interactions between DA release and CIN activity, with DA suppressing CINs and CINs enhancing DA release. These results support the hypothesis that motivation-related ramps in NAc release are locally controlled by CINs.

Title: Nucleus accumbens dopamine ramps reflect dynamic value estimates of possible future goals.

Authors: *T. KRAUSZ[1], A. COMRIE[1], L. M. FRANK[3], N. D. DAW[4], J. D. BERKE[2]; [1]Neurosci. Grad. Program, [2]Neurol., UCSF, San Francisco, CA; [3]Dept. of Physiol., UC San Francisco, San Francisco, CA; [4]Psychology, Princeton Univ., Princeton, NJ

Abstract: Dopamine (DA) in the nucleus accumbens (NAc) has been identified as a critical motivational signal. Our lab has found that DA correlates with estimates of future reward (value) as rats perform an operant reinforcement learning task. Consistent with a value signal, multiple groups have observed that NAc DA increases in a ramp as rats approach a distant goal. In many natural environments, however, there exist numerous navigational choices that lead to distinct rewarding locations. How does the NAc DA system estimate value in these contexts? We measured DA release dynamics in the NAc using the fluorescent biosensor dLight1.3b in Long-Evans rats (n=5) as they navigated for reward in a novel naturalistic foraging task, the Triangle Maze. This task leverages probabilistic reward delivery and movable barriers to vary the benefits and costs from discretized maze locations. Reinforcement learning algorithms allow us to estimate state values on a trial-by-trial basis. Rats adapted their navigational decisions to track changes in expected rewards and distance costs. State value was a significantly better predictor of DA dynamics during navigation than behavioral metrics such as velocity or acceleration. NAc

DA most strongly correlated with estimates of value for the chosen goal. However, early in a run, DA also correlated with values of the most rewarding alternative. Our results support the hypothesis that NAc DA is an evaluative signal, and they provide insight into how the brain assigns credit to states distant from reward.

Title: Reward prediction error signals from slow pacemaker neurons in the globus pallidus

Authors: M. A. FARRIES[1], T. W. FAUST[2], A. MOHEBI[2], J. D. BERKE[2];
[1]Knoebel Inst. for Healthy Aging, Univ. of Denver, Denver, CO; [2]Neurol., UCSF, San Francisco, CA

Abstract: The globus pallidus pars externa (GPe) is a central node within basal ganglia circuits. GPe neurons fall into distinct subtypes based upon anatomical connectivity and expression of molecular markers, but identifying these subtypes in extracellular recordings in behaving animals has been challenging. We previously reported (Mallet *et al*. 2016) that "Arkypallidal" neurons (Arky; projecting solely to striatum) can be distinguished from "Prototypical" (Proto) cells by their more irregular firing and diminished spiking during slow-wave-sleep. Here, we recorded from many individual GPe neurons (n=1,367) in freely-behaving rats across the sleep-wake cycle, and during performance of Pavlovian and reinforcement learning (RL) tasks. We again found a clear distinction between Arky and Proto GP neuron clusters; using optogenetic tagging we confirmed that parvalbumin-positive neurons are near-exclusively found in the Proto cluster. Furthermore, we observed a novel, smaller population of cells (n = 96) with low firing rates (4.8 ± 1.8 Hz) and regular spiking (CV: 0.59 ± 0.15); we refer to these cells as "slow pacemakers." The firing patterns of these cells showed striking similarities to midbrain dopamine neurons recorded in the same tasks (Mohebi *et al*. 2019). In particular, they showed brief increases in firing to Pavlovian cues, in proportion to the cued reward probability, and brief increases in firing at reward delivery in inverse proportion to the cued reward probability. In the RL task, slow pacemakers showed a brief increase in firing at reward delivery that scaled inversely with

recent reward rate - i.e. it was stronger when rats had less expectation to reward - consistent with a positive reward prediction error. Slow pacemakers also responded to other cues in the RL task (trial initiation light, *Go!* trigger sound) in a very similar manner to midbrain dopamine neurons, and with similar timing.
Our results demonstrate a second source of reward prediction error signals within the basal ganglia, supplementing and potentially contributing to reward prediction error coding by midbrain dopamine cells.

Title: Behavior-related activity of optogenetically-identified ChAT+, PV+, and SST+ interneurons in the rat striatum.

Authors: *M. DUHNE[1], J. R. PETTIBONE[2], A. MOHEBI[1], T. W. FAUST[1], J. D. BERKE[3]; [1]Neurol., UCSF, San Francisco, CA; [2]Suomi Col. of Arts and Sciences, Finlandia Univ., Hancock, MI; [3]Neurol., Univ. of California San Francisco, San Francisco, CA

Abstract: The striatum is an essential structure for adapting behavior to changing reward conditions. Local circuits within the striatum have a critical role in orchestrating striatal output. Activity in these circuits is heavily influenced by striatal interneurons, including cholinergic (ChAT+), parvalbumin-positive (PV+), and somatostatin-positive (SST+) cells. Dysfunction of these striatal interneurons is linked to a range of neurological disorders such as Parkinson's Disease, Huntington's Disease and Tourette Syndrome. Yet, exactly how local striatal circuits work remains poorly understood. *In vivo* recordings in behaving animals have found distinct neuronal subpopulations, such as "tonically-active neurons" presumed to be ChAT+ and fast-spiking cells presumed to be PV+. However, positive identification of striatal interneurons in behaving animals has proven extremely challenging, and the spiking activity of even presumed SST+ interneurons has not been reported at all. We have developed enhanced methods for optogenetic identification of extracellularly-recorded neurons in behaving rats. Using this approach we have begun to examine and compare the activity patterns of identified PV+, ChAT+ and SST+ interneurons in dorsal striatum, as rats perform Pavlovian and instrumental tasks. In awake rats (n=3 PV-Cre; n=3 ChAT-Cre; n=2 SST-Cre) all three cell types are consistently tonically-active, confirming that tonic activity alone is a poor guide to cell type. All three cell types also showed complex movement-dependent changes in firing rate, but only ChAT+ showed brief pauses with reward-related cues. These pauses were selectively observed in dorsal-

lateral, but not dorsal-medial striatum. Our results confirm that only a fraction of "tonically-active neurons" are ChAT+, demonstrating that positive identification will be very important for deciphering the operations of striatal microcircuits during behavior.

Title: Midbrain inhibitory modulation of exploratory behavior and value-based action selection through dopamine neurons

Authors: *Z. ZHANG, N. K. GUT, J. MENA-SEGOVIA;
Behavioral and Neural Sci., Rutgers Univ., Newark, NJ

Abstract: The pedunculopontine nucleus (PPN) has traditionally been regarded as a midbrain motor structure. However, emerging evidence suggests that PPN influences behavior beyond locomotor control through its projections to areas of the basal ganglia involved in value processing, salience and novelty, thus supporting its broader involvement in the basal ganglia network. We previously reported a GABAergic PPN projection that innervates the substantia nigra pars compacta (SNc) and selectively affects goal-directed behavior, but not general motor programs. Dopamine has been shown, in animal models as well as computational studies, to affect the exploration-exploitation trade-off by mediating the basal ganglia output. To further explore this connectivity in the framework of dopamine-mediated exploration-exploitation, VGAT-Cre transgenic mice were optogenetically stimulated during a battery of behavioral tests. Mice were bilaterally injected with a Cre-dependent construct encoding channelrhodopsin-2 or a fluorescent reporter (controls) in the PPN, and bilateral optic fibers were implanted above the SNc. We trained the mice in a runway task, where animals learned to run through a straight corridor to get a food reward at the end; animals were food restricted and over-trained. To perform the task efficiently, corrective measures were used to minimize exploratory behaviors such as stopping, sniffing and rearing. Thus, successfully trained mice walked between the entry port and the food reward area without interruption. During the test, mice were challenged with optogenetic stimulation at the midpoint of the corridor or while they were eating the reward once they reached the end of the corridor. Consistent with our previous results, stimulation during reward consumption did not affect exploitative behavior. However, stimulation at the midpoint of the corridor resulted in a significant reduction of speed, where animals exhibited markedly impaired locomotion, but still managed to reach the food reward. In contrast, stimulation in the

open field, where there was no association with reward, led to full locomotor arrest. Next, mice will be tested in a two-choice foraging task to further explore the role of PPN GABAergic neurons in the modulation of exploratory/exploitative behavior through their influence over dopamine neurons. Our results support a role for PPN GABAergic neurons in goal-directed behavior through the modulation of dopamine neurons.

Title: The dopaminergic encoding of task completion in dorsal striatum

Authors: *J. GALANAUGH[1], E. DIAZ-HERNANDEZ[1], A. SANCHEZ-FUENTES[3], F. TECUAPETLA[3], M. V. FUCCILLO[2];
[2]Neurosci., [1]Univ. of Pennsylvania, Philadelphia, PA; [3]Inst. de Fisiología Celular, Mexico City, Mexico

Abstract: While the dorsal striatum has been implicated in action selection and initiation, less is known about how this region contributes to the completion of motor tasks. Perturbations to the neural encoding of task completion may contribute to the manifestation of compulsive and impulsive behaviors seen in multiple neuropsychiatric disorders. Dopaminergic signaling within the basal ganglia has been implicated broadly in motor planning, learning, and action execution. Here we test the potential contributions of this dopaminergic signaling to the encoding of task completion in lateral and medial compartments of dorsal striatum (DLS & DMS). We sought to investigate these signals in these regions with an adapted completion sequence task in mice (n=20). In this task, mice are presented with 2 levers on different walls of an operant box and are expected to complete a sequence (4 presses) on the first lever (sequence lever) and report completion of this sequence on the second lever (report lever) after which a reward is delivered. We record DA activity in DLS and DMS during behavior via the GRAB-DA optical dopamine sensor. Errors in this completion task took the form of incomplete sequences (<4 presses) or extended sequences (>5 presses) and served as phenotypes of impulsivity and compulsivity respectively. By the last day of training, the animals achieved a high level of performance, accurately self-reporting completion of a normal sequence (4 presses on the sequence lever, 1 press on the report lever) for 70% of trials. In the remaining trials, mice performed extended and incomplete sequences 11% and 19% of the time respectively. Distinct patterns of DA activity

were associated with each lever in normal sequence trials, and preliminary data suggests this activity is uniquely modulated in impulsive and compulsive trial types. This work will broaden our understanding of striatal dopamine signals in signaling the completion of motor sequences.

Title: Dopamine neuron stimulation induces progressive context-dependent abnormal involuntary movements in healthy rats

Authors: J. HUNTER[1], A. BOVA[2], ***D. LEVENTHAL**[3,4];
[1]Neurol., [2]Neurosci. Grad. Dept., [3]Univ. of Michigan, Ann Arbor, MI; [4]Neurol., VA Ann Arbor Healthcare Syst., Ann Arbor, MI

Abstract: Levodopa alleviates many Parkinson Disease (PD) symptoms, particularly bradykinesia and rigidity. With continued levodopa treatment, many patients develop levodopa-induced dyskinesias (LIDs) - abnormal involuntary movements (AIMs) characterized primarily by chorea. Clinically, LIDs depend on progression of striatal denervation and sensitization to repeated levodopa doses. However, the degree of dopamine denervation is correlated with the magnitude of levodopa-induced changes in striatal dopamine, raising the possibility that elevated striatal dopamine can induce AIMs independently of nigrostriatal degeneration. We optogenetically stimulated SNc dopamine neurons in healthy, non-Parkinsonian rats as they performed a skilled reaching task. Repeated dopamine neuron stimulation was sufficient to induce progressive AIMs in the absence of nigrostriatal denervation. Additionally, AIMs severity was modified by behavioral context. AIMs were milder in rats engaged in skilled reaching during stimulation, and more severe if stimulation occurred between reaches. These data indicate that nigrostriatal denervation is not necessary for fluctuating striatal dopamine levels to induce AIMs, and that behavioral context plays a role in dyskinesia induction and expression.

Title: Neural regulation of juvenile aggression in a social tadpole

Authors: *J. MCKINNEY, S. LUDINGTON, J. BUTLER, L. A. O'CONNELL;
Stanford Univ., Stanford, CA

Abstract: Aggression in juveniles is an evolutionarily adaptive behavior documented in many species, but the neural mechanisms behind these displays are poorly understood. In the Mimetic poison frog (*Ranitomeya imitator*), tadpoles live in small pools with limited resources and have evolved offensive aggressive tendencies towards conspecific tadpoles in defense of these resources. Tadpoles will attack, kill, and cannibalize other tadpoles as a primary resource defense mechanism. We examined the neural basis of neonate aggression in these tadpoles by comparing individuals that were placed in aggressive encounters and individuals placed in an environment with a non-threatening stimulus. We first did a longitudinal study to determine that the tadpoles were most aggressive when they were around five or six weeks old. We then compared patterns of generalized neural activity using immunohistochemical detection of phosphorylated ribosomes and a candidate neuropeptide, arginine vasotocin, which has been implicated in aggression in other vertebrates. Vasotocin cells in the preoptic area of the hypothalamus were not more active in aggressive tadpoles. We then examined neural activation across several brain regions suspected to be involved in aggression: the amygdala, ventral hypothalamus, preoptic area of the hypothalamus, and medial pallium. We found that the ventral hypothalamus had the most neural activation in aggressive tadpoles compared to controls and the other brain regions. To determine what cell types influence aggression, we used phosphoTRAP to moleculary profile active neurons in aggressive tadpoles. This approach identified proopiomelanocortin (POMC), a precursor polypeptide with multiple post-translational subunits, as enriched in active neurons in the diencephalon during aggression. Forkhead box protein 2 (FOXP2), a transcription factor involved in communication, was depleted in the telencephalon of aggressive tadpoles. Current work is focusing on doing pharmacological manipulations and neural tracing experiments to determine individual neuropeptide influence on aggressive behavior. Overall, this project is advancing our understanding of how aggression is regulated in the juvenile brain.

Title: The effects of fluoxetine on approach and avoidance behavior by Xenopus laevis in a predator-based anxiety test

Authors: N. M. MENON, *J. A. CARR;
Biol. Sci., Texas Tech. Univ., Lubbock, TX

Abstract: There are two neuronal pathways in mammals that detect and respond to visual threats: an LGN-striate cortex pathway and a subcortical pathway through the superior colliculus. Both pathways trigger defensive responses in the central nucleus of the amygdala through a thalamic relay. Here we use a novel ecologically relevant tradeoff test to investigate subcortical aspects of anxiety in anurans, which rely entirely on a subcortical visual processing pathway for responding to visual threats. We hypothesized that administration of fluoxetine (10 mg/kg administered alternate days for 30 d) may reverse anxiety-like behavior, improve feeding, and decrease abundance of anxiety-related transcripts in the African clawed frog *Xenopus laevis*. We divided adult male *X. laevis* into three groups: untreated, 0.6% saline, and fluoxetine injected i.p. (n = 9-10/group). After 30 d we placed individual frogs into the behavioral arena and co-presented a repeating looming threat and food, mimicking an ecological tradeoff where animals can forage at the risk of predation. We analyzed behavior during three test periods: a 10 min pre-test without either stimulus (A); a 30 min test-period with both the visual predator stimulus and food (B); and a 30 min post-test period with food only (C). After behavioral tests we euthanized frogs, flash froze optic tecta for RNA extraction, cDNA transcription and qRTPCR. Fluoxetine administration did not affect food intake relative to untreated and saline controls. Fluoxetine-treated frogs took significantly longer to start swimming in the tank during time period A compared to the other groups. Fluoxetine-treated frogs spent significantly less time swimming and more time in 'safe' side of the tank away from the predator in time period C compared to the untreated animals. We observed a significant increase in the abundance of transcripts for the serotonin 1A receptor and CRF in the vehicle-treated group compared to other groups. In summary, fluoxetine administration in *X. laevis* seems to enhance predator avoidance and promote sedentary behavior and did not improve exploratory in the recovery phase after exposure to a visual predator stimulus.

Title: Social rank predicts neural and behavioral responses to social stimuli

Authors: *D. R. BLACKMAN[1], A. R. MINERVA[1], O. C. TIMMERMANS[1], A. P. FINK[2], C. E. SCHOONOVER[2], A. L. FALKNER[1];
[1]Princeton Univ., Princeton, NJ; [2]Neurosci., Columbia Univ., New York, NY

Abstract: Social dominance hierarchies create ranking systems among conspecifics within the same social group. In order to achieve and maintain stable hierarchies, animals must engage in flexible and context-specific rank-appropriate behaviors. For example, dominants may approach and engage with conspecifics that subordinates will avoid. In addition, these behavioral responses must be flexibly updated if individual rank or social context changes. Here, we explore the role of a hypothalamic circuit in flexibly updating rank state and associated behaviors. To do this, we develop a novel assay to quantify behavioral responses to social sensory information as a function of rank. We combine this with quantitative behavioral characterization of variables related to aversion, engagement, and arousal. We find that in both sexes, social dominance hierarchies are linear, transitive, and stable, and behavioral responses to socially salient stimuli vary as a function of rank. Specifically, dominant animals show higher levels of engagement with these stimuli relative to subordinates; conversely, subordinates show higher levels of aversion relative to dominants. Further, we observe flexibility in these responses. Changes in social rank are correlated with corresponding behavioral changes: animals who ascend in the hierarchy show increased engagement, while animals who descend show increased aversion. To assess the neural correlates of these responses, we explored the role of a subpopulation of the ventral premammillary nucleus (PMvDAT), a glutamatergic node in the social behavior network that has been implicated in encoding both social rank and sensory information. We find that suppression o fthis node using DREADD Gi creates a subordinate-like state, changing behavioral responses to social and non-social stimuli to resemble the responses of subordinate individuals. In addition, fiber photometry results show that PMvDAT activity levels are higher in dominant animals relative to subordinates in both sexes, suggesting that social rank may modulate the gain of representations of social sensory information in the PMv. Together, these data provide an

understanding about how behavioral changes in rank state change computations at the neural level.

Title: Dissociable neural mechanisms of reactive and appetitive aggression

Authors: *N. L. GOODWIN[1], L. BLOOM[2], K. PITTS[2], V. TSAI[2], Y. ZHANG[2], S. A. GOLDEN[3];
[1]Grad. Program in Neurosci., [3]Dept. of Biol. Structure, [2]Univ. of Washington, Seattle, WA

Abstract: Background Maladaptive aggression characterizes - or is comorbid with - many neuropsychiatric illnesses, and can have devastating effects on individuals, their caretakers, and healthcare professionals. Human aggression is typically demarcated as exhibiting either reactive (defensive) or appetitive (rewarding) components. Despite a significant clinical awareness of the differences between these aggression presentations, preclinical characterization of their relative circuitry and associated neuronal mechanisms are absent. Using outbred CD1 male mice, we examined the dissociable behavioral and neural mechanisms of reactive and appetitive aggression phenotypes.
Methods To cleanly dissociate appetitive and reactive aggression, we used operant aggression self-administration paired with yoked non-contingent aggression procedures, respectively. Briefly, for appetitive aggression, we trained male CD1 or CD1 transgenic mice to self-administer a novel subordinate intruder over 7 days using a trial design. In the reactive yoked condition, we non-contingently administered intruders with the same frequency distribution as the self-administration mice. To examine the neuronal ensembles engaged by aggression, residents were euthanized following testing and used for targeted Fos activity mapping with a focus on the lateral septum and anterior cingulate cortex. In parallel experiments, we used CD1xVgat-Cre or CD1xVglut1-Cre mice to examine cell-type specific activity in the lateral

septum.
Results Preliminary Fos activity mapping identified divergent patterns of neuronal ensemble engagement within the lateral septum.
Conclusions Preliminary results indicate that reactive and appetitive aggression differentially engage brain regions classically attributed to control only reactive aggression. Ongoing experiments will examine the endogenous population dynamics and causal role of these cell types in driving these aggression phenotypes.

Title: Hippocampal area CA2 activity supports resilience following an acute social stress

Authors: *D. RADZICKI[1], K. E. MCCANN[2], G. M. ALEXANDER[1], S. M. DUDEK[1];
[1]Natl. Inst. of Envrn. Hlth. Sci. (NIEHS/NIH), Research Triangle Park, NC; [2]Emory Univ., Atlanta, GA

Abstract: Neuronal activity in the hippocampus is critical for memory acquisition and retrieval and influences an animal's response to stress. Moreover, the molecularly distinct principal neurons of hippocampal area CA2 are required for social recognition memory and aggression in rodents. Given the high concentration of the mineralocorticoid stress hormone receptor in area CA2, this region is also positioned to play an important role in the greater hippocampal stress response. To further interrogate the effects of stress on CA2 dependent behaviors, we chemogenetically manipulated neuronal activity *in vivo* during an acute, socially derived stressor and tested whether memory for the defeat was influenced.
We used the acute social defeat (ASD) paradigm where male subject C57 mice undergo a five-minute bout of social defeat in the home cage of a large male CD1 aggressor. 24 hours after the defeat, we observed that defeated mice spent, on average, significantly less time investigating a novel CD1 mouse when compared to control mice that had not been exposed to the aggressor mice (50.3 +/-10.5 vs. 99.4 +/-5.1 s, n=22,18, p=0.0001). Furthermore, we found that this avoidant phenotype persisted for up to one month following a single defeat: mice exhibited either a susceptible/avoidant or a resilient/investigative behavioral phenotype when CA2 activity was left unperturbed. When CA2 activity was inhibited using cell-type specific expression of the

inhibitory Gi-DREADD receptor during the defeat, however, subject mice exhibited a significantly higher amount of social avoidance one day later when compared to defeated littermates not expressing the DREADDs (241.6 +/-12.7 vs. 188.6 +/-16.4 s, n=18,18, p=0.02). This increased avoidance was driven by a loss of the 'resilient' population of defeated mice. We also observed ASD-dependent changes in neuronal activity following social investigation, as measured by the immediate early gene (IEG) c*fos*, in direct downstream targets of CA2 (rostral CA1, lateral septum). Lastly, given CA2's known role in aggression, we asked whether inhibition of CA2 also modulated the behavior of subjects during the defeat itself. We observed a significant reduction in the amount of defensive submission during defeat when CA2 was inhibited (24.5 +/-5.1 vs. 44.1 +/-6.3 s, n=18,18, p=0.02).
Taken together these results indicate that CA2 neuronal activity supports resilience following an acute social stressor and that submissive defensive behavior during the defeat (vs. fleeing) is a predictor of future resilience to social stress.

Title: Kolliker-fuse nucleus in the hindbrain parabrachial complex sends long-range glutamatergic (vglut1/2) projections containing pacap, cgrp and neurotensin, to identified gabaergic neurons in the extended amygdala during pain processing: new vistas of calyx-of-held-like synapse in the telencephalon of rat under focused ion bean scanning electron microscopy (fibsem) and transmission electron microscopy (tem)

Authors: *L. ZHANG[1], V. S. HERNANDEZ[2], D. M. GIRALDO[3];
[1]Dept. of Physiol., [2]Dept. of Physiology, Fac. of Med., [3]Fac. of Med., Natl. Autonomous Univ. of Mexico, Mexico City, Mexico

Abstract: Kolliker (1886) - Fuse (1913) described a nucleus located in the dorsolateral pons in human that today carries their names (KFn). In rodent, it is located on the latero-ventral side of the superior cerebellar peduncle (scp) and comprises one of the three parabrachial subdivisions. It sends signals to the lower medulla oblongata, the spinal cord, the extended amygdala, and the

lateral hypothalamus. The KFn is more developed in humans than in other animal species. Chronic stimulation of the KFn region has resulted in relief of intractable pain in patients and the effect is comparable to that of PAG/periventricular stimulation. Using duplex and multiplex ISH, we report here a distinct neuronal population in the KFn that co-expresses VGLUT1, VGLUT2, PACAP, CGRP and neurotensin (NT) RNA. Using in vivo juxtacellular labeling, we observed that some of these neurons send long-range monosynaptic projections to the central amygdala (capsular division, CeC) and to bed nucleus of stria terminalis, oval division (BNSTov), making contact with PKCdelta immunopositive neurons co-expressing VGAT, PAC1 and VPAC2 mRNA, which were seen to project to lateral preoptic region, detected by in vivo labeled single neuron reconstruction. Using focused ion beam electron microscopy (FIBSEM) and transmission electron microscopy (TEM), we demonstrate for the first time that the PACAP-glutamatergic pathway from hindbrain establishes Calyx of Held-like synapses in extended amygdala and Gray type I synapses from PACAP immunopositive axons to GABAergic neuron somata. Fos activation was evaluated after formalin injection in the paws of urethane anesthetized rats. Strong neural activation was observed in the PBN / KFn and its targets in BSToval and CeC. Our results suggest the PACAP signaling pathway in KFn>CEC/BNSTov>LPO may serve as a "high-fidelity (HiFi)" circuit interaction for critical defensive locomotion toward survival.

Title: Dominance status alters stress-related neural activity in medial amygdala circuits

Authors: *M. A. COOPER, M. S. JENKINS, M. K. HOOKER, C. J. WHITTEN; Psychology, Univ. of Tennessee Knoxville, Knoxville, TN

Abstract: Dominance hierarchies are a central aspect of mammalian social organization. While social subordination is associated with increased stress sensitivity, social dominance is linked with stress resilience. The neuronal mechanisms by which social dominance improves stress coping are not well understood and sex differences are poorly delineated. We used a Syrian hamster model to investigate the neuronal mechanisms controlling sex- and status-dependent differences in neural activity within the medial amygdala. We created dominance relationships by pairing same-sex individuals in daily dyadic encounters over a 12-day period. We also injected the retrograde tracer cholera toxin B (CTB) into the bed nucleus of the stria terminalis

(BNST). Then, we used the immediate early gene c-Fos as a marker for neural activity in the dorsal and ventral portions of the posterior medial amygdala (MePD and MePV) following the formation of dominance relationships and after social defeat stress. We hypothesized that dominant animals would activate a MePV-BNST pathway during both dominance encounters and social defeat stress. We found that both male and female hamsters formed stable dominance relationships with dominants showing elevated aggression and only subordinates showing submissive behavior. In males, but not females, dominants showed greater c-Fos immunoreactivity in MePD neurons projecting to the BNST during dominance encounters compared to subordinates. Similarly, male dominants showed greater c-Fos immunoreactivity in BNST-projecting MePD neurons during social defeat stress. These findings support the possibility that maintaining social dominance activates a MePD-BNST pathway in males, which allows for the sex-dependent activation of this neural circuit during acute social stress. Overall, this work provides insight into experience-dependent neural plasticity contributing to sex differences in stress resilience.

Title: The role of estrogen receptor alpha neurons in the medial amygdala in status-dependent differences in stress resilience in female hamsters

Authors: *M. K. HOOKER[1], C. J. WHITTEN[2], L. M. HENNON[2], M. A. COOPER[3];

Abstract: While many people will encounter a traumatic experience during their lifetime, only 7-8 percent of those people go on to develop post-traumatic stress disorder (PTSD). Furthermore, the prevalence of PTSD in women is almost double compared to men. Unfortunately, much of the past neurobiological research regarding stress psychopathologies has focused on male subjects, leaving a translational gap when it comes to treatment options for women. Dominance status is known to influence stress responses with subordination being associated with increased stress sensitivity. In our laboratory we used a Syrian hamster (*Mesocricetus auratus*) model to better understand the mechanisms controlling status-dependent differences in stress resilience in females. This model allows us to create dyadic dominance relationships among female hamsters

over a 12-day period. Following establishment and maintenance of dominance relationships, females were subjected to social defeat followed by an approach/avoidance behavior test. To investigate the neuroendocrine mechanisms controlling status-dependent stress responses, we measured the activation of estrogen receptor alpha (ERα) immunopositive neurons within the posteroventral (MePV) and posterodorsal (MePD) medial amygdala. During the maintenance of dominance relationships, we found dominant females showed significantly increased attack rates compared to their subordinate counterparts while subordinates demonstrated higher flee rates compared to dominants. We found a main effect of defeat on social interaction time during an approach/avoidance behavior test; however, dominants did not differ from subordinates in their social investigation. Further, we found a main effect of defeat on social vigilance during approach/avoidance testing, although dominants did not differ from subordinates. Currently, we are using immunofluorescent staining to quantify cFos expression in ERα neurons within the MePD and MePV in dominant and subordinate female hamsters. By better understanding the neurobiological and environmental factors contributing to stress sensitivity in female animal models, we can better identify treatment options for stress-induced psychopathologies in women.

Title: The role of androgen receptor-expressing neurons in the medial amygdala in the effects of dominance status on responses to social defeat stress

Authors: *C. J. WHITTEN[1], L. M. HENNON[1], R. M. RODRIGUEZ[1], J. E. KING[1], M. A. COOPER[2];
[1]Univ. of Tennessee Knoxville, Knoxville, TN; [2]Dept. of Psychology, Univ. of Tennessee, Knoxville, TN

Abstract: Social stress is a negative emotional experience that produces behavioral, physiological, and biochemical changes that leads to individual differences in fear and anxiety. Dominance status is an environmental factor that can alter the way individuals react to or cope with stressful events. The underlying neurobiology of how dominance status produces resistance to stress remains elusive. Androgen receptor (AR) expression has been shown to upregulate in stress-sensitive brain regions in dominant individuals compared to subordinate counterparts.

Using a Syrian hamster (*Mesocricetus auratus*) model we investigated whether dominant individuals display resistance to social defeat stress in a social anxiety test and whether they activate more AR-expressing medial amygdala postereodorsal (MePD) and postereoventral (MePV) neurons than their subordinate counterparts. We allowed male hamsters to form and maintain a dyadic dominance relationship for 12 days, exposed them to social defeat stress, and then tested their approach and avoidant behaviors in a novel environment. During the formation of dominance relationships, we found that dominant males showed a higher rate of attacks than subordinates and subordinates displayed a higher rate of flees compared to dominants. Following social defeat stress, we found a main effect on defeat such that those who were defeated spent significantly less time interacting with a novel conspecific, however, there was no effect of dominance status. Dominant and subordinate animals both showed greater social vigilance compared to animals not given the opportunity to from dominance relationships. We also found an effect on flank marking during a social anxiety test, such that non-defeated individuals flank marked more than animals exposed to social defeat. However, dominant and subordinate animals did not differ from each other in flank marking or social investigation. We are currently investigating status-dependent differences in activation of AR-expressing neurons in the MePD and MePV using immunofluorescent staining. This work can give insight to potential neural networks and biological mechanisms that govern status-dependent differences in stress responsivity.

Title: Aggression associated with differential activity of neural regions implicated in retaliation

Authors: *A. MATHUR, R. ZHANG, J. BASHFORD-LARGO, J. ELOWSKY, M. DOBBERTIN, S. BAJAJ, K. BLAIR, J. BLAIR;
Boys Town Natl. Res. Hosp., Omaha, NE

Abstract: Background: While neuro-cognitive work examining aggression has examined patients with conditions at increased risk for aggression or individuals self-reporting past

aggression, little work has attempted to identify neuro-cognitive markers associated with observed/recorded aggression. The goal of the current study was to determine the extent to which aggression by youth in the first three months of residential care was associated with atypical responsiveness to retaliation.
Methods: This functional magnetic resonance imaging (fMRI) study involved 83 (56 male: mean age =16.18 [s.d. = 1.37]) adolescents in residential care performing a retaliation task during fMRI. Of the 83 adolescents participating in this study, 42 showed aggression within their first 3 months of residential care while 41 did not. During the retaliation task, participants were offered either a fair or unfair division of $20 pot (allocation phase) between the participant and imaginary partner, thereafter, the participants could either accept the offer or reject it and, by spending $1, $2, or $3 to punish the partner (retaliation phase).
Results: The post-hoc follow-up analysis (repeated measure ANOVAs) were conducted to identify association of aggression with atypical responding when retaliating to unfair offers for - (1) decision making regions representing expected value - vmPFC and posterior cingulate cortex (PCC) and (2) response control regions- particularly right IFG and bilateral anterior insula. The results of rmANOVA for decision making regions indicate significant differences in activity across the two groups of participants. The aggressive participants showed a significant less downregulation for retaliation phase for both vmPFC and PCC than the non-aggressive participants. Similarly, for response control regions, the aggressive participants showed less recruitment for retaliation phase as compared to non-aggressive participants.
Conclusion: On the basis of these results, we suggest that individuals with a greater propensity for aggression show reduced representation of the negative consequences of retaliation (reflected in the reduced down-regulation of vmPFC and PCC) and associated reduced recruitment of regions potentially involved in over-ruling these negative consequences in order to engage in retaliation (reflected in the reduced recruitment of right IFG and bilateral anterior insula).

Title: Evaluating the ability of UNC-33L to rescue dauer formation in unc-33 mutants

Authors: *A. VACIO, J. CANTU, S. BECK, A. HOLGADO;
Biol., St. Edward's Univ., AUSTIN, TX

Abstract: Aging in itself is a disease, and with aging comes susceptibility. Aging is an undeniable truth that introduces the body to additional diseases through macromolecular degeneration. Neurological diseases, such as Alzheimer's and Parkinson's, are due to the acceleration of neuronal degeneration that result in functional decline, deterioration of the body, and reduced standard of living. Although aging may be an undeniable truth for us, the nematode, C. elegans, can halt the aging process by molting into a stage termed "dauer." The *unc-33* mutant strain of the C. elegans, however, cannot enter into this stage, and the cause is unknown. The *unc-33* gene is responsible for axonal elongation, microtubule organization, and axon dendrite sorting all of which are essential for the establishment of an organism's nervous system. UNC-33 codes for three alternatively spliced isoforms UNC-33L, UNC-33M, and UNC-33S. Previous studies have shown that the isoform UNC-33L was able to rescue the *unc-33* mutant phenotype. To examine the ability of UNC-33L to rescue dauer formation, we examined *unc-33*(mn407) mutants expressing isoform UNC-33L and assessed them for dauer formation.The N2 wildtype, *unc-33*(mn407), and daf-7(e1372) were used as a control. To quantify and assess the ability of each strain to produce dauers, we used 1 percent SDS resistance assays. We conducted 3 separate trials for each strain and found that isoform UNC-33L fails to rescue the dauer formation defects characterizing unc-33(mn407) mutants. Quantification of 1 percent SDS resistance showed 73.14 percent of N2 wild type worms were dauers, while 96.68 percent of daf-7(e1372), 3.48 percent of *unc-33*(mn407) and 6.74 percent of *unc-33*(mn407) expressing isoform UNC-33L were dauers. Statistical analysis denoted that the percent of dauer formation was significant between the wild type and the strain containing the UNC-33L isoform. However, pairwise comparison of *unc-33*(mn407) mutants with *unc-33*(mn407) expressing isoform UNC-33L showed no statistically significant difference. Moving forward, as UNC-33L does not rescue the dauer defective phenotype of *unc-33* mutants, we will assess whether other UNC-33 isoforms regulate dauer formation. Together, these investigations look into the molecular machinery that slows down aging and minimizes susceptibility to age-related diseases; the mechanisms that are evolutionarily conserved from worms to humans.

Title: Investigating the vulvar blood flow response to short-term pudendal and tibial nerve stimulation in intact and spinalized rodents

Authors: *E. C. BOTTORFF, T. M. BRUNS;
Biomed. Engin., Univ. of Michigan, Ann Arbor, MI

Abstract: Female sexual health is an important determinant in quality of life, contributing to both increased meaning in life and general well-being. Unfortunately, approximately 40% of women suffer from female sexual dysfunction (FSD). Neuromodulation is a potential treatment option for women with FSD. Some women receiving neuromodulation for bladder dysfunction have reported off-target benefits in sexual function. We recently studied neuromodulation in women with FSD but without bladder disorders and found that transcutaneous pudendal and tibial nerve stimulation improved FSD symptoms. We theorize that neuromodulation-driven improvements in FSD symptoms may occur via increases in blood flow to sexual organs.
We designed a set of anesthetized rat experiments (N = 10) to determine the impact of spinal cord transection on the peripheral circuitry modulating vulvar blood flow (VBF) responses to short-term stimulation, building upon prior studies on vaginal blood flow. For each 45-minute trial, we measured VBF with laser speckle imaging (arbitrary perfusion units; APU) for 5 minutes prior to stimulation, during 20 minutes of pudendal or tibial nerve stimulation, and for 20 minutes after stimulation ended. The trial was then repeated for the other nerve target. Next we performed a laminectomy and transected the spinal cord (T6 level). After a 15-minute or greater rest, we then repeated the two stimulation trials in the same order as before transection. The average VBF was 183 ± 44 APU prior to pudendal stimulation, which increased to 354 ± 110 APU ($p < 0.01$ versus prior) during pudendal stimulation and returned to 186 ± 53 APU post-stimulation. After spinal cord transection, mean VBF trends were similar (193 ± 61; 337 ± 131, $p < 0.01$ versus prior; 188 ± 65 APU, respectively). For tibial stimulation trials, VBF was 183 ± 50 APU pre-stimulation, 192 ± 48 APU during stimulation, and 181 ± 52 APU post-stimulation. After spinal cord transection, VBF remained steady at 192 ± 74, 211 ± 87, and 196 ± 65, prior to, during, and post-stimulation respectively.
These results suggest that single trials of short-term pudendal nerve stimulation have a direct effect on VBF, but short-term tibial nerve stimulation does not. The pudendal nerve stimulation response is likely due to direct activation of motor efferents that are not affected by the removal of supra-T6 spinal circuits. Further research is required to understand the impact of neuromodulation on changes in blood flow to the vulva and other genitals over a longer period time as the benefit of neuromodulation for FSD may improve with multiple sessions.

Title: A behavioral animal model for non-continuous neuromodulation of bladder function

Authors: *M. ORTIZ-LOPEZ[1,2], Z. OUYANG[1,2], A. KOTKAR[1,2], M. WILLEN[1,2], R. LIU[1,2], J. OLSZEWSKI[1,2], A. RYBICKI[3,2], M. STEVEN[1,2], E. KENNEDY[1,2], T. M. BRUNS[1,2]; [1]Biomed. Engin., [2]Biointerfaces Inst., Univ. of Michigan, Ann Arbor, MI; [3]Dept. of Bioengineering, Univ. of Pennsylvania, Philadelphia, PA

Abstract: Overactive bladder (OAB) is a medical condition that affects life quality, particularly for elderly individuals. Current sacral neuromoduation (SNM) therapy uses open-loop continuous stimulation to treat OAB symptoms. A system with a closed-loop or on-demand non-continuous strategy may increase therapeutic efficacy and efficiency. In this study we performed non-continuous nerve stimulation in an awake and behaving animal model, to expand upon prior studies performed with anesthetized animals. We implanted seven felines with microelectrodes in sacral-level dorsal root ganglia (DRG) towards real-time estimation of bladder pressure. In addition the animals were instrumented as follows; stimulation electrodes at one sacral nerve and a cuff electrode on a pudendal nerve for neuromodulation; catheters in the bladder for volume control and pressure monitoring; and fixed connections in a backpack mounted at the lower back. In the first three animals we established logistics for tethered neuromodulation and neural signal monitoring while animals were awake and moving around in an enclosure. In each of the following four test animals we performed seven separate test sessions across three-week periods. In each session the bladder was infused at least three times until the animal voided for each of three types of nerve stimulation: no neuromodulation, closed-loop neuromodulation initiated at DRG-estimated rising bladder pressures, and continuous neuromodulation. The choice of stimulation and sensing varied varied among experiments because of experimental issues such as failures of DRG microelectrodes and one test animal was removed from the study due to a health complication. In two test animals, closed-loop neuromodulation and non-continuous neuromodulation initiated at half-capacity and each had significantly larger bladder capacity than no-stimulation trials (37%, 32% respectively). These paradigms resulted in similar bladder capacity increases as continuous stimulation but used significantly less stimulation time (~50%). One animal was a non-responder to neuromodulation, with all nerve stimulation types yielding similar bladder capacities. The bladder voiding efficiency and maximum pressure change were not statistically different within the test animals across the different stimulation paradigms. This study demonstrates that neuromodulation can be delivered in a non-continuous paradigm that increases bladder capacity to a similar level as continuous neuromodulation in some awake and behaving felines. Further studies are needed to develop robust hardware and artifact-resistant algorithms.

Title: Bladder Infection with Uropathogenic E. coli Increases the Excitability of Afferent Neurons

Authors: *N. MONTALBETTI[1], M. G. DALGHI[1], S. I. BASTACKY[1], D. R. CLAYTON[1], W. G. RUIZ[1], G. APODACA[1], M. D. CARATTINO[2];
[2]Med., [1]Univ. of Pittsburgh, Pittsburgh, PA

Abstract: Introduction: Urinary tract infections (UTIs) are among the most common bacterial infections affecting humans. Urinary urgency, frequency and pelvic pain are the main symptoms experienced by patients with UTI. The goal of this work was to define the contribution of afferent pathways to symptom generation in a mouse model of UTI induced by uropathogenic *E. coli* (UPEC). **Methods:** Female C57BL/6J mice were inoculated intravesically with UPEC strain UTI89. Immunofluorescence and histopathological analysis was conducted to characterize the infection and inflammatory process triggered by UTI89. Somatic sensitivity in the pelvic area was determined with von Frey filaments. Voiding was evaluated in conscious freely moving mice with a novel video analysis system. Electrical properties of bladder sensory neurons were evaluated with the patch-clamp technique. **Results:** Mice with UTI developed a robust inflammatory response with diffusive edema and leucocytic and lymphocytic infiltrate in the bladder mucosa. Mice with UTI exhibited a larger number of voids per hour and lower voided volume than controls inoculated with saline. Consistent with sensitization, bladder sensory neurons with both tetrodotoxin-resistant (TTX-R) and TTX-sensitive (TTX-S) action potentials harvested from mice inoculated with UTI89 exhibited aberrant firing in response to electrical stimulation. Spontaneous firing activity was observed in approximately 30% of bladder sensory neurons from mice with UTI. The incubation of naïve bladder sensory neurons with supernatants from UPEC cultures promoted the sensitization of neurons with both TTX-R and TTX-S neurons. Unexpectedly, lipopolysaccharide (LPS)-reduced supernatants only increased the excitability of bladder sensory neurons with TTX-R action potentials. **Conclusion** Our studies demonstrate that mice infected with UTI89 present with hallmarks of UTI including edema and

lymphocytic infiltration of the bladder wall, increased voiding frequency, and pelvic allodynia. The intravesical inoculation of UTI89 promoted the sensitization of bladder afferent sensory neurons with both TTX-R and TTX-S action potentials, supporting the notion that sensitized bladder afferents are the primary driver of symptoms in mice. Furthermore, our studies indicate that multiple virulence factors, besides LPS, likely contribute to the sensitization of bladder afferents.

Title: Soft silicone-based neural interface to modulate bladder function

Authors: *R. KUMAR[1,2], C. GOPINATH[3,2], T. W. SIMPSON[3,2], D. M. WEIR[3,2], A. THIESSEN[4], D. MCDONNALL[4], R. A. GAUNT[3,2,1];

Abstract: Direct bladder wall stimulation has been attempted for decades to restore bladder function in people with spinal cord injury and other voiding dysfunctions. However, these efforts were limited by co-activation of the urethra, legs and other pelvic organs at stimulus intensities that evoked bladder contractions. Neural interfaces for the detrusor muscle itself face several challenges due to its structure and the volume changes it undergoes in normal function. We designed a stretchable silicone net that can be placed around the bladder body to anchor a soft electrode array that interfaces directly with the base of bladder to generate bladder contractions. We created implantable versions of the electrode nets and tested them in chronic experiments. We implanted 5 healthy cats (4 females, 1 male) and tested them with and without anesthesia for 2-3 months. A pressure catheter was implanted into the bladder to control volume and measure pressure. Bladder wall stimulation through various electrode configurations (monopolar, bipolar), temporal patterns (single electrode, sequential stimulation of multiple electrodes) and stimulus intensities were able to generate complete bladder emptying. In behaving cats, bladder wall stimulation at many different stimulus intensities elicited efficient voiding at physiological bladder pressures (med: 41, IQR: 27-60 cmH_2O). However, there was little relationship ($r<0.28$)

between stimulation amplitude and bladder pressure itself. Rather, stimulation amplitude had an effect on the time between stimulation onset and bladder contraction onset. At low stimulation amplitudes, there was a longer time between stimulation onset and voiding (med: 35s, IQR: 13.5-68.2s) than occurred at higher amplitudes, which evoked more rapid voiding (med: 23s, IQR: 10-45s). This contrasts with anesthetized tests, where stimulation at 3 ± 2 mA evoked increases in bladder pressure up to 35 cmH_2O. These results suggest that stimulation of the bladder wall recruits sensory pathways leading to an urge to void, but that can be suppressed by the animals. For most of the duration of the implants, stimulation evoked functional voiding with consistent electrical stimulation thresholds. However, after several months there was a failure of an implanted bond that limited the overall duration of the implants. Chronic experiments demonstrate that these electrode nets can be used as a neural interface to generate or initiate comfortable, complete bladder emptying in awake behaving cats. Future efforts include understanding the effects of evoked sensations on voiding and improving the integrity of the bonding between the flexible conductors and the lead wire.

Title: Urethral recruitment during clinical pudendal neurostimulator implant surgery

Authors: *P.-J. CHEN[1], A. C. LAGUNAS[1], V. SORIANO[1], P. GUPTA[2], T. M. BRUNS[1]; [1]Biomed. Engin., [2]Urology, Univ. of Michigan, Ann Arbor, MI

Abstract: Patients with pelvic pain and/or urinary dysfunctions may receive a neurostimulator implant at the pudendal nerve, in an off-label use of sacral neuromodulation. During the implant surgery, surgeons typically monitor external anal sphincter (EAS) electromyography (EMG) responses to help determine the position of the four-electrode lead. The pudendal nerve also innervates the urethra. Monitoring urethral pressure responses during the implant surgery may also indicate lead positioning. Here, we use a multi-sensor catheter during the neurostimulator stage-1 implant at the pudendal nerve to map stimulation-driven pressure changes across the urethra. Each patient was situated for their implant surgery, with a multi-sensor catheter placed in the urethra to the bladder and EAS EMG needles inserted on either side of the anus. Once the neurostimulator lead was positioned near the nerve, we performed short 3 Hz stimulation trials of

different amplitudes (at and above the threshold level per electrode for driving EAS EMG, EASt), pulse widths (60, 210, 450 μs), and electrode combinations (E0 through E3). For each trial we are quantifying the average stimulation-driven pressure change (ΔP) on each urethra sensor. Our preliminary results are very diverse among our first five female patients: two patients had no urethral responses within our stimulation ranges, one patient had greater responses towards the proximal urethra, and two patients had greater responses towards the distal urethra. In the distal urethra responders, Patient 1 had pressure responses at EASt while responses in Patient 2 required at least twice EASt. In general, as we increased the stimulation amplitude, we observed larger distal and proximal urethra pressure increases. To our knowledge, this is the first multi-sensor recording of urethral pressure changes during clinical pudendal nerve stimulation. The difference in recruitment profiles among patients suggests that the relative electrode-to-nerve positions may vary across implant procedures. This mapping study will enhance our understanding of the spatial recruitment of the urethra by pudendal nerve stimulation in patients. Furthermore, this study may help improve the precision of neurostimulator lead placement and thus has the potential to benefit future clinical practice.

Title: Sparc - effects of sacral root stimulation on bladder and pelvic floor activity in awake, behaving cats

Authors: *D. BOURBEAU[1,2], S. MAJERUS[3], B. HANZLICEK[3], M. CAVENEY[4], A. RIETSCH[4], B. M. BALOG[4,6], **M. S. DAMASER**[5,7];

Engin., [4]Cleveland Clin., Cleveland, OH; [6]Dept. of Neurosci., Case Western Reserve Univ., Cleveland, OH; [7]Advanced Platform Technol. Ctr., Louis Stokes Cleveland VA Med. Ctr., Cleveland, OH

Abstract: Introduction: Following spinal cord injury many individuals develop detrusor-sphincter-dyssynergia (DSD), which results in difficult bladder emptying due to discoordinated reflex urethral sphincter contractions. Sacral anterior root stimulation (SARS) has effectively

restored bladder emptying for thousands of individuals with SCI. For individuals with DSD, reflex sphincter contraction can impede bladder emptying. This problem has been addressed by the addition of a posterior rhizotomy of the sacral sensory nerves to eliminate the unwanted reflex sphincter activity as well as unwanted bladder reflexes for continence. Unfortunately, the rhizotomy also inhibits desirable reflexes, such as bowel and sexual reflexes, and removes any remaining sacral sensation. Therefore, there is a pressing need for alternatives to rhizotomy. In this study, we have tested the effects of sacral root stimulation to reduce urethral sphincter activity.
Methods: In N=6 cats, cuff electrodes were implanted bilaterally around sacral roots S1 and S2, and EMG electrodes were implanted bilaterally in the pelvic floor muscles. Pelvic floor EMG was used as a proxy for urethral sphincter activity. The UroMOCA, a wireless, catheter-free pressure sensor, was implanted in the bladder. During a 4-week chronic experiment, data were collected with the animal awake, behaving, and untethered. Tolerance limits were determined based on animal behavior. Bladder pressure and pelvic floor muscle EMG were recorded during normal activities, including bladder emptying events, and in response to sacral root stimulation with frequency, amplitude, and location randomized. Stimulation frequencies included 20 Hz, 500 Hz, and 10 kHz.
Results: Stimulation at 20 Hz activated pelvic floor muscles. Stimulation at 500 Hz resulted in a brief initial onset response in pelvic floor muscles, followed by a rapid, significant reduction in activity. 10 kHz stimulation resulted in an onset response and more rapid and significant reduction in muscle activity. Muscle fatigue was not observed. These results are consistent with the literature for animals under anesthesia. Some bladder responses were observed at the stimulation amplitudes tested, but the thresholds were significantly higher than for pelvic muscle.
Conclusion: Sacral root stimulation at 500 Hz or 10 kHz has potential to reduce unwanted urethral sphincter activity during bladder emptying. New wireless sensors allow detection of effect in conscious animals. These approaches should be further tested for possible clinical translation.

Title: High-resolution spinal cord stimulation produces micturition and continence reflexes in anesthetized and chronically-implanted awake behaving animals.

Authors: *C. GOPINATH[1,3], M. K. JANTZ[2,3], A. K. MC CUMBER[1,3], R. KUMAR[2,3], L. E. FISHER[1,3], C. CHIN[4], Z. HU[4], B. MCLAUGHLIN[5], R. A. GAUNT[1,3];

Abstract: Epidural spinal cord stimulation (SCS) is a readily-translatable technology with recent demonstrations of its effectiveness in improving locomotion, alleviating high blood pressure and other dysfunction in people with spinal cord injury[1-3]. Our previous work showed that high-resolution SCS (HR-SCS) can target and recruit lower urinary tract nerves selectively[4], but these experiments were not designed to investigate the functional effects of stimulation. Here, we demonstrate that HR-SCS can evoke continence and micturition reflexes in both anesthetized and awake behaving cats at 90 days. We implanted HR-SCS electrodes in healthy chloralose-anesthetized animals for terminal procedures (n=6) and during sterile recovery surgeries to test performance in awake behaving animals (n=2). A bladder dome catheter was implanted for controlling volume and recording intravesical pressure. At constant volumes, low (3 Hz) and high frequency (33 Hz) stimulation was delivered (300-800 µA, 30-60 s, 200 µs pulsewidth) on all channels sequentially while monitoring for changes in bladder pressure. Responsive channels were then evaluated in filling and voiding cystometry trials. In implanted cats, trials were conducted bimonthly under dexmedetomidine anesthesia to identify channels producing changes in the bladder.Micturition and continence reflexes were evoked on responsive electrodes (53 bipolar channels; 6 cats) simply by altering the stimulus frequency. In terminal experiments, 33 Hz stimulation generated voiding pressures (27±5 cmH2O) with incomplete voiding in all animals. This voiding along with increase in pressure was abolished after a thoracic spinal transection in all animals. 3 Hz stimulation resulted in robust continence effects characterized by abolishment of non-voiding contractions and by decreases in bladder pressure in all animals (ΔP = -14±3 cmH2O) indicating relaxation of the detrusor muscle. This stimulation-evoked neural circuit was intact despite the transection of the thoracic cord. Similar frequency-dependent effects on the bladder were observed in chronic implanted free-behaving cats where 3 Hz stimulation produced a continence effect along with decreasing the desire to void measured by digging behavior. 33 Hz stimulation, which evoked large pressure increases in anesthetized animals, was largely ineffective in awake animals, possibly due to voluntary inhibition. These results indicate that HR-SCS could be an effective neuromodulation strategy, potentially even after spinal cord injury. Our future efforts are focused on investigating these in chronic spinalized animals as well as feasibility studies in clinical trials.

Title: Restoration of bladder function with lumbosacral spinal cord epidural stimulation in persons with chronic spinal cord injury

Authors: *A. HERRITY[1], S. ASLAN[1], S. MESBAH[1], B. UGILIWENEZA[1], A. MOHAMED[1,2], C. HUBSCHER[1,3], S. HARKEMA[1,4];

Abstract: One of the major challenges impacting overall health and quality of life following spinal cord injury (SCI) is the development of lower urinary tract dysfunction. Daily bladder management typically includes a combination of catheterization (either self-intermittent or suprapubic) and pharmacotherapies, which help manage the symptoms and signs of bladder dysfunction, but do not promote recovery of function. Spinal cord epidural stimulation (scES) has shown clinical effectiveness for the restoration of voluntary and reflex control of the lower urinary tract. The objective of this functional mapping study was to identify personalized neuromodulation with selective cohorts (anode and cathode assignment, pulse width, frequency, and amplitude) interleaved for specific scES configurations that promoted optimal neural control of both urinary storage (US-scES; bladder capacity at safe detrusor pressure without incontinence or triggering of autonomic dysreflexia) and timed detrusor emptying (UV-scES; high voiding efficiency within safe leak point pressures). Daily, at-home training with US-scES and UV-scES configurations were also conducted to evaluate the long-term effectiveness of lumbosacral neuromodulation for bladder function. Six participants (5 males, 1 female; 4 self-intermittent, 2 suprapubic; unable to voluntarily void) having motor complete SCI and implanted at lumbosacral spinal cord levels with a Medtronic 5-6-5 electrode array and neurostimulator, underwent bladder mapping experiments including cystometry with continuous measurements of blood pressure and heart rate using a non-invasive blood pressure monitoring system. Over a period of 4-6 weeks, mapping identified specific US-scES configurations for improved bladder compliance within the recommended International Continence Society guidelines (detrusor filling pressure <10 cmH_2O up to target capacity range of 400 - 450 mL for intermittent catheterization and > 300 mL for those using suprapubic catheters) as well as including cohorts targeted to maintain blood pressure below hypertensive values. All participants were able to

initiate voluntary voiding in the presence of UV-scES, regaining up to 70% maximum voiding efficiency. Lumbosacral neuromodulation with personalized mapping can be used to simultaneously and safely control urinary continence and modulate timely emptying while managing distention-associated blood pressure dysregulation. Importantly, these initial findings reveal the complex dynamics and interplay between autonomic systems that is being integrated and regulated within the spinal cord below the level of SCI.

Title: Quantifying anal sphincter recruitment during clinical pudendal nerve stimulation

Authors: *A. LAGUNAS[1], P.-J. CHEN[1], L. RUIZ PEREZ[1], A. U. KOTKAR[1], S. LEMPKA[1], P. GUPTA[2], T. BRUNS[1];
[1]Biomed. Engin., [2]Urology, Univ. of Michigan, Ann Arbor, MI

Abstract: Overactive bladder and urinary retention have a negative impact on quality of life for millions of Americans. Unfortunately, as the population continues to age these problems will become even more widespread. Electrical stimulation of the pudendal nerve is a promising off-label treatment for bladder dysfunction. The goal of this study is to investigate the effects of differing pudendal nerve stimulation parameters on the evoked anal sphincter muscle response in human subjects. During the electrode implant surgery, the stimulator lead is placed adjacent to the pudendal nerve, which innervates the urethra and the anal sphincter. Needle electrodes placed on either side of the anus are used to record the anal sphincter electromyogram (EMG). Each lead electrode is stimulated at and above the EMG activation threshold at 3 Hz monopolar, with up to three different pulse widths: 60 μs, 210 μs, and 450 μs. For each tested set of stimulation parameters, the area under the curve (AUC) for ten rectified and averaged EMG responses to stimulation pulses were used to quantify muscle recruitment. Data from 4 patients (all female) are analyzed so far, in this on-going clinical study. The non-normally distributed AUC measures were square-root transformed to reduce the distribution skewness prior to linear regression analyses. Across all trials there was a slowly increasing linear relationship between AUC and stimulation amplitude (slope = 0.17, R^2 = 0.27, p = 1.46e-5) that varied slightly between the 60 μs (slope = 0.19, R^2 = 0.20, p = 0.048), 210 μs (slope = 0.21, R^2 = 0.34, p = 3.33e-5), and 450 μs

(slope = 0.27, R^2 = 0.33, p = 0.0055) pulse width trials. Overall, there is an increasing trend in the sphincter response as more stimulation current is applied across the stimulation amplitude range used (0.5-10 mA). While the linear fit slopes are similar, our preliminary results show trials with longer pulse widths evoke a larger muscle response over all applied currents. Further data collection and analysis may reveal additional insights into how varying stimulation parameters can help improve the effectiveness of pudendal nerve stimulation.

Abstract: Background & Aims: The neurological mechanisms contributing to bowel dysfunction are not yet fully understood, in part because of the slow actions of the bowel and the limitations in wireless gut manometry systems. To enable multimodal data collection with a route to endoscopic implantation, we developed the Colonic Monitor of Conscious Activity (ColoMOCA). After implant, the ColoMOCA wirelessly transmits colonic pressures and electrical properties of stool over multiple days. We evaluated the accuracy of the ColoMOCA acutely in conscious swine, and the feasibility of characterizing bowel activity in awake, untethered swine over several days. **Methods:** The ColoMOCA (85 mm long, 8 mm diameter) included pressure-sensing electronics, electrodes for measuring stool salinity, and wirelessly transmitted data. The ColoMOCA measured pressure from 2 locations 63 mm apart, and measured stool conductivity in 3 overlapping regions.ColoMOCAs were tested in N=3 minipigs chronically and N=1 pig acutely. Acute insertions in conscious restrained animals included micro-tip pressure catheters alongside the ColoMOCA. Data were recorded acutely in 3 sessions.

Chronic ColoMOCAs were sutured to the colon luminal-wall through laparotomy. Daily recordings of up to 2 hours of colonic activity began the day after implantation. Colonic pressures and electrode readings were made with animals conscious and untethered. Data were received by a wireless radio worn by the animal. During recordings each animal ate food, walked, urinated, and defecated freely. Recorded pressure data were analyzed in MATLAB. The amplitude, duration, and periods between rhythmic peaks in colonic pressure waveforms were calculated. Statistical analysis was performed in JASP. Data from implanted animals were quantitatively and qualitatively analyzed. **Results**: 100 minutes of ColoMOCA data with concomitant micro-tip catheter measurements were obtained. Statistical analysis confirmed accuracy between ColoMOCA and reference pressure sensor data. In the chronic study, all animals recovered well and showed no signs of distress after 24 hrs. Implanted ColoMOCAs remained patent and did not obstruct stool for 6-7 days of implantation. 435 minutes of ambulatory, catheter-free colon pressure and conductivity data were recorded and analyzed. As in the acute case, implanted sensors showed a significant difference in contraction amplitudes between proximal and distal sensors. **Conclusion**: Small wireless sensors can remain in the bowel for at least 7 days, permitting catheter-free untethered recordings of colonic activity. These sensors will improve neurophysiological research of the bowel.

Title: Psilocybin reduces impulsive decision-making without affecting motivation

Authors: *B. F. ROBERTS[1], J. D. CROWDER[3], S. J. LOBERGER[1], J. HINEGARDNER-HENDRICKS[1], M. PALUMBO[4], J. A. JONES[2], M. S. MCMURRAY[1];
[1]Psychology, [2]Chemical, Paper, and Biomed. Engin., Miami Univ., Oxford, OH; [3]Wittenberg Univ., Springfield, OH; [4]The Peddie Sch., Highstown, NJ

Abstract: Substance abuse and gambling disorders are strongly associated with increased preference for risky rewards and reductions in impulse control, resulting in harmful consequences. Although these disorders are highly prevalent, there are limited treatments available. Previous research has indicated clinical benefits of psilocybin, but its role in impulsive

decision-making has not been established. The serotonergic systems affected by psilocybin have established roles in decision-making, suggesting it may have significant effects.Therefore, this study investigated whether psilocybin impacts decision-making in probability and delay discounting tasks in male and female rats. In the probability discounting task, subjects chose between a certain, small reward and a risky, large reward that occurred with declining probability across days of testing. In the delay discounting task, animals chose between a small, immediate reward or a large reward delivered after increasingly longer delays across days of testing. Animals were administered 1mg/kg psilocybin via gavage, 15 minutes before each day's behavioral testing. Preliminary results suggest psilocybin decreases preference for the large risky reward in the probabilistic discounting task and increases preference for the larger delayed reward in the delayed discounting task. To determine if these effects are related to changes in motivation, subjects were tested on a progressive ratio task, in which the number of lever presses required to obtain reward increases with each subsequent reward. We found no effects of psilocybin on total responses or breakpoints. This pattern of results suggests that psilocybin may have utility as a novel therapeutic for gambling disorder and other impulse control disorders, such as addiction and ADHD.

Title: Effects of a novel potential antidepressant norbaeocystin

Authors: *S. J. LOBERGER[1], J. D. CROWDER[3], *J. HINEGARDNER-HENDRICKS[1], J. A. JONES[2], M. S. MCMURRAY[1];

[1]Psychology, [2]Chemical, Paper, and Biomed. Engin., Miami Univ., Oxford, OH; [3]Wittenburg Univ., Springfield, OH

Abstract: Clinical trials on the use of psilocybin to treat depression are promising, but still in preliminary stages. Additionally, they are confounded by the presence of hallucinations, which may not be necessary for its clinical effectiveness but create significant challenges in experimental design. Thus, there is a need to determine if other tryptamines have similar molecular targets, but do not cause hallucinations. Our research group recently identified a novel E. coli-based method for synthesizing norbaeocystin, a minor metabolite of psilocybin present in "magic" mushrooms. When administered alone, norbaeocystin did not cause head twitch responses in rats at any dose, implying it may not cause hallucinations. However, norbaeocystin did enhance the number of head twitch responses caused by psilocybin, implying that it may bind with overlapping molecular targets. Therefore, in this study we determined if norbaeocystin alone or combined with psilocybin has potential as an antidepressant using the sucrose preference and force swim tests. Preliminary results suggest that norbaeocystin alone causes a moderate decrease in immobility during forced swim and a moderate increase in sucrose preference. Additionally, when combined with psilocybin, the magnitude of effect in both tasks increases. Combined, these results suggest norbaeocystin may have strong potential as an antidepressant, alone or when combined with psilocybin. Future studies will validate these effects in other behavioral models and determine the mechanisms of these effects and drug interactions. Additionally, we will evaluate the potential therapeutic efficacy of other tryptamines present in "magic" mushrooms.

Title: Aeruginascin and norbaeocystin enhance the psychoactive effects of psilocybin in the rat

Authors: *J. D. HINEGARDNER[1], N. ANAS[2], J. CROWDER[1], S. LOBERGER[1], J. A. JONES[3], M. S. MCMURRAY[1];
[1]Psychology, [2]Biol., [3]Chemical, Paper and Biomed. Engin., Miami Univ., Oxford, OH

Abstract: Psilocybin has been shown to have numerous potential clinical benefits, and in the near future it could be used to treat a wide variety of human disease processes. However, other tryptamines present in "magic" mushrooms may have similar therapeutic effects without causing hallucinations, or may interact with psilocybin to enhance its therapeutic effect. Our lab has previously shown that norbaeocystin, one such tryptamine, interacts with psilocybin to enhance rodent head twitch responses, a metric of 5HT2A activation. Other tryptamines may work similarly, including aeruginascin, a compound recently synthesized by our research group. To test this hypothesis, we administered aeruginascin to rats via gavage, and compared its effect alone and in combination with psilocybin, to the effects of norbaeocystin alone and in combination with psilocybin. We found that like norbaeocystin, aeruginascin also enhances the number of head twitches caused by psilocybin, but causes no increase in head twitches when administered alone. To determine potential mechanisms of action, all compounds were screened by the NIMH Psychoactive Drug Screening Program, which found that norbaeocystin and aeruginascin have weak affinities for the 5HT2A receptor, but show stronger affinities for other serotonin receptor types. These data suggest that when administered concurrently with psilocybin, competitive binding for non-5HT2A targets may cause psilocybin to preferentially bind to 5HT2A receptors, enhancing the behavioral effects of psilocybin. Future studies will determine if norbaeocystin and aeruginascin have antidepressant and anxiolytic effects, either alone or in combination with psilocybin.

Title: Oral administration of psilocybin and/or norbaeocystin cause persistent effects on the gut microbiome

Authors: *N. ANAS[1], J. HINEGARDNER-HENDRICKS[1], F. XU[2], H. SHI[2], J. A. JONES[3], M. S. MCMURRAY[1];
[1]Psychology, [2]Biol., [3]Chemical, Paper, and Biomed. Engin., Miami Univ., Oxford, OH

Abstract: Recent clinical studies suggest that psilocybin may have antidepressant potential, although the mechanisms of these effects remain elusive. While significant progress has been made in understanding the brain systems responsible for depression, and their overlap with psilocybin's effects, a growing body of literature has also highlighted the importance of the gut-brain axis in mental health. Alterations to the gut microbiome have been shown to cause and maintain a variety of mental health disorders. Many gut bacteria express serotonin receptors and could be affected by psilocybin. Therefore, psilocybin may exert its therapeutic effects by altering the gut microbiome, similarly to other fast-acting antidepressants (e.g. ketamine). In this study, we determined if oral psilocybin treatment alters bacterial concentrations in the gut. Additionally, we determined if action on the 5-HT2A receptor was necessary for these effects by comparing psilocybin's effects with those of norbaeocystin, a minor metabolite of psilocybin with poor affinity for the 5-HT2A receptor. To accomplish these studies, we gavaged a variety of doses of psilocybin and norbaeocystin into male rats, both alone and in combination, and then compared bacterial concentrations in fecal samples collected at a variety of timepoints for each of the doses administered. We found that psilocybin and norbaeocystin both caused pronounced changes in gut microbiome that persisted up to 3 weeks following treatment, and that these effects were amplified when animals were given both drugs simultaneously. Specifically, we saw dose-dependent increases in the concentration of *Lactobacillus* and *Turicibacter*, paired with decreased concentrations of *Ruminococcus* after psilocybin and/or norbaeocystin administration, similar to the effects seen after ketamine. These effects demonstrate that psilocybin and other tryptamines may exert their therapeutic effects through non-5-HT2A receptor dependent alterations to the gut microbiome. These results have significant implications on our understanding of the mechanisms of these drugs, and imply that even isoforms of these compounds that cannot cross the blood brain barrier may have therapeutic utility.

Title: Effect of cannabidiol (CBD) in two animal models of depression

Authors: L. M. A. ZERMEÑO-FLORES[1], E. J. ROBLES-SIERRA[1], A. M. VILLARREAL-ZUÑIGA[1], F. D. ANCER-LEAL[2], F. J. ALMAGUER-DE AVILA[2], D. MATINEZ-CHAPOY[2], F. J. CRUZ-ARROYO[2], D. MOTIEL-CONDADO[1], A. C. GONZALEZ-HORTA[1], M. F. BERMUDEZ-DE LEON[3], *B. GONZALEZ-HERNANDEZ[1];

Abstract: The world health organization estimates that there are currently 350 million people suffering from major depressive disorder. This is characterized by dysphoric mood and among the most serious consequences suiciding can became an option, apart from the social and economic burden it has. Although there are a lot of antidepressants, it is considered that 30% of patients do not respond to the treatment, in addition they are multiple side effects associated. That is why we are exploring a new therapeutic alternative such as the *Cannabis* plant that has about 500 compounds from these, 60 are considered psychoactive and one of the most studied is *Cannabidiol* (CBD), because it lacks in psychotropic properties and is well tolerated. This activates the endocanabinoid system, which participate in the regulation of mood and therefore in depressive processes. The objective of this work is to study the effect of CBD on acute and chronic depression in an animal model. Male and female Wistar rats of 210-260gr were used. The acute model of depression we used was the forced swimming test combined with a "time-sampling" analysis, which consists in forcing the rats to swim individually in two occasions: 1) A pre-session of 15 minutes and 24 hours later, 2) An experimental session of 5 minutes, in which they are three main behaviors that are recorded in intervals of 5 seconds: scaling, swimming and immobility. For chronic depression, the unpredictable chronic stress model (CUS) was used, a 4-week stressor regimen, in which each of the seven stressors (physical restrain, cage tilted, wet bedding, nip pinch, overcrowding, water and food deprivation), was applicated once a week, alternatively switching the test for each group, every day. At the end, the depression levels were quantified using the forced swim test. In the acute model, the single application of CBD (30mg / kg IP) decreased immobility in females, similar results we have as

we applied imipramine (15mg / Kg IP; positive control) having a very significant result in males. In the chronic model, the application of CBD (30mg / kg IP), during the last 5 days of CUS, showed no difference with respect to the result we have from the acute application in females and in males it shows an effect with a with a better trend than imipramine. These results indicate that CBD has an antidepressant effect in both models but shows a differential profile depending on the gender and the degree of depression, being the same in females regardless of the degree, but better antidepressant in males in the acute model.

Title: Lithium Orotate: A Superior Option for Lithium Therapy?

Authors: *A. G. PACHOLKO[1], L. K. BEKAR[2];
[1]Anatomy, physiology and pharmacology, [2]Pharmacol., Univ. of Saskatchewan, Saskatoon, SK, Canada

Abstract: Lithium carbonate (Li_2CO_3) is a mainstay treatment option for the prevention of mood-episode recurrences in bipolar disorder (BD). However, Li_2CO_3 is not without its faults, specifically a narrow therapeutic index that is associated with common thyroid and renal complications; consequently, lithium-based therapies are plagued by high rates of patient non-compliance. Lithium orotate (LiOr) is an alternative compound that is suggested to possess uptake properties that would allow for the use of markedly reduced dosages in treatment regimens, which would theoretically mitigate lithium-associated toxicity concerns and improve treatment compliance.
As a first step in exploring LiOr as a replacement for traditional lithium compounds in therapy, we established dose response curves for a range of LiOr, Li_2CO_3, and lithium chloride (LiCl) concentrations (0, 1, 1.5, 2.5, 5, 10 and 15 mg/kg for LiOr; 0, 1, 5, 10, 15, 20 and 25 mg/kg for Li_2CO_3/LiCl; all concentrations represent elemental lithium) following a single injection in both male and female wild-type mice using an amphetamine-induced hyperlocomotion (AIH) model

(3 mg/kg *d*-amphetamine). AIH is mania-mimetic and sensitive to a dose-dependent blockade via pre-treatment with lithium. Lithium was injected intraperitoneally (IP) 30 minutes prior to IP administration of *d*-amphetamine. Animals were recorded for 120 minutes in an open field and scored for total locomotion. Data was analyzed offline using Ethovision 11.x and Prism software. Application of *d*-amphetamine elevated locomotor activity chiefly within the 5-35- and 70-120-minute time bins post-injection, with the 70-120-minute window representing the peak period of hyperlocomotion. LiOr, but not LiCl/Li_2CO_3, elicited attenuation of AIH between minutes 5-35 at concentrations of 10 mg/kg or greater. For minutes 70-120 (the peak period of locomotor activity), a partial block of AIH was maintained by LiCl and Li_2CO_3 doses of 15 mg/kg or greater in males and 20 mg/kg or greater in females. In contrast, a complete blockade was observed for LiOr concentrations equal to or exceeding 2.5 mg/kg or 1.5 mg/kg in males and females, respectively, indicating both improved efficacy and potency relative to LiCl/Li_2CO_3. In sum, LiOr demonstrates superior efficacy to LiCl and Li_2CO_3 in the attenuation of the mania-mimetic AIH in both male and female wild-type mice, as evidenced by reduced dosage requirements and an enhanced strength of blockade at equivalent concentrations.

Title: Contribution of adult born granule cells to the mechanism of action of electroconvulsive stimulation

Authors: *J. CASTELLO[1,2], V. LUNA[1,2,3], R. HEN[1,2,3];
[1]Res. Fndn. for Mental Hygiene, Inc., New York, NY; [2]Columbia Univ., New York, NY; [3]New York State Psychiatric Insitute, New York, NY

Abstract: Electroconvulsive therapy (ECT) is a safe, effective treatment with a fast onset of action in patients that suffer from treatment-resistant depression. However, the mechanism of action of ECT has not been elucidated. In the dentate gyrus (DG) of the hippocampus, ECT increases the production of adult born granule cells (abGCs), through a process termed adult hippocampal neurogenesis. We have successfully established a mouse model of ECT, named Electroconvulsive stimulation (ECS) and shown that abGCs are required for the behavioral effects of ECS. In this model, ECS stimulates the production of abGCs, increases the number of presynaptic boutons coming from abGCs in the molecular layer of the dentate gyrus and

decreases c-Fos activation.
In addition, optogenetic stimulation of abGCs induce an inhibitory current in mature granule cells mediated through mGluR2 receptors in ECS treated animals. Thus, our overarching hypothesis is that ECS, through stimulation of neurogenesis, incrases the number of presynaptic boutons from abGCs which lead to the activation of postsynaptic mGluR2 receptors on mature granule cells. We propose that the resulting inhibition of the dentate gyrus is responsible for the antidepressant-like effects of ECS.

Title: Behavioral Effects and Neurobiological Mechanisms of 3-Aminobenzimide ina Rodent Model of Chronic Psychological Stress

Authors: *L. J. WILLS[1], L. D. PEETERS[2], H. WANG-HEATON[2], M. J. CHANDLEY[2], G. A. ORDWAY[2], R. W. BROWN[2];
[1]Psychology, [2]Biomed. Sci., East Tennessee State Univ., Johnson City, TN

Abstract: Stress-related disorders are a leading cause of disability worldwide. Antidepressant drugs are commonly used in the treatment of stress-related disorders, but patient estimates suggest that the rate of treatment resistance to antidepressants are over 30%. Since antidepressant drugs are modulators of monoamine transmission, the high level of treatment failure indicates that monoamine disruption is not the sole factor in the etiology of these disorders. Our lab has shown an increase in the expression of poly (ADP ribose) polymerase-1 (PARP1) in the white matter of the prefrontal cortex of brain donors who had major depressive disorder (MDD) at the time of death as compared to psychiatrically normal brain donors. To investigate the potential role of PARP1 in stress-induced behavioral disruption, the present study used a rodent "double-hit" model consisting of exposure to social defeat stress (SDS) and chronic unpredictable stress (CUS) to induce a state of chronic psychological distress. Male Sprague-Dawley rats were either in a no-stress group or were exposed to SDS and CUS. Stressed animals were administered with either a PARP-inhibitor, 3-aminobenzamide (3-AB; 40 mg/kg; s.c.); the selective serotonin reuptake inhibitor (SSRI) antidepressant fluoxetine (FLX; 10 mg/kg; i.p.); or saline each day prior to exposure to stressors. Stressors were administered over a 10-day period. SDS was implemented by introducing a male "intruder" rat into a male "aggressor" rat's cage, at which

point the “aggressor” established dominance over the “intruder”. There were five stressors used for CUS, including a 30-min restraint, 1h shaking and crowding, 10-min cold water swim, 15-min warm water swim, and a 24h cage tip which were randomly administered twice to animals during the 10-day period. To assess responsiveness to rewarding stimuli, we conducted the sucrose preference task on experimental days 8-10 during the first two-hours of the animal’s dark cycle. A social interaction test was conducted on day 11 to measure anxiolytic behavior in the rats. Stressed rats that were chronically administered 3-AB exhibited a significantly increased sucrose preference and social interaction times when compared to all other groups, and FLX failed to. We investigated PARP activation and protein expression in the PFC using immunohistochemistry and ELISAs, IBA-1 expression in PFC microglial cells, and cytokine levels in hippocampal tissue using ELISAs, which will be presented. These findings elucidate the impact and mechanism of PARP pertaining to chronic stress and the novel use of PARP-inhibitors as therapeutic alternatives for the treatment of stress-related disorders.

Title: Nr4a2 dominant negative in medial habenula cholinergic neurons attenuates reinstatement of cocaine-self administration in mice

Authors: *J. E. CHILDS[1,2], S. MORABITO[1], S. DAS[1], C. SANTELLI[1], V. ALIZO VERA[1], V. PHAM[1], D. MATHEOS[1], V. SWARUP[2], M. A. WOOD[3];
[2]Neurobio. and Behavior, [3]Neurobiol & Behavior, [1]Univ. of California Irvine, Irvine, CA

Abstract: Substance use disorder is complicated by a lifelong risk of relapse. Relapse vulnerability is programed partly during drug use, when the action of drugs of abuse in the reward circuit enables the formation of abnormally strong context/reward memories. These memory processes underlie common relapse triggers such as exposure to drug-associated cues or environments and can be extremely long lasting. This persistence may be attributed to epigenetics (i.e. modulation of gene expression that occurs through altered chromatin structure without fundamental changes to the DNA sequence itself), which has been shown to establish stable changes in cell function, and in turn changes in behavioral outcomes. Recent studies have begun to implicate the medial habenula (MHb) in cocaine-associated behaviors, yet the role of

the MHb in regulating reinstatement of cocaine self-administration remains largely unknown. Recent work in the lab has identified the histone deacetylase 3 (HDAC3; a powerful epigenetic regulator of gene expression) target gene, *Nr4a2*, as an important regulator of cocaine-associated behavior. NR4A2 is a transcription factor that regulates aspects of dopamine signaling during development, and is densely expressed in the MHb. To study the effect of MHb *Nr4a2* on relapse to drug-seeking behavior, we expressed the dominant negative form of NR4A2 (NURR2C) in the cholinergic neurons of the medial habenula in ChAT-Cre mice. Then, animals were trained to self-administer cocaine. To facilitate reinstatement behavior, we used an incubation of craving model wherein after self-administration, animals were given 30 days of homecage withdrawal. On the last day of testing, animals were extinguished for 5 hours, and were then re-exposed to drug-associated cues to drive a cued reinstatement. Control animals expressed normal reinstatement compared to NURR2C animals, which had reduced reinstatement. To develop a more in-depth understanding of the MHb response to reinstatement of cocaine-seeking, we next used single nuclei RNA sequencing to look for changes in cell type proportions, gene expression and gene networks both as a result of behavioral reinstatement and as a result of NR4A2 manipulations. In this study we show that NR4A2 in the MHb is a powerful regulator of reinstatement of cocaine-seeking behavior, and we identify Nr4a2-dependent mechanisms in the MHb related to reinstatement behavior.

Title: Interaction of kappa opioid receptor activation and dopaminergic signaling in the nucleus accumbens core mediate escalated cocaine intake

Authors: *R. D. FARERO[1], L. GORDON-FENNELL[1], L. M. BURGENO[5], J. MCALEER[2], A. ASARCH[2], A. D. ABRAHAM[2], N. L. MURRAY[2], C. I. CHAVKIN[6], L. S. ZWEIFEL[3], P. E. PHILLIPS[4];

Abstract: Alterations of dopaminergic signaling are hypothesized to be associated with several aspects of drug addiction. Cues that are repeatedly paired with delivery of drugs of abuse can become conditioned stimuli (CS) and are capable of driving dopamine (DA) release in the nucleus accumbens core (NAc). Recent work in our lab has demonstrated that an attenuation of CS driven dopaminergic signaling in the NAc during drug taking is correlated with escalated consumption of cocaine. Systemic administration of L-DOPA restored this neurochemical changed and returned drug consumption to pre-escalated levels. More recently, we found that precise increases in dopamine transmission during the CS paired with drug delivery decrease drug consumption. We accomplished this by injecting a viral vector that expresses ChR2 under the control of the CaMKIIα promoter, bilaterally into the ventral tegmental area, and implanted optic fibers in the NAc of male Wistar rats. Photostimulation (6 pulses, 30 Hz) paired with response-contingent drug cues decreased drug consumption in animals that escalate daily drug intake ($p<0.01$), indicating that low phasic DA drives escalation of consumption. Thus, preventing the attenuation of dopamine transmission in the NAc would inhibit the development of escalated cocaine consumption. One potential mechanism promoting the decrement of dopamine signaling is dynorphin via action on Kappa opioid receptors (KOR). To test this, we locally injected the KOR antagonist, norbinaltorphimine (norBNI) into the NAc. Animals treated with norBNI had no significant increase in drug intake across weeks ($p>0.05$), whereas animals treated with vehicle showed significant escalation ($p<0.05$). To further assess which population of KORs in the NAc is contributing to the effect on drug-consumption seen with norBNI we utilized CRISPR/SaCas9 to induce mutagenesis of KOR within the NAc. SaCas9 was packaged into an AAV1 viral vector and injected into either the NAc, to target cell bodies, or into the VTA, to inactivate KOR on DA terminals. This experiment revealed that inactivation of KOR on DA terminals led to a decrease in overall drug consumption ($p<0.05$) and blocked the development of escalation ($p>0.05$), whereas animals with KOR mutagenesis on cell bodies within the NAc still presented significant escalation of intake ($p<0.05$), similar to controls. These data support our proposed model that NAc KOR activation attenuates response-contingent CS dopaminergic signaling to promote escalated cocaine consumption. Development of KOR antagonists as a pharmacological therapy may have harm-reduction benefits for persons living with addiction.

Title: Involvement of endogenous ghrelin on the maintenance and reinstatement of cocaine addiction-like behaviors: a role of adrenergic action at the peripheralβ1 receptors

Authors: *M. CRISSMAN, S. PARI, *Z.-B. YOU, L. LEGGIO, E. L. GARDNER; NIDA-IRP/NIH/DHHS, Baltimore, MD

Abstract: Involvement of endogenous ghrelin on the maintenance and reinstatement of cocaine addiction-like behaviors: a role of adrenergic action at peripheral β1 receptors
Madeline Crissman, Sruti Pari, Zhi-Bing You, Lorenzo Leggio and Eliot L Gardner
Intramural Research Program, National Institute on Drug Abuse, National Institutes of Health, Department of Health and Human Services, Baltimore, MD 21224
ABSTRACT
Ghrelin, an orexigenic hormone secreted primarily from endocrine cells located primarily in the stomach, and gut, has been recently found not only to stimulate in its acylated form, mesolimbic dopamine transmission and modulate food reward, also to be involved in the regulation of the rewarding effects of most abused drugs - including alcohol, opioids and psychostimulants as tested using classical place conditioning. In this study, we systematically investigated the responses of ghrelin in bloodstream to cocaine self-administration and to systemic injection of cocaine, and the effects of ghrelin receptor antagonism on cocaine-related behaviors using the selective ghrelin receptor antagonist JMV2959 in rats. The potential involvement of adrenergic action at peripheral β1 receptors was explored by pretreatment with atenolol, a peripherally active restricted β1 receptor antagonist. We found that both cocaine self-administration (1 mg/kg /infusion) and i.p. injection of cocaine (10 mg/kg, i.p.) significantly elevated plasma ghrelin and des-acyl ghrelin levels. Cocaine self-administration had no effect on plasma LEAP2, a recently identified endogenous ghrelin receptor antagonist. Pretreatment of cocaine-trained rats with JMV2959 (0-6mg/kg, i.p.), a potent ghrelin receptor antagonist, dose-dependently inhibited cocaine self-administration and reinstatement of cocaine-seeking induced by cocaine (10 mg/kg, i.p.) in cocaine-trained and subsequently behaviorally extinguished rats. Pretreatment with atenolol (0-15 mg/kg, i.p.) also dose-dependently inhibited cocaine self-administration and cocaine-induced reinstatement. Atenolol at 15 mg/kg also blocked the elevation in plasma ghrelin induced by cocaine. Our findings reveal an important role of endogenous ghrelin in cocaine self-administration and reinstatement and indicate that activation of peripheral β1 adrenergic receptors may be an essential process for cocaine to elevate ghrelin and for ghrelin to mediate the rewarding and motivational effects of cocaine. Thus, manipulations of the ghrelin system may represent a feasible approach for psychostimulant addiction treatment.

Title: Abstinence from cocaine self-administration alters expression of circHomer1 in the nucleus accumbens shell.

Authors: *M. C. JOHNSON[1], G. L. POWELL[1], A. VANNAN[1], M. DELL'ORCO[2], N. MELLIOS[3], N. PERRONE-BIZZOZERO[2], J. L. NEISEWANDER[1];
[1]Sch. of Life Sci., Arizona State Univ., Tempe, AZ; [2]Neurosciences, Univ. of New Mexico HSC, Albuquerque, NM; [3]Dept. of Neurosciences, Univ. of New Mexico Sch. of Med., Albuquerque, NM

Abstract: Cocaine and other psychostimulants induce long lasting changes in mesolimbic 'reward' circuits of the brain that persist or emerge after cessation of substance use. These lingering changes include the neuronal plasticity that is thought to underlie the chronic relapsing nature of substance use disorders. Genes encoding proteins involved in neuronal plasticity can also generate circular RNAs (circRNAs), which are a group of stable, non-coding RNAs produced through back-splicing of pre-mRNAs. CircRNAs are highly expressed in neuronal tissues, specifically synapses; however, their role in the brain is not well understood. The *Homer1* gene encodes several proteins associated with cocaine-induced changes in postsynaptic plasticity, and generates the circRNA *circHomer1*. Preliminary evidence from environmental enrichment (EE) studies in our lab show that relative changes in *circHomer1* and its linear RNA counterpart *Homer1b* in the nucleus accumbens (NAc) shell may be involved in incentive motivation for cocaine. To further examine the relationship between *circHomer1* and drug motivation, we used different lengths of forced abstinence to vary the degree of motivation for cocaine. Male (n=14) and female (n=15) Sprague Dawley rats were trained to self-administer cocaine (0.75 mg/kg/infusion, IV) or were yoked saline controls while advancing through increasingly difficult schedules of reinforcement until they ultimately reached VR5, the highest level of difficulty to obtain the drug reward. Following either 1 or 21 days in forced abstinence, rats were given a 1-h cue reactivity test and were sacrificed immediately after. *CircHomer1* expression was then measured from crude synaptosomal fractions of NAc shell tissue punches using RT-qPCR. Lever pressing during the cue reactivity test was significantly greater in animals abstinent for 21 days, in support of the incubation of craving effect. Preliminary results show a decrease of *circHomer1* expression in male rats abstinent from cocaine for 21 days compared to 1 day of abstinence. However, no difference in *circHomer1* levels was seen in female rats regardless of abstinence length. These preliminary results suggest that *circHomer1* expression is inversely associated with the incubation of craving effect in male rats, but that sex differences may underlie *circHomer1* expression and subsequent modulation of synaptic plasticity.

Title: Pairing extinction of cocaine-seeking with vagus nerve stimulation (VNS) reduces reinstatement via TrkB activation

Authors: *C. M. DRISKILL[1], A. J. PHENSY[1], S. R. RODRIGUEZ[1], K. L. LINDQUIST[1], J. F. MCGINTY[2], S. KROENER[1];
[1]Univ. of Texas at Dallas, Dallas, TX; [2]Neurosci., Med. Univ. South Carolina, Charleston, SC

Abstract: Cocaine induces neuroadaptations in the prefrontal cortex that contribute to drug-seeking and relapse. Vagus nerve stimulation (VNS) causes the release of several neuromodulators, including BDNF, which modulate cortical plasticity, and this plasticity can be used to increase learning and memory in both rats and humans. We have recently shown that VNS facilitates extinction learning and reduces cue-induced reinstatement in cocaine self-administering rats. Repeated exposure to cocaine and withdrawal can lower the levels of BDNF in the mPFC. Replacement of BDNF via a single infusion into the prelimbic cortex immediately after cocaine self-administration reduces relapse to cocaine-seeking after abstinence, as well as cue- and cocaine prime-induced reinstatement following extinction. Inhibiting TrkB BDNF receptors, or NMDA receptors blocks this effect, indicating an important interaction between glutamatergic synaptic activity and TrkB signaling in BDNF's suppressive effects on drug-seeking. Here we tested if VNS-induced BDNF release can modulate extinction and reinstatement of cocaine-seeking. VNS-treated rats showed elevated levels of BDNF (as measured via ELISA) in the mPFC after a single day of extinction. Systemic injections of the TrkB receptor antagonist ANA-12 during the 10d extinction period greatly reduced the effects of VNS on drug-seeking during cue-induced reinstatement. VNS-treated rats that received vehicle infusions made fewer lever presses during reinstatement when compared to sham-stimulated rats. In contrast, VNS-treated rats that received ANA-12 during extinction responded similar to Sham-stimulated rats. Following reinstatement rats were sacrificed for whole cell patch-clamp recordings to measure how VNS-induced BDNF affects glutamatergic transmission in the mPFC. Pyramidal neurons from Sham-stimulated rats animals showed reduced AMPA:NMDA ratios compared to drug-naïve animals, and treatment with VNS reversed this effect. AMPA:NMDA ratios in VNS+ANA-12-treated rats were similar to those in Sham-stimulated rats. In order to further test changes in glutamatergic synaptic transmission we recorded spontaneous EPSCs,

which at -70mV almost exclusively represent AMPAR currents, and measured changes in amplitude and frequency. Sham-stimulated rats showed a significant reduction in the average amplitude of sEPSCs compared to drug-naïve and VNS-treated rats, without changes in the frequency of sEPSCs. Taken together, these data suggest that cocaine-seeking alters AMPA currents in the mPFC and that VNS-induced BDNF release can reverse these changes to consolidate extinction learning and reduce reinstatement.

Title: Effect of systemic protein synthesis inhibition on reconsolidation of adolescent-formed drug-context associations

Authors: *A. N. HERRERA CHARPENTIER, B. R. CHO, D. I. OLEKANMA, C. A. REEVES, A. A. ARGUELLO;
Michigan State Univ., East Lansing, MI

Abstract: Adolescents are at increased risk to develop substance use disorders and suffer from relapse throughout life due to the strong associative memories formed during drug use. Previous research has used adult rodent models of relapse to investigate the role of reconsolidation mechanisms in strengthening maladaptive drug memories. Specifically, systemic treatment with the protein synthesis inhibitor cycloheximide (CHX) after a brief re-exposure to a previous drug-related cue diminished relapse behavior. However, it is unknown whether adolescent-formed, drug-context associations can be modified to reduce risk of relapse. To answer this question, we used an abbreviated self-administration paradigm that allows us to manipulate reconsolidation and test subsequent relapse-like behavior during adolescence. Adolescent male Sprague-Dawley rats (P33) received jugular catheterization surgery and were taken through cocaine self-administration training (Coc-SA; distinct contextual environment, FR1 schedule of reinforcement, 2-hr session, 2x/day, minimum of 10 sessions) and extinction training (EXT; alternate context, 2-hr session, 2x/day, minimum of 8 sessions). After the last session of EXT, rats underwent a single memory reactivation (MR) session to retrieve cocaine context memories. During MR, rats were returned to the previous Coc-paired context for a 5min or 15min session, followed immediately with a subcutaneous injection of vehicle (VEH) or CHX. Rats went

through two additional EXT sessions followed by reinstatement tests in the Coc-paired context. During the test session, levers responses were not reinforced and therefore measured drug-seeking behavior. Adolescent rats displayed similar levels of reinstatement regardless of treatment (CHX/VEH) or length of retrieval (5 vs 15 min MR session). Our results suggest that weakening contextual cocaine memories with a systemic protein synthesis inhibitor does not impair relapse during adolescence. Future directions will assess whether these observed effects are due to the specific stage of development or type of drug-associated stimuli (i.e. adolescence vs adulthood; context vs cue). Understanding the mechanisms of reconsolidation that can be influenced from adolescence can help in the development of treatments for relapse.

Title: Investigating the role of tachykinin 2 (Tac2)/neurokinin B (NkB) in medial habenula-dependent reinstatement

Authors: *V. ALIZO VERA, J. CHILDS, M. A. WOOD;
Neurobiol & Behavior, Univ. of California Irvine, Irvine, CA

Abstract: Recently, our lab discovered that a unique set of neurons in the ventral medial habenula (MHb) are sufficient to drive drug-induced reinstatement behavior using a cocaine conditioned place preference (CPP) task and cocaine self-administration (new, unpublished data). Activating these ventral MHb neurons resulted in complete reinstatement of drug seeking, even in the absence of re-exposure to the drug, demonstrating how important these neurons are for relapse-like behavior. A key open question is, what molecular mechanisms are responsible for these processes within these neurons? Our preliminary data suggest that TAC2 may be pivotal.*Tac2* belongs to the family of neuropeptides called Tachykinins. Tachykinins and their receptors are known to be involved in motivated behaviors and are found to be highly expressed in brain regions associated with reward-related behaviors such as the MHb. Indeed, *Tac2* is expressed in the ventral component of the MHb. Although very little is known about the function of TAC2 in the MHb, a recent study demonstrated that nicotine-dependent effects on the MHb are dependent on NK3R, the receptor used by TAC2 (Biasi, Mariella De, et al., 2016). Additionally, TAC2 was found to act locally on different brain regions coordinating a variety of behavioral consequences as a result of chronic social isolation stress (Zelikowsky et al., 2018). This data suggests there may be an important interaction between stress and stress-induced

reinstatement of drug seeking. We aimed to understand how *Tac2* expression is regulated during different cocaine-seeking behavioral phases. In order to do so, wild type mice underwent cocaine CPP, and expression of *tachykinin* family mRNA was examined using RT-qPCR following different phases of CPP. A trend towards increased *Tac2* in the MHb was observed following cocaine-primed reinstatement as compared to saline-primed reinstated animals. To determine whether *Tac2* is necessary to drive cocaine-seeking behaviors, siRNA smart pool against Tac2 will be bilaterally injected into brain regions with upregulated *Tac2* prior to CPP. Results from this investigation will provide a clearer understanding of the molecular basis of addictive behaviors.

Title: PPL-138 (BU10038): a bifunctional mu-NOP partial agonist that reduces cocaine taking and does not maintain self-administration behavior

Authors: *A. CIPPITELLI[1], ***M. MARTINEZ**[1], G. ZRIBI[1], G. CAMI-KOBECI[2], S. M. HUSBANDS[2], L. TOLL[1];
[1]Florida Atlantic Univ., Boca Raton, FL; [2]Univ. of Bath, Bath, United Kingdom

Abstract: In recent years, cocaine overdose deaths have been on the rise. Despite being a public health problem for decades, there are currently no medications approved for the treatment of cocaine use disorder (CUD). However, the development of compounds with bifunctional agonist activity at both mu-opioid and nociceptin opioid peptide (NOP) receptors has appeared as a potential pharmacotherapeutic strategy. Formerly known as BU10038, PPL-138 is one such compound that has partial agonist activity at both mu-opioid and NOP receptors. Here we show that PPL-138 effectively decreased the total number of cocaine infusions and burst-like intake in both male and female rats using an intermittent access (IntA) operant cocaine-self administration model, meant to closely mimic the binge pattern of consumption in human cocaine users. Doses of PPL-138 that effectively reduced parameters of cocaine self-administration had no effect on lever presses for food in an IntA model of food self-administration for either sex, although locomotor activity was increased in female but not male rats. J-113397, a selective antagonist of NOP receptors (5 mg/kg), did not impede the anti-cocaine effect of PPL-138 in contrast to naltrexone, a mu-opioid receptor antagonist (1 mg/kg), which prevented the decrease in cocaine

self-administration induced by PPL-138 treatment. Additionally, treatment with the mu-opioid receptor agonist morphine (1, 3, 10 mg/kg) dose-dependently reduced the measures of IntA cocaine self-administration. This suggests that the anti-cocaine properties of PPL-138 are mechanistically mediated by mu-opioid receptors. Finally, although PPL-138 initially appeared rewarding under our experimental conditions, self-administration of the compound was not maintained. These findings demonstrate that the approach of combining partial mu-opioid/NOP receptor activation successfully decreases cocaine intake, is endowed with low abuse potential, and thus may provide a possible method for treating cocaine use disorder.

Title: 5-ht1b receptor agonist produces similar abstinence dependent modulation of motivation for cocaine in male and female rats

Authors: *S. SCOTT, B. RUSCITTI, T. CHAPMAN, R. GARCIA, G. POWELL, J. NEISEWANDER;
Sch. of Life Sci., Arizona State Univ., Tempe, AZ

Abstract: Previous findings from our lab and others indicate that serotonin 1B receptors ($5HT_{1B}$Rs) modulate cocaine self-administration (SA) in opposite directions depending on the phase of the addiction cycle in male rats. In particular, the $5HT_{1B}$R agonist, CP 94,253 (CP) enhances cocaine intake during *maintenance* of daily cocaine SA on a low effort fixed ratio (FR) and a high effort progressive ratio (PR) schedule of reinforcement in male rats, while attenuating cocaine intake as well as drug-seeking behavior following 21 days of protracted *abstinence*. In contrast to male rats, however, we recently discovered that CP attenuates cocaine intake on an FR5 schedule in female rats, regardless of abstinence. In this study, we compared CP effects across sexes on cocaine SA under a PR schedule of reinforcement and on cue-induced cocaine-seeking behavior after protracted abstinence. Male and female Sprague-Dawley rats were trained to self-administer 0.75 mg/kg, IV cocaine on an FR1 schedule of reinforcement for 3 hours/day.

Once reinforcement rates stabilized, rats transitioned to self-administering 0.375 mg/kg, IV cocaine on a PR schedule. After reaching stability once again, rats were repeatedly tested for the effects of CP (0, 3.2, 5.6 and 10 mg/kg, SC) given 15 minutes prior to the start of a session of cocaine SA on the PR schedule. To examine the effects of CP on cue reactivity, male and female rats with a history of SA were placed into abstinence for 21 or 60 days. Following abstinence, rats were tested twice after pretreated with vehicle prior to one test and CP (5.6 mg/kg, SC) 15 minutes prior to the other test, with order of vehicle and CP tests counterbalanced across rats. Test sessions lasted 2 h during which the cocaine-conditioned light and tone cues previously paired with cocaine infusions were delivered on an FR1 schedule without cocaine. Results indicate that CP (5.6 mg/kg) increases cocaine intake on the PR schedule regardless of sex in rats that have not experience prolong abstinence, but attenuates active and inactive lever responses in rats after 21 or 60 days abstinence. These findings suggest that regardless of sex, CP has opposing effects on motivation for cocaine depending on whether or not rats experience abstinence from cocaine. Thus, the 5-HT_{1B}R agonist may be a useful treatment for cocaine use disorder after a period of abstinence.

Title: Effects of chronic stress on cocaine seeking behavior after forced abstinence in male and female rats

Authors: *R. MORALES SILVA[1], U. GELPI-DOMINGUEZ[2], G. RODRIGUEZ-TORRES[1], J. PEREZ TORRES[1], Y. PEREZ PEREZ[1], M. T. SEPULVEDA ORENGO[1];
[1]Basic Sci., [2]Psychology, Ponce Hlth. Sci. Univ., Ponce, Puerto Rico

Abstract: Generally, Post-Traumatic Stress Disorder (PTSD) and Substance Use Disorder (SUD) are studied independently in preclinical studies, although they can occur concurrently in

patients and in fact, PTSD patients exhibit higher rates of SUD. Exposure to stressful or traumatic events can lead to the development of PTSD, and stress has been associated with a higher probability of relapse. Previous studies have shown that modified single prolonged stress reduces cocaine self-administration in rats, as well as a reduced cue-induced reinstatement of cocaine seeking behavior, without any effects on acquisition and extinction of cocaine self-administration. These studies used a short-access cocaine self-administration paradigm, and the effects of chronic stress on extended-access cocaine self-administration remain to be studied. Our objective is to determine the effects of chronic stress on cocaine seeking behavior in male and female rats. We hypothesize that unescapable footshocks prior cocaine self-administration will increase cocaine seeking behavior in both sexes. To test this hypothesis, we used unescapable footshocks for a period of 5 days at an intensity of 0.50mA (presented randomly), followed by 6-hour sessions of extended-access cocaine self-administration for 10 days, and a 30 day forced abstinence period. Subsequently, we examined conditioned stimulus- and cocaine-induced cocaine-seeking behavior. Our data show that unescapable footshocks prior cocaine acquisition increases cocaine-primed memory retrieval after withdrawal in male and female rats. Interestingly, only female rats show an increase in cue-induced cocaine seeking behavior in the stress group, compared with the control group. Furthermore, preliminary data show that the stress group exhibits an increase in motivation for drug-seeking behavior in a fixed ratio 3 schedule of self-administration sessions, compared with control group. These results suggest that chronic stress prior cocaine exposure increases the reinforcing effects of cocaine after forced abstinence in male and female rats, as well as the compulsivity of cocaine seeking behavior.

Title: Granulocyte-macrophage colony-stimulating factoralters cocaine-induced behavioral responses and transcriptional regulation in the nucleus accumbens

Authors: *K. E. LUCERNE[1], C. D. TEAGUE[1], D. D. KIRALY[2];
[1]Neurosci., Icahn Sch. of Med. At Mount Sinai, New York, NY; [2]Psychiatry / Neurosci., Icahn Sch. of Med. at Mount Sinai, New York, NY

Abstract: Increasing evidence from recent years shows the gut microbiome markedly effects behavioral and neurobiological responses to cocaine. Here we investigate the potential role of the immune system as a mechanism underlying gut-brain communication in cocaine use. To this end, we performed serum multiplex analysis of circulating cytokines in mice with intact or depleted gut microbiomes after chronic cocaine or saline. This analysis identified granulocyte-macrophage colony-stimulating factor (GM-CSF) to be significantly increased by chronic cocaine only in animals with an intact gut microbiome. To examine whether GM-CSF regulates behavioral responses to cocaine, we performed a cocaine conditioned place preference (CPP) assay on mice with intact or depleted microbiomes, receiving daily injections of GM-CSF (10μg/kg) or vehicle. On this CPP test, GM-CSF treatment normalized cocaine preference in microbiome-depleted animals, and significantly attenuated cocaine preference in microbiome-intact animals. Furthermore, GM-CSF (10μg/kg) 30 minutes prior to an acute dose of cocaine (7.5mg/kg) attenuated cocaine-induced locomotion. Given the effect of GM-CSF on cocaine behavioral responses, we then sought to investigate the biological consequences of GM-CSF on cocaine-induced transcriptional responses in the NAc. To this end, we performed quantitative polymerase chain reaction (qPCR) and RNAscope *in-situ* hybridization to quantify GM-CSF receptor expression in the nucleus accumbens (NAc) following cocaine treatment. qPCR and RNAscope showed cell-type specific cocaine-induced increases in GM-CSF receptor expression in the NAc. Based upon this evidence for altered GM-CSF signaling in the NAc following cocaine, we then performed RNA-sequencing on NAc tissue from GM-CSF+cocaine treated animals. We found that treatment with GM-CSF+cocaine altered genes related to synaptic function in the NAc. Altogether, these data indicate GM-CSF participates in cocaine-induced behavioral and molecular plasticity, poising it as a novel neuroimmune signal in cocaine use.

Title: Hypocretin Receptor 1 Antagonism Blocks Incubation of Cocaine Craving and Normalizes Nucleus Accumbens Adaptations

Authors: *P. J. CLARK, R. A. ESPAÑA;
Neurobio. and Anat., Drexel Univ. Col. of Med., Philadelphia, PA

Abstract: Relapse remains a major obstacle to recovery from drug dependence. Across all major drugs of abuse, drug craving has been reported to intensify during periods of abstinence. This phenomenon-known as incubation of craving-is thought to promote drug seeking, thereby increasing the risk of relapse. The neurobiology that underlies drug craving is complex, but recent work has revealed that incubation of cocaine craving is linked to aberrant glutamate plasticity within the nucleus accumbens (NAc). While the mechanisms remain unclear, dopamine (DA) transmission in the NAc is posited to mediate the emergence of these adaptations. Furthermore, we and others show that NAc DA terminals exhibit dysfunction during abstinence from cocaine, including increased baseline uptake rate, enhanced sensitivity to cocaine, and increased phosphorylation of the DA transporter (pDAT). Hypocretin receptor 1 antagonists have been shown to decrease each of these metrics and consistently reduce motivation for cocaine. These features position hypocretin receptor 1 as a potential therapeutic target for the treatment of drug craving and its associated neuropathology. To examine the trajectory of NAc adaptations during abstinence from cocaine, we first trained rats to self-administer cocaine on an intermittent access (IntA) schedule of reinforcement followed by one week of abstinence. As expected, we found that IntA and abstinence produced robust incubation of cocaine craving. Then, using *ex vivo* fast scan cyclic voltammetry (FSCV), we saw that incubation of craving was tied to higher DA uptake rate in the NAc and enhanced DA terminal sensitivity to cocaine. In NAc tissue from the same animals we found increased pDAT levels as well as elevated NMDA receptor protein levels using Western blots. Next, we examined whether treatment with the hypocretin receptor 1 antagonist, RTIOX-276, early in abstinence prevents incubation of cocaine craving and reduces aberrant dopaminergic and glutamatergic adaptations in the NAc. We again trained animals to self-administer cocaine on an IntA schedule followed by one week of abstinence. On the first day of abstinence, rats were treated with a single injection of RTIOX-276 or vehicle. We found that a single RTIOX-276 treatment blocked incubation of cocaine craving. Ongoing experiments will use western blots and *ex vivo* FSCV to examine the functional and biochemical consequences of RTIOX-276 treatment. Together, these data suggest that antagonism of hypocretin receptor 1 early in abstinence from cocaine blocks incubation of cocaine craving and may normalize NAc adaptations.

Title: A novel role for amygdalar GLP-1 circuits in the reinstatement of cocaine-seeking behavior during withdrawal

Authors: *R. MERKEL, K. RAGNINI, R. HERMAN, Y. ZHANG, H. D. SCHMIDT; Univ. of Pennsylvania, Philadelphia, PA

Abstract: Cocaine is a widely abused illicit drug and cocaine use disorder (CUD) is a major public health concern as nearly 1 million American adults met the diagnostic criteria for CUD in 2018. Preventing relapse and promoting long-term abstinence remain the greatest challenges for successfully treating CUD. Unfortunately, there are currently no FDA-approved pharmacotherapies to reduce the rate of cocaine relapse. Thus, further exploration of the neurological mechanisms underlying relapse is imperative to fill this gap in knowledge. An emerging literature indicates that activation of central glucagon-like peptide-1 receptors (GLP-1Rs) reduces the rewarding effects of cocaine and attenuates cocaine-taking during voluntary self-administration and -seeking during abstinence. However, the neural circuits mediating these effects are not fully described. The central nucleus of the amygdala (CeA) is necessary for drug-related learning and the reinstatement of cocaine-seeking behavior. We hypothesized that activation of GLP-1Rs in the CeA via direct administration of the GLP-1R agonist, exendin-4, would attenuate the reinstatement of cocaine-seeking behavior. Here, we show that intra-CeA administration of exendin-4 dose-dependently attenuated the ability of an acute priming injection of cocaine and drug-paired cues to reinstate cocaine seeking during withdrawal. To date, GLP-1R-expressing circuits in the amygdala have not been characterized. Neural tracing and fluorescent *in situ* hybridization techniques were used to determine if GLP-1R-expressing neurons in the CeA send monosynaptic projections to the bed nucleus of the stria terminalis (BNST). We hypothesized that the BNST is a primary downstream target of CeA GLP-1R-expressing neurons due to its role in withdrawal phenotypes. Preliminary data suggest that GLP-1Rs are expressed on a subset of neurons that project from the CeA to the BNST. Together, these findings establish a novel, functional role for CeA GLP-1R signaling in cocaine reinstatement and further support re-purposing GLP-1R agonists for treating CUD. Future studies will determine if, and quantify the extent to which, GLP-1Rs are expressed on GABA neurons that project from the CeA to the BNST. We also aim to explore how CeA GLP-1 signaling influences stress-induced reinstatement of cocaine seeking and withdrawal-induced anxiety-like behaviors. Given the critical role of the CeA in cocaine reinstatement and stress, it is possible that CeA GLP-1 signaling mediates drug reinforcement indirectly by attenuating stress responses that drive drug-seeking behaviors during withdrawal.

Title: Synaptic vesicle protein, synaptogyrin-3, alters dopamine system function and reduces cocaine self-administration.

Authors: *E. G. PECK[1], P. M. ESTAVE[2], S. R. JONES[2];
[1]Wake Forest, Winston Salem, NC; [2]Physiol. and Pharmacol., Wake Forest Sch. of Med., Winston Salem, NC

Abstract: Synaptogyrin-3 (SYG3) is a synaptic vesicle protein highly expressed in dopamine-containing neurons that directly interacts with the dopamine transporter (DAT), suggesting a role in synaptic dopamine dynamics. We tested the hypothesis that chronic exposure to cocaine will disrupt SYG3 function, leading to alterations in DAT that drive subsequent excessive cocaine taking. Rats were trained to self-administer cocaine, and after successful acquisition, rats were tested on a progressive ratio (PR) schedule of reinforcement. Western blots indicated a significant positive correlation between relative SYG3 and DAT protein levels in the ventral tegmental area, and a significant negative correlation between SYG3 and PR breakpoint. We then overexpressed SYG3 in the VTA of naive rats to assess alterations in baseline behavior and terminal dopamine dynamics. Anxiety-like behavior was assessed using the novel open field test, elevated plus test, and social interaction test. Then, cocaine self-administration behavior was assessed using a long access schedule of reinforcement. In a separate cohort of rats, nucleus accumbens dopamine terminal function was assessed using *ex vivo* fast-scan cyclic voltammetry (FSCV). Overexpression of SYG3 in the VTA resulted in greater time spent in the center of the open field, reduced cocaine self-administration, as well as augmented dopamine release and reuptake kinetics in brain slices containing the nucleus accumbens. Together, these data suggest that SYG3 is a powerful modulator of dopamine kinetics and dopamine-related behavior, indicating this as a fruitful potential target for pharmacotherapeutics to treat cocaine use disorder.

Title: The role of Grin2c expression in PFC ensemble neurons that encode cocaine conditioned place preference in mice

Authors: *L. A. RAMSEY, K. E. SAVELL, R. MADANGOPAL, C. N. MILLER, C. T. RICHIE, F. J. RUBIO, B. T. HOPE;
NIDA IRP, Baltimore, MD

Abstract: Learned associations between rewards, such as food or drugs of abuse, and reward-predictive stimuli, are critical to motivated behavior. Associative learning is thought to be encoded by functional alterations within activity-dependent neuronal ensembles. The specific mechanism by which learned associations are encoded within activity-dependent ensembles remains unknown. To examine these drug-based learned associations, we used cocaine conditioned place preference (CPP) in mice. We performed immunohistochemistry for the immediate early gene Fos, which is a marker of strong neuronal activation. We found that the prelimbic cortex is strongly active during cocaine-paired context re-exposure. We then used a combination of fluorescence activated cell sorting (FACS) and subsequent qPCR, as well as RNAscope in situ hybridization, to identify genetic targets that distinguish Fos-positive ensemble neurons from Fos-negative neurons in the prefrontal cortex following context re-exposure. We found an upregulation in expression of Grin2c, which encodes the NR2C subunit of the NMDA receptor, primarily in activated neurons after context re-exposure. Future studies will use miRNA-mediated knockdown of Grin2c to examine its role in the acquisition and expression of cocaine CPP.

Abstract: Reelin protein marks cocaine-sensitive *Drd1+* medium spiny neurons and modulates the transcriptional and physiological response to dopamine

Kasey L. Brida[1], Robert A. Phillips III[1], M. Natalie Davis[1], Kelsey Montgomery[2], Kristen R. Maynard[2], Keri Martinowich[2], & Jeremy J. Day[11]Department of Neurobiology, University of Alabama at Birmingham, [2]Lieber Institute for Brain Development

Reelin, a large, secreted glycoprotein encoded by the gene *Reln*, is expressed at high levels in the adult striatum, hippocampus, and cerebellum. *Reln* expression plays a critical role in brain development and experience-dependent plasticity. While the role of reelin protein in neurodevelopment has been extensively studied, reelin's cellular and molecular role in the adult brain remains to be characterized, despite genetic links to neuropsychiatric disorders, such as psychostimulant abuse. To assess *Reln* mRNA distribution within specific cell types of the rat nucleus accumbens (NAc), we queried a recently described transcriptional atlas generated from single-nucleus RNA-seq of rat NAc tissue collected following acute cocaine exposure. This dataset demonstrated that *Reln* mRNA marks a population of cocaine-responsive *Drd-1+* medium spiny neurons (MSNs). These results were mirrored in postmortem human brain tissue, where multiplexed fluorescent in-situ hybridization showed enrichment of *RELN* mRNA in NAc *Drd1+* MSNs. We next designed a CRISPR sgRNA targeting the *Reln* promoter, allowing us to bidirectionally manipulate *Reln* mRNA and protein levels with CRISPR activation or CRISPR interference. Notably, CRISPR activation of *Reln* in rat primary striatal neuron cultures enhanced stimulus-dependent transcription of immediate early genes following dopamine stimulation. Likewise, knockdown of *Reln* blunted the dopamine-induced increases in MSN firing rate, without altering baseline electrophysiological properties. These results suggest that Reelin may contribute to dopamine-dependent transcriptional and physiological changes caused by cocaine. Ongoing studies are assessing the effects of CRISPR-mediated *Reln* manipulations on cocaine-induced behavioral responses.

Title: Multiomic profiling of the rat nucleus accumbens reveals cell-type specific chromatin remodeling and transcriptional alterations after cocaine experience

Authors: *J. J. TUSCHER[1], R. A. PHILLIPS, III[1], E. WAN[1], M. E. ZIPPERLY[1], C. G. DUKE[1], L. IANOV[1], S. L. FULTON[2], A. LEPACK[2], I. S. MAZE[2], J. J. DAY[1];

Abstract: Cocaine use elevates dopamine levels in the nucleus accumbens (NAc) and alters transcriptional programs believed to promote long-lasting synaptic and behavioral adaptations. However, even with well-studied drugs of abuse such as cocaine, transcriptional responses remain poorly understood. This is in part due to the cellular heterogeneity of the NAc, which contains multiple neuronal and non-neuronal cell types, and the complex actions induced by drugs of abuse via multiple neurotransmitter systems. Here, we performed single-nucleus RNA-sequencing (snRNA-seq) on nuclei isolated from male and female rats after acute (15,631 nuclei) or repeated (23,557 nuclei) cocaine exposure to generate a molecular atlas of the NAc. This approach revealed 16 transcriptionally distinct cell subtypes in the NAc, and identified population-specific transcriptional responses to initial cocaine experience, including a core set of activity-dependent immediate early genes. Next, to examine long-lasting chromatin and transcriptional alterations induced by volitional drug use, we performed multiomic profiling with snRNA-seq and single-nucleus Assay for Transposase Accessible Chromatin (snATAC-seq) on 39,325 nuclei from the rat NAc after a 30 day withdrawal period from extended access cocaine self-administration. Together, these datasets reveal a cell-type specific immediate early gene signature engaged by initial drug use, and identify long-lasting transcriptional and chromatin alterations maintained 30 days after drug taking. These results provide key insights into how cellular diversity contributes to chromatin remodeling and transcriptional alterations to distinct types of cocaine experience, and suggest the importance of cell-type specific gene targets for the treatment of substance use disorders.

Title: An atlas of transcriptionally defined cell types in the rat ventral tegmental area

Authors: *R. PHILLIPS[1], J. J. TUSCHER[1], D. FITZGERALD[1], S. BLACK[1], L. IANOV[1], J. J. DAY[2];
[1]Univ. of Alabama at Birmingham, Birmingham, AL; [2]Neurobio., Univ. of Alabama At Birmingham, Birmingham, AL

Abstract: The ventral tegmental area (VTA) is a complex brain region that is essential for reward function, but is also implicated in neuropsychiatric diseases including substance abuse. While decades of research on VTA function have focused on the role of dopaminergic neurons, recent evidence has identified critical roles for VTA GABAergic and glutamatergic neurons in reward processes as well. Interestingly, molecular characterization has revealed that subsets of these neurons express genes involved in the transport, synthesis, and vesicular packaging of multiple neurotransmitters, providing evidence for co-release neurons. However, these studies have largely relied on low-throughput methods, and the molecular architecture of the VTA has not been comprehensively examined. Here, we performed single nucleus RNA-sequencing (snRNA-seq) on 21,600 VTA cells from male and female adult Sprague-Dawley rats to generate a transcriptional atlas of the rat VTA. We identified 16 transcriptionally distinct cell types within the VTA, including 7 neuronal populations. Further subclustering revealed several VTA neuronal populations expressing markers for more than one neurotransmitter system, with one cluster exhibiting high expression levels of genes involved in the synthesis and transport of GABA, glutamate, and dopamine. Finally, snRNA-seq enabled the de novo identification of thousands of marker genes for each transcriptionally distinct population, revealing cluster-specific enrichment of gene sets implicated in neuropsychiatric and neurodevelopmental disorders, as well as specific phenotypes associated with alcohol and tobacco use. Together, these results highlight the heterogeneity of cellular populations in the VTA and identify novel markers and disease-linked genes enriched in distinct neuronal subtypes.

Title: Epigenetic effects of sex and early-life stress on cocaine addiction vulnerability

Authors: D. ROCKS[1], I. JARIC[1], J. M. GREALLY[2], M. SUZUKI[2], ***M. KUNDAKOVIC**[1]; [1]Dept. of Biol. Sci., Fordham Univ., Bronx, NY; [2]Ctr. for Epigenomics, Dept. of Genet., Albert Einstein Col. of Med., Bronx, NY

Abstract: Early-life traumas, such as neglect and abuse, significantly increase the risk for drug abuse and addiction, including cocaine use disorder, in later life. In addition, there are sex differences in cocaine addiction, with females progressing more rapidly into substance use disorder than males, which is at least in part due to sex hormone effects. However, the interaction between sex and stress and, in particular, the biological mechanisms underlying stress- and sex hormone-induced addiction vulnerability remain poorly understood. To study this, we used an early-life stress (maternal separation) paradigm in mice, which included 3-hour daily separations of pups from their mothers from postnatal day P1-14. We then performed the cocaine-induced conditioned place preference (CPP) from P54-60, with the low (2.5 mg/kg) or high (10 mg/kg) cocaine dose, and RNA-seq analysis of the key brain reward area nucleus accumbens (NAc) at P54. We show that early-life stress increases cocaine preference in a sex-dependent manner. Early-life stress-exposed male mice showed cocaine preference after receiving the suboptimal, low dose, not sufficient to induce CPP in controls. In females, both low and high cocaine doses had stronger effects in maternally-separated mice than in controls. Cocaine CPP also varied with the estrous cycle in females, with early-life stress skewing this behavior toward higher preference. Interestingly, we also found female-biased gene expression changes in the NAc in response to early-life stress, involving synaptic transmission-, brain disorder-, and estrogen receptor signaling-relevant genes and pathways. To test whether epigenetic mechanisms are involved in sex-specific and estrous cycle-dependent cocaine responses, at P54, we performed chromatin accessibility (ATAC-seq) analysis of neuronal nuclei from the NAc of proestrus (high-estrogenic) females, diestrus (low-estrogenic) females and males, following 1-hour and 4-hour cocaine (10 mg/kg) treatments. We found sex-specific chromatin changes in the NAc; ~1,000 gene regions in NAc neurons showed differential chromatin accessibility following cocaine exposure in both male and proestrus female mice, with a very little overlap between sexes. Chromatin differences were found nearby genes involved in neuronal function, synaptic plasticity, and the brain reward pathway, implicating different genes and pathways in cocaine-induced plasticity in males and females. Overall, our study increases an understanding of the role of stress and sex hormones in addiction vulnerability, and reveals candidate epigenetic mechanisms underlying sex differences in drug abuse and addiction.

Title: Estradiol interacts with extracellular matrix metalloproteinase-9 (MMP-9) to enhance hippocampal memory consolidation

Authors: *K. S. GROSS, C. M. LINCOLN, M. M. ANDERSON, G. E. GEIGER, K. M. FRICK;
Psychology, Univ. of Wisconsin, Milwaukee, WI

Abstract: The potent estrogen 17β-estradiol (E_2) is a powerful modulator of hippocampal plasticity and memory. Research on molecular mechanisms of hippocampal E_2 signaling has uncovered multiple intracellular pathways that contribute to these effects, but few have questioned the role that extracellular signaling processes may play in E_2-induced plasticity. The extracellular matrix (ECM) is increasingly recognized as a critical synaptic component, and ECM modifying enzymes like matrix metalloproteinase-9 (MMP-9) are required for hippocampal learning and memory. Little is established about the extent to which E_2 regulates MMP-9 in the hippocampus, and the influence this interaction may have on hippocampal memory is unknown. Therefore, we sought to determine whether E_2 increases MMP-9 activity in the hippocampus to promote memory consolidation on object placement and recognition tasks. Female C57BL/6 mice were ovariectomized and cannulated in the dorsal hippocampus (DH) and dorsal third ventricle (ICV). Immediately following object training, mice were infused with vehicle or a non-memory impairing dose of an MMP-9 inhibitor into the DH and vehicle or E_2 into the ICV. Object placement or object recognition memory was then tested 24 or 48 hours later, respectively. We found that MMP-9 inhibition blocked the memory enhancing effects of E_2, suggesting that ECM modification may be a critical factor in estrogenic regulation of memory. Further experiments found that E_2 rapidly increases hippocampal MMP-9 activity without influencing its protein expression. Continuing work is examining mechanisms and outcomes of E_2-induced MMP-9 activation.

Title: Chronic high-dose testosterone does not decrease myelination of corticostriatal tracts in rat brain

Authors: *A. DONOVAN[1], R. I. WOOD[2];
[1]USC, Los Angeles, CA; [2]Keck Sch. Med. USC, Los Angeles, CA

Abstract: INTRO- Anabolic androgenic steroids (AAS) are controlled substances. Despite this, AAS are used by professionals and amateurs to improve performance and increase muscularity. AAS are associated with risky behavior, aggression, and reduced connectivity between cognitive and limbic networks in the brain. Increased risk taking is correlated with lowered connectivity of the prefrontal cortex (PFC) and the nucleus accumbens (Acb). Both neurons and glia have been shown to be sensitive to AAS, even though myelinating oligodendrocytes do not express androgen receptor (AR). Testosterone increases remyelination after demyelinating injury in an AR-dependent fashion, but can exaggerate neuronal apoptotic effects when applied at supraphysiologic doses. This suggests androgens moderate myelination, potentially via axo-myelinic signaling. Accordingly, we hypothesized that myelination of the medial corticostriatal tract connecting PFC to Acb would be sensitive to AAS. If so, AAS may impair communication through the medial corticostriatal tract, leading to decreased executive function, and the adoption of high-risk/high-reward behaviors.
METHODS- Male Long-Evans rats received high-dose testosterone (7.5 mg/kg daily, 5d/wk) or vehicle (n=8 each) for 7 weeks. They were sacrificed and brains sectioned coronally at 40 um. We evaluated myelin in the medial corticostriatal tract and forceps minor of the corpus callosum. As positive and negative controls, we also examined the stria terminalis, a tract connecting steroid-sensitive regions in ventral forebrain, and the mid-body of the corpus callosum, a tract connecting steroid-insensitive cortical regions. Myelination was compared using immunohistochemistry for Myelin Basic Protein (MBP), and Oligodendrocyte 2+ (Olig2+) as an oligodendrocyte-specific nuclear marker. Photomicrographs were analyzed using NIH ImageJ.
RESULTS- MBP measurements of fiber tract area showed no effect of testosterone. Olig2+ measurements of normalized stained area, mean gray value, oligodendrocyte cell count, and integrated optical density showed no effect of testosterone. Across all measurements there was a

significant effect of tract on MBP and Olig2+ staining, even after adjusting for differences in tract area.
CONCLUSIONS- AAS increase risk-taking and aggressive behavior. Studies examining the neurobiological basis of these changes have previously focused on neuronal effects of AAS. Our study explored myelination as a new potential mechanism. Although we found no effect of testosterone on myelination at the light microscopic level, examination at the ultrastructural level has potential to reveal further effects.

Title: Effects of estradiol treatment on ubiquitin-proteasome activity in the dorsal hippocampus of male and female mice

Authors: *S. B. BEAMISH[1], K. S. GROSS[1], R. K. KUEHN[1], T. J. JAROME[2], K. M. FRICK[1]; [1]Psychology, Univ. of Wisconsin-Milwaukee, Milwaukee, WI; [2]Virginia Tech., Blacksburg, VA

Abstract: Sex steroid hormones like 17β-estradiol (E_2) enhance hippocampal function and long-term memory formation in both sexes, however, the molecular mechanisms through which E_2 exerts its effects remain unclear. One overlooked mechanism that may play a key role in the memory-enhancing effects of E_2 in both sexes is protein degradation mediated by the ubiquitin-proteasome system (UPS). In this system, proteins are tagged with multiple ubiquitin modifications at lysine 48 (K48 polyubiquitination) to become substrates for degradation by the 26S proteasome complex. The 26S proteasome is a multi-subunit structure that is activated by phosphorylation of its regulatory subunits following synaptic activity. Preliminary data from our lab demonstrate sex differences in hippocampal proteasome activation following object training, such that males, but not females, have increased phosphorylation of the proteasomal regulatory subunit RPT6 relative to male homecage controls. However, the extent to which these learning-induced sex differences are regulated by sex-steroid hormones such as E_2 is unknown. The present study examined whether dorsal hippocampal (DH) infusion of E_2 alters UPS activity in male and ovariectomized female mice. Adult male and female C57BL/6 mice were implanted with bilateral guide cannulae into the DH and females were then bilaterally ovariectomized. Following surgical recovery, mice received DH infusion of either E_2 or vehicle, and DH tissue was collected 4 and 6 h later for Western blot analysis of K48 polyubiquitinated proteins. Our

findings indicate that DH infusion of E_2 increases degradation-specific K48 polyubiquitination in both sexes, however, E_2-treated males have increased K48 tagging at 6 h, whereas E_2-treated females have increased K48 tagging at both 4 and 6 h. These findings suggest that E_2 treatment alone stimulates ubiquitin tagging to a greater degree in females than in males. Current work is examining whether E_2-induced increases in K48 polyubiquitination concomitantly increase proteasome activity and whether proteasome activity is required for successful spatial and object recognition memory consolidation in gonadectomized male and female mice. This work ultimately aims to reveal a potential new mechanism through which E_2 regulates hippocampal memory formation in male and female mice.

Title: Chronic metformin treatment effects on steroid hormones and behaviors relevant to autism

Authors: *S. GREENE, B. BORDAS, G. ALCALA, P. JIMENEZ, Y. R. SANCHEZ, M. K. PENTA, L. C. DAWS, G. G. GOULD;
Cell. and Integrative Physiol., Univ. of Texas Hlth. Sci. Ctr. San Anto, San Antonio, TX

Abstract: Despite increases in diagnoses of autism spectrum disorder, there still remains no comprehensive treatment to combat the debilitating restrictive-repetitive and inhibited social behavioral symptoms. Often adolescents have multiple prescriptions, with metformin commonly co-administered to offset weight gain caused from antipsychotics. Metformin has been reported to have other properties, such as androgen suppression that may counter increased steroid levels found in many children with autism. For this project, we focused on testing the hormonal suppression effects caused by metformin as a means to ameliorate the behavioral symptoms of autism using a mouse model. BTBR T+Itpr3tf/J (BTBR) mice were used because this strain is a popular behavioral autism model with high testosterone, corticosterone, and progesterone levels, and low serotonin (5-HT) transporter (SERT) density as compared to C57BL/6J (C57) mice,

which were used as a strain control. Acute IP injections with metformin in BTBR enhanced social behavior in the three-chamber social interaction and social novelty test. Therefore, metformin was administered chronically over six weeks via drinking water to see if the effect remained consistent. Mice were tested in several behaviors including three-chamber tests for social interaction and social novelty, marble burying for restrictive repetitive behavior, tube test for social dominance, and water t maze for cognitive flexibility. Once behavioral testing ended, serum was collected to measure testosterone, corticosterone, and progesterone, in addition to fasting blood glucose. Overall, metformin exposure did not prove effective at increasing BTBR social behavior in the three-chamber test, but it did increase dominance in the tube test for both BTBR and C57 mouse models. Marble burying by mice over 30 min did not differ by strain, sex or metformin treatment. Cognitive flexibility in the water t maze, measured by number of errors, percent of error free trials, and time to swim to the platform showed negative impacts for both number of errors and time swimming on C57 mice after exposure to chronic metformin. Physiological measures showed no changes in steroid hormones, and increased blood glucose after exposure to chronic metformin in both BTBR and C57 mouse models. Overall, our findings indicate chronic use of metformin may increase social dominance but impair cognitive flexibility via mechanisms independent of blood glucose or steroid hormones.

Title: Effects of dorsal hippocampal 17b-estradiol infusion and APOE genotype on dendritic spine densities in the hippocampus and prefrontal cortex in a mouse model of Alzheimer’s Disease

Authors: *A. W. FLEISCHER, L. R. TAXIER, K. M. FRICK;
Univ. of Wisconsin - Milwaukee, Milwaukee, WI

Abstract: Rationale: The menopausal loss of circulating hormones is associated with heightened risk for the development of Alzheimer’s Disease (AD) in women relative to men. Additionally, women carriers of the *APOE4* allele, the greatest genetic risk for developing AD, are at higher risk of developing AD relative to women of any other *APOE* genotype. Thus, there appears to be a strong link between hormonal status and *APOE* genotype which could mediate

cognitive decline in AD and provide a potential therapeutic target to improve outcomes in women with AD. Our lab and others have demonstrated that infusion of 17β-estradiol (E2), the potent estrogen, into the dorsal hippocampus (DH) improves spatial and object recognition memories in ovariectomized (OVX) wildtype mice, effects associated with proliferation of dendritic spines in the DH and medial prefrontal cortex (mPFC). However, whether E2 affects dendritic spine densities similarly in a mouse model of Alzheimer's Disease has yet to be determined. **Objective:** The goal of this study was to determine the effects of DH-infused E2 on basal and apical spines in the DH and mPFC. **Methods:** 6-month-old female EFAD mice ($5xFAD^{+/-}/APOE^{+/+}$), including E3FAD, E4FAD, and E3/4FAD were ovariectomized. Following behavioral testing, mice were infused bilaterally into the DH with vehicle or E2. Mice were euthanized 2 hours later, and their brains were collected for Golgi staining. Secondary and tertiary apical spines and secondary basal spines were counted in the CA1 subfield of the dorsal hippocampus and layer II/III of the prelimbic mPFC. Spines were classified as stubby, thin, or mushroom, based upon their morphology. **Results:** Preliminary results show that direct DH infusion of E2 increased CA1 apical, but not basal, spines in E3FAD and E3/4FAD mice 2 hours later. E4FAD mice had reduced basal and apical spine densities in CA1 compared to E3FAD and E3/4FAD mice, regardless of E2 treatment. Finally, our preliminary results suggest no effect of genotype or DH E2 infusion on basal or apical dendritic spine densities in the mPFC. **Conclusions:** E2 infusion into the DH of E3FAD and E3/4FAD, but not E4FAD, OVX mice facilitates dendritic spine growth in the DH, but this effect does not extend to the mPFC, a downstream target of DH neurons. Given that DH infusion of E2 increases spine densities in the mPFC of young, OVX wildtype mice, this suggests disrupted circuitry in EFAD mice that cannot be overcome by E2's actions in the DH. Therefore, although E2 may be a promising treatment for memory deficits in AD, further work is needed to elucidate the mechanisms by which it does so both at the local and circuit levels.

Title: Rapid synthesis of estrogen is required for hippocampal long-term plasticity in absence of ovarian hormones in female mice.

Authors: *M. MAROTEAUX[1,3], J. M. DANIEL[1,3], L. A. SCHRADER[2,3];
[1]Psychology, [2]Cell & Mol. Biol, Tulane Univ., New Orleans, LA; [3]Tulane Brain Inst., New Orleans, LA

Abstract: Menopause is characterized by cessation of ovarian function, leading to a decrease in the level of circulating estrogens which support neuronal functions. Although still debated in humans, estrogens, mainly 17-β-estradiol (E2), improve memory related behavioral tasks in rodents. Estrogens enhance connectivity and neuronal plasticity, which underpin memory formation, consolidation, and maintenance. For instance, E2 enhances excitatory neurotransmission through an NMDA receptor-dependent mechanism as well as an increase in pre-synaptic release of glutamate. It also facilitates and enhances long-term potentiation (LTP) in the hippocampus. In addition to ovarian synthesis, estrogens are locally produced in the brain of both sexes. Importantly, the enzyme p450 aromatase (ARO) which converts testosterone into E2 has been found in several brain areas, including the hippocampus. This local synthesis of E2 can support estrogen-dependent transcription and blocking it with ARO inhibitors like letrozole (Let) impairs hippocampus-dependent memory as well as LTP. Although existing evidence points to a critical role of local estrogen synthesis in hippocampal memory formation, little is known on the regulation of this process, particularly after the loss of ovarian functions.
In this study we tested the hypothesis that rapid, local and on demand synthesis of E2 is necessary for LTP after removal of ovarian hormones. To address this question, we performed field recordings of evoked post synaptic potentials on hippocampal slices of ovariectomized mice. We blocked ARO activity by applying Let for 30 minutes and induced LTP at the CA3 to CA1 synapses using a theta burst protocol. We found that in the absence of ovarian estrogen, blocking ARO attenuated the development of LTP. We also verified that the ARO inhibition did not affect the response to the stimulation or the presynaptic release of neurotransmitters. These findings support a role for locally synthesized neuroestrogens as regulators of hippocampal synaptic plasticity after cessation of ovarian functions. Better understanding of the mechanism regulating neuroestrogen production in the brain could help therapy development against cognitive aging.

Title: Memory Impairment in Female Mice Lacking Membrane Estrogen Receptor Alpha

Authors: *A. F. DELARGE[1,2], M. J. STANLEY[3], J. M. DANIEL[1,2,3];
[1]Psychology Dept, [2]Tulane Brain Inst., [3]Neurosci. Program, Tulane Univ., New Orleans, LA

Abstract: Previous work from our lab has shown the capacity of estradiol, the primary estrogen produced by the ovary, to improve spatial memory in rodents. These memory enhancing effects are mediated in part by estrogen receptor alpha (ERα) which can be localized to the nucleus and cellular membrane. ERα located in the nucleus utilize the classical genomic signaling pathway which leads to transcriptional changes that occur over hours to days. In contrast, membrane ERα receptors utilize a rapid signaling pathway with effects occurring in seconds to minutes. In order to examine the effects of ERα cellular location on spatial memory, female mice containing only nuclear ERα (NOER) and wildtype (WT) female mice underwent acquisition training on an eight-arm radial maze. Delay-dependent effects on memory were tested by inserting a delay, which ranged from 30 minutes to 5 hours, between the 4th and 5th arm choices. Performance was assessed by number of proactive errors made, defined as reentry into an arm previously visited in the current trial, and number of retroactive errors made, defined as reentry into an arm previously visited prior to the delay period. Results revealed that NOER mice made significantly more proactive errors across trials than WT mice, regardless of delay. Conversely, the effect on retroactive errors was delay-dependent, and NOER mice made significantly more errors than WT mice after a 5-hour delay. Despite significant differences in spatial memory, NOER and WT mice displayed similar anxiety-related behavior and locomotor activity as measured by the elevated plus maze and open field test, respectively. These results suggest that membrane ERα plays an important role in short term working memory as well as delay-dependent memory as indicated by increases in both proactive and retroactive errors made by NOER mice. Although, significant increases in retroactive errors were not seen until the longest delay period when memory load was highest. In addition, behavioral differences did not extend to anxiety-related behavior or locomotor activity, suggesting that the effects of lacking membrane ERα are specific to memory. However, because NOER mice have superphysiological estradiol levels due to an impaired negative feedback loop, further experiments are needed to confirm that memory impairment in NOER mice is a result of the absence of membrane ERα and not increased levels of circulating estradiol. Nevertheless, this study determined that female mice lacking the rapid actions of membrane ERα exhibit spatial memory impairment in comparison to WT controls.

Abstract: The loss of ovarian hormones during menopause coincides with cognitive decline and increased risk of age-related dementias. Due to serious health risks associated with prolonged estrogen exposure, current health guidelines recommend using postmenopausal estrogen treatment for as short a time as possible. Work from our lab in a rodent model of menopause has demonstrated long-lasting benefits of short-term estradiol treatment on hippocampal function and memory through sustained activation of estrogen receptor (ER) α that persists long after estradiol treatment is terminated. A history of previous midlife estradiol treatment enhances performance on the radial-arm maze and increases levels of hippocampal ERα in aging ovariectomized rodents, an effect that is dependent on insulin-like growth factor-1 receptor (IGF-1R) and results in sustained ER-dependent transcriptional activity. The results of the current experiments demonstrate a mechanism through which the activation of hippocampal ERα can enhance memory following long periods of ovarian hormone deprivation. First, we showed the necessary role of brain-derived neuroestrogens in IGF-1-mediated activation of ERα via the MAPK pathway and its subsequent enhancements in memory in aging ovariectomized rats. Then we tested the interactive relationship between neuroestrogens and IGF-1 receptors in activating hippocampal ERα using two models of menopause in rats: one in which long-term ovariectomized aging females received no estradiol treatment in midlife and one in which long-term ovariectomized aging females received midlife estradiol treatment that was terminated after 40 days. In the long-term ovariectomized rats that did not receive previous midlife estradiol treatment, IGF-1R and neuroestrogens were no longer able to interact to activate ERα and impact memory. However, a history of previous midlife estradiol treatment reversed this effect and facilitated maintenance of the interactive relationship between IGF-1R and neuroestrogens, resulting in sustained increases in activation of ERα and enhanced memory. Together, these results provide a potential model for combatting postmenopausal cognitive decline in which short-term estradiol treatment following the loss of ovarian hormones sustains hippocampal function and memory beyond the period of estradiol treatment by permanently altering the dynamic relationship between IGF-1R signaling and neuroestrogen synthesis, allowing for long-term activation of hippocampal ERα.

Title: A mouse model of oral contraceptive exposure: effects on depression-like behavior

Authors: *K. M. SCHUH[1], I. J. PAT-OSAGIE[2], T. T. DAVIS[1], J. AHMED[1], N. C. TRONSON[1];

Abstract: Hormonal contraceptives (HCs), including combined oral contraceptives, are an important part of women's healthcare and confer massive economic benefits to women worldwide. 85% of women in the United States use this form of contraceptive at some point in their lifetime with 14% currently using oral contraceptives and 11% currently using long-acting reversible contraceptives. Despite the massive number of women that use them, HCs affect mood, behavior, and the brain in ways that are not fully understood. Anecdotally, some women report increased depression and anxiety, a finding that is corroborated by some studies, while others have found that HCs are protective against mood disorders. Studying whether and how HCs contribute to risk and resilience of depression, anxiety, and other stress-related disorders is extremely difficult with human participants due to multiple formulations of HCs, and individual differences in durations of HC use, genetic predispositions to psychiatric disorders, and prior/current stress exposures. The current project aimed to develop and validate a mouse model of HC-like exposure by examining the effects of two different combinations of hormones (0.075 μg/mL ethinyl estradiol and either 3 μg/mL levonorgestrel or 15 μg/mL drospirenone in 0.25mL of 10% sucrose, daily at 5pm) on vulnerability to depressive-like and anxiety-like behaviors in mice after subchronic variable stress. Estrous cycles were tracked using both visual and vaginal cytology methods. We found that HCs alone did not affect locomotor activity, behavioral despair, or memory in a context fear conditioning task. However, HC exposure did decrease both sucrose drinking and sucrose preference, suggesting that HC exposure may specifically affect motivational circuits and motivation- or anhedonic-related components of depression. Overall, we demonstrate that this mouse model of hormonal contraceptive-like exposure is a valid and tractable method for identifying effects of oral contraceptives on the brain, including how HCs affect hypothalamic-pituitary-adrenal axis regulation and thereby influence risk or resilience to depression.

Title: Regulation of the acute stress response by oral contraceptive hormones

Authors: I. J. PAT-OSAGIE[1], K. M. SCHUH[2], T. T. DAVIS[2], J. AHMED[2], *N. C. TRONSON[2];
[1]Psychology Dept., Hunter Col., New York, NY; [2]Psychology Dept., Univ. of Michigan, Ann Arbor, MI

Abstract: "The Pill" and other hormonal contraceptives (HCs) are a central part of women's healthcare. They provide control over reproductive timing, and additional health benefits to many individuals. For some people, HCs trigger depression and other negative affective states; yet for others, HCs exert protective effects against depression. In this project, we aim to understand how interaction between HC hormones and the HPA axis contributes to vulnerability or resilience to negative affective states. Specifically, we aimed to determine how different progestins commonly used in HCs regulate the stress response. We used a mouse model of HC hormone exposure recently developed in our lab, ELISA assays to assess corticosterone concentration, and cFos immunohistochemistry to identify stress-induced activation of brain regions and networks. We examined both C57Bl/6N and the more stress-responsive Balb/c mice to understand how individual differences in stress responsivity might contribute to changes in HC-induced risk for depression. Young adult female mice were given either ethinyl estradiol (EE; 0.075 μg/mL) and levonorgestrel (LNG; 3 μg/mL), a progestin with androgenic properties; or EE and drospirenone (DRSP; 15 μg/mL), a progestin with anti-androgenic properties, in a 10% sucrose suspension (0.25 mL) daily at 5pm. Based on data from women HC users, we hypothesized that HC hormone exposure would cause suppression of the corticosterone response to an acute stressor. We observed that mice exposed to EE+LNG showed significant blunting of the stress response as measured by serum corticosterone concentration. Surprisingly, mice treated with EE+DRSP did not show this effect. These data demonstrate that different progestins differentially modulate the HPA axis, thus progestin androgenicity may be a central factor in altered risk or resilience to depression for women on HCs. Future work will further establish whether the effects of different progestins on stress response are mediated via androgenic receptors, or via mineralocorticoid and glucocorticoid receptors. This work lays the foundation

for guiding the choice of HC formulation to increase individual women's resilience to negative affective states including depression.

Title: Differences in striatal dopamine synthesis and task switching performance between hormonal contraceptive users and non-users

Authors: *C. M. TAYLOR[1], D. J. FURMAN[3], A. S. BERRY[5], R. L. WHITE[4], W. J. JAGUST[6], M. DESPOSITO[7], E. G. JACOBS[2];

Lab., Berkeley, CA; [6]Helen Wills Neurosci Inst., [7]Helen Wills Neurosci. Inst., Univ. of California Berkeley, Berkeley, CA

Abstract: Accumulating evidence suggests that sex steroid hormones regulate dopamine (DA) neurotransmission. In rodents, 17ß-estradiol and progesterone modulate DA synthesis and release, and impact the basal firing rate of DA-ergic neurons. In nonhuman primates, DA-D2 receptor availability varies across the menstrual cycle. Further, sex hormone receptors have been localized to regions that receive major projections from midbrain DA neurons, including prefrontal cortex, dorsal striatum and the nucleus accumbens. However, much less is known about hormonal regulation of the dopamine system in the human brain. Here, we begin to address this gap by comparing dopaminergic function between female hormonal contraceptive users and non-users in a multimodal molecular PET imaging study. Pre- and postsynaptic DA signaling was assessed along three domains: dopamine synthesis capacity using the PET radioligand 6-[^{18}F]fluoro-l-m-tyrosine ([^{18}F]FMT), baseline D2/3 receptor-binding potential using [^{11}C]raclopride, and dopamine release using methylphenidate-paired [^{11}C]raclopride PET.

Participants consisted of 36 healthy females (age 18-28 years old, n=15 hormonal contraceptive users, HC; n=21 naturally cycling females, NC). Cognitive flexibility, a behavioral measure previously shown to be sensitive to DA synthesis, was also assessed. Results indicate that hormonal contraceptive users exhibit greater dopamine synthesis capacity (greater ROI-based, partial volume corrected [^{18}F]FMT K_i values) than naturally cycling females in dorsal caudate (NC_{avg}= 0.0256, HC_{avg} = 0.0295; $t(34) = -4.29$, $p = .0001$, $d = -1.49$) as well as greater cognitive flexibility (indexed as a lower behavioral switch cost on a task switching paradigm) ($t(28.99) = -2.0763$, $p = 0.0468$). We observed no group differences in D2/3 receptor binding or dopamine release. Together, this study provides a unique opportunity to examine differences in basal dopamine receptor occupancy, stimulated dopamine release, and dopamine synthesis capacity in a single cohort, based on women's hormonal contraceptive status. Hormonal contraception (in the form of pill, shot, implant, ring or IUD) is used by ~300 million women worldwide, yet few studies have examined how chronic hormone manipulations impact basic properties of the dopamine system. Findings from this study begin to address this critical gap in women's health.

Title: On characterizing the narrative speech N400 using semantically-tuned language models

Authors: *J. DOU[1], A. J. ANDERSON[2], A. WHITE[3,4], E. C. LALOR[1,2];
[1]Dept. of Biomed. Engin., [2]Dept. of Neurosci., [3]Dept. of Linguistics, [4]Dept. of Computer Sci., Univ. of Rochester, Rochester, NY

Abstract: The human brain understands speech heard at rates of around 120–200 words per minute. A well-known signature of this process is the N400 electrophysiological component – a prominent centroparietal negativity that occurs 200-600ms after word onset. Although the N400 has been the subject of thousands of research studies, what it represents is incompletely understood. This is especially so for continuous natural speech. One possibility is that the N400 is the product of a neural predictive processing mechanism(s) that: (1) anticipates linguistic properties of upcoming words, and (2) generates an error signal when predictions are wrong reflecting the degree of inaccuracy (or surprise). Furthermore, error signals may be generated in parallel at multiple levels of a linguistic processing hierarchy, thus there may be semantic, syntactic and discourse-level error components contributing to the N400 signal. Computational language-models that are trained to predict properties of upcoming words (much

the same as the brain mechanism underpinning the N400 is thought to do) present new opportunities for interrogating neural responses to narrative speech. We here present pilot work seeking to better characterize neural processing at the semantic level using a tuned language model, as a precursor for future more comprehensive tests. Specifically, we took a "baseline" language model pretrained to predict the identity of upcoming words (XL-Net) and fine-tuned that on a semantic-role labelling task to produce high quality semantic representations attuned to "who did what to whom". We hypothesized that this semantic tuning would improve our ability to predict EEG signal in the N400 range.
We tested this hypothesis on a pre-existing EEG dataset recorded as 19 participants listened an audiobook. We computed a semantically-tuned N400 predictor by computing the correlation-dissimilarity between the final layer of network activations for the current word and the word preceding it. We repeated this for the baseline model. Dissimilarity values were placed at word onset times, lagged to correspond to +200 to +600ms range and aligned to the EEG. Regularized regression was deployed to map the EEG onto the model in a cross-validation framework. The regression mapping was evaluated by predicting held out EEG data. Mean prediction accuracies (across channels) were significantly greater for the semantically tuned model than the baseline (signed rank=190,p=1e-4,n=19). These results suggest that semantic-tuning led to a better characterization of semantic processing in the brain and provide a promising foundation for future research based on computational language modeling.

Title: Neurophysiological timescales in dynamic Bayesian inference of syllable segmentation and speech speed

Authors: *B. PITTMAN-POLLETTA[1], J. CANNON[2], L. DILLEY[3];
[1]Boston Univ., Boston, MA; [2]MIT, Cambridge, MA, Canada; [3]Michigan State Univ., East Lansing, MI

Abstract: Evidence increasingly suggests that both the timing and content of speech contribute to speech segmentation and understanding, and that neuronal rhythms play key roles in these computations. Yet the computational principles by which timing, content, and top-down

information are combined in speech perception remain poorly understood. To illuminate the potential mechanisms underlying speech segmentation, we construct an explicit computational model of a predictive coding account of speech segmentation, the Syllable Inference (SI) hypothesis. SI was proposed to explain distal rate effects, in which altering the rate of context speech changes the perception of an unaltered target segment, making short words such as the preposition ``a'' appear or disappear. Under the SI hypothesis, candidate speech interpretations, syllable-specific duration estimates, and estimated speech rate are used to infer a predicted duration for each segment that is then compared and updated with acoustic data to yield speech understanding and segmentation. In this work, we propose and implement a Bayesian framework for syllable inference, and apply it to both data-derived artificial stimuli and real speech. In line with recent predictive coding hypotheses, in our framework a forward model and a backward model operate at different timescales, and alternate in time. These alternating prediction and update cycles occur at beta and gamma timescales, respectively, while lexical retrieval operations update the prior on syllable likelihood at a theta timescale. We test this framework using a synthetic language consisting of strings of syllables, with syllabic and phonemic durations taken from the TIMIT corpus, which allows us to derive distal rate effects while abstracting away higher-order linguistic information. Incorporating neurophysiologically realistic timescales at the algorithmic level, our model sheds light on how the timing of human speech perception is constrained by neurophysiology, and on how these timescales shape speech understanding. Our work generates a number of hypotheses, suggesting further experiments and connections to both biophysical computational models of cortical rhythms (at the implementation level) and recent theories about the level of detail in predictive processing (at the algorithmic/computational level).

Title: Development of language-related white matter tracts and their relationships with single word reading ability among healthy children and adolescents

Authors: Y. KIM, P. THOMAS, S. CROWELL, B. LANEY, E. NELSON, W. MATTSON, *K. R. HOSKINSON;
Ctr. for Biobehavioral Hlth., Abigail Wexner Res. Institue At Nationwide Children's Hosp., Columbus, OH

Abstract: Objectives
As children get older, white-matter fiber tracts often show increased fractional anisotropy (FA), possibly reflecting white matter maturation and pruning. Certain specific tracts, including the arcuate fasciculus (AF), inferior longitudinal fasciculus (ILF), superior longitudinal fasciculus (SLF), inferior fronto-occipital fasciculus (IFOF), and uncinate fasciculus (UF) are thought to play a role in supporting language processing and reading abilities. In this study, we investigated age-related changes in these fiber bundles among typically developing children and adolescents to examine links among specific white matter pathways and word reading ability.
Methods
Participants included 76 healthy children and adolescents aged 8 to 21 years (27 males, M_{age}=13.86). Participants completed the word reading subtest from the Wide Range Achievement Test, Fifth edition (WRAT-5) and underwent diffusion weighted imaging (DWI) on a Siemens Prisma 3Tesla scanner. Analyses of white matter fiber tracts were completed using Automated Fiber Quantification (AFQ) which yielded quantified FA values of the bilateral AF, ILF, SLF, IFOF, and UF. All statistical analyses were performed using SPSS, and included bivariate correlations and mediation modeling using ordinary least squares path analysis.
Results
As expected, participants scored within the average range on the WRAT-5 Word Reading subtest (*M*=106.55, *SD*=16.34). Bivariate correlations revealed a strong relationship between WRAT-5 raw scores and FA within the left (*r*=.31) and right ILF (*r*=.38; *p*s<.01), though not the other tracts. Age was also positively associated with FA within the right SLF, bilateral ILF, and right IFOF (*r*s=.26 to .32; *p*s<.05) The indirect effect of age on WRAT-5 performance via left ILF was positive but not statistically significant: *b*=.1356, 90%CI [-.0271, .3925]. The indirect effect of age on WRAT performance via right ILF was positive and statistically significant: *b*=.1964, 90%CI [.0347, .3859].
Conclusions
In this sample of healthy children and adolescents, age-linked maturation in the bilateral ILF mirrored improved performance on a measure of word reading, highlighting the role of this fiber pathway on supporting language processing. Moreover, FA in the right ILF accounted for significant variance in word reading, above and beyond that accounted for by age alone. Future analyses will examine more complex language processing tasks to determine the relative contribution of white matter substrates to basic vs. higher-order language.

Title: Predicting language processing in the speaking brain

Authors: *A. J. ANDERSON, D. DODDELL-FEDER, E. C. LALOR;
U. Rochester, Rochester, NY

Abstract: Understanding how linguistic meaning is represented in the human brain presents a major scientific challenge. One approach that has emerged from advances in functional neuroimaging, big data, and machine learning, is to computationally model meaning, and use models to predict brain activity. Over the past fifteen years this approach has helped to map out a network of brain regions engaged in representing the meaning of noun, verb, sentence and continuous narrative speech comprehension. To date, one major stone that has remained unturned is the case of speech production. Although we may suppose that the same neural mechanisms process semantics during both speech production and comprehension, direct brain imaging evidence for this is scant. We present initial results of an fMRI study seeking to bridge this gap and chart neural correlates of language processing during natural speech production comparative to comprehension. We tested a pair of participants who spoke ad lib about six general topics (e.g. people, places, events) for a total of 36mins. This was first in a mock scanner to get them accustomed to speaking with minimal head motion. They then took turns to again speak about the topics whilst undergoing fMRI. In a later fMRI visit they listened to the other participant's speech (the higher quality mock-scanner sound recording was used). To enable us to identify neural correlates of high-level language processing, we deployed an artificial neural network language model (Transformer-XL) to represent each word spoken. Transformer-XL is pretrained to predict the identity of upcoming words (which interestingly also enables it to produce language) and layer activations produce word vectors reflecting semantic information structure. To account for spurious covariation between high and low-level features of speech we also modeled articulatory features of spoken phonemes and the acoustic spectrogram. To isolate correlates of linguistic processing in the speaking/listening fMRI data, we mapped each voxel's activation time-series on to a time-lagged representation of the three models using regularized regression in a cross-validation framework. Predictions were evaluated on held out fMRI data. During natural speech production the language model was able to accurately predict fMRI activation in medial parietal, inferior parietal and inferior frontal cortex (all consistent with memory retrieval) but less so in lateral temporal cortex. A similar selection of regions, including lateral temporal cortex, could be predicted in listening. These results provide an exciting glimpse into language processing in the speaking brain and how it relates to listening.

Abstract: Departing from traditional linguistic models, advances in deep learning have resulted in a new type of predictive (autoregressive) deep language models (DLMs). Using a self-supervised next-word prediction task, these models are trained to generate appropriate linguistic responses in a given context. We provide empirical evidence that the human brain and autoregressive deep language models share three fundamental computational principles as they process natural language: 1) both are engaged in continuous next-word prediction before word-onset; 2) both match their pre-onset predictions to the incoming word to calculate post-onset surprise (i.e., prediction error signals); and 3) both represent words as a function of the previous context. We recorded intracranial recordings from nine patients while free listening to a 30 min podcast to support these three principles. Our findings indicate that: a) the intracranial neural activity before word-onset contains predictive information about forthcoming words, even hundreds of milliseconds before the words are perceived. In addition, autoregressive deep language models can be used to track the content of the brain's pre-onset prediction, even when the predictions are inaccurate; b) the neural activity after word-onset reflects the surprise level and prediction error; c) the autoregressive deep language model's contextual embeddings capture the neural representation of context-specific word meaning better than arbitrary or static semantic embeddings. Together, our findings suggest that autoregressive DLMs provide a novel and biologically feasible computational framework for studying the neural basis of language.

Title: Visualizing lexical activation during speech production

Authors: *A. MORGAN[1], W. DOYLE[2], O. DEVINSKY[2], A. FLINKER[1];
[1]Neurol., [2]NYU Sch. of Med., New York, NY

Abstract: Lexical retrieval is central to language, but the spatial and temporal neural codes that subserve it remain elusive. Here we employ direct neural recordings (ECoG) in humans and leverage a machine learning (decoding) approach to elucidate the neural instantiations of two central aspects of lexical retrieval during overt language production: First, the spatiotemporal patterns of neural activity that code for a word's activation. Second, the neural states that correspond to discrete stages of lexical representation (conceptual, phonological, articulatory; Levelt, 1989; Indefrey, 2011). Four patients undergoing neurosurgery for refractory epilepsy repeatedly produced 6 nouns (dog, ninja, etc.) in response to cartoon images while electrical potentials were measured directly from cortex. During a picture naming block, patients saw cartoon characters and responded overtly ("dog"). Subsequently, the same characters engaged in static scenes were shown and patients produced corresponding sentences (e.g. "The dog tickled the ninja"). We were able to predict above chance ($p<0.05$, permutation, accuracy ~=22%) which of the 6 nouns a subject was about to produce in the ~500ms leading to articulation using cross-validated multi-class classifiers. Accuracy increased leading up to production onset and then decreased, suggesting that the classifiers capture a neural process akin to lexical activation rather than signatures of articulatory processing (or early visual features which were removed from analysis). We tested the generalizability of the finding by applying the same trained classifier to nouns produced in sentences, showing above-chance accuracy for the first noun in the sentence.Next, in order to test for discrete neural stages corresponding to lexical processes we employed a temporal generalizability approach: we trained classifiers on each time sample, then tested each of these on held out trials from each time sample (following King & Dehaene, 2014; Gwilliams et al., 2020). If lexical activation involves passing through discrete representational stages, the temporal generalizability pattern should show distinct temporal patches representing neural states. Our results provide direct evidence for 2-4 distinct neural states during lexical retrieval within subjects. These states commenced approximately 600 ms prior to articulation and continued until articulation onset. The neural states likely represent temporally stable patterns supporting conceptual, phonological, and articulatory planning processes. Our results provide an important step towards linking neural spatiotemporal codes to theoretical lexical states.

Abstract: Understanding brain function requires sampling activity from widely distributed neural circuits at high temporal resolution during behavior. While state of the art systems are beginning to enable thousand channel experiments, current systems are limited in their flexibility and dynamic range. First, the lack of high density connectors has driven the development of monolithic silicon probe and hardware solutions that cannot easily be redesigned for many different species or use cases. Second, the analog front-end of the conventional design is space-constrained by the large capacitors needed to AC-couple with a cutoff frequency < 1 Hz. While a DC-coupled circuit would obviate this need for large capacitors and thus be easier to scale, it would have to deal with large DC offsets in the electrode-electrolyte interface. We have created EChip, a novel DC-coupled, high-channel-count integrated circuit for full bandwidth neurophysiology to overcome these challenges. EChip is designed to be bonded directly to a variety of different recording devices, allowing for flexibility and adaptability to many use cases. The 6.9 mm x 8.2 mm chip acquires data from 512 channels at a sampling rate of 30kS/s, and is integrated with a commercially available recording system from SpikeGadgets. Each channel includes amplification, filtering, and a 14-bit digitization. EChip can operate in a purely DC-coupled mode or in a DC feedback mode that keeps the operating point balanced on average. To validate EChip, we performed in vivo recordings in anesthetized rats using a silicon laminar polytrode (Cambridge Neurotech) in the primary auditory cortex while presenting auditory stimuli. We observed prominent stimulus-evoked potentials, where median responses across trials were 10 σ above baseline. Application of spike sorting showed high quality single units and several multi-unit clusters that were modulated by the stimulus. These results demonstrate that

EChip's novel DC feedback circuit can capture neurophysiological signals. While further development and validation are needed, these results pave the way for the planned integration with polymer polytrodes that can record from single units stably for long periods of time. By integrating multiple EChips together, we aim to record from 4096 channels distributed throughout the rat brain over long time scales to advance our understanding of information processing in local and distributed neural circuits.

Title: A toolbox to study cortical physiology in primates

Authors: *K. KHATEEB[1], J. BLOCH[1], J. ZHOU[1], M. RAHIMI[1], D. J. GRIGGS[2], M. LE[1], V. KHARAZIA[4], R. K. WANG[1], A. YAZDAN-SHAHMORAD[3];

Abstract: The primate cortex is a highly complex structure responsible for a variety of sophisticated tasks and behaviors including facilitating long-term memory storage, sensation, movement, and vision. Historically, lesioning and stimulation studies have been crucial for

elucidating the functions of broad cortical regions. However, little is understood with respect to the underlying cortical physiology and dynamics following injury or perturbation. To allow for clinical translation, it is vital that these phenomena are studied in a model sharing a high degree of complexity and evolutionary history with human cortex: the non-human primate (NHP) cortex. Such studies would allow for the development of improved therapies for neurological disorders. However, commonly employed tools for probing cortical physiology in NHP pre-clinical studies often require great surgical skill, produce variable results, and lack adaptability with other advanced tools. To address these challenges and accelerate the development of novel therapies, we developed a versatile toolbox for studying NHP cortical physiology. First, we demonstrated the photothrombotic technique, wherein intravenous infusion of a photosensitive dye, Rose Bengal, followed by targeted cortical illumination leads to the formation of localized thrombi in the vasculature. With this technique, we induced ischemic lesions extending through all layers of sensorimotor cortex in 7 adult macaques. Complementarily, we created a computational model to predict lesion sizes based on illumination parameters. Neuronal death in illuminated areas was validated and lesion sizes were measured via histological staining. With this toolbox, blood flow in the cortical microvasculature were monitored using optical coherence tomography angiography (OCTA) imaging, enabling in vivo lesion validation. Additionally, we incorporated a semi-transparent electrocorticography array to record and stimulate neural activity as lesions developed. The transparency of the array enabled illumination through the array to induce lesions, acquire OCTA images, and subsequently identify electrodes corresponding with ischemic areas in vivo. Thus, we observed the dynamics of the underlying neural activity before, during and after lesioning and stimulation. The tools presented here are compatible with previously established interfaces offering large-scale access for optical and electrical stimulation as well as imaging. In combination with behavioral findings, this toolbox can provide critical pre-clinical insights into fundamental cortical functions and drive the development of novel therapies for neurological disorders.

Title: Intrinsic network activity in human brain organoids

Authors: *T. SHARF[1], T. VAN DER MOLEN[1], E. GUZMAN[1], S. GLASAUER[1], A. BUCCINO[2], G. LUNA[1], Z. CHENG[1], M. AUDOUARD[1], K. RANASINGHE[3], K. KUDO[3], S. NAGARAJAN[3], K. TOVAR[1], L. Abstract: Human brain organoids replicate much of the cellular diversity and developmental anatomy of the human brain. However, the physiological behavior of neuronal circuits within organoids remains relatively under-explored. With high-density CMOS microelectrode arrays (26,400 electrodes) and shank electrodes (960 electrodes), we probed broadband and three-dimensional spontaneous activity of human brain organoids. These recordings simultaneously captured local field potentials (LFPs) and single unit activity as determined by Kilosort2. From spiking activity, we estimated a directed functional connectivity graph of synchronous neural network activity which showed a large number of weak functional connections enmeshed within a network skeleton of significantly fewer strong connections. Increasing the intrinsic inhibitory tone with a benzodiazepine altered the functional network graph of the organoid by altering the distribution of firing rates along a non-linear scale that produced a characteristic drug signature. Simultaneously examining the spontaneous LFPs and their phase alignment to spiking showed that spike bursts were coherent with theta oscillations in the LFPs. Our results demonstrate that human brain organoids have self-organized neuronal assemblies of sufficient size, cellular orientation, and functional connectivity to co-activate and generate field potentials from their collective transmembrane currents that phase-lock to spiking activity. These results point to the potential of brain organoids for the study of neuropsychiatric diseases, drug mechanisms, and the effects of external stimuli upon neuronal networks.

Title: Protocols for acute head-fixed recordings in awake mice with multiple Neuropixels probes

Authors: *T. K. RAMIREZ, G. R. HELLER, C. BENNETT, P. A. GROBLEWSKI, A. WILLIFORD, J. LUVIANO, S. DURAND, J. H. SIEGLE, S. R. OLSEN;
Allen Inst. for Brain Sci., Seattle, WA

Abstract: Recent years have seen a substantial leap forward in extracellular electrophysiology with the development and widespread distribution of Neuropixels probes (Jun et al., 2017). These probes' high electrode density (100 sites/mm) and long length (10 mm) make it possible to record from thousands of neurons simultaneously across dozens of brain regions, especially when multiple probes are used in parallel. However, producing stable recordings from multiple probes presents several experimental challenges, including brain stabilization and precise targeting. Here we present methods for reliable recordings in head-fixed awake mice using multiple acutely inserted Neuropixels probes. First, mice are implanted with a headframe and a removable glass window. This window allows optical access for mapping the boundaries of cortical visual areas using intrinsic signal imaging. Once the visual areas of interest are defined, we employ a set of targeting procedures to plan the insertion path for each Neuropixels probe. Our goal is to precisely target retinotopically matched locations in primary and higher-order visual areas (Juavinett et al., 2017). Our protocol employs techniques for brain stabilization which are a key component for successful recording sessions. To this end, on the day of the recording, we remove the glass window and replace it with a perforated plastic window ("insertion window") that allows the probes to be inserted into the brain. An agarose mixture is injected under the insertion window to stabilize the brain. This results in reduced brain movement and probe drift, allowing us to obtain stable recordings for over two hours with six Neuropixels probes. We have optimized this procedure for recording from the visual system, but it can be adapted to other brain regions and recording configurations. We describe our protocol steps in detail and share our experience with troubleshooting these powerful multi-probe recordings in the mouse brain.

Title: Functional modules in local networks of the human temporal lobe

Authors: *J. I. CHAPETON[1], J. H. WITTIG, JR[1], S. K. INATI[2], K. A. ZAGHLOUL[1];
[1]Surgical Neurol. Br., [2]Office of the clinical director, Natl. Inst. of Neurolog. Disorders and Stroke, NIH, Bethesda, MD

Abstract: A fundamental question in neuroscience is how brain circuits and networks are organized. One hypothesis is that neural networks are modular and consist of groups of nodes that have denser connectivity to each other than to the rest of the network. Networks organized into spatially compact modules possess evolutionary, metabolic, and computational advantages, and can produce complex dynamics that may be particularly relevant for the human brain. Functional and structural modules have been identified in the primary sensory cortices of many mammals. In the human brain, fMRI has been used to identify modules in large scale brain networks such as the fusiform face area, and high magnetic field experiments have successfully identified orientation columns. However, direct evidence that higher-order regions of the human cortex are organized into functional modules at the sub-millimeter scale of local circuits has been lacking.

The strongest evidence that neural circuits are organized in a modular manner arises when measures of connectivity, structure, and function converge. A prime example of such convergence is the rodent barrel cortex in which neural circuits within individual cortical columns encode information about individual whiskers, and excitatory synaptic connections are typically constrained to neurons within the same barrel. Here, we map local functional connectivity as well as quantify the responses of individual neurons during an image classification task to show that the human anterior temporal lobe, a higher order brain region involved in semantic processing, exhibits a modular composition.

We use local field potential recordings and single unit spiking activity captured from microelectrode arrays in order to probe connectivity and functional significance at the sub-millimeter scale. We find that local networks in the anterior temporal lobe are composed of spatially compact and temporally persistent modules with a diameter of about 1.3mm. Information regarding image category is shared between neurons that are members of the same module, but largely independent across neurons belonging to different modules. Together, our results demonstrate that local circuits in the human temporal lobe can be naturally partitioned into modules based on functional connectivity, and that these modules exhibit neural responses that render them functionally distinct.

Title: Long-lived organotypic slice culture model of rat basolateral amygdala.

Authors: S. D. MICHAELSON[1], T. M. MULLER[1], M. BOMPOLAKI[2], A. MIRANDA TAPIA[1], H. SILVEIRA VILLARROEL[1], J. P. MACKAY[1], P. J. BALOGUN[1], J. H. URBAN[2], *W. F. COLMERS[1];

Abstract: Our recent work has focused on the development of a behavioral stress resilience induced in male rats by repeated daily injections of Neuropeptide Y (NPY) into the basolateral amygdala (BLA). The resilience develops over time and persists to at least 8 weeks after NPY injections. To help unravel the underlying cellular mechanisms, we have developed and validated *in vitro* organotypic slice cultures (OTC) of BLA to identify neural mechanisms underlying NPY-induced stress resilience (Michaelson et al, J Neurosci. 40: 3231-3249). Originally developed in the early 1980s, OTCs have proved extremely useful for studying neural systems such as the hypothalamus, hippocampus and spinal cord. We have developed a model OTC of BLA tissue which maintains the electrophysiological and anatomical properties of BLA neurons *in vivo*. Rat BLA continues to develop until postnatal (P) day 28, but only OTCs prepared from younger (P14-P16) rats remained consistently viable to equivalent postnatal (EP) ages P70-P84; cultures prepared from male and female rats are equally viable. Principal neurons (PNs) in BLA OTCs (EP70-P84) were electrophysiologically similar to acute neurons from older (P70-P84) rats, though considerably smaller, and electrically more compact. Repeated daily treatment of OTCs (EP~42) with NPY resulted predominantly in reduced PN whole-cell capacitance, which correlated with reductions quantified in PN dendritic length and dendritic spine number in reconstructions of neurobiotin-filled cells. Conversely, treatment with the stress hormone, corticotropin-releasing factor (CRF), resulted in increased dendritic extent and spine density, consistent with increases in dendrite length and spine density observed in stressed animals. Pharmacological studies in OTCs unexpectedly showed the NPY5 receptor to underlie these structural changes. Subsequent *in vivo* experiments confirmed the morphological, pharmacological and behavioral consequences of NPY agonists on BLA neurons as was predicted in OTCs. BLA OTCs also permitted the determination of downstream signaling pathways for the Y5 receptor (calcineurin) and CRF (CaMKII) and showed that the effects of repeated NPY or CRF entirely reversed the effects of the other.
BLA OTCs have provided entirely unexpected, long-term physiological and pharmacological

results that were borne out *in vivo*, supporting the validity of BLA OTC as a model for BLA neurocircuitry.

Abstract: In vitro cell culture models of neural tissues are highly engineerable and scalable systems that are amenable to pairing with developments in robotic automation, microfluidics, and probes. Additionally, electrophysiological recordings are critical for the investigation and analysis of human neurological diseases.Currently, both cell culture experiments and electrophysiological recordings are limited by the need for technical expertise, expensive equipment, and material cost. This bottleneck limits broader influences that can be achieved by increasing sample throughput. Therefore, a massively scalable and cost efficient platform for tissue experiments, particularly experiments with functional readouts, would benefit genomics,

neuroscience, and translational medicine by enabling advanced high throughput tissue screens. To overcome limitations in equipment and cost, we leveraged two recent advances by our group. We developed an IoT architecture to allow horizontally scalable distance experiments. This architecture takes advantage of cloud computing tools to offer an online environment where researchers can run thousands of cell culture experiments at once.We also introduced an inexpensive neurophysiological recording platform (Piphys) that can be controlled through that online environment. We connected a Raspberry Pi to an Intan bioamplifier to design a hardware expansion circuit board with software to enable voltage sampling and user interaction. This standalone system was validated with primary human neurons, showing reliability in collecting real-time neural activity.Finally, we demonstrate the potential for integrating these technologies with 3D brain organoids. Through this, we illustrate feasibility for the hardware modules and cloud software to remotely control neural recording experiments. We also demonstrate horizontal scalability, enabling long-term observations of neural activity at scale. More broadly, these technologies offer opportunities for democratizing access to advanced tissue models by reducing costs and enabling new avenues of high throughput research.

Title: Metastable dynamics during decision-making in mouse gustatory cortex

Authors: *L. LANG, G. LA CAMERA, A. FONTANINI;
Neurobio. & Behavior, Stony Brook Univ., Stony Brook, NY

Abstract: Recent evidence suggests mouse gustatory cortex (GC) is involved in taste-guided decision-making in addition to sensory processing. Existing work has shown rodent GC exhibits metastable ensemble dynamics during ongoing and stimulus-evoked activity, but how these dynamics might evolve in the context of a taste-based decision-making task remains unclear. Here we employed analytical and modeling approaches to i) extract metastable dynamics in ensemble spiking activity from GC of mice performing a perceptual decision-making task; ii) investigate the computational mechanisms underlying metastability in this task. To extract

metastable dynamics, we applied Hidden Markov Model (HMM) analysis to spiking data from mice performing a 2-alternative choice task. In this task, 4 tastants cue correct licking directions according to the rule: Sucrose or Quinine → Lick Left; Maltose or Sucrose Octaacetate → Lick Right. HMMs were fit to ensemble spiking activity recorded in GC of mice performing the task at criterion. Decoded hidden states from HMMs were classified into categories according to differential frequencies of occurrence between trials of opposite type (e.g. Sweet cue vs. Bitter cue, Left cue vs. Right cue, Left action vs. Right action). We analyzed within-trial onset times of these states among the different categories and found that states related to taste information ('Quality-coding') preceded those related to cued directions ('Cue-coding'), which preceded those related to actions ('Action-coding'). This result is consistent with a view of neural activity evolving from sensory processing to abstract cue representation to decision and action in this task. To investigate computational mechanisms underlying this phenomenon, we modeled GC with a metastable spiking neural network (SNN) able to represent key task variables (stimuli, cued directions, and actions). The salient model features were clustered connectivity of excitation and inhibition, partially overlapping clusters, and a gating preparatory signal. Performing the same HMM analysis on SNN-generated data yielded coding state onset time distributions similar to those resulting from experimental data, which suggests our model captures the essence of GC's dynamics during perceptual decision-making. We conclude that activity in GC during perceptual decision-making is metastable, and that this metastability may serve as a substrate for sequentially encoding sensory, abstract cue, and decision information over time. Specific manipulations of the model may indicate aspects crucial for information processing and shed light on circuit-level mechanisms for coding via metastability.

Title: A model of electrical stimulation of a cortex-like phase-oscillator sheet

Authors: *T. FRACZEK[1], M. WILLY[2], Y. LIN[3], B. FLETCHER[4], H. J. CHIZECK[5], J. A. HERRON[6], E. T. SHEA-BROWN[2];
[1]Neurosci., [2]Dept. of Applied Mathematics, [3]Dept. of Mechanical Engin., [5]Dept. of Electrical and Computer Engin., [6]Dept. of Neurolog. Surgery, [4]Univ. of Washington, Seattle, WA

Abstract: Phase oscillator-based models are increasingly investigated to model neural interactions across large brain regions. This modeling method is more computationally approachable than raw biophysical systems, while maintaining reproducibility of biologically

relevant behavior. However, no consistent method is proposed to relate the results of these models to empirical brain data. One method of investigating this relationship is to study the response of this model to realistic electrical stimulation for eventual comparison to real brain data.

We propose a model of electrical stimulation applied to a cortical sheet. The cortical sheet model, originally proposed by Breakspear et. al. is an extension of the Kuramoto model. This system describes individual phase oscillators, each representing a cortical column, embedded in physical space. The coupling function is based on the phase oscillator reduction of the Hodgkin Huxley model. Coupling strength is modulated by a spatial kernel, representing both transmission delays and a diminished coupling strength with distance. Our extension to this spatial phase oscillator model adds periodically stimulating electrodes at several locations on the cortical sheet. We then represent the effect of electrical stimulation on the sheet considering the known conductance properties of brain tissues. This may be used to study the responses of the model to realistic perturbations and track how cortical regions close to the electrode affect regions further away. In contrast to previous phase oscillator models of stimulation, such as those used to predict the effects of deep brain stimulation, our approach allows us to investigate how the effect of stimulation propagates.

We find that the behavior depends on the specific oscillators' coupling function parameters, the geometry of the stimulating electrodes, and the stimulation frequency relative to the oscillators' natural frequencies. Exploring combinations of these variable values, we find stimulation can entrain periodic ripples that propagate across the sheet, collapse all oscillators into a phase-locked state, or prevent phase locking altogether.

Future work will implement a similar model for sensing local field potentials, such as an ECoG electrode. Combined, these models may provide insight into medically relevant, large-scale models of electrical stimulation.

Title: Scalable unified analysis in human systems neuroscience

Authors: A. NANDA[1], **M. RUBINOV**[2];
[1]Biomed. Engg, Vanderbilt Univ., Nashville, TN; [2]Janelia Res. Campus, Howard Hughes Med. Inst., Ashburn, VA

Abstract: A basic aim of science is to find truer models of observed reality. But because the ground truth is unknown and inaccessible, models can only be truer relative to rival models. Science makes progress when it selects progressively truer models relative to progressively stronger rivals. Model comparison drives this important process. It does so, in large part, through reducing model specification bias, by guarding against the selection of overly complicated or overly simple models. In practice, specification of rival models constrained by competing explanatory features defines data distributions. Unbiased sampling from these distributions generates surrogate data, and in this way allows to select between competing models. In this work, we will present results that use this approach to evaluate fundamental organizational principles of human neuroimaging networks. We will specifically present several interpretable models of whole-brain voxel-resolution activity that account for much of the structure of the default network, dynamic functional connectivity, architectural gradients and other higher-order phenomena. These results illustrate how rigorous model comparisons can reduce redundant explanations, clarify explanatory gaps and drive progress in human systems neuroscience.

Title: Modeling Cortical Cholinergic Reversal of Network Behavior induced by Synaptic Effects of Anesthesia

Authors: *B. ENIWAYE[1], V. BOOTH[2], A. G. HUDETZ[3], M. R. ZOCHOWSKI[4];
[1]Univ. of Michigan, ANN ARBOR, MI; [2]Mathematics & Anesthesiol., [3]Dept. of Anesthesiol., [4]Physics, Univ. of Michigan, Ann Arbor, MI

Abstract: General anesthesics are typically used in the clinical setting to produce sedation and loss of consciousness. A variety of anesthetic agents can be used to reach similar behavioral end points while invoking different synaptic mechanisms. The administration of common inhalation anesthetics generally leads to changes in EPSPs and IPSPs associated with synaptic effects of glutamatergic and GABAergic neurotransmitters, respectively (Rudolph & Antkowiak, 2004) Recently, it was shown that intracerebral administration of acetylcholine (ACh) agonists can elicit wake-like behavior in the continued presence of an inhalational anesthetic in rodents (Mateos-Aparicio, 2020; Pal et al. 2018We focus on understanding the neuronal mechanisms responsible for the pharmacological reversal of anesthetic state by developing a computational neuron network model that captures the changes in neural firing behavior in response to ACh as well as the anesthetic-induced changes in postsynaptic potentials. We used a genetic algorithm to optimize model parameters to fit experimentally measured changes in firing behavior in the rat visual cortex *in vivo* in response to the application of the anesthetic desflurane. We then simulated the reversal of network connectivity and firing dynamics for increases in ACh concentration via its effect on the slow conductance potassium current. Results suggest that ACh-induced recovery from anesthesia may be related to increased neuronal excitability in response to ACh. Interestingly, the reversal of functional connectivity was incomplete, suggesting that cognitive function may remain impaired in the ACh reversal state.

Title: Towards a functional evaluation of memory recall performance in a large-scale neuronal network model of hippocampus: How the recall quality of a CA3 network scales with increasing complexity of network topology and synaptic mechanisms

Authors: *Z. CHOU[1], G. J. YU[1], J.-M. C. BOUTEILLER[2], T. W. BERGER[2];
[2]Biomed. Engin., [1]USC, Los Angeles, CA

Abstract: Our previous work in developing a large-scale, spiking neuronal network model of hippocampus has shown that large-scale simulations have the potential to capture emergent network dynamics such as spatiotemporal clustering of spiking activity. However, we currently lack a direct way of measuring the functional significance of these emergent phenomena, namely how they affect the role that the hippocampus plays in memory. In this work, we adapt an experimental paradigm that quantifies recall quality of a network via several cycles of storage and retrieval of cue patterns (Cutsuridis et al., 2009) to a CA3 microcircuit with the ultimate goal of examining how recall quality, and consequently storage capacity, in the CA3 is influenced at the large-scale. The CA3 network consists of biophysically detailed compartmental morphologies of pyramidal cells and interneurons, and receives mossy fiber inputs from granule cells, entorhinal cortex projections, and associational inputs from recurrent connections. The number of interneuron types incorporated into the network (basket, axo-axonic, OLM) was modified while normalizing their inhibition to the pyramidal cells to isolate the effects of the change in network topology. The storage capacity of the CA3 model was then characterized by generating a "forgetting" curve by measuring the decrease in recall quality as an increasing number of patterns was stored in the same network. We repeated these evaluations at small (n=100), medium (n=1000), and large (n=100,000) network sizes to compare the results at different scales. Finally, the STDP learning rule for potentiation was modified from an additive rule to a log-normal STDP update function (Gilson and Fukai, 2011) to examine the influence of more complex synaptic mechanisms on recall quality. This preliminary work in the CA3 microcircuit provides a step towards evaluating memory recall in a large-scale simulation of the entire hippocampus. It may also constitute a useful platform to investigate the effects of multiple parameters on memory recall performance, allowing the simulation of not only the changes taking place in neurodegeneration but also the effects of novel drug therapies.

Title: Recording and clustering action potentials from the surface of the human brain using conformable, organic, high spatiotemporal resolution neural interface devices

Authors: *A. HASSAN[1], Z. ZHAO[2], S. A. SHETH[3], D. KHODAGHOLY[2], J. GELINAS[4]; [1]Biomed. Engin., [2]Electrical Engin., Columbia Univ., New York, NY; [3]Neurosurg., Baylor Col. of Med., Houston, TX; [4]Columbia Univ. Med. Ctr., New York, NY

Abstract: Recording neurophysiological signals at the spatiotemporal resolution of action potentials is a fundamental step to understand the mechanisms underlying diverse brain functions, but acquiring such data from the human brain is challenging due to restricted spatial resolution and invasiveness of currently available technologies. We developed an organic mixed-conducting particulate composite material (MCP) to establish a scalable and biocompatible interface between soft and hard electronics. MCP enabled integration with conducting polymer-based electrode arrays (NeuroGrids) and creation of neural interface devices that can be placed on the surface of the human through small craniotomies and burr holes. These devices recorded both actional potentials and local field potentials from superficial cortical neurons of human subjects without penetrating the brain surface (n = 64 channels per array). Subsequently, we performed spike sorting followed by cluster-cutting to identify putative single-units. We then assessed the effect of the electrodes' spatial distribution on the quality metrics of clustered units. We identified 229 putative single-units (85 pyramidal cells, 144 interneurons; n = 7 subjects). Action potential detection was strongly dependent upon length of recording and noise floor. Neurons showed consistent modulation and phase-locking in the spindle band, and we also identified reciprocal monosynaptic interactions between putative pyramidal cells and fast-spiking interneurons. When action potential waveforms were detected across multiple channels, deliberate elimination of neighboring channels (mimicking access to only a single electrode) was associated with loss of detection or decreased isolation distance, increased L-ratio, and increased contamination rate. These results suggest that MCP- and NeuroGrid-based neural interface devices are capable of acquiring neurophysiological signals at the resolution of individual neurons from the surface of the human brain. Spatial configuration of surface electrodes that permits acquisition of a single action potential waveform on multiple channels increases yield and quality of single-units, with key ramifications for design of human neural interface devices.

Title: Deep architectures for predicting in vivo local field potential

Authors: *M. CARROLL[1], Z. CHEN[2], D. B. HEADLEY[4], S. S. NAIR[3];
[1]Univ. of Missouri, Columbia, Columbia, MO; [2]Electrical Engin. and Computer Sci., [3]Electrical & Computer Engin., Univ. of Missouri Columbia, Columbia, MO; [4]Rutgers, The State Univ. of New Jersey, Newark, NJ

Abstract: Deep Architectures for Predicting In Vivo Local Field Potential Matthew Carroll[1], Ziao Chen[1], Drew B. Headley[2], Satish S. Nair[11]Electrical Engineering & Computer Science Dept., University of Missouri, Columbia, MO[2]Center for Molecular and Behavioral Neuroscience, Rutgers, The State University of New Jersey, Newark, NJ**Abstract** Local field potential (LFP) measurements are widely used in neuroscience to characterize the interactions among neurons. This is because the temporal synchronization of the membrane potentials of principal neurons (PNs) is partly reflected in oscillations of the LFP. These oscillations are thought to be relevant to the computations carried out by networks of neurons, and recently methods have been developed to modulate them using closed-loop stimulation conditioned on the LFP signal. Since closed-loop approaches have to be run in real-time, their accuracy and precision for targeting specific events in the LFP is limited to relying purely on past values. Towards overcoming this, the present study explores the capabilities of statistical learning models in predicting future values of the LFP for enhancing the efficacy of closed-loop control. We focus on predicting the temporal properties of transient gamma-band activity (30-80 Hz) using online in vivo LFP measurements from behaving rodents. Specifically, on predicting the amplitude of future transient burst cycles in the LFP using past values with statistical learning models.
As a first step, we used LFP from a physiologically-based computational model of a rodent amygdala that matched the in vivo LFP characteristics. In particular, it matched the transient gamma bursts which occur over brief durations of 3-4 cycles, which present exceptional challenges to closed-loop detection. A comparison of the various types of networks to predict future model LFP values is shown in the table below. In comparison to the filtered LFP, accuracy of raw LFP prediction using simple architectures was limited to the 1 to 5 ms horizon. However, future values of a 4^{th} order band-pass filtered LFP output were predicted well using 50 ms of raw LFP values are input with comparable performance among the networks.
Entries list mean-square error (R^2) values
Adding the firing rate of interneurons as another input feature did improve the prediction and increase the R^2 values for the 40 ms and 50 ms cases to .51 and .23, respectively. Ongoing investigation of the underlying mechanisms showed that suitable architectures could learn both the dynamics of the filter as well as the oscillations. The next step will be to explore XAI architectures to ascertain the salient features that could predict future values of the LFP.

Title: Scalable parallel data management for large-scale computational models of neuronal networks

Authors: *I. RAIKOV[1], A. D. MILSTEIN[3], P. MOOLCHAND[2], D. HADJIABADI[1], A. CHATZIKALYMNIOU[2], I. SOLTESZ[1];
[2]Neurosurg., [1]Stanford Univ., Stanford, CA; [3]Dept. of Neurosci. and Cell Biol., Rutgers Univ., Piscataway, NJ

Abstract: Large-scale computational models of the brain are necessary to accurately represent anatomical and functional variability in neuronal biophysics across brain regions and also to capture and study local and global interactions between neuronal populations on a behaviorally-relevant spatial scale.
We present a flexible HDF5-based data format for storing morphological, synaptic, and connectivity information of large neuronal network models, and an accompanying open-source software library that provides efficient, scalable parallel storage and MPI-based data movement capabilities. The set of operations provided by the data management library includes scalable routines for iterating over data elements associated with an individual model cell, parallel data read and write, parallel map and reduce, and data generator routines that enable the iterative processing of data sets that are too large to fit in memory. This set of operations facilitates common functionality for construction, simulation and analysis of computational neuronal network models at a scale of millions of neurons on high-performance computing systems, while still permitting analysis and simulations of parts of the model on single computers.
We highlight the use of the data management library for a highly scalable infrastructure for simulation, optimization, and analysis of large-scale models of neuronal networks comprised of detailed biophysical models of diverse neuron types, based on the NEURON simulator. The functionality thus offered is centered on several core principles that are crucial for the development large-scale neural modeling systems:
1) reproducibility, or the ability to conduct simulation and analysis with consistent model parameters, such as synaptic placement and connectivity; 2) flexibility to allow the rapid iteration of scientific hypotheses about model structure on any level of the neural hierarchy; 3) scalability, or the ability to efficiently use a broad range of computing hardware, from single computers to large high-performance computing clusters. We demonstrate the use of this infrastructure, to construct, simulate and analyze a full-scale, anatomically and physiologically

detailed models of the dentate gyrus (DG) and CA1 regions in the rodent hippocampus that contain anatomically accurate numbers of neurons and synaptic connectivity.

Title: In vivo investigation of astrocyte calcium activity in the mouse hypothalamic paraventricular nucleus

Authors: *K. SANDOVAL, J. RYCHLIK, K. Y. CHOE;
Psychology, Neurosci. & Behaviour, McMaster Univ., Hamilton, ON, Canada

Abstract: Neurons and astrocytes in the hypothalamic paraventricular nucleus (PVN) exist in a structurally compact microenvironment, where bidirectional communication between the two cell types influences the physiological and behavioural output of this brain region. Stress and social stimuli are both potent modulators of neuronal activity in the PVN. As a part of the hypothalamic-pituitary-adrenal axis, corticotropin-releasing hormone (CRH) neurons in the PVN are activated by stress-induced increase in noradrenaline levels (Bains et al., 2015). Social stimuli activate oxytocin neurons in the PVN to cause oxytocin neuromodulation of downstream brain regions, facilitating social interactions (Resedez et al., 2020). Recent *in vitro* experiments demonstrated that PVN CRH neurons dendritically release vasopressin in an activity-dependent manner, which activates V1a receptors in surrounding astrocytes to induce calcium (Ca^{2+}) responses (Chen et al., 2019). Another study showed that oxytocin, which can be released dendritically in response to social stimuli, activates oxytocin receptors in cultured hypothalamic astrocytes and triggers Ca^{2+} responses (Di Scala-Guenot et al., 1994). Based on these reported findings, we hypothesize that PVN astrocytes encode both stress and social stimuli as Ca^{2+} events *in vivo*. To examine this, we performed *in vivo* fiber photometry recordings in the mouse PVN with astrocyte-specific expression of GCaMP6, a genetically-encoded Ca^{2+} indicator (induced by AAV2/5-promGFAP-GCaMP6f). We recorded Ca^{2+} signals in the PVN of freely behaving mice while they were subjected to stressful stimuli (e.g., looming shadow) or during reciprocal social interaction with a novel stimulus mouse in a home cage setting. During these sessions, the behaviours of mice were also video-recorded and manually scored by an

independent observer. We found that PVN astrocytes exhibit a large spike in Ca^{2+} signal in response to stressful stimuli (z dF/F= >10). In contrast, social interactions induced smaller Ca^{2+} responses (z dF/F= ~1-2) that varied depending on the social stimulus type. Social touching by stimulus mouse reliably elevated the Ca^{2+} signal in experimental mice, while anogenital sniffing of the stimulus mouse reduced it. These demonstrations show that PVN astrocytes exhibit robust, stimulus-specific Ca^{2+} responses to both stress and social stimuli *in vivo*. To extend these findings, we are currently investigating whether these Ca^{2+} responses are dependent on the spiking activity of CRH and oxytocin neurons in the PVN, as well as their potential functional impact on PVN neuronal activity and behaviour.

Title: Molecular clock synchronization among segregated neural populations

Authors: *L. GIANTOMASI, J. F. RIBEIRO, O. BARCA-MAYO, D. DE PIETRI TONELLI, L. BERDONDINI;
Fondazione Inst. Italiano di Tecnologia, Genova, Italy

Abstract: In mammals the suprachiasmatic nucleus (SCN) of the hypothalamus is considered the master circadian pacemaker, which coordinates circadian rhythms in the central nervous system (CNS) and across the entire body. The SCN receives light input from the eyes through the retinohypothalamic tract and then it synchronizes other clocks in the CNS and periphery, thus orchestrating rhythms throughout the body. However, little is known about how so many cellular clocks within and across brain circuits can be effectively synchronized.In this work we investigated the implication of two possible pathways: i) paracrine factors-mediated synchronization and ii) astrocytes-mediated synchronization. To study these pathways, we adopted an *in vitro* research model based on a lab-on-a-chip microfluidic device developed in our laboratory. This device allows growing and compartmentalizing distinct neural populations connected through a network of astrocytes or through a cell-free channel in which the diffusion of paracrine factors is allowed. By taking advantage of this device, we synchronized rat cortical neurons (Embryonic day 18) in one compartment and analyzed, in different experimental conditions, the induced expression of clock genes in a distant neural network grown in the second compartment. Results show that both pathways can be involved, but might have different roles. Neurons release factors that can diffuse to synchronize a neuronal population. The same factors can also synchronize astrocytes that, in turn, can transmit astrocyte-mediated molecular

clocks to more distant neuronal populations. Using microfluidic devices featuring different channel lengths, we found that paracrine factors-mediated synchronization occurs only in the case of a short distance between neuronal populations. On the contrary, interconnecting astrocytes define an active channel that can transfer molecular clocks to neural populations also at long distances. The study of possibly involved signaling factors indicate that paracrine factors-mediated synchronization occurs through GABA signaling, while astrocytes-mediated synchronization involves both GABA and glutamate.These findings strength the importance of the synergic regulation of clock genes among neurons and astrocytes, and suggest a previously unknown role of astrocytes as active cells in distributing signals to regulate the expression of clock genes in the brain.

Title: Neuron-astrocyte interactions underlying noradrenergic modulation of wake-promoting vPAG^{DA} neurons

Authors: *N. PETERSEN[1], S. W. CENTANNI[1], G. J. SALIMANDO[1], K. E. MCCANN[2], M. A. STAVARACHE[3], D. WEINSHENKER[2], D. G. WINDER[1];
[1]Mol. Physiol. and Biophysics, Vanderbilt Univ. Sch. of Med., Nashville, TN; [2]Human Genet., Emory Univ. Sch. of Med., Atlanta, GA; [3]Neurosurg., Weill Cornell Med. Col., New York, NY

Abstract: Sleep and arousal disorders are commonly comorbid with many psychiatric illnesses, however the basic underlying physiology governing wakefulness is not well known. Previous work has implicated a small population of dopamine (DA) neurons in the ventral periaqueductal gray (vPAG) as being important in arousal. Activation of these DA neurons (vPAG^{DA}) is sufficient to increase arousal, and lesioning or direct inactivation of these neurons decreases arousal. Recently, we delineated a novel arousal circuit from the noradrenergic locus coeruleus (LC) to the vPAG^{DA} neurons. Specific activation of G_q-coupled alpha$_1$-adrenergic receptors (α_1ARs) with phenylephrine increases excitatory drive onto vPAG^{DA} neurons and promotes arousal. α_1AR expression is enriched on vPAG astrocytes, and activation of astrocytic $G_q$signaling is sufficient to promote wakefulness. However, the mechanism of this neuron-astrocyte interaction is unknown. Activation of astrocytes is known to induce release of

extracellular “gliotransmitters”, including the purines ATP and adenosine. We hypothesize that purinergic transmission via ATP from neighboring astrocytes mediates noradrenergic modulation of $vPAG^{DA}$ neurons. Application of 3μM phenylephrine in *ex vivo* mouse brain slices significantly increases calcium transients in $vPAG^{DA}$ neurons of TH-Cre mice expressing the fluorescent calcium indicator GCaMP7f. In parallel, phenylephrine also increased the frequency of calcium oscillations in GCaMP7s expressing astrocytes in the vPAG. In TH-Cre mice injected with a viral mixture of an astrocyte-specific Gq-DREADD (AAV5-GfaABC1D-hM3Dq) and Cre-dependent GCaMP7f (AAV9-Syn-FLEX-GCaMP7f) into the vPAG, direct activation of astrocyte G_q signaling significantly increases calcium transients in $vPAG^{DA}$ neurons, suggesting astrocytic modulation of these cells. Additionally, whole-cell recordings from these cells reveal that antagonism of purinergic P2X ligand-gated ion channels with PPADS or TNP-ATP followed by co-application of phenylephrine prevents the increase in excitatory drive onto $vPAG^{DA}$ neurons via α_1AR activation. Together, these data suggest that vPAG astrocytes may play an important role in mediating arousal via regulation of wake-promoting $vPAG^{DA}$ neuron activity by way of extracellular ATP release. Future experiments will further test our hypothesis with the goal of elucidating the synaptic mechanisms underlying noradrenergic modulation of $vPAG^{DA}$neurons.

Carilion Sch. of Med., Roanoke, VA

Abstract: Visual thalamus receives direct inputs from retinal ganglion cell (RGC) axons and is important for both image-forming and nonimage-forming visual functions. Recent studies have shown that these RGC inputs play important roles in the development of cell types and circuits in these regions. For example, retinal inputs regulate the long-distance recruitment of GABAergic interneurons into two regions of visual thalamus - the dorsal and ventral lateral geniculate nuclei. Our lab recently discovered that these retinal inputs induce astrocytes to generate fibroblast growth factor 15 (FGF15), a potent motogen that is essential for interneuron migration into these regions. However, how retinal inputs induce the astrocytic expression of FGF15 remains unresolved. Here, we tested the role of RGC-derived Sonic Hedgehog (SHH) in this process since RGCs are known to release SHH in the brain and SHH is known to induce FGF15 expression in other parts of the embryonic brain. Using transcriptomic analysis, *in situ* hybridization, and reporter line, we observed that thalamus-projecting RGCs express SHH, and SHH receptors and signaling pathway components are expressed in the developing visual thalamus. Specifically, we discovered that thalamic astrocytes express the downstream components of SHH-signaling such as Patched-1, Smoothened, and Glioma-associated oncogene transcription factors. To assess the importance of this pathway in developing visual thalamus, we next generated a conditional mutant mouse line that lacks SHH specifically from RGCs. In thalamic sections of these mutants, as compared to littermate controls, we observed a significant decrease in both *Fgf15* mRNA expression and GABAergic interneuron number. Thus, these data identify a novel axo-glial signaling pathway in the development of visual thalamus and shed light on new ways in which astrocytes mediate the recruitment of interneurons into the developing visual thalamus.

Title: Identification of cellular and pathway targets for treatment in post hemorrhagic hydrocephalus

Authors: C. ADEYEMI, ***K. ABDI**;
Duke Univ., Durham, NC

Abstract: Post hemorrhagic hydrocephalus (PHH) is a prevalent condition leading to increased morbidity and disability related to neurocognitive impairment and motor dysfunction. Identification of target-able cells, pathways, and effective drug compounds that can treat PHH are needed, since the current standard of care involving shunts fail at a high rate and contain

many drawbacks for patients. Frequently observed damage to the brain ventricular lining and an abundance of genetic evidence points to multiciliated ependymal cells as an important mediator of hydrocephalus etiology. Here we identify that acute exposure to the inflammatory cytokine TNF-a during the developmental phase of radial glial progenitors derails their programming into multiciliated ependymal cells. A 48 hour exposure to TNF-a blocked upregulation of Foxj1, Multicilin, and c-Myb and dramatically reduced the number of multiciliated ependymal cells in primary cultures. We found that while Notch pathway is downregulated during normal development of progenitors into multiciliated cells, this pathway remained highly elevated during TNF-a exposure. Co-incubation of radial glial progenitors with the notch inhibitor, DBZ, and TNF-a completely rescued the number of multiciliated ependymal cells produced and enhanced the expression of Multicilin, Foxj1, and c-Myb above untreated levels. Additionally, the same rescue could be achieved with DBZ added after the acute exposure to TNF-a, potentially offering broader time window to treat PHH. Since multiciliated ependymal cells are essential to the proper flow of cerebrospinal fluid in brain ventricles and their damage has readily been observed in PHH, we believe our study reveals a sensitive period for multiciliated cell development that could be derailed by inflammatory exposure and rescued by notch inhibition. This acute inflammatory exposure and the effect on developing multiciliated cells could underlie some of the mechanisms in PHH seen after intraventricular hemorrhage in newborns and preterm infants.

Title: Functional interpretation of SARS-CoV-2 coding mutations in brain-derived organoids using variants discovered from sewage and clinical samples

Authors: *V. VO[1], R. GU[1], K. PAPP[2], C. CHANG[1], S. SHANG[1], H. BAKER[1], R. TILLETT[1], D. GERRITY[2], E. C. OH[1];
[1]Nevada Inst. of Personalized Med., Univ. of Nevada, Las Vegas, Las Vegas, NV; [2]Southern Nevada Water Authority, Las Vegas, NV

Abstract: The decline in diagnostic testing for SARS-CoV-2 is expected to delay the tracking of COVID-19 variants in the United States and limit the interpretation of viral sequence variation in the brain. We hypothesize that wastewater surveillance programs, which are agnostic to clinical

testing, can provide an effective alternative for detecting emerging viral variants and an opportunity to interrogate functional consequences from these genotypes using brain-derived organoids. Here, we performed amplicon-based whole genome sequencing of SARS-CoV-2 for 86 wastewater samples in Southern Nevada and identified the B.1.1.7 and B.1.429 lineages in December 2020. Whole genome sequencing for both lineages in 575 clinical samples failed to identify the variants until January 2021, suggesting that pooled wastewater samples may expedite viral variant detection when sequencing of clinical samples is limited. During our investigations, we identified novel mutations in the coding genome of SARS-CoV-2. To evaluate the functional impact of viral variants, we infected brain-derived organoids and examined cell growth and proliferation status, as well as transcriptional and proteomic changes. Our data highlight novel modules that are altered in response to viral mutations and provide a mechanism for the association of SARS-CoV-2 infection and brain pathology in humans.

Title: Planar Sholl analysis of astroglial filaments in optically cleared thick tissue

Authors: R. ROOMES-DELPEACHE[1], O. AVIVI[3], J. LOPEZ GROSS[2], R. AKASAKA[4], M. ZANJIR[1], M. J. GASTINGER[5], *L. AVIVI-ARBER[1];
[2]Dent., [1]Univ. of Toronto, Dent., Toronto, ON, Canada; [3]UNIVERSITY OF TORONTO, Toronto, ON, Canada; [4]Tokyo, Tokyo, Japan; [5]Oxford Instruments, Concord, MA

Abstract: Neuronal and astroglial processes networks can span through multiple layers of the sensorimotor cortex. It is unknown whether injury, disease, as well as learning, can result in layer-dependent structural changes manifested as differential generation, degeneration, or regeneration of cellular processes, and reflected in differential changes in processes density within and across the cortical layers. Such changes may reflect or allow for altered cellular functions which can impact sensory-motor behaviors.
To quantify the differential density of astrocyte processes across multiple cortical layers, we developed a novel Imaris XTension implementing a planar modification of the spherical Sholl

Analysis. It quantifies the number of intersections of astroglial processes with multiple horizontal planes within the rat primary motor cortex.
Our XTension to Imaris software application (version 9.5.1) takes the 3D positions from an automatic tracing of all astroglial processes within motor cortex layer 1 of a 1 mm-thick brain tissue optically cleared with the CLARITY technique and subsequently immunolabeled with the astroglial marker glial fibrillary acidic protein (GFAP). It computes the distance to a plane generated from three user defined points. Spot objects are then created within the application to display all filament intersections with horizontal planes spanning through the cortex. The number and spacing of the planes can be defined by the user. The XTension then compares all intersection spots at once using matrix multiplication and categories and color-coded spots based on their distance from the original plane of interest. An error parameter is introduced to control underfitting issues that result from working with floating point numbers. Our novel XTension can work on 2D and 3D (planar and volumetric) datasets and is a useful tool to investigate layer-dependent structural differences or changes in cellular processes density.

Abstract: It is estimated that 1 in every 54 US children are diagnosed with autism spectrum disorder (ASD). Studies have indicated that the environmental and genetic factors have been implicated in the development of ASD, however the neural underpinnings of ASD are complex. Recently the cerebellum has gained more attention and been identified as one of the brain areas associated with ASD etiology. How the cerebellum contributes to ASD is unclear, but identifying how a loss of or mutation in ASD-linked genes alters cerebellar anatomy and function may be important to understanding this relationship. Loss of function mutations in the

dscam gene have been consistently identified in individuals with ASD and like disorders and its homolog, *dscaml1,* is expressed in cerebellar granule cells. The *dscaml1* gene encodes DSCAML1 protein that is important for the formation and maintenance of excitatory synapse and neuronal organization, but little is understood about how DSCAML1 impacts cerebellar GC anatomical and functional circuit properties, perturbations in which will impact cerebellar output and related motor and non-motor circuits or behaviors. To address our hypothesis that that DSCAML1 plays a significant role in GC dendritic development we evaluated the structure of cerebellar GC dendrites that receive excitatory input from mossy fibers. The purpose of this study is to determine DSCAML1-dependence of cerebellar GC dendritic development that is key to shaping signal integration in the cerebellar cortex. Our study used a mouse model which carries null Dscaml1 alleles generated by gene trap insertion in *dscaml1*. By using Golgi-Cox staining and 3D digital reconstruction of cerebellar granule neurons with Neurolucida software (MBF Biosciences), we assess the DSCAML1-dependence of cerebellar GC dendritic development in heterozygous (*dscaml1*$^{GT/+}$) and homozygous (*dscaml1*$^{GT/GT}$) *dscaml1* null mice. Our preliminary analysis of cerebellar GC dendrites revealed that the average dendritic length and dendritic complexity (branching) of homozygous DSCAML1 null mice was reduced relative to heterozygous mice. This finding indicates the possible role of DSCAML1 in cerebellar GC dendritic development and their receptive fields. This study will help to identify the roles for *dscaml1* in determining key components of cerebellar GC synaptic anatomy and physiology that may underpin both motor and non-motor behavioral phenotypes.

Title: Abnormal microglial morphology and phagocytic function in Down syndrome developing brain

Authors: *I. RIVERA[1], M. LIOUDYNO[1], B. S. HSU[2], J. BUSCIGLIO[1];
[1]DEPARTMENT OF NEUROBIOLOGY AND BEHAVIOR, UNIVERSITY OF CALIFORNIA-IRVINE, Irvine, CA; [2]BIOLOGICAL SCIENCES, UNIVERSITY OF CALIFORNIA-IRVINE, IRVINE, CA

Abstract: As the primary immune cell of the mammalian CNS, microglia play an important role in maintaining normal brain structure and function. Our lab and collaborators have reported increased inflammatory molecule levels and altered microglia morphology in brains of children with Down syndrome (DS), a genetic disorder caused by the presence of a partial or fully triplicated copy of chromosome 21. However, much is still unknown regarding when microglia alterations emerge in DS brains. Thus, it is critical to identify the role of microglia in the neuroinflammatory process during prenatal and early postnatal DS brain development. Here, we explore microglia morphology and function in prenatal human cortical tissue. To characterize microglial morphology, we performed immunofluorescence (IF) staining and image analysis on euploid control and DS prenatal human cortical tissue using the microglia-specific marker IBA1. In euploid control prenatal cortical tissue, we observed only amoeboid (spherical) microglia, which characterizes the earliest stage of microglia in the developing mammalian brain. In contrast, in DS prenatal cortical tissue, we observed both amoeboid and intermediate stage microglia, exhibiting short processes. To evaluate microglial function, microglia cultures from control and DS prenatal cortical tissue suspensions were established and developed for 34 days *in vitro*. Phagocytic function was tested using pHrodo Zymosan A bioparticles and then the cultures were fixed, processed for IF, and labeled with IBA1. Interestingly, we observed that trisomic microglia displayed significantly increased particle engulfment per cell compared to euploid cultures. The results suggest that the early phenotypic alterations observed may represent an advanced developmental stage of DS microglia, raising the possibility of an accelerated microglial differentiation phenotype, consistent with the presence of a chronic neuroinflammatory process in DS brains. To further characterize prenatal DS microglia, microglial cells were isolated using Percoll density gradients and fluorescence-activated cell sorting (FACS). Ongoing experiments are aimed to establish the relationship between abnormal morphology and function and gene expression changes in DS prenatal microglia.

Title: Effects of the pro-cognitive agent RIV5061 in a mouse model of Down Syndrome

Authors: K. A. TRESIDDER, P. J. GAGOLEWICZ, R. H. MEHDER, R. D. ANDREW, *B. M. BENNETT;
Biomed. and Mol. Sci., Queens Univ., Kingston, ON, Canada

Abstract: Down syndrome (DS) is a leading genetic risk factor for early-onset Alzheimer's disease (AD), and there is a high incidence of AD in adults with DS. The current study assessed the effects of RIV5061 on behavioral, biochemical and electrophysiological properties of the *Dp(16)1Yey/+* (Dp16) mouse model of DS. RIV5061 is a novel dual pharmacophore with partial agonist activity at $GABA_A$ receptors combined with activation of NO/cGMP/CREB signalling. RIV5061 has been shown to have pro-cognitive, anti-inflammatory and disease-modifying effects in several mouse models of AD. Male and female Dp16 mice (2-4.5 months of age), along with their wild-type (WT) littermates, were administered either vehicle or 27 mg/kg/day of RIV5061 in the drinking water for 14 weeks, with an additional daily oral bolus of vehicle or 3 mg/kg of RIV5061. Behavioural analyses (Morris Water Maze, Y-Maze, and Light/Dark (L/D) Box) were performed prior to and following drug treatment. Upon conclusion of drug administration, we assessed the levels of a number of relevant protein markers in neocortical and hippocampal homogenates, CA3-CA1 long-term potentiation (LTP) in hippocampal slices, and spine density of dorsal hippocampal CA1 pyramidal cells.
At each time point assessed, control male Dp16 mice performed significantly worse than WT in the Y-maze and L/D box tasks ($p < 0.05$), indicating a deficit in spatial working memory and increased anxiety, respectively. These differences were not observed in control female mice. There were no differences in MWM task performance between control Dp16 and WT mice of either sex. RIV5061 did not affect performance in any of the behavioural tasks. Immunoblot analysis of a number of AD-relevant markers showed few differences between genotypes and following drug treatment, except for glial fibrillary acidic protein (GFAP), which was reduced following RIV5061 administration to both WT and Dp16 mice. Slice electrophysiology revealed no difference in LTP magnitude between control male Dp16 and WT mice, but RIV5061 did facilitate LTP induction in WT mice. Spine density in CA1 pyramidal cells from female Dp16 mice was significantly less than in WT mice; assessment of the effect of RIV5061 on spine density is ongoing.
Our results indicate that Dp16 mice up to 8-9 months of age do not display robust AD-like phenotypic changes compared with their WT counterparts. Consequently, the pro-cognitive and disease-modifying effects of RIV5061 seen in transgenic AD mouse models were not observed here - with the exception of an anti-inflammatory effect, as indicated by the reduction in the levels of GFAP, a marker for activated astrocytes.

Title: Sleep impairment rescue in Dp16 Down syndrome model mice by RCAN1 gene dose correction

Authors: *P. CAIN, H. WONG, C. BORSKI, A. COOPER-SANSONE, L. LAPLANTE, J. LEVENGA, M. OPP, C. HOEFFER;
Inst. for Behavioral Genet., Univ. of Colorado, Boulder, Boulder, CO

Abstract: Sleep impairment rescue in Dp16 Down syndrome model mice by *RCAN1* gene dose correction
Down syndrome (DS) occurs in 1 of 700 to 1000 births and is the most common cause of intellectual disability. DS also results in sleep abnormalities affecting up to 60% of the DS population. Although some sleep disturbances are caused by anatomically derived sleep apnea, many are not. Genes arising from the triplication of human chromosome 21 (Hsa21) may also contribute to sleep disturbances in DS. These abnormalities include increased latency to non-rapid eye movement (NREM) sleep, sleep fragmentation and reduced rapid eye movement (REM) sleep. Among the genes triplicated in DS is the gene for *Regulator of Calcineurin 1* (*Rcan1*, also known as *Down Syndrome Critical Region 1 (DSCR1), calcipressin, modulatory calcineurin interacting protein (MCIP)),* which is chronically overexpressed in the brains of DS individuals and known to impact learning, memory, affective behavior, and synaptic plasticity. Overexpression of RCAN1 can lead to age-dependent cognitive and synaptic impairments. Previously we observed sleep defects in Dp(16)1Yey mice (Dp16) mice (*Levenga* et al. 2018). Because RCAN1 plays a role in circadian function, we hypothesized that increased levels of RCAN1 protein resulting from trisomy Hsa21 may be responsible for sleep disruption in DS individuals. Dp16 are trisomic for ~115 genes orthologous to Hsa21 syntenic regions (Mmu16) while not being confounded by additional genes unrelated to DS. Experimenters blind to genotype examined sleep architecture and EEG patterns in both male and female, young (6-7/group) and aged (7-9/group) WT and Dp16 mice. We also restored disomic levels of RCAN1 in Dp16 mice (Dp16/*Rcan1*^{2N}) and tested sleep and EEG parameters in this RCAN1 dose corrected group (young and aged) to determine if RCAN1 dosage correction could restore normal sleep patterns in Dp16 model mice. Surprisingly, young (2-6 months) Dp16 mice exhibited no sleep architecture or EEG abnormalities relative to wild-type (WT) littermates. However, in aged (10-18 months) mice we found marked sleep and EEG changes compared to WT mice and that RCAN1 dosage correction reduced sleep deficits and partially rescued EEG phenotypes compared to Dp16 mice.

Title: Oligodendrocyte Development is Perturbed in a Region Dependent Manner in Down Syndrome

Authors: *J. A. KLEIN[1], Z. LI[2], S. RAMPAM[3], J. CARDINI[3], E. ZELDICH[4], T. F. HAYDAR[2];
[1]Boston Univ. Grad. Program For Neurosci., Boston, MA; [2]Ctr. Neurosci. Res., Children's Natl. Med. Ctr., Washington, DC; [3]Biomed. Engin., [4]Anat. and Neurobio., Boston Univ., Boston, MA

Abstract: Down syndrome (DS) is caused by triplication of chromosome 21 (HSA21). It is the most common genetic form of intellectual disability (ID) with a prevalence of 1 in 750 live births. Trisomy 21 results in global transcriptional dysregulation and previous work has shown that one of the alterations is the downregulation of a network of genes regulating the oligodendrocyte (OL) lineage. This suggests that perturbed OL development may be cause of the decrease in white matter in the brains of people with DS that contributes to the ID. To study the mechanism of this deficit, we differentiated isogenic lines of iPSCs derived from people with DS into OLs using small molecules and growth factors to mimic intrinsic development. Additionally, to examine the intersection of spatial patterning and trisomy 21 on OL development, we patterned our cultures to either brain-like or spinal-cord like fate. Using this system, we have identified changes in OL differentiation that are dependent both on genotype and on regional patterning as well as phenotypes that are consistent between regions. One phenotype that is dependent on spatial patterning is the transition of trisomic cells from the neural progenitor cell (NPCs) to pre-OL progenitor cell (pre-OPC) state. This transition is tightly regulated by two transcription factors, OLIG2 and NKX2.2, which are essential to promote OL lineage commitment. In the brain-like pre-OPCs, trisomic cells show a significant increase in OLIG2 expression and a decrease in the expression of NKX2.2. However, in the spinal cord-like condition, there is no difference in expression of OLIG2 or NKX2.2 in trisomic cells. The changes in gene expression in trisomic cells in the spatially patterned cultures is not restricted to changes in OLIG2 and NKX2.2. Using RNA-seq, we found thousands of genes that are dysregulated in trisomic cells between conditions, with a minority of the genes dysregulated in both conditions. These differences emphasize the importance of recognizing the spatial heterogeneity in DS and that different regions may not be dysregulated in the same manner based on their developmental history and trajectory.

Abstract: Down syndrome (DS) is one of the most complex genetic disorders and a leading genetic causeof developmental intellectual disability. The mouse has been an essential modeling organism inDS research because human chromosome 21 (Hsa21) is orthologously conserved with threeregions in the mouse genome. Recent studies have revealed complex interactions amongdifferent triplicated genomic regions and Hsa21 gene orthologs which underlie major DSphenotypes. Since we do not know conclusively which triplicated genes are dispensable in suchinteractions for a specific phenotype, it is desirable that all evolutionarily conserved Hsa21 geneorthologsaretriplicatedinacompletemodel.Forthisreason,Dp(10)1Yey/+;Dp(16)1Yey/+;Dp(17)1Yey/+ mouse is the most complete model of DS to reflectgene dosage effects because it is the only mutant triplicated for all Hsa21 orthologous regions.Recently, several groups have expressed the concern that the efforts needed to generate thetriple compound model would be so overwhelming that it may be im-practical to take advantageof its unique strength. To overcome such an impression, we presented a strategy to drasticallyimprove the efficiency of developing the triple compound model with aid of the targeted coatcolor and confirmed that the mutant generated via such an approach exhibited cognitive deficits.

Title: Genetic reduction of eEF2K ameliorates memory deficits and rescues synaptic failure in a mouse model of Down syndrome

Authors: *X. WANG[1], Q. YANG[4], X. ZHOU[2], T. MA[3];
[1]Wake Forest Univ. Sch. of Med., Winston Salem, NC; [2]Wake Forest Univ. Sch. of Med., Winston-Salem, NC; [3]Intrnl. Medicine-Geriatrics, Wake Forest Univ. Sch. of Med., Winston Salem, NC; [4]Geriatrics, Wake Forest Sch. Sch. of Med., Winston-Salem, NC

Abstract: Down syndrome (DS) is one of the commonest genetic diseases. Patients with DS usually develop Alzheimer's disease (AD) in their 40s, which will exacerbate their cognitive dysfunction. Previous studies have shown that synaptic failure is a common character of both AD and DS, while *de novo* protein synthesis is vital for synaptic plasticity, leading to the hypothesis that impaired *de novo* protein synthesis might contribute to the pathogenesis of DS. Eukaryotic elongation factor 2 (eEF2) is a part of the ribosome machinery and facilitates transfer of tRNA from A site to P site, thus plays important role in *de novo* protein synthesis. eEF2 can be phosphorylated and deactivated by the only known kinase, eukaryotic elongation factor 2 kinase (eEF2K), which will impair *de novo* protein synthesis. Here we explored the role of eEF2 in cognitive dysfunction of DS. We first checked whether eEF2 was hyperphosphorylated in the brain of Down syndrome patients and we found that phosphorylation of eEF2 was indeed increased in DS patients compaired to controls. The increase of eEF2 phosphorylation in DS patients was also recapitulated in the Ts65Dn mouse model of DS. To further explore the role of eEF2 in DS, we crossed eEF2K+/- mice to Ts65Dn mice, generating four genotypes: WT, eEF2K+/-, Ts65Dn, and Ts65Dn; eEF2K+/-. We found that memory deficits were ameliorated in Ts65Dn; eEF2K+/- mice compared to Ts65Dn mice as assessed by Novel Object Recognition and Morris Water Maze tests. Electrophysiological study showed that synaptic failure (LTP) in Ts65Dn mice was rescued by knocking down eEF2K. These data suggest that genetic reduction of eEF2K can ameliorate memory deficits and rescue synaptic failure in a mouse model of Down syndrome, which provides a potential pharmaceutical target for the treatment of cognitive dysfunction in DS.

Title: Developmental Regulation of Homeostatic Plasticity in Mouse Primary Visual Cortex

Authors: *W. WEN[1], G. TURRIGIANO[2];
[1]Dept. of Biol., [2]Dept of Biol., Brandeis Univ., Waltham, MA

Abstract: Homeostatic plasticity mechanisms maintain both neuronal and network stability by adjusting excitation, inhibition, or the intrinsic excitability of neurons, but the developmental regulation of these distinct forms of homeostatic plasticity remains poorly understood. A major reason behind this information gap is the lack of a uniform paradigm for chronically manipulating activity at different developmental stages. To overcome this limitation, we utilized Designer Receptors Exclusively Activated by Designer Drugs (DREADDs) to directly suppress neuronal activity of pyramidal neurons in layer (L) 2/3 of mouse primary visual cortex (V1) at two essential developmental timepoints: the classic visual system critical period (CP, P24-29), and adulthood (P45-55). We show that 24 hours of DREADD-mediated activity suppression simultaneously induces excitatory synaptic scaling up and intrinsic homeostatic plasticity in L2/3 pyramidal neurons during the CP, consistent with previous observations using prolonged visual deprivation. Importantly, DREADD-mediated homeostatic mechanisms show similar molecular characteristics as those induced pharmacologically or via visual deprivation, such as protein interactions involving GluA2 C-terminal tail and Shank3. We next applied the same paradigm to adult animals. Surprisingly, while excitatory synaptic scaling persisted into adulthood, intrinsic homeostatic plasticity was completely absent. Instead, we found that these adult neurons homeostatically adjusted quantal inhibitory inputs, which was absent in their younger counterparts. Thus, the same population of neurons can express distinct sets of homeostatic plasticity mechanisms at different development stages. Our findings suggest that individual homeostatic plasticity mechanisms can be recruited in a modular manner, and can be turned on and off according to the evolving developmental needs.

Abstract: The ability of any cell to mount an adaptive response and, thereby, counteract a physiological stress is fundamental to basic cell biology. Many of these adaptive mechanisms are at the forefront of efforts to combat disease such as the unfolded protein response and autophagy. Homeostatic plasticity refers to a suite of adaptive physiological mechanisms that allow neurons to respond to disruptions that alter their electro-chemical signaling. In particular, presynaptic homeostatic plasticity (PHP) describes how neurons adjust the release of neurotransmitter to offset disruptions that impair synapse integrity and function. To date, the mechanisms of PHP have been documented, and molecular mechanisms described primarily at neuromuscular synapses in *Drosophila*, mouse and human. Little is known about the process of PHP within the mammalian brain, and the molecular mechanisms remain largely uncharacterized. Now we provide evidence for the rapid induction of PHP at synapses in the CA1 region of adult hippocampus. Partial antagonism of postsynaptic AMPA receptors induces a compensatory increase in presynaptic vesicle release, assessed both electrophysiologically and by direct optical imaging of presynaptic glutamate release. This homeostatic mechanism can be induced within minutes and current evidence argues that the activity of both NMDA receptors and kainate receptors are required. Remarkably, the expression mechanism includes evidence of rapid, *de novo* synapse formation as determined by ultrastructural reconstruction of hippocampal volumes.

Title: Changes in spiking activity as a trigger for GABAergic versus AMPAergic synaptic scaling in mouse cortical neurons

Authors: *C. GONZALEZ-ISLAS[1,2], P. BULOW[1], P. A. WENNER[1];
[1]Physiol., Emory Univ. Sch. of Med., Atlanta, GA; [2]Doctorado en Ciencias Biológicas, Univ. Autonoma de Tlaxcala, Tlaxcala, Tlax., Mexico

Abstract: Neuronal circuits respond to perturbations that challenge their spiking activity by triggering a set of homeostatic plasticity mechanisms, which are thought to restore firing rates. The most widely studied form of homeostatic plasticity is synaptic scaling. Synaptic scaling is characterized by multiplicative changes in the strength of the synaptic inputs onto a neuron, measured as the amplitude of miniature postsynaptic currents (mPSCs). Since the upscaling of excitatory AMPAergic synapses can be produced experimentally by chronic treatments of either a voltage-activated sodium channel blocker (TTX) or AMPA receptor antagonists such as CNQX in neuronal cultures, it had been assumed that excitatory synaptic scaling was triggered by a decrease in spiking activity produced by the AMPAergic blockade. However, we showed previously in cortical cultures that chronic blockade of AMPAergic transmission with CNQX produced the same level of upscaling of AMPA mPSCs whether spiking was reduced or optogenetically maintained at control levels. This suggested that reductions in glutamatergic neurotransmission, rather than spiking activity was the trigger for AMPAergic synaptic scaling. We now have evidence that the mechanisms triggering AMPA- and GABAergic scaling are distinct. Chronic treatments that reduce both spiking and AMPA receptor activation, trigger compensatory GABAergic downscaling. Conversely, chronic treatments that increase spiking and AMPA receptor activation, trigger compensatory GABAergic upscaling. Using mouse cortical cultures we have tested the importance of spiking vs. glutamatergic transmission in triggering GABAergic scaling. We have found that combining treatments that block spiking activity (TTX, triggers GABAergic downscaling) but increase AMPA receptor activation (cyclothiazide, triggers GABAergic upscaling) triggers GABAergic downscaling. This result is consistent with the idea that GABAergic synaptic scaling is triggered by changes in spiking levels and not by changes in AMPAergic transmission. Further, we show that blocking glutamatergic neurotransmission with CNQX while optogenetically maintaining spiking activity at normal levels prevents the GABAergic downscaling that is observed with CNQX treatment alone. These striking results suggest that GABAergic scaling is triggered by alterations in spiking activity and therefore can homeostatically regulate spike frequency. On the other hand, AMPAergic scaling is triggered by altered glutamatergic transmission, not spiking, suggesting that this form of scaling is less well suited for homeostatic regulation of spiking activity.

Title: Spatial regulation of coordinated excitatory and inhibitory synaptic plasticity at dendritic synapses

Authors: *M. RUBEN, T. RAVASENGA, V. REGIO, A. I. POLENGHI, E. PETRINI, A. BARBERIS;
Inst. Italiano di Tecnologia, Genova, Italy

Abstract: Traditionally, the flexibility of neuronal network has been shown to mainly rely on the potentiation and depression of excitatory synapses. However, recent evidences revealed several forms of inhibitory plasticity, raising the important question of how GABAergic and glutamatergic plasticity are coordinated during neuronal activity. Here, we characterized a non-Hebbian form of inhibitory postsynaptic potentiation (iLTP) induced by postsynaptic depolarizations of principal cells in hippocampal. Interestingly, the same protocols induced depression at glutamatergic synapses (LTD), thus indicating an anti-homeostatic relation between inhibitory and excitatory plasticity. Photolysis of caged glutamate or caged GABA revealed that the aforementioned glutamatergic glutamatergic LTD and GABAergic iLTP are expressed postsynaptically. Subsequently, we investigated how synaptic plasticity induced at individual glutamatergic spines affects the strength of neighboring GABAergic synapses. To this end we induced “single spine LTP” by pairing the postsynaptic depolarization with repetitive glutamate uncaging at individual spines while simultaneously measuring the strength of adjacent dendritic GABAergic synapses by GABA uncaging. Interestingly, we found that, following the delivery of this hebbian-like protocol, GABAergic synapses located within 3 micrometers from a stimulated spine showed depression (iLTD), while GABAergic synapses at distances > 3 micrometers showed iLTP. This spatial dependent reversion of inhibitory plasticity induced by heterosynaptic plasticity from spines was dependent by calcium influx through L-type voltage gated calcium channels and the activation of the protease calpain. Our findings indicate that local changes of calcium concentration can finely coordinate both glutamatergic and GABAergic synaptic plasticity at dendritic level suggesting that the dendritic E/I balance are selectively tuned in spatially restricted dendritic sub-regions.

Title: Homeostatic plasticity in preganglionic and postganglionic sympathetic neurons

Authors: *A. RATLIFF[1,2], M. HALDER[1,2], S. HOCHMAN[1,2], P. WENNER[1,2];
[1]Dept. of Physiol., [2]Dept. of Cell Biol., Emory University, Sch. of Med., Atlanta, GA

Abstract: *Homeostatic plasticity* describes an array of mechanisms that a cell might use in order to maintain a biologically relevant level of output in response to a change in input, and this has been identified throughout the nervous system. Spinal motoneurons (MNs) have been shown to utilize such mechanisms in response to chronic reductions in synaptic input during embryonic development, when the circuit is first functional. Homeostatic mechanisms include compensatory changes in synaptic strength and intrinsic cellular excitability. Regulation of activity in the sympathetic nervous system (SNS) is imperative for healthy organ function and is under tight homeostatic control. However, homeostatic plasticity has been largely ignored in the sympathetic preganglionic neurons (SPNs) and postganglionic neurons (PGNs) of the central and peripheral arms of the SNS. To test the homeostatic capacity of these neurons in embryonic development, we are examining cellular responses to synaptic blockade in the embryonic chick. First, the synapse between SPNs and PGNs was tested for functional connectivity using extracellular stimulation and recording. Consistent with previous data, the synapse was found to be immature at embryonic day 10 (E10), but capable of propagating signals from E12 on. Application of sub-saturating concentrations of the ganglionic nAchR blocker Hexamethonium (Hex), leads to reductions in PGN-evoked spiking in E17 PGNs, which do not appear to homeostatically recover within several hours. E13 embryos were then treated with either vehicle or Hex in vivo for 2 days. Intracellular whole cell patch clamp recordings of PGNs were then performed at E15. At present, Hex-treated neurons did not appear to be more excitable than vehicle-treated neurons. These results suggest that the PGNs - the final output of the SNS - may not homeostatically alter their excitability in response to synaptic blockade at this age. Next, SPNs were inspected for evidence of homeostatic plasticity. Previous data has shown that 2-day *in ovo* treatment from E8-10 with the $GABA_A$ antagonist Gabazine (GBZ) triggers a form of homeostatic plasticity called synaptic scaling. To test whether SPNs experience synaptic scaling we are blocking GABAergic synaptic transmission from E8-10. We are currently conducting experiments using a genetically encoded chloride indicator, Clomeleon, to determine whether GBZ treatment triggers scaling in SPNs, identified by an increase in chloride accumulation. This would be the first data of its kind to indicate that the SNS can respond with mechanisms of homeostatic plasticity to changes in synaptic signaling during embryonic development.

Title: Sustained Depolarization Induces Homeostatic Plasticity in Mouse and Human Sensory Neurons

Abstract: Structural and functional remodeling of the nervous system, as result of intrinsic and extrinsic environmental changes, serves as a protective mechanism to assure adequate maintenance of overall network activity in the face of mounting experience-induced changes. These adaptive changes, known as homeostatic plasticity, include both synaptic scaling and regulation of intrinsic neuronal excitability. While there is abundant evidence suggesting that alterations in neuronal excitability of nociceptors contribute to the development of different forms of chronic pain, it is still not known whether nociceptors undergo homeostatic plasticity in the context of persistent excitation, or whether dysregulation of these homeostatic mechanisms contributes to the pathophysiology of chronic pain. Using a combination of pharmacologic and optogenetic approaches, we show that sustained depolarization of nociceptors in dorsal root ganglia (DRG) strongly reduces intrinsic excitability of mouse and human DRG neurons. These changes include decreases in input resistance, action potential (AP) fall time and AP half width, an increase in rheobase associated with an overall decrease in AP firing. This suggests that homeostatic mechanisms are present in mouse and human nociceptors. Surprisingly, RNA sequencing studies of mouse and human DRG neurons did not reveal significant changes in gene expression associated with the induction of this homeostatic plasticity, suggesting the likelihood of potential post-translational modifications as underlying mechanisms. Our data reveal the presence of intrinsic mechanisms of regulation of neuronal excitability in response to sustained depolarization of mouse and human nociceptors. Dysregulation of these homeostatic mechanisms could contribute to the understanding of the pathophysiology of chronic pain syndromes.

Title: Spike frequency within a burst, rather than overall spike frequency, is homeostatically maintained in the embryonic chick spinal cord

Authors: *A. LAKHANI[1], Z. SABRA[1], N. AU YOUNG[1], P. A. WENNER[2];
[2]Physiol., [1]Emory Univ. Sch. of Med., Atlanta, GA

Abstract: Spontaneous network activity (SNA) produces highly synchronized patterns of activity that occur in almost all developing neural networks, including the hippocampus, retina, neocortex, and spinal cord. The episodic bursts are important for numerous functions, such as neurogenesis, neuronal survival, and neurotransmitter expression. Importantly, SNA is crucial for the developing system to shift from a silent to a fully functioning structure with a myriad of synapses and signals. SNA in the spinal cord recruits motoneurons and therefore drives embryonic limb movements, which are crucial for proper muscle and joint development. In the isolated spinal cord of the chick embryo, SNA is expressed as episodes of activity that occur every ~10 minutes and last up to a minute. Each episode is composed of several bursts of depolarizations. Homeostatic plasticity represents a set of mechanisms that ensures the maintenance of activity levels following perturbations and has been well-studied in this system. Previous research from our lab has demonstrated that following in ovo GABAergic blockade, when GABA is excitatory, embryonic movements decrease, but then are homeostatically recovered within 12 hours. However, this is a gross measurement of muscle activity; thus, it is unclear what specifically is maintained in terms of spiking at the cellular level. To address this issue, I isolated embryonic day 11 spinal cords and used a 32-channel NeuroNexus probe to record neuronal spiking during episodes before and after GABAergic blockade. This perturbation, with some variability, reduced episode frequency and number of spikes per episode, which never fully recovered. On the other hand, the average spike frequency within a burst (SFWB) was homeostatically recovered in many motoneurons. Shortly after adding a GABAergic antagonist, there was a dramatic increase in SFWB, but after 1.5-2 hours, SFWB decreased and returned to baseline levels, even though total spikes did not recover. The bursts in the isolated spinal cord correspond to limb movements that occur in the living embryo. These results suggest that the developing system aims to preserve this crucial kicking behavior by monitoring and homeostatically maintaining the SFWB within an episode. By ensuring that motoneurons respond to a synaptic barrage in a consistent manner, the system can appropriately

maintain motor output of the developing cord. We are now examining the correlates of this finding in two different in vivo systems - the chick embryo and the mouse barrel cortex.

Sch. of Med., New York, NY; [7]NYU Neurosci. Inst., New York, NY; [8]Neurosci., NYU Med. Ctr., New York, NY

Abstract: In neurons, homeostatic plasticity maintains synaptic strength within a functional range through forms of negative feedback.While it is conceptually thought to oppose destabilizing positive-feedback changes of Hebbian plasticity, many molecular components implicated in one are key for the other. Computational models using homeostatic synaptic scaling with Hebbian learning rules fail to maintain stable networks due to temporal discrepancies. These observations raise questions about the current conceptual frameworks of synaptic homeostasis. We discovered that homeostatic synaptic plasticity is a slow damped oscillatory response that links both Hebbian and homeostatic plasticities via L-Type Calcium Channels. Ca^{2+}/CaM-dependent kinases and phosphatases both act on AMPARs to homeostatically regulate synaptic weight by transiently appropriating elements involved in long-term potentiation (LTP) and depression (LTD). We propose a model of synaptic activity that uses pre- and postsynaptic feedback mechanisms that invites a broad reconsideration of Hebbian and homeostatic plasticity as unified, rather than oppositional forces.

Title: Lack of antibody response to SARS-CoV-2 infections and vaccinations in MS patients on anti-CD20 therapy may be independent of CD19 B-cell counts

Authors: J. LIU[1], G. FEUER[1], V. KIRSCHNER[1], J. LEI[1], M. MALIN[1], M. ROCHE[1], *J. LIN[2], R. ALFONSO[1], S. A. SADIQ[3];

Abstract: The COVID-19 pandemic has resulted in an unprecedented accelerated vaccine development against SARS-CoV-2. The vaccines have been shown to effectively induce immune responses in healthy individuals against the virus. However, for multiple sclerosis (MS) patients on anti-CD20 therapy, the ability to generate a protective antibody response may be compromised. At Tisch MS Research Center of New York (MSRCNY), we are exploring the antibody responses of these MS patients after receiving COVID-19 vaccines or after naturally occurring infections. To assess overall IgG antibody response, we used an in-house ELISAs to detect IgG antibodies against the recombinant SARS-CoV-2 S1 subunit's receptor binding domain. To confirm antibody response, samples must show a change in antibody levels from a pre-pandemic or pre-vaccination serum sample. If these prior samples are not available, samples must show positive neutralization activity with a surrogate virus neutralization ELISA. The serum samples used in these assays were obtained from MS patients who have been on anti-CD20 therapies for at least 6 months and were vaccinated and/or naturally infected with COVID at least 1 month prior to blood collection. As part of patients' routine clinical management, CD19 B-cell counts were obtained prior to their next therapy, allowing us to access B-cell counts at the time of serum analysis. Control samples were obtained from non-MS staff members of Tisch MSRCNY at least 1-month post-vaccination or after natural infection. Of 76 vaccinated and/or infected MS patients on anti-CD20 therapy, only 10 had detectable antibody responses. In contrast, all the vaccinated or infected control samples (n=38) that we tested neutralizing antibodies and IgG levels for had detectable antibody responses. These results show decreased antibody response in anti-CD20 treated MS patients. Interestingly, 9 out the 10 MS patients with detectable antibody responses had below normal CD19 B-cell levels, suggesting that the ability to mount a protective antibody response may involve more than just the presence of B-cells.Our results indicate an impaired antibody response to SARS-CoV-2 vaccination and/or natural SARS-CoV-2 infections in MS patients on anti-CD20 therapy. However, the impaired antibody

response may not correlate completely with CD19 B-cell levels. This project is still ongoing as we continue to collect more data to corroborate the findings from this preliminary data.

Title: Delayed oligodendrocyte progenitor cell recruitment and maturation in large volume demyelination

Authors: *J. J. M. COOPER, J. J. POLANCO, D. SARASWAT, J. J. PEIRICK, F. J. SIM; Univ. at Buffalo-Jacobs Sch. of Med. and Biomed. Sci., Buffalo, NY

Abstract: Remyelination-inducing therapies have the potential to restore neurologic function and prevent progression in multiple sclerosis (MS). However, preclinical therapies capable of driving oligodendrocyte differentiation and enhancing remyelination in murine models have not yet yielded meaningful clinical improvement. These setbacks suggest that small animal models may be inadequate for the development and identification of promising regenerative therapies. Unlike MS, rodent models of demyelination undergo highly efficient remyelination, have typically very small volumes and exhibit abundant oligodendrocyte recruitment rapidly following demyelination. We hypothesized that oligodendrocyte progenitor cell (OPC) recruitment becomes rate-limiting as lesion volume increases leading to a failure of oligodendrocyte differentiation and endogenous remyelination. In this study, we utilized lysolecithin injection into the large white matter tracts of the rabbit to create demyelinated lesions that have cross-sectional areas 20-fold larger than those previously reported in mice, and volumes 8-fold larger. Unlike rodent lesions which show robust supernumerary OPC recruitment (representing a 3-10 fold increase in $Olig2^+$ cell density), recruitment in the rabbit never exceeds normal levels. Importantly, the density of mature $CC1^+$ oligodendrocytes failed to return to NAWM levels by 56 dpl and the percentage of differentiated oligodendrocytes drastically lagged behind that of rodent lesions. These results suggest that as lesion volume increases the requirement for increased OPC proliferation and migration becomes limiting. As oligodendrocyte differentiation from human OPCs is dependent on the local density of progenitors, the reduced density of progenitors in large lesions may contribute to failed

differentiation and remyelination. Together, we show that large volume demyelination in the white matter of the rabbit recapitulates several key features of human MS lesions, and represents an important preclinical model for the assessment of remyelination therapies in human demyelinating disease.

Title: Cerebrospinal fluid antibody analysis of multiple sclerosis patients reveals binding to primarily ubiquitous intracellular antigens

Authors: *G. FEUER, J. LIN, Q. J. YAN, S. A. SADIQ;
Tisch Multiple Sclerosis Res. Ctr. of New York, New York, NY

Abstract: Oligoclonal bands (OCBs) are present in over 90% of patients with multiple sclerosis (MS) and indicate the presence of IgG in cerebrospinal fluid (CSF). In order to determine the antigenic target of these IgG, we isolate B cells from the CSF, determine the DNA sequence encoding the variable region, insert this sequence into an expression vector, and produce the antibodies using a human cell expression system. We then utilize the HuProt Human Proteome Microarray produced by CDI Labs. This array consists of over 21,000 GST-purified recombinant proteins grown in Yeast, which allows us to determine antibody specificity on properly folded three-dimensional human proteins. We sent antibodies generated from 22 unique B cells from 15 patients to CDI Labs to be used as probes on the HuProt microarray. All but one of these B cells was clonally expanded. These patients include 8 males and 7 females comprising 5 cases of relapsing-remitting multiple sclerosis (RRMS), 7 cases of primary progressive multiple sclerosis (PPMS), and 3 cases of secondary progressive multiple sclerosis (SPMS). The patients range in age from 24 to 70.
6 of the 22 distinct antibodies sent to CDI Labs had significantly high affinity and specificity for proteins on the array. These 6 antibodies represent 3 RRMS cases, 2 PPMS cases, and 1 SPMS case. Proteins bound by our antibodies include MRPL1 (Mitochondrial Ribosomal Protein L1), MST1 (Macrophage-Stimulating Protein), AKR7A3 (Aldo-Keto Reductase Family 7 Member A3), VCL (Vinculin), HNRNPD (Heterogeneous Nuclear Ribonucleoprotein D), TIA1 (TIA1 Cytotoxic Granule Associated RNA Binding Protein), and MBP (Myelin Basic Protein). They

are all intracellular proteins, except for MST1, which is secreted, and MBP, which is a structural protein in myelin sheaths. 4 out of 7 of these proteins are ubiquitously expressed. We have confirmed binding to TIA1, MRPL1, and MBP through western blotting, which may indicate the presence of a linear epitope that is conserved in the primary structure of the protein upon being denatured. Failure to confirm binding on a western blot for the other proteins may simply be due to differences in binding to the native proteins of the array compared to denatured proteins in the western blot. Binding to MBP has been further confirmed through immunohistology. Our results indicate that antibodies produced in the CSF during disease course may target individualized antigens that vary from patient to patient rather than some antigen common in all cases of MS. Ongoing research seeks to determine the relevance of these particular antigens or if the antigenic targets are truly unique and varied amongst individuals with MS.

Title: Increased light scattering in Multiple Sclerosis measured by frequency-domain near-infrared spectroscopy

Authors: *A. HANSEN[1], D. D. ADINGUPU[1], A. SOROUSH[1,2,3], Q. SHAFQAT[1], T. EVANS[1,2,3], S. JARVIS[3,4], L. BROWN[2], J. F. DUNN[1,2,3];
[1]Radiology, [2]Clin. Neurosciences, Cumming Sch. of Medicine, Univ. of Calgary, Calgary, AB, Canada; [3]Hotchkiss Brain Institute, Cumming Sch. of Medicine, Univ. of Calgary, Calgary, AB, Canada; [4]Alberta Neurologic Ctr., Calgary, AB, Canada

Abstract: Multiple sclerosis (MS) is a chronic illness characterized by inflammation, demyelination, and neurodegeneration within the central nervous system. Previously, we utilized frequency-domain near-infrared spectroscopy (fdNIRS) to show that hypoxia is present in the frontal lobe grey matter of about 40% of individuals with multiple sclerosis (MS). The causes of this hypoxia are not known but may relate to a metabolic disorder. It has been proposed that changes in tissue light scattering relate to changes in mitochondrial structure and density and/or to edema. We applied fdNIRS to quantify scattering in three groups: controls, patients with MS

that were normoxic, and patients with MS that were hypoxic. Total oxyhemoglobin and deoxyhemoglobin were quantified with fdNIRS and used to calculate microvessel tissue oxyhemoglobin saturation (S_tO_2) in addition to the reduced scattering coefficient (μ_s) at 690 and 824nm from the frontal cortex of 52 controls and 78 MS patients. S_tO_2 values that were 2 standard deviations below the healthy control mean were defined as hypoxic (<55.7%). Of the individuals with MS, 28 were hypoxic and 50 were normoxic and μ_s was examined between groups with a Kruskal Wallis test followed up with a Dunn's test. The mean ± SD of S_tO_2 was 61.0±5.3 %, 61.9±3.5 % and 49.6±7.1 % in controls, normoxic MS patients and hypoxic MS patients, respectively. Significant differences in μ_s were found between groups when measured at both 690nm and 824nm using the Kruskal Wallis test (p=0.014; p=0.041, respectively). The μ_s at 690nm and 824nm was found to be significantly higher in normoxic MS patients as compared to healthy controls using a Dunn's post-hoc test (10.1±1.3 cm^{-1} vs. 9.3±1.3 cm^{-1}, p=0.009; 8.6±1.3 cm^{-1} vs. 7.9±1.4 cm^{-1}, p=0.017, mean±S.D., respectively). The hypoxic MS population had significantly higher μ_s compared to controls at 690nm (10.0±1.6 cm^{-1}, vs. 9.3±1.3 cm^{-1}, p=0.030) but no detectable difference was found at 824nm (8.2±1.5 cm^{-1}, 7.9±1.4 cm^{-1}, p=0.202). The increased light scattering in MS patients may be a consequence of MS pathology. Previous studies have shown that edema and mitochondrial structure alterations can cause changes in scattering. Mitochondria are dominant scatterers in the near infrared region. Thus, light scattering has been used experimentally to investigate mitochondrial density and volume in literature. These data show that fdNIRS can detect a unique biomarker in patients with MS. This biomarker may relate to mitochondrial dysfunction or edema. fdNIRS may be a useful tool to noninvasively detect underlying pathologies in MS such as cerebral edema, mitochondrial swelling, and hypoxia.

Abstract: Multiple sclerosis (MS) is characterized by demyelination and lesion formation in gray and white matter (WM), leading to impaired neurological and cognitive function. MS is a major cause of disability worldwide, with higher prevalence in women compared to men. Currently there is no cure, and the underlying molecular dysregulation is not well understood. Histone deacetylases (HDACs) have been associated with MS, and as such are considered therapeutic targets. Three key lines of evidence link HDAC dysregulation to MS, including altered HDAC expression in postmortem lesion tissue, HDAC mis-localization and interference in axonal transport in both *in vitro* and preclinical models, and multiple studies using several classes of HDAC inhibitors consistently demonstrate symptom amelioration in animal models of demyelination. However, specific alterations to HDAC and their influence on pathology or symptomology in humans remains unknown. Recently, a new window to understanding HDACs in the human brain has opened with [^{11}C]Martinostat, a radiotracer for positron emission tomography (PET). We hypothesize that HDACs will be altered in MS in areas of known pathology and to test this, we measured [^{11}C]Martinostat uptake in six people with relapsing remitting MS (2f/4m;50.3±11.52years) compared to six age- and sex-matched controls (2f/4m;49.16±11.95 years). Dynamic PET images were acquired after bolus injection (controls 5.22±0.41mCi; MS 5.37±0.14mCi) using a combined 3-Tesla:magenetic resonance (MR)-PET system. PET images were reconstructed in units of standard uptake value (SUV), normalized to whole-brain mean (SUVR) and registered to standard space using FreeSurfer and Functional Magnetic Resonance Imaging of the Brain Software Library (FSL). [^{11}C]Martinostat uptake was lower in cortical and subcortical areas in MS compared controls including thalamus, parahippocampus, perirhinal and entorhinal areas and pons (voxelwise analysis using FSL FEAT comparing SUVR between groups; Z>2.3, P-cluster=0.05).
Altered HDAC expression in these areas carry clinical implications. For example, lower HDAC levels in thalamus, an area affected early in the disease course, may lead to altered thalamo-cortical connectivity as sensory inputs relayed from the thalamus influence cortical activation. Future analyses will assess uptake in lesions, normal appearing WM and will evaluate the relationship between HDAC expression and WM microstructure, biological sex as well as neurological function and cognition to establish links between HDAC alterations and symptomology as an important step towards dissecting the involvement of HDACs in MS pathology.

Disorders and Stroke, NIH, Bethesda, MD; [2]Dept. of Neurology, Div. of Multiple Sclerosis and Neuroimmunology, Northwestern Univ., Chicago, IL; [3]Psychiatry, Semel Inst. for Neurosci. and Human Behavior, David Geffen Sch. of Med., UCLA, Los Angeles, CA

Abstract: Multiple sclerosis (MS), a chronic disease that impacts 2.8 million people worldwide, is characterized by aberrant autoimmune attack against myelin components in the central nervous system (CNS). The loss of myelin-producing cells, oligodendrocytes, is the hallmark of MS; however, the etiology of the initial events is still unclear. Preclinical animal models have been established to investigate different aspects of MS. One such model, the diphtheria toxin A chain (DTA) oligodendrocyte ablation mouse model (*Plp1-CreERT;ROSA26-eGFP-DTA*), involves "inside-out" demyelination, in which autoimmunity against myelin originates from oligodendrocyte death or myelin disruption. After an initial demyelinating phase that peaks 5 weeks post tamoxifen injection (wpi) and resolves 5 weeks later (10 wpi), a secondary phase of demyelination commences about 7 months later. Focal demyelinating lesions form, and neurological disability of suspected autoimmune origins accrues. This model presents an interesting phenotype that parallels the secondary progressive phase of MS. To understand how different types of cells in the CNS participate in oligodendrocyte death and myelin loss, we undertook an in-depth transcriptome characterization of brain cells in white and gray matter of DTA mice across the disease course. Corpus callosum, cortex, and brain stem were examined at symptom onset (3 wpi), at the peak of the initial demyelinating phase (6.3 wpi), during the intermediate recovery phase (17 wpi), and during late-onset secondary demyelination (45 wpi) using single nucleus RNA-sequencing (snRNA-seq). As expected, we observed oligodendrocyte lineage cell (*Mog+* and *Pdgfra+)* loss in both phases of demyelination with temporary reconstitution during the intermediate recovery phase. Neuronal populations (*Slc17a7+* and *Gad1+)* were mostly unaffected, and microglia/immune population elevation (*Ptprc+)* is most prominent at the onset of the first demyelination phase. Interestingly, astrocytic reactivity (*Gfap+)* persists throughout the onset, peak, and recovery phases of demyelination but is attenuated during secondary demyelination, indicating the presence of divergent microenvironments between the two demyelination events. Delineating the differences between these two phases of disease is relevant to understanding the complex pathophysiology of MS.

Title: Vagus Nerve Stimulation (VNS) enhances myelin repair and behavioral recovery following demyelinating injury

Authors: *R. HUANG[1,3], E. G. HUGHES[2,3], C. G. WELLE[1,3];
[1]Dept. of Neurosurg., [2]Dept. of Cell and Developmental Biol., Univ. of Colorado Anschutz Med. Campus, AURORA, CO; [3]Neurosci. Grad. Program, Univ. of Colorado, Anschutz Med. Campus, Aurora, CO

Abstract: Multiple Sclerosis (MS) is an inflammatory, demyelinating disorder that damages oligodendrocytes, resulting in myelin loss and eventual axonal degeneration. While demyelination occurs throughout the central nervous system (CNS), increasing evidence suggests that grey matter demyelination is directly correlated with impaired cognitive and motor dysfunction. Current pharmacological therapies mitigate the frequency of demyelinating events, but do not promote repair of lesions, leading to cumulative damage and functional impairments. There is an unmet need to develop innovative therapeutic approaches that focus on restoration of function through remyelination. Previous studies show that increasing neuronal activity enhances oligodendrocyte generation and myelin plasticity in the healthy CNS. Recent work from our group shows that enhancing neuronal activity via motor learning following demyelination promotes oligodendrocyte regeneration and myelin repair. Vagus nerve stimulation (VNS) drives neuronal activity and plasticity, leading to functional recovery from neuronal injury in stroke, tinnitus and traumatic brain injury. However, whether VNS can be utilized to drive myelin repair and plasticity remains unexplored. We applied chronic VNS to mice with cuprizone-mediated demyelination and used longitudinal two-photon *in vivo* imaging to track the loss and regeneration of oligodendrocytes in motor cortex over time. We found that VNS, when applied in a closed-loop paradigm during dexterous motor learning, enhances remyelinating capacity and results in an increased generation of new oligodendrocytes in motor cortex. To determine if VNS promotes motor function, we evaluated motor performance on a novel dexterous motor learning task. Preliminary data suggests that VNS restores demyelination-induced learning deficits and provides long-term benefits on motor performance. In conclusion, we found that VNS enhances remyelination and the timing of VNS, paired with task execution, may be essential for this improvement. Our results also strongly implicate that VNS accelerates the restoration of deficits

in motor learning and provides long-term improvement in performance following demyelination injury.

Title: Critical role for astrocyte NAD^+ glycohydrolase in myelin injury and regeneration

Authors: *M. R. LANGLEY, C.-I. CHOI, T. R. PECLAT, Y. GUO, W. SIMON, H. YOON, L. KLEPPE, C. F. LUCCHINETTI, C. C. S. CHINI, E. N. CHINI, I. A. SCARISBRICK;

Abstract: Myelin disturbances and oligodendrocyte loss can leave axons vulnerable leading to permanent neurological deficits. The results of the current study suggest that metabolic disturbances, triggered by consumption of a diet high in fat, cause disruptions in myelinating cells and astrocytes within the mouse CNS. CD38 shows increased expression in the cuprizone and EAE models of demyelination and is the main NAD^+ depleting enzyme in the CNS. Altered NAD^+ metabolism has been linked to both high fat consumption and multiple sclerosis (MS). Here we identify increased CD38 expression in the male mouse spinal cord following chronic high fat diet consumption, after focal toxin (lysolecithin)-mediated demyelinating injury and in reactive astrocytes within active MS lesions. We show that CD38-catalytically inactive mice are significantly protected from high fat-induced NAD^+ depletion, oligodendrocyte loss, oxidative damage, and astrogliosis. Significantly, oral administration of a CD38 inhibitor,78c, increased counts of oligodendrocytes and remyelinated axons after focal lysolecithin-induced spinal cord demyelination. Using a Ribotag approach, we identify a unique *in vivo* brain astrocyte translatome profile induced by 78c-mediated CD38 inhibition in mice, including decreased expression of pro-inflammatory astrocyte markers and increased growth factors. Moreover, in the spinal cords of mice subjected to focal lysolecithin-induced demyelination, the astrocytes had

increased pro-repair markers and reduced pro-inflammatory response markers in the group treated with 78c. Our data suggests that high fat diet impairs oligodendrocyte survival and differentiation through astrocyte-linked mechanisms mediated by the NAD^+ase CD38 and highlight the use of CD38 inhibitors as potential therapeutic candidates to improve myelin regeneration. Together these findings point to a new metabolic targeting strategy positioned to improve disease course in MS and other conditions in which the integrity of myelin is a key concern.

Title: Role of HCMV Infection in Alzheimer’s Disease Pathology

Authors: *J. W. ADELMAN[1], M. SCHUMACHER[2], B. O'BRIEN[1], R. MOKRY[2], S. TERHUNE[2], A. EBERT[1];
[1]Cell Biology, Neurobio. and Anat., [2]Microbiology and Immunol., Med. Col. of Wisconsin, Milwaukee, WI

Abstract: Alzheimer’s Disease (AD) is a common, incurable form of progressive dementia characterized by declining short term memory and reduced mental function. While the mechanisms of AD remain unclear, many modern hypotheses focus on synaptic dysfunction - the earliest pre-clinical manifestation of AD. Previous studies highlight the contributions of environmental pathogens to this process, with Herpes Simplex Type 1 being the archetypal virus. However, other members of Herpesviridae, such as Human Cytomegalovirus (HCMV), are also being interrogated for roles in AD pathogenesis. In animal studies, HCMV infection appears to mirror the AD phenotype via disruption of key synaptic proteins. Further, HCMV has been demonstrated to affect calcium flux and amyloid beta (Aß) accumulation, signaling further overlap with AD. Here, both 3D (cerebral organoid) and 2D (forebrain neuron) cultures will be

used to test whether HCMV infection can influence AD pathology. All cultures utilize induced pluripotent stem cells (iPSCs) derived from either AD (Presenilin-2 mutation) or control (no AD-associated mutations) patients. At day 30 (D30) of differentiation, cultures are either infected with a clinical HCMV strain (TB40/E-GFP variant) or mock treated, with collection at D60. Subsequently, samples will be processed for protein, RT-qPCR, and functional analyses. Preliminary RNA sequencing data of brain organoids reveal HCMV's ability to broadly downregulate gene transcripts, including key synaptic targets affected in AD (Synaptophysin, PSD-95, NMDA/AMPA subunits). If maintained at the protein level, HCMV-mediated loss of these proteins could lead to further synaptic impairment, with potential implications for memory. Further, early experiments show viral modulation of phosphorylated tau (pTau) - the primary component of neurofibrillary tangles (NFTs) in AD - with HCMV driving increases in AD organoids and decreases in control tissues. We hypothesize that HCMV contributes biochemically to the AD phenotype via further downregulation of synaptic proteins and increases in NFT accumulation. In support of this hypothesis, our preliminary electrophysiological results show disproportionate increases in synaptic potentials for AD organoids aligning with hyperexcitability. HCMV infected cells, alternatively, show decreased calcium signaling and synaptic potentials. To date, no studies have investigated potential cooperative effects of HCMV and AD on neuronal function. Together, our current studies will better elucidate HCMV's influence on both the biochemical and functional aspects of AD pathology.

Title: Pannexin1 activation by NMDA receptors is STIM dependent and associated with excitatory synapse deficits caused by amyloid-β oligomers

Authors: *C. S. PATIL, N. E. LAVINE, M. F. JACKSON;
Pharmacol. and Therapeut., Univ. of Manitoba, Winnipeg, MB, Canada

Abstract: Introduction: During the initial stages of Alzheimer's disease, accumulation of soluble amyloid-β oligomers (AβOs) is associated with loss of Ca^{2+} homeostasis underlying impaired glutamatergic synaptic function. Identifying candidate mechanisms triggering Ca^{2+} dysregulation can thus provide targets for development of novel therapeutics. The focus of our study is to understand synaptic deficits mediated by AβOs through its effect on NMDA receptors (NMDARs) and its downstream signalling effectors, including pannexin1 (Panx1) channels, which have previously been linked to neurological disorders. Overactivation of NMDARs leads to activation of Panx1 is known but we now show that this is regulated by endoplasmic resident stromal interacting molecule proteins (STIMs). Moreover, we show that AβOs sensitizes Panx1 activation, which then promotes synaptic deficits. Methods: Our study utilised two cellular models: Hippocampal neurons cultured from CD1, Panx1 WT and Panx1 KO mice were used for electrophysiology experiments. HEK 293T cells were used for mapping the Panx1-STIM interaction interface. Each result discussed consists of minimum 3 independent experimental replicates. Results: First we show that Panx1 activation by NMDARs was augmented in neurons treated with AβOs. Increased Panx1 activation, coupled with reduced frequency of excitatory synaptic events mediated by AβOs, was observed in WT neurons but not in neurons cultured from Panx1 KO mice. Moreover, Panx1 activation was abrogated in neurons with knockdown of STIMs. Thus, we reasoned modulating STIM-dependent Panx1 activation can serve as a candidate therapeutic target to prevent Aβ mediated synaptic deficits. We created Panx1 deletion mutants and show that STIM activates Panx1 via interaction with a Panx1 N-terminal domain. Moreover, Panx1 activation by NMDARs was abolished in cultured neurons expressing a STIM binding deficient Panx1 mutant. Lastly, using an N-term recognising Panx1 antibody we validated our mechanism of STIM-dependent Panx1 activation. Altogether our results establish the significance of Panx1-STIM interaction in regulating Panx1 channel activation by NMDARs. Future investigations are directed to develop therapeutic targets within our discovered region to inhibit Aβ induced increased Panx1 activity and alleviate synaptic deficits. Conclusion: Our work will help in understanding the role of NMDAR-STIM-Panx1 signalling in mediating physiological and pathological functions in neurons. Further, we hope to provide rationale for developing modality specific therapeutics targeting dysregulated Panx1 function and impeding detrimental effects of AβOs.

Title: The effects of amyloid beta protein on excitatory transmission and AMPA receptor phosphorylation in layer II of the entorhinal cortex

Authors: *M. E. SUVANTO[1], O. J. OLAJIDE[3], J. SARAGOSA[2], C. A. CHAPMAN[1]; [1]Ctr. for Studies in Behavioral Neurobio., [2]Concordia Univ., Montreal, QC, Canada; [3]Anat. (Neuroscience Unit), Univ. of Ilorin, Ilorin, Nigeria

Abstract: In Alzheimer's Disease (AD), neurodegeneration is first found in layer II of the entorhinal cortex, and the degeneration in the EC likely contributes to memory deficits and cognitive impairments that occur early in AD. Current hypotheses regarding the early stages of AD suggest that toxic accumulation of soluble amyloid beta peptides (Aβ) contribute to neurodegeneration. In the hippocampus, elevated Aβ levels interfere with excitatory synaptic transmission by facilitating postsynaptic calcium influx into the neuron via NMDA glutamate receptors, leading to phosphorylation of AMPA glutamate receptors which increase synaptic strength. Chronically elevated calcium levels may contribute to excitotoxicity and eventual cell death in both the EC and hippocampus. Aβ-mediated excitotoxicity and the effects of Aβ on excitatory transmission have been studied extensively in the hippocampus. However much less is known about the effects of Aβ on excitatory synaptic transmission in layer II of the EC. We studied the effects of incubating 400 μm horizontal slices of rat medial EC in 100 nM $A\beta_{(1-42)}$ (n=24) or a dimethylsulfoxide control (n=25) for 45 minutes to 3 hours on excitatory synaptic transmission in layer II EC using field excitatory postsynaptic potentials (fEPSPs) recorded in vitro. We then examined the effects of incubating slices with the addition of 50 μM of D-AP5 to the Aβ incubation (n=13) and the control (n=12). All experiments were blinded. The amplitude of fEPSPs was increased in slices incubated in Aβ relative to control slices. The facilitation of synaptic responses induced by Aβ was blocked by constant bath application of the NMDA receptor blocker D-AP5, indicating that the activation of NMDA receptors is required for the facilitation of synaptic excitability. The facilitation of synaptic responses induced by Aβ likely results from activation of postsynaptic NMDA receptors that enhance calcium influx that can activate CaMKII to result in phosphorylation of AMPA receptors. We assessed tissue samples of the medial EC using the western blotting to measure the expression of CaMKII, AMPA receptors, and phosphorylated AMPA receptors following a one hour incubation in either 100 nM $A\beta_{(1-42)}$ (n=6) or a dimethylsulfoxide control (n=6). We then replicated these experiments with the inclusion of 50 μM of D-AP5 to both incubations (n=6 and n=6). Results of protein analysis were consistent with the electrophysiological recordings. These effects of exposure to Aβ may contribute to mechanisms of excitotoxicity and cognitive decline observed early during the progression of Alzheimer's Disease.

Title: Impaired alpha-tubulin re-tyrosination leads to synaptic dysfunction and is a feature of Alzheimer's Disease

Authors: *J. PARATO[1], L. QU[2], A. KUMAR[1], L. PERIS[3], M. PERO[1], A. SPROUL[1], M.-J. MOUTIN[3], A. ANDRIEUX[3], F. BARTOLINI[1];

Abstract: Microtubules in neurons give support to dendrites and axons, provide tracks for transport, and contribute to synaptic plasticity. Dynamic microtubules are composed of tyrosinated tubulin, while a detyrosinated state is associated with increased stability. In the Tyr/deTyr cycle, the C-terminal tyrosine of α-tubulin is removed by tubulin carboxypeptidases and is re-added by tubulin-tyrosine-ligase (TTL). We found that in sporadic Alzheimer's disease (AD), TTL expression is significantly reduced. This finding was recapitulated in a cellular model of familial AD, with human APPV717I London mutation neurons having lower levels of TTL, as well as a decrease in dynamic microtubules. When TTL was knocked down in rat hippocampal neurons, widespread spine loss occurred. Furthermore, we found that spines entered by dynamic microtubules are more resistant to oAβ_{1-42}-induced pruning and that ectopic TTL expression, by promoting microtubule entry into spines, protected the neurons from oAβ_{1-42}-induced spine pruning. Our results demonstrate that tubulin re-tyrosination is decreased in AD, that the Tyr/deTyr cycle contributes to synapse maintenance, and that TTL can prevent oAβ_{1-42}-induced spine pruning.

Title: Amyloid beta (1-42) peptide-induced impairments in synaptic elements in the entorhinal cortex are associated with perturbed mitochondrial function

Authors: *O. J. OLAJIDE[1], A. BERGDAHL[2], C. A. CHAPMAN[1];
[1]Dept. of Psychology, Ctr. for Studies in Behavioral Neurobio., [2]Dept. of Health, Kinesiology & Applied Physiol., Concordia Univ., Montreal, QC, Canada

Abstract: Accumulating evidence suggests that mitochondrial dysfunction and increased reactive oxygen species (ROS) play crucial roles in the synaptic degeneration and neuropathology that drives memory deficits in Alzheimer's disease (AD). We recently showed that solubilized human amyloid beta peptide 1-42 ($hA\beta_{1-42}$) causes rapid alterations at glutamatergic synapses in the entorhinal cortex (EC) through the activation of both GluN2A- and GluN2B-containing subunits of NMDA receptors. Whether the disruption of mitochondrial function contributes to the mechanisms of $hA\beta_{1-42}$-induced synaptic perturbations in the EC is however unknown. The present study focused on assessing the early impacts of $hA\beta_{1-42}$ on EC mitochondrial respiration and the immunoexpression of key components of the mitochondrial respiratory machinery, as well as to determine whether reducing $hA\beta_{1-42}$-induced ROS generation could diminish synaptic dysfunction in the EC. Acute 400 μm horizontal entorhinal slices obtained from 6 to 9-week-old wild-type male long-Evans rats were incubated in artificial cerebrospinal fluid (saturated with 95% oxygen and 5% carbon dioxide) containing exogenous $hA\beta_{1-42}$ (0.5 and 1 μM) or control solution for 3 hours at room temperature. High-resolution respirometry analysis using the Oroboros Oxygraph revealed slight modifications to mitochondrial respiratory measurements in the EC following 0.5 μM $hA\beta_{1-42}$ incubation (n=5), but treatment with 1 μM $hA\beta_{1-42}$ (n=5) caused marked reduction in oxygen consumption relative to control (n=6). $hA\beta_{1-42}$ therefore mediates rapid mitochondrial perturbations in the entorhinal cortex, and this may contribute substantially to early AD-related neuropathology and synaptic degeneration. Changes in the expression of mitochondrial-related proteins and synaptic elements, and the effects of mitochondria-targeted antioxidant compound (Mito-Q) and a synthetic superoxide dismutase and catalase mimetic (EUK 134) on $hA\beta_{1-42}$-treated EC slices will also be discussed.

Abstract: Alzheimer's disease (AD) is a neurological disorder characterized by the overproduction and accumulation of amyloid-beta (Aβ) and phosphorylation and intraneuronal aggregation of tau. These events promote synaptic dysfunction and loss, which in turn leads to neurodegeneration. Astrocytes, intimately associated with neurons and synapses, are activated by Aβ in a process defined as astrogliosis, emerging as neurotoxic entities. Although astrogliosis has been characterized in AD, the contribution and mechanisms by which reactive astrocytes participate in neurodegeneration remains understudied. Here we show that astrocytic tau is a key factor in the process of synaptic loss. When tau was ablated from astrocytes, the synaptotoxic effects of Aβ-induced astrogliosis were avoided. Interestingly, these tau KO astrocytes showed a neuroprotective phenotype, marked by the upregulated expression of PTX3. Importantly, these results were confirmed by decreasing tau expression on Aβ-stimulated WT astrocytes with a shRNA. Taken together, our results indicate that astrocytic tau is necessary for Aβ-induced astrogliosis to produce synaptic damage. Dissecting the mechanism by which Aβ exerts its neurotoxic effect via tau and identifying new cellular interplays of molecular components in AD will contribute to formulating new strategies for managing this disease.

Abstract: Introduction: Intracellular inclusions comprised of tau protein correlate with, and precede, cognitive deficits in multiple neurodegenerative disorders, such as Alzheimer's disease (AD). The molecular mechanisms by which intracellular tau disrupts synaptic function and impairs cognition, however, remain incompletely elucidated. To address this, we used a highly sensitive, high throughput single molecule array (SIMOA) assay to quantify phosphorylated tau (phospho-tau) and total tau in synaptic fractions and assessed differences when stratified by sex (M/F) and APOE genotype. **Methods**: Frozen tissue was used from entorhinal (ENT) and middle frontal (MF) cortices from 50 age- and sex-matched individuals, 26 of which were female (Northwestern and Mayo Clinic Alzheimer's Disease Centers and Mayo Clinic Study of Aging). Inclusion criteria required a full spectrum of AD Neuropathologic Change (ADNC) severity while excluding significant co-existing lesions. 18 individuals had at least one APOE 4 allele. A fractionation protocol was performed on human brain tissue. Tau was quantified in each separate fraction using Quanterix Simoa-HD1 Platform and Quanterix Tau 2.0 and p-Tau231. Western blotting ensured protein enrichment in appropriate fractions (e.g., PSD95 for P4). Fractional percentages of pTau231 and total tau were calculated. Spearman's Rank-Order correlation was used to detect relationships across ADNC designations. Welch's T-test was used to assess changes in tau by sex and APOE 4 allele status. $P < 0.05$ was considered statistically significant.**Results**: pTau231 ratios of P4 (post-synaptic density) to S4 (pre-synaptic) were initially compared across clinical and neuropathologic designations, demonstrating an increasing trend in the percent of phospho-tau present in P4 fractions of the MF cortex as well as S2 fractions in the ENT cortex with worsening disease. The S4 fraction of the ENT cortex demonstrated an inverse relationship. No significant sex (M/F) differences were identified across groups in S2 ENT cortex ($p=0.9$), S4 ENT cortex ($p=0.7$), or P4 MF cortex ($p=0.9$). When groups were compared with matched levels of tau pathology, those with an APOE 4 allele had decreased pTau231 levels in S4 fraction (e.g., Int. Braak stage cases $p=0.01$).
Conclusions: No, sex specific differences related to total or pTau231 mislocalization were identified across groups. However, the presence of an APOE 4 allele does appear to play a role in the mislocalization of tau in the pathobiologic development of AD. This may be related to neuronal loss with decreased pre-synaptic soluble pTau231. Future studies will focus on clarifying potential underlying mechanisms.

Title: Defining the neuroprotective mechanisms of neuritin in cognitive resilience to Alzheimer's disease

Authors: *C. D. HURST[1], D. A. PUGH[2], D. M. DUONG[1], D. A. BENNETT[3], J. H. HERSKOWITZ[2], N. T. SEYFRIED[1];
[1]Biochem., Emory Univ., Atlanta, GA; [2]Neurol., The Univ. of Alabama At Birmingham, Birmingham, AL; [3]Rush Alzheimer's Dis. Ctr., Rush Univ. Med. Col., Chicago, IL

Abstract: There is increasing recognition of a subpopulation of “cognitive-resilient” individuals that live to advanced age with intact cognitive function despite the presence of moderate to severe Alzheimer’s disease (AD) pathology. Thus, identifying molecular mechanisms in brain associated with cognitive resilience may reveal novel therapeutic pathways and targets for the treatment and prevention of AD and related dementias. Towards this goal, neuritin (NRN1) was recently identified as the most significant protein associated with cognitive resilience in a proteome-wide association study conducted in the Religious Order Study and Memory and Aging Project longitudinal cohorts (ROSMAP, n=391 individuals), in which higher levels of cortical NRN1 at autopsy correlated with a slower rate of cognitive decline in life. Moreover, in our recent large-scale, multi-center proteomic analysis of >500 human brain tissues, network analysis identified NRN1 as a hub protein in a module enriched with synaptic proteins that positively correlated to global cognitive function and stable cognitive trajectory in life. Collectively, these data support our hypothesis that NRN1 is protective against AD neuropathology and subsequent cognitive decline. To further validate our systems-level data and explore the potential neuroprotective mechanisms of NRN1, we treated rat primary neuronal cultures with recombinant NRN1 protein with or without toxic Amyloid-beta 1-42 (Aβ) oligomer insult followed by dendritic spine morphometric analysis and in-depth proteomics. Morphometric analysis revealed NRN1 treatment in the presence of Aβ oligomers rescued overt

dendritic spine density loss observed with Aβ insult alone. In parallel, multiplex proteomics coupled with off-line fractionation allowed quantification of over 8000 proteins from primary neurons, in which differential and co-expression network-based approaches were applied to identify targets and pathways impacted by NRN1. Notably, modules enriched with proteins involved in biological functions associated with GTPase activity and synaptic transmission were decreased following Aβ insult but rescued when co-incubated with NRN1. Together, our findings support that neuritin protects against amyloid-induced neurotoxicity that may in turn promote cognitive resilience in AD.

Title: Protective effects of Mitophagy Enhancers against Amyloid beta-induced Mitochondrial and Synaptic toxicities

Authors: *S. KSHIRSAGAR, H. MORTON, N. SAWANT, A. REDDY, H. REDDY; TTUHSC, Lubbock, TX

Abstract: The aim of our study is to examine the neuroprotective role of mitophagy enhancers such as Nicotinamide, Tomatidine, Urolithin A and Actinonin against Alzheimer’s disease (AD). In recent years, several studies have found reduced fusion and increased mitochondrial fragmentation in a large number of human diseases with mitochondrial dysfunction. Therefore, several groups have found interest in studying mitophagy enhancers. Methods: In our ongoing project, we have examined the protecting role of mitophagy enhancers Nicotinamide, Tomatidine, Urolithin A and Actinonin against impaired defective mitochondrial biogenesis, mitochondrial dynamics, synaptic dysfunction and defective mitophagy in immortalized mouse primary hippocampal cells (HT22) expressing mutant APP (SWI/IND) mutations. From the group of above mentioned mitophagy enhancers, Urolithin A showed strongest effect as compared to others. For our study, we used quantitative RT-PCR, western blot analysis, Seahorse Flux analyzer, biochemical methods and transmission electron microscopy. We

evaluated mutant full-length APP/C-terminal fragments, Aβ levels, mRNA and protein levels of mitochondrial biogenesis, dynamics, mitophagy, and synaptic genes in mAPP-HT22 cells and mAPP-HT22 cells treated with mitophagy enhancers. Results: Increased levels of mitochondrial fission proteins, decreased levels of fusion, biogenesis, mitophagy and synaptic proteins were found in mAPP-HT22 cells relative to HT22 cells. On the other hand, mAPP-HT22 cells treated with mitophagy enhancers compared to mAPP-HT22 cells, we found reduced levels of the mitochondrial fission proteins, enhanced fusion, biogenesis, mitophagy, and synaptic proteins. Our protein data agrees with mRNA levels. Transmission electron microscopy data showed significantly reduced mitochondrial length and increased mitochondrial numbers in mAPP-HT22 cells; these were reversed in mitophagy enhancers treated mAPP-HT22 cells. Cell viability rates were increased in mitophagy enhancers treated mAPP-HT22 relative to mitophagy enhancers-untreated mAPP-HT22. Additionally, seahorse data also showed significantly increased maximal OCR in mAPP-HT22 cells treated with mitophagy enhancers relative to untreated mAPP-HT22 cells, indicating that all mitophagy enhancers showed increased maximal OCR, however, Urolithin A maximal respiration is the highest. Conclusions: These findings suggest that mitophagy enhancers reduces mutant APP and Aβ and mitochondrial toxicities and may have a protective role of mutant APP and Aβ-induced injuries in patients with AD.

Title: The Neuroprotective Actions of an Active Core Sequence of Amyloid Beta on Amyloid Beta-Induced Synaptic Dysfunction

Authors: *R. M. TAKETA, R. A. NICHOLS;
Cell & Mol. Biol., Univ. of Hawaii, Honolulu, HI

Abstract: Alzheimer’s disease (AD) is a devastating neurodegenerative disorder characterized by cognitive decline and progressive memory loss. Pathological aggregation of soluble beta-amyloid (Aβ) into insoluble Aβ-plaques is one of two prominent histopathological hallmarks of the disease, the other being hyperphosphorylated tau in the form of neurofibrillary tangles (NFTs). Aβ is produced through sequential enzymatic cleavage of the amyloid precursor protein (APP) resulting in a series of Aβ peptides. At physiological levels (pM-nM), we and others have

shown that soluble Aβ acts as a neuromodulator enhancing synaptic plasticity. However, at pathological levels (μM), the accumulation of the $A\beta_{1-42}$ ($A\beta_{42}$) peptide contributes to the significant neuronal cell death and synaptic transmission impairments. Our laboratory has shown that an endogenously cleaved N-terminal Aβ fragment (N-$A\beta_{1-15,16}$) and an essential core sequence, YEVHHQ (N-Aβcore) within the fragment, is neuroprotective against $A\beta_{42}$-induced oxidative stress and apoptosis in *in vitro* and ex *vivo* studies. In an APP/PS1 mouse model, the N-Aβcore injected bilaterally into the hippocampus rescued spatial memory deficits. Furthermore, we have recently reported that the N-Aβcore reversed the impairment in synaptic plasticity in hippocampal slices for both long-term potentiation (LTP) and long-term depression (LTD) in a PI3K/mTOR-dependent manner. However, the molecular mechanisms of the regulatory actions of the N-Aβcore at the synaptic level have yet to be uncovered. Here, we have further investigated the neuroprotective actions of the N-Aβcore on $A\beta_{42}$-induced synaptic dysfunction. To examine at which stage in LTP the N-Aβcore is most effective, acute hippocampal slices were subjected to applications of the N-Aβcore in the presence of exogenous $A\beta_{42}$ for wild-type slices or endogenous $A\beta_{42}$ for slices from the 5xFAD APP/PS1 mouse model at various times across the extracellular recording period. Immunohistochemistry and immunoblots of protein lysates were assessed in parallel for differential expression of AMPAR, NMDARs, and mGluRs at the different time points. To delineate and confirm the involvement of PI3K/mTOR signaling pathways, primary hippocampal neuronal cultures and organotypic slice cultures were treated with $A\beta_{42}$ without or with the N-Aβcore. Protein expression of downstream and upstream signaling of PI3K/mTOR were compared. Elucidating the neuroprotective molecular mechanisms of the N-Aβcore at the synaptic level will provide essential guidance for future use as a potential therapeutic.

Title: Altered temporal discounting, reduced motivation, and impaired executive functions in the TgF344AD rat model of Alzheimer’s Disease during young adulthood

Authors: C. M. HERNANDEZ, ***N. L. JACKSON**, *L. L. MCMAHON;
Cell, Developmental, & Integrative Biol., Univ. of Alabama at Birmingham, Birmingham, AL

Abstract: The relative weight that individuals give to rewards and "costs" (such as delay to reward delivery) in making decisions varies significantly across the population and disease states. One aspect of decision making involves weighing the relative benefits and costs associated with immediate versus delayed outcomes. This aspect of decision making is often referred to as temporal discounting (or intertemporal choice) and can be assessed on tasks in which subjects are required to choose between small, immediate rewards and larger rewards delivered after varying delays. Furthermore, intact executive functioning and motivation are foundational to the decision-making process. Recent literature shows there is a great deal of variability in the temporal discounting phenotype between individuals with mild cognitive impairment, frontal temporal dementia, and Alzheimer's Disease (AD), with some showing no differences relative to healthy controls and others showing altered rates of temporal discounting. Even beyond these disorders, individual differences in choice behavior (either maladaptive or normative) in young adults predict a variety of life outcomes, including educational success and socioeconomic status. The current study used a behavioral approach to determine the effect of genotype on phenotypic differences in temporal discounting, motivation, and executive function in the TgF344AD (TgAD) rat model of AD.
Young adult (6-7 mo) wild-type (WT; n=6) and TgAD (n=6) were trained on several operant tasks including temporal discounting (decision making), progressive ratio (motivation), set shifting (cognitive flexibility), and delayed response (working memory) tasks. Results suggest TgAD rats showed a greater preference for the large, delayed reward relative to WT, however, this preference did not translate to a greater number of total rewards earned. Additionally, TgAD rats were less motivated to obtain the larger reward, were less cognitively flexible, and showed impaired working memory relative to WT controls. Interestingly, young TgAD rats show a similar decision-making and cognitive phenotype as old rats and these data suggest AD pathology may manifest as maladaptive decision making in addition to impaired executive functions early in life.

Title: Lysosome-autophagosome defects mediate proteinopathy in Alzheimer's disease pathogenesis

Authors: *S. MUSTALY[1], A. GILMAN-SACHS[2], R. A. MARR[1], D. A. PETERSON[1], K. D. BEAMAN[2], G. E. STUTZMANN[1];

Abstract: Alzheimer's disease (AD) is a neurodegenerative disorder characterized by abnormal protein aggregates, intracellular Ca^{2+} dysregulation and memory loss. The catabolic degradation of misfolded protein aggregates, or autophagy, is primarily regulated by lysosomes which require an acidic intralysosomal pH, maintained by the H^{+}-ATPase (V-ATPase). In AD, V-ATPase defects can lead to abnormal β-amyloid and p-tau accumulation. A concurrent mechanism with V-ATPase deficits is intracellular Ca^{2+} dyshomeostasis, which disrupts ion exchange resulting in alkalinization of pH within lysosomes. We hypothesize that Ca^{2+} dyshomeostasis disrupts V-ATPase ion exchange and instigates AD pathology. Here, we performed immunoassays and live cell imaging in model cells, AD mouse models, and induced human neurons (iNs) derived from AD patients to explore this hypothesis. Immunohistochemistry in fixed hippocampal slices from 3-month old 3xTg-AD mice revealed diminished expression of V-ATPase subunits (V1B2, V0a1), lysosomes (Lamp1), and increased expression of mature autophagosomes (LC3B), and hyperphosphorylated tau (p-tau; S262) relative to non-transgenic (NTg) controls. These phenotypes in 3xTg-AD mice were restored to NTg levels by normalizing calcium homeostasis via 30-day treatment with the RyR modulator, Ryanodex (10mg/kg). Similarly, autophagosomes accumulated in iNs derived from AD patients were restored to control levels with Ryanodex treatment. The decreased V-ATPase expression and increased autophagosomes reflect impaired lysosomal function, which is mediated through upstream RyR-Ca^{2+} dyshomeostasis. When measuring lysosomal pH (Lysosensor Y/B Dextran) on iNs and RyR-overexpressing HEK293 cells, it revealed lysosomal alkalization upon RyR stimulation (caffeine 10mM). Ryanodex pre-treatment attenuated this alkalization, suggesting that RyR-Ca^{2+} signaling regulates lysosomal pH and disrupts autophagosome-lysosome mediated protein degradation. Protein aggregates, such as β-amyloid and hyperphosphorylated tau, were increased in iNs with V-ATPase inhibition (bafilomycin 125 nM), which was resolved with Ryanodex treatment. Prior to overt histopathology or cognitive deficits, abnormal RyR-mediated Ca^{2+} release disrupts lysosomal function leading to altered autophagic-mediated protein clearance that contributes to AD proteinopathy.

Title: Functional analysis of GWAS candidate gene, SCYL3, and its role in TDP-43 function and regulation

Authors: *M. NGO[1], J. C. MAUNA[2], J. K. KOFLER[3], C. J. DONNELLY[2];
[1]Human Genet., [2]Neurobio., Univ. of Pittsburgh, Pittsburgh, PA; [3]Dept. of Pathology, Univ. Pittsburgh, Pittsburgh, PA

Abstract: TDP-43 (transactive response DNA-binding protein of 43 kDa) is a DNA/RNA binding protein involved in RNA alternative splicing, metabolism, and trafficking. TDP-43 is mislocalized from the nucleus to the cytoplasm where it forms pathological insoluble inclusions formed through aberrant liquid-liquid phase separation (LLPS) in a number of neurodegenerative diseases including Alzheimer's Disease (AD), Amyotrophic Lateral Sclerosis (ALS), and Frontotemporal Lobar Degeneration (FTLD-TDP). A recent genome-wide association study (GWAS) investigating a cohort ranging from moderate to severe AD cases identified several candidate markers associated with increased severity in TDP-43 pathology. SCY1 Like Pseudokinase 3 (SCYL3) encodes a protein with a kinase domain and four HEAT repeats, was implicated as a high potential gene candidate. SCYL proteins are thought to regulate cellular processes such as intracellular trafficking and cell migration; however, the role of SCYL3 in neurodegenerative diseases and TDP-43 pathology remains unclear. To investigate how SCYL3 might contribute to TDP-43 pathology, we performed functional studies in HEK293 cells and iPSC-derived neurons to characterize SCYL3's role in TDP-43 regulation and function. We also examined how SCYL3 affects intracellular aberrant LLPS using a novel optoTDP stable cell line. Our results suggest that SCYL3 may modify TDP-43 cytoplasmic inclusions and is a risk factor for TDP-43 pathology. Taken together, this work integrates data from a GWAS study and functional cell biology analysis to validate a potential gene candidate.

Title: Molecular and cellular pathobiology underlying ALS/FTD causing TDP-43 G295R mutation

Authors: *J. C. MAUNA[1,2], A. M. GLEIXNER[1,2], H. L. CRABLE[1,2], O. R. SHAPIRO[1,2], D. LACOMIS[3,2,4], C. J. DONNELLY[1,2];

Abstract: Amyotrophic Lateral Sclerosis (ALS) and Frontotemporal lobar Degeneration (FTLD) are highly related fatal neurological disorders that manifest by the progressive degeneration of neurons in the motor cortex and spinal cord or frontal and temporal lobes, respectively. TAR DNA-binding protein 43 (TDP-43) is a predominantly nuclear protein involved in splicing and RNA processing that forms cytoplasmic and insoluble inclusions in ~97% of all ALS cases and ~50% of frontotemporal lobar degeneration (FTLD) cases. The study of TDP-43 pathobiology in endogenous model systems remains challenging and, to date, most induced pluripotential stem cell-derived (iPSC) neurons from ALS/FTD patients do not recapitulate significant TDP-43 pathobiology. In this study, we generated iPSC neurons derived from fibroblasts of siblings harboring a c.883GtoC heterozygous missense mutation variant in the TARDBP gene, which results in a TDP-43 p.Gly295Arg substitution. Despite being carriers of the same TDP-43 G295R missense mutation, each sibling presented with different ALS phenotypes: one had spinal onset without ever exhibiting cognitive dysfunction and the other presented with cognitive and behavioral symptoms of FTLD. Notably, TDP-43 G295R iPSC neurons exhibited abnormal TDP-43 staining showing changes in nuclear, cytosolic, and axonal TDP-43 compared to healthy controls suggestive of dysfunctional TDP-43. In this study, we characterize TDP-43 in TDP-43 G295R iPSC neuron lines and examine how this mutation alters TDP-43 function. Specifically, we examined the effect of this mutation on TDP-43 localization/trafficking and autoregulation. Stress granules (SGs) are dynamic membraneless organelles that recruit TDP-43 and other RNA binding proteins and are formed through liquid-liquid phase separation (LLPS). These structures form during periods of cell stress and function to inhibit non-essential protein synthesis until the stress is resolved. Recent work from us and others indicate that pathological TDP-43 liquid-to-solid transitions are driven through aberrant LLPS, thus impaired stress granule dynamics may act as a driver of TDP-43 deposition. Thus, we tested how endogenous TDP-43 G295R affects SG dynamics and whether these are sufficient to induce endogenous TDP-43 inclusions. Taken

together, these data provide insight into the consequence of ALS/FTD causing TDP-43 G295R mutations and highlight a novel iPSC model system of endogenous TDP-43 dysfunction.

Title: The study of Circular RNAs and their regulation of TAR DNA binding protein 43 (TDP-43) pathological aggregation

Authors: *J. XU[1,2,3], W. M. TENNANT[1,2,3], J. K. KOFLER[1], C. J. DONNELLY[2];
[1]Dept. of Pathology, Univ. Pittsburgh, Pittsburgh, PA; [2]Dept. of Neurobio., [3]Live Like Lou Ctr. for ALS Res., Univ. of Pittsburgh, Pittsburgh, PA

Abstract: TAR DNA binding protein 43 (TDP-43) is a nuclear RNA binding protein (RBP) that is found mislocalized to the cytoplasm and forms insoluble inclusions in the CNS of Amyotrophic Lateral Sclerosis (ALS) patients. Functional TDP-43 exists as a soluble protein that condenses to form dynamic liquid-like droplets and localizes to membraneless organelles through liquid-liquid phase separation (LLPS) under physiological conditions. However, recent work indicates that abnormal LLPS, hypothesized to be driven by genetic or environmental factors, initiates the deposition of pathological TDP-43 aggregates observed in neurodegenerative disorders. Work from our lab and others indicates that TDP-43's RNA binding status contributes to the ability of purified and cellular TDP-43 protein to undergo aberrant LLPS and RNA engagement to TDP-43 prevents its pathological condensation. Circular RNAs (circRNAs) are covalently closed circular RNA previously thought of splicing by-products of longer mRNAs transcripts. Recent evidence indicates circRNAs are highly enriched in brain and play a role in neurodegenerative diseases like Alzheimer′s disease (AD), Parkinson's disease (PD) and ALS. While the specific role of circRNAs in neurodegenerative disease pathogenesis remains unknown, a possible explanation is that circRNAs bind to RBPs (i.e. TDP-43) as cytoplasmic molecular sponges to prevent their aberrant LLPS and pathological aggregation. Thus, we hypothesize that circRNA binding to TDP-43 contributes to the maintenance of normal LLPS and prevents the transition to of insoluble and pathological TDP-43 depositions observed in disease. To test this, we first performed in depth RNA sequencing

analyses for circRNAs in postmortem brain samples of neurodegenerative disease patients with and without TDP-43 pathology to identify differentially regulated circRNA species in regions of degeneration. We also performed functional cellular assays using circRNA-expression system to determine how specific RNA species affect the material properties and function of TDP-43. This includes the optoTDP43 cell model that allow for the induction of aberrant LLPS and TDP-43 deposition upon blue light stimulation. This work provides foundational understanding of circRNA:RBPs regulation, which could provide new insight into neurodegenerative disease pathogenesis.

Abstract: Amyotrophic lateral sclerosis (ALS) and Frontotemporal Lobar Degeneration (FTLD) share clinical, neuropathological, and genetic features. A G4C2 repeat expansion mutation in the *C9orf72* gene (C9-ALS/FTLD) is one genetic cause of disease onset. Furthermore, these diseases exhibit cytoplasmic and insoluble protein depositions of the TDP-43 occur in areas of neurodegeneration. Proposed mechanisms of toxicity in C9-ALS/FTLD are the production of

repeat expansion transcripts and their dipeptide repeat proteins (DPRs) products which are hypothesized to drive nucleocytoplasmic transport defects. Nucleocytoplasmic trafficking is facilitated, in part, by the nuclear pore complex (NPC) that contains a selectivity and permeability barrier comprised of phenylalanine glycine nucleoporins (FG nups). However, the relationship between FG nups and TDP-43 pathology remains elusive. Here, we show Nup62 nuclear depletion and cytoplasmic localization in C9-ALS/FTLD and sALS/FTLD and this effect is promoted through interactions with TDP-43. In C9-ALS/FTLD, poly-GR initiates the formation of TDP-43 containing stress granules (SGs) aligning with the nuclear loss and recruitment of Nup62 *in vitro* and *in vivo*. Absent of poly-GR, we find aberrant TDP-43 to sequester Nup62 into pathological inclusions both in cellular systems and postmortem tissue. These changes in nucleoporin localization also show broad implications on a variety of neuronal functions.

Title: Sequence determinants of TDP-43 partitioning into neuronal RNP granules: Effects of ALS linked TDP-43 mutations on neuronal RNP granule properties, function and pathology.

Authors: *S. S. VISHAL, P. P. GOPAL;
Pathology, Yale Sch. of Med., New Haven, CT

Abstract: Amyotrophic lateral sclerosis (ALS) is a disease of motor neuron degeneration with pathologic inclusions composed of TDP-43, an RNA/DNA-binding protein of 43 kDa. Moreover, mutations in *TARDBP*, the gene that encodes TDP-43, have been linked to both familial and sporadic ALS. TDP-43 regulates critical cellular functions like transcription, RNA splicing, mRNA translation and transport. We and others have shown that TDP-43 undergoes liquid-liquid phase separation and that neuronal TDP-43 ribonucleoprotein (RNP) granules display dynamic liquid-like biophysical properties. TDP-43 contains two RNA recognition motifs (RRM1 and RRM2) flanked by N-terminal domain containing NLS and a C-terminal domain with G/Q/N-rich low complexity domain (LCD). LCD is necessary for interaction with

different proteins and contains an alpha-helical region important for liquid-liquid phase separation. Although most of the ALS-linked mutations in *TARDBP* occur within the LCD of TDP-43, these mutants were reported to have different effects on phase separation in vitro and show distinct biochemical properties, i.e. increased protein half-life vs increased propensity for aggregation vs increased cytoplasmic localization. We asked whether different TDP-43 ALS-linked mutations, LCD mutations and NLS mutation, affect the biophysical properties, axonal transport and recruitment into neuronal RNP granules differently. To test this, we expressed eGFP tagged wild type (WT) TDP-43 or eGFP tagged TDP-43 mutants in rat primary cortical neurons and used live cell confocal microscopy to study TDP-43 WT and mutant RNP granule properties. Kymographs and a custom automated tracking software that measures the anterograde and retrograde flux, velocity, displacement, and run length etc. of each track were used to analyze the motility of RNP granules containing WT or mutant TDP-43. Our results suggest that all the ALS-linked TDP-43 mutations used in this study severely impaired motility of RNP granules. Interestingly, ALS-linked TDP-43 mutations adjacent to the alpha-helical region show substantial impact on long-range transport of TDP-43 RNP granules, reduce anterograde flux and may inhibit partitioning into neuronal RNP granules. Additional preliminary findings suggest that residues within the NLS may be important for intracellular phase separation into neuronal RNP granules. We will now use these ALS-linked TDP-43 mutations and additional LCD mutations (aromatics, alpha helical domain) to determine the contributions of specific residues to intracellular phase separation of TDP-43, how these defects affect critical functions of TDP-43 and promote ALS disease progression.

Abstract: The 'GGGGCC' repeat expansion in *C9orf72* is the most frequent genetic cause of ALS. Three disease-causing mechanisms have been proposed, including a loss-of-function of C9orf72 and two gain-of-functions resulting from either sequestration of essential repeat RNA-binding proteins (RNA toxicity) or from the formation of toxic dipeptide repeat proteins (DPR toxicity). In this study, a C9orf72 ALS zebrafish model was used to identify and investigate modifiers of RNA toxicity. This unique *in vivo C9orf72* RNA toxicity model is characterized by ALS-related motor neuron deficits, including shortened axonal length and aberrant branching in 30 hours post fertilization (hpf) zebrafish embryos. In our modifier screen, mRNA encoding candidate RNA-binding proteins was co-injected with RNA containing 90 repeats of 'GGGGCC' in 1- to 2-cell stage zebrafish oocytes. One of these RNA-binding proteins, hnRNPK, was able to successfully rescue the *C9orf72* repeat RNA-induced axonal phenotype in zebrafish embryos. Functional analysis of the RNA-binding protein hnRNPK uncovered two types of structural domains being essential for modifying RNA toxicity: the nuclear localization signals and RNA-binding domains. These findings suggest that both subcellular localization and RNA recognition play a role in the observed effect. Combined with a distinct cytoplasmic mislocalization of hnRNPK in C9orf72 ALS patient fibroblasts, iPSC-derived motor neurons and post-mortem central cortex, our data hint towards a disrupted hnRNPK function in C9orf72 ALS. Interestingly, using zebrafish bulk RNAseq analysis and CLIPseq datasets we discovered a DNA damage response-related transcriptional target of hnRNPK being involved in the C9orf72 RNA toxicity mechanism. Dysregulation of this downstream effector was also observed in C9orf72 ALS patient post-mortem central cortex. Moreover, siRNA-mediated knockdown of hnRNPK in HeLa cells, confirmed the link between hnRNPK and its target, revealing DNA damage as a novel lead in the understanding of C9orf72 ALS.

Title: Poly(adp-ribose) promotes the condensation of c9orf72 arginine-rich dipeptide repeat proteins

Authors: J. GAO, R. PUNATHIL, T. GENDRON, ***K. ZHANG**;
Mayo Clinic, Florida, Jacksonville, FL

Abstract: Arginine-rich dipeptide repeat proteins (R-DPRs) is critical to the pathogenesis of *C9ORF72*-mediated amyotrophic lateral sclerosis (ALS) and frontotemporal dementia (FTD), the most common familial ALS and FTD (c9ALS/FTD). As a pathological hallmark of c9ALS/FTD, R-DPRs aggregate, and sometimes co-aggregate with their interacting proteins, in patient postmortem tissues and animal models. However, what promotes R-DPR aggregation or co-aggregation with other proteins is unclear. Here, we show that poly(ADP-ribose) (PAR) interacts with R-DPRs, promoting their condensation and co-condensation or co-aggregation with their interacting proteins. Loss of PAR polymerase 1 (PARP1) function suppresses PAR levels, R-DPR aggregation, and neurodegeneration in cellular or animal models of c9ALS/FTD. Furthermore, PAR levels are increased in c9ALS/FTD patient postmortem brains. Our findings identified PAR as a contributor to R-DPR toxicity in c9ALS/FTD pathogenesis, suggesting it as a potential therapeutic target and biomarker.

Title: C9orf72 associated Dipeptide Oligomers in ALS and FTD

Authors: *N. BHATT, N. PUANGMALAI, M. MONTALBANO, U. SENGUPTA, C. JEREZ, M. KIDD, R. KAYED;
Neurol., Univ. of Texas Med. Br., Galveston, TX

Abstract: The hexanucleotide repeat expansion in *C9orf72* is one of the most common causes of amyotrophic lateral sclerosis (ALS) and frontotemporal dementia (FTD). The hexanucleotide expansion is a structural polymorphism formed by a GGGGCC repeat region that impedes traditional transcription, and leads to several error-prone transcripts. These transcripts can undergo non-AUG dependent translations, producing several dipeptide repeat-containing proteins (DPRs) including GP, GA, GR, PA and PR. The DPRs form toxic neuronal inclusions in patients with ALS and FTD as suggested by several studies. Some dipeptide repeats such as GA, aggregate as well as sequester other cellular proteins. Given increasing evidence that soluble

species, like oligomers, are the main cause of neurotoxicity in neurodegenerative conditions such as Alzheimer's and Parkinson's disease, we investigated the ability of DPRs to aggregate and form toxic oligomers. Here, we have taken a reductionist approach by synthesizing short dipeptides repeats (GA, PR, and GR) of varying lengths and used biophysical as well as biochemical assays to characterize the aggregates *in vitro*. The results suggest the propensity for DPR, specially GR and PR to form oligomeric structures which can cause toxicity. We also tested the toxicity of the varying DPR aggregates alone and in the presence with tau protein *in vivo*. Moreover, we investigated the presence of DPR oligomers in ALS and FTD human samples and their potential role in disease pathogenesis. Thus, the ability to detect and characterize oligomeric DPR has great potential to further the understanding of these diseases and aid in the development of targeted therapeutics.

Title: The role of miRNAs on TDP-43 proteopathic seeding

Authors: *J. ZHU[1], S. CHEN[2], M. JACKREL[2], C. WEIHL[1];
[1]Neurol., [2]Chem., Washington Univ., St. Louis, MO

Abstract: TDP-43 is a key component of protein inclusions in 90% of ALS and 50% of FTD patients. In addition, more than 45 different TDP-43 mutations have been identified, accounting for 5-10% of fALS. Similar to other genetic causes of ALS-FTD, TDP-43 belongs to the hnRNP family and functions in RNA metabolism. TDP-43 contains a highly disordered prion-like domain. Recent studies support that TDP-43 can seed and propagate *in vitro* and *in vivo*. We developed a TDP-43 seeding assay using hippocampal neurons, which phenocopied pathologic TDP-43 inclusions. Using this assay, we performed miRNA microarray on TDP-43 seeded vs monomer treated neurons, and identified 8 miRNAs that were significantly changed in TDP-43 seeded neurons but not in controls. Our subsequent studies focused on miR-34a, miR-127, and miR-381, which are conserved across species. Notably, TDP-43 seeding activities were suppressed with overexpression of these miRNAs. Our study supports an effect of selected miRNAs on TDP-43 seeding and enlightens potential targets for ALS-FTD therapy.

Title: Exploring the sex differences in neuropathic pain relief from a macrophage targeted COX-2 inhibiting nanotherapeutic

Authors: *B. S. DEAL[1,3], L. M. REYNOLDS[4,1,3], J. M. JANJIC[2,3], J. A. POLLOCK[1,3]; [1]Biol., [2]Pharm., Duquesne Univ., Pittsburgh, PA; [3]Chronic Pain Res. Consortium, Pittsburgh, PA; [4]Jefferson Univ., Philadelphia, PA

Abstract: Chronic pain effects almost a quarter of the population, but only 5% of those suffering from chronic pain have reported complete relief and satisfaction from their treatment. Because males have historically been the only sex used in pre-clinical research, the parallels in the development of a neuroinflammatory response and formation of pain in females is less understood. Currently, the macrophage is known to be a principal influencer in the development of neuroinflammatory pain. Macrophages give rise to neuroinflammatory pain via the activation of their cyclooxygenase 2 (COX2) enzyme which leads to the production of prostaglandin E_2 (PGE_2) influencing leukocyte infiltration. Our previous work with males has shown that rats experiencing mechanical allodynia caused by chronic constriction injury (CCI) of the sciatic nerve can achieve multi-day pain relief (equal to baseline) from a single injection of a novel nanotherapeutic containing celecoxib (0.24 mg/kg). The nanotherapeutic works by exploiting the natural neuroinflammatory role of macrophages. Once injected into the blood stream, monocytes phagocytose the nanotherapeutic and then accumulate at the site of injury where PGE_2 production is attenuated. This, in turn, results in a reduction of the number of infiltrating macrophages. Our current study shows that although males and females display quantitatively the same degree of mechanical allodynia post CCI, their responses significantly differ when treated with the same dose of celecoxib-loaded nanotherapeutic. Females exhibit an attenuated level of pain relief when compared to males. Females treated with the celecoxib nanotherapeutic

have a significant reduction in the number of infiltrating macrophages, but still have significantly more than the celecoxib treated males.

Title: Sex distinctions in the impact of microglia on preformed fibril-induced α-synucleinopathy

Authors: *T. N. BHATIA[1], R. N. CLARK[1], K. M. MINER[1], E. A. ECKHOFF[1], M. N. CHANDWANI[1], N. ABRAHAM[1], A. S. JAMENIS[1], X. HU[2], L. A. O'DONNELL[1], J. CHEN[2], K. C. LUK[3], R. K. LEAK[1];
[1]Div. of Pharmaceut. Sci., Duquesne Univ., Pittsburgh, PA; [2]Dept. of Neurol., Univ. of Pittsburgh, Pittsburgh, PA; [3]Dept. of Pathology and Lab. Med., Univ. of Pennsylvania, Philadelphia, PA

Abstract: It is well established that the substantia nigra displays microglial activation in Parkinson's disease subjects of both sexes. However, in the olfactory bulb (OB), Parkinson's-induced microgliosis is observed in male but not female subjects (Flores-Cuadrado *et al* 2021). In the postmortem OB of patients with dementia with Lewy bodies (DLB), we observed higher expression of microglial activation marker Iba1 in male (but not female) subjects compared to unaffected controls. However, the functional impact of these sex differences remains unknown. Here, we tested the impact of sex-stratified primary hippocampal microglia on α-synucleinopathy in sex-matched primary hippocampal neurons. Microglia from male rat pups (as determined by the *Sry* gene) reduced the numbers of α-synuclein^{+} inclusions, average sizes of

inclusions, and the total area occupied by inclusions in cocultured male neurons. Female microglia did not affect the numbers of inclusions or the total area occupied by the inclusions, and, unexpectedly, increased average inclusion sizes in cocultured female neurons. Preliminary data showed no robust sex differences in primary microglial uptake of $ATTO_{647}$-conjugated α-synuclein fibrils after 0, 6, 16, 24, 72, and 96 h. These observations suggest that male microglia mitigate inclusion formation better than female microglia and that these sex-dependent effects are not attributable to fibril uptake per se. Next, we hypothesized that *in vivo* microglial depletion for 2 weeks followed by repopulation for 6 weeks may affect deficits associated with α-synuclein fibril infusions. Eighteen month-old male and female mice were fed control chow or chow supplemented with 1200 mg/kg of PLX5622 – an inhibitor of the colony stimulating factor 1 receptor (CSF1R) known to deplete microglia. After 7d on this diet, we injected preformed fibrils into the rear of the mouse OB, as a preclinical model of limbic-centered α-synucleinopathy (Mason *et al.* 2016, 2019). We performed the open field test to assess hyperactive, exploratory, and anxiety-like behaviors 14d after microglial depletion (immediately prior to repopulation). Microglial depletion increased hyperactivity (*i.e.,* distance traveled and speed) in mice of both sexes. Microglia-depleted females showed an increase in the number of central square entries and the time spent within central squares. In contrast, male mice preferred the corner squares after microglial depletion. These data may reflect baseline sex differences in the impact of microglial depletion. Ongoing studies are testing the impact of microglial repopulation on pathology and neurological deficits in this animal model.

Title: Impact of sex and age on cognitive deficits and inflammatory profile following a lipopolysaccharide induced immune challenge.

Authors: *J. DARLING, A. PRABHAKAR, S. GRANT, R. ANIRUDHAN, C. MANNERS, L. FONKEN;
Univ. of Texas at Austin, Austin, TX

Abstract: Aging is a major risk factor for cognitive decline. Neuroinflammation, which can contribute to cognitive decline, is modulated in aged individuals. Biological sex regulates the onset and severity of various neurodegenerative diseases that involve neuroinflammation including Parkinson's disease, Alzheimer's disease, and multiple sclerosis. Here we determined the impact of aging and sex on cognitive function and inflammatory profile in rats following a lipopolysaccharide (LPS) immune challenge. Young adult (3 month) and aged (24 month) male and female F344xBN rats received an intraperitoneal injection of 40μg of LPS or vehicle (saline) and then were trained and tested in a contextual fear conditioning paradigm. Briefly, 48h following LPS exposure, rats were placed into a novel chamber and received a 2 sec, 1.5mA shock through a floor grid. 48 hours later, rats were returned to the chamber and contextual fear memory (presented as time spent freezing) was measured. LPS exposure led to a reduction in freezing in aged male rats as compared to young LPS males and age matched saline controls, indicating an immune challenge induced sustained impairment in contextual memory. In contrast, no significant change in freezing behavior occurred in aged females relative to age matched saline controls nor young adults. Differences in cognitive function may relate to neuroinflammatory changes induced by microglia: microglia isolated from the hippocampus of aged male but not female rats exhibit exaggerated pro-inflammatory cytokine responses to ex vivo LPS challenge. Moreover, aged male but not female rats exhibit potentiated hippocampal IL-1β mRNA and protein 6, 24, and 48h following LPS exposure. These results suggest aged male rats are at higher risk for cognitive dysfunction following neuroimmune challenge versus females. This work highlights the importance of inclusion of sex as a variable when investigating age-related disorders. Ongoing investigation will further determine the mediating mechanisms underlying this age-related sex difference in behavior.

Title: Sex differences in the protective mechanism of action of caffeine on microglia in a rodent model of preterm hypoxic ischemic injury

Authors: *R. M. MCLEOD[1], R. KOSKI[2], T. ROSENKRANTZ[3], R. H. FITCH[1];
[1]Univ. of Conneticut, Storrs, CT; [2]Univ. of Minnesota Med. Shcool, Minneapolis, MN;
[3]Univerity of Connecticut Hlth., Farmington, CT

Abstract: Currently 11% of infants are born prematurely, and a substantial portion experience hypoxic ischemic (HI) injury (i.e., transient or chronic reduction in blood and/or oxygen supply to the brain). Such events can lead to deficits in motor and cognitive ability. Though no neuroprotective treatments are approved for preterms, caffeine is routinely used to treat apnea of prematurity. This drug has also shown benefits to cognitive outcomes in premature infants, as supported by animal studies. Despite accumulating evidence of neuroprotective benefits, it is unclear *how* caffeine exerts protective effects in the preterm brain. Caffeine is a known adenosine antagonist, but it is unknown if adenosine acts directly on neurons (e.g., to prevent apoptosis), as an indirect anti-inflammatory, or on other targets like microglia. It is also unclear whether A1 and/or A2A receptors (expressed in neurons/microglia) modulate effects. Further, little is known about variables that may *modulate* caffeine action (e.g., sex, gestational age, or comorbid infection/inflammation). For example, evidence shows that female preemies have better outcomes than males, and also that hypothermia is more effective for neonatal females with HI, based on animal research (Wood et al., 2020). Thus sex might also modulate protection from caffeine. The current study investigated the role of microglia in caffeine-mediated neuroprotection in both neonatal male and female rats with HI, following a model of a 32-week gestational age HI injury (Rice-Vannucci method). Male and female rats with HI or sham surgery were further treated with caffeine or saline. All subjects were perfused 48 hours post injury. Brains were sectioned and stained for chromatin condensation, an indicator of cell death, using 4',6-diamidino-2-phenylindole (DAPI), as well as for microglia using ionized calcium binding adaptor molecule 1 antibody (IBA-1, which binds specifically to microglia). Results demonstrated increased chromatin condensation in both HI-saline and HI-caffeine rats relative to shams, as well as reduced cell death in caffeine-treated HI vs HI-saline subjects. However, females did ***not*** show reduced microglia activation (increased microglial soma size), which was seen in caffeine-treated HI males. This disparity points to differences in the neuroprotective mechanisms of caffeine, which may be of clinical significance. Work was supported by CCMC Fellows Fund.

Title: Sex-specific gene expression profiles of neonatal rabbit brain diminish with inflammation and dendrimer-N-acetylcysteine therapy in a cerebral palsy model

Authors: *A. FOWLER[1], N. SAH[1], A. CHIME[1], E. SMITH KHOURY[1], A. SHARMA[2], R. KANNAN[2], S. KANNAN[1];
[1]Anesthesiol. and Critical Care Med., [2]Ctr. for Nanomedicine, Dept. of Ophthalmology, Wilmer Eye Inst., Johns Hopkins Univ. Sch. of Med., Baltimore, MD

Abstract: Sex plays an important role in the occurrence and severity of cerebral palsy (CP). According to epidemiologic data, incidence of CP in males is 30% higher compared to females. To understand the mechanisms behind conspicuous sex-specific susceptibility to CP, we studied the gene expression profile of male and female neonatal rabbit brain in a model of maternal-inflammation induced cerebral palsy. Furthermore, we compared the gender-specific therapeutic effects of dendrimer-N-acetylcysteine (DNAC), a potent antioxidant and anti-inflammatory drug, at the transcriptional level. Significant differences are observed in the transcriptome of healthy male and female brains, possibly originating from neuron and glia exposed to the perinatal surge of sex steroids. Endotoxin-exposed kits showed similar sexually dimorphic gene expression pattern, however, differences decreased between the male and female compared to healthy control. Surprisingly, DNAC administration changed the transcriptome profile of brain cells in both male and female CP kits such that sexual dimorphism is abolished to a large extent. Since DNAC uptake is primarily in glial cells in the brain, it's intriguing to speculate that glial cells and its oxidative state might shape sexual dimorphism. Overall, our study provides a basis for sexual bias in cerebral palsy susceptibility and therapeutic outcomes, that might necessitate gender-specific treatment paradigms.

Title: Dysfunction of the descending pain-modulation system is involved in the augmented pain response after traumatic brain injury

Authors: *Q. CHEN, J. CLARK;
Dept. of Anesthesiology, Pain and Perioperative Med., Stanford Univ., Stanford, CA

Abstract: Individuals with histories of traumatic brain injury (TBI) commonly exhibit prolonged recovery after peripheral injuries and experience chronic pain. Recent laboratory and clinical data suggest dysregulated central pain-modulating circuits could be involved. We hypothesized that TBI exacerbates pain in response to a subsequent soft tissue injury by virtue dysfunctional descending pain-modulation. In a mouse model of mild TBI, we observed prolonged allodynia in the bilateral hindpaws of animals with TBI lasting up to 10 days. When hindpaw incisions were made in control and TBI mice after recovery of normal pain thresholds, mechanical thresholds in control mice returned to baseline after 7 days, while those animals with prior TBI experienced prolonged sensitization lasting up to 38 days. Furthermore, blockade of central but not peripheral mu opioid receptors (MORs) led to mechanical sensitization in both hindpaws in animals recovered from TBI. Control animals and those with incision alone did not experience changes in their pain thresholds after MOR blockade. Increased neuronal activation, marked by c-Fos staining, was observed in brain regions important for descending pain-modulation, such as rostral ventrolateral medulla, in animals recovered from TBI after MOR blockade. Collectively, these data suggest that dysfunctional descending pain-modulation is responsible for the slow resolution of pain after peripheral injury in the setting of TBI. The endogenous opioid system is important for the subsequent recovery of pain sensitivity after TBI but not after peripheral injury alone. Identifying ways to enhance endogenous pain control mechanisms may help those with pain after TBI.

Title: Closed-head injury increased avoidance in rats

Authors: *O. MARTÍNEZ GUZMAN, M. CACERES-CHACON, M. RIVERA-LÓPEZ, H. HADDOCK-MARTINEZ, D. SIERRA-MERCADO;
Anat. and Neurobio., Univ. of Puerto Rico Sch. of Med., San Juan, PR

Abstract: Closed-head injury increased avoidance in rats
Osmarie Martínez-Guzmán[1], Mauricio Cáceres-Chacón[1], Melissa Rivera-López[1], Héctor Haddock-Martínez[2], and Demetrio Sierra-Mercado[11]Department of Anatomy & Neurobiology, University of Puerto Rico (UPR) School of Medicine; [2]UPR Piedras
The most common form of brain injury, concussion, is frequently seen in contact sports and military combat. Converging lines of evidence suggest that concussion may impair fear-related behaviors. One type of fear-related behavior, avoidance, occurs when the need to escape from difficult situations such as an aversive stimulus (i.e. footshock) is presented in the presence of a reward (i.e. sucrose pellets). The effects of concussion on avoidance remains unknowns. Concussion can be modeled in rodents with a closed head injury (CHI). Here, a guide tube is placed above the head of anesthetized rats, and a weight is dropped through the tube. In the current study, we hypothesize that CHI will impair avoidance. One hour after CHI or Sham injury, locomotion behaviors were assessed in an open field to test for motion deficits, and CHI did not affect the distance travelled. In the platform-mediated avoidance, rats were conditioned in an operant chamber to auditory tones co-terminating with a mild footshock. An acrylic platform in the opposite corner of the sucrose-delivering bar allowed rats to avoid the shocks. Animals that underwent a CHI spent more time on the platform throughout the test session during the absence of the tone, even though they learn previously that the absence of tone was a safe period. These suggesting that brain injury results in excess avoidance ($p=0.0127$). The translational relevance of this work suggests that brain injury may contribute to mental health disorders, since excess avoidance is characteristic of patients with fear and anxiety disorders.

Title: Effects of photobiomodulation light therapy (PBM) on traumatic brain injury-induced opioid seeking

Authors: *N. ALESAWY[1], S. LLOYD[3], J. MALEWICZ[2], K. E. BOSSE[3], A. C. CONTI[4]; [1]Neurosci., [2]Wayne State Univ., Detroit, MI; [4]Translational Neurosci. Program, [3]Wayne State Univ. Sch. of Med., Detroit, MI

Abstract: While traumatic brain injury (TBI) has extensively been identified as a risk factor for development of substance use disorder related to nicotine, alcohol and cocaine, comparably less has been established for its relationship with opioids. However, understanding this association is imperative since over 70% of TBI patients suffer ongoing pain and are five times more likely to be prescribed opioids for pain management, which could lead to increased addiction liability in those with TBI, potentially through mechanisms involving oxidative stress and neuroinflammation, which are key pathological consequences of both TBI and opioid action. Photobiomodulation (PBM) is a potent, noninvasive light therapy useful in treating pain, inflammation and wound healing with known effects to mitigate oxidative and inflammatory signaling, making it safer therapeutic option. We hypothesized that TBI-induced opioid seeking behavior would be diminished by PBM through its anti-inflammatory and oxidative stress reduction mechanisms. Male, 10-12 week-old C57BI/6 mice were randomly assigned to receive a midline, closed-skull impact injury or sham surgery (n=6/condition). At 30 days post-TBI, voluntary consumption was measured in a two-bottle choice, 24-hour free access model with initial access (four daily sessions) to morphine (0.1 mg/ml in 0.2% sucrose) opposed to a quinine (0.02 mg/ml in 0.2% sucrose) solution, during which average morphine consumption was comparable across injury groups (sham: 16.4 ± 2.1 mg/kg; TBI: 15.4 ± 1.8 mg/kg). When quinine was substituted for the vehicle sucrose solution, morphine drinking over four daily sessions remained unchanged in TBI mice (14.5 ± 1.6 mg/kg), but markedly diminished in sham subjects (6.9 ± 1.8 mg/kg). A single session of PBM exposure (Quantum Devices, 670 nm LED; 50 mW/cm2; 90 sec) significantly attenuated the potentiated morphine intake in the TBI mice. Subsequent PBM exposure, repeated daily, reduced morphine consumption in TBI mice, while intake by sham controls was unaffected. Together, these data suggest that PBM is effective in reducing post-TBI induced opioid seeking behavior and may represent an effective treatment for opioid misuse after TBI in the clinical population. Program in Neurosci., [4]Dept. of Psychiatry and Behavioral Sci., [5]Dept. of Med., [6]Dept. of Pharmacol., Univ. of Washington, Seattle, WA

Abstract: Mild traumatic brain injury (mTBI), called the "signature injury" of Veterans of the wars in Iraq and Afghanistan, is highly comorbid with post-traumatic stress disorder (PTSD), depression, and chronic pain. Repetitive blast exposure is a common cause of these mTBIs with over 400,000 affected Veterans, yet effective treatment options are limited. Repetitive blast mTBI is often associated with aversion/dysphoria (a profound state of unease or dissatisfaction) mediated largely through activation of the endogenous dynorphin/kappa opioid receptor (KOR) system. Critically, trauma-induced KOR activation can exacerbate affective disorders and increase the risk for substance use disorder. However, little is known about the role KOR signaling plays in these behavioral symptoms of Veterans with a history of blast trauma nor in

animal models of blast. We and others have reported that mice exposed to repetitive blast exposure develop PTSD-like behaviors that include chronic aversion/dysphoria to previous blast-paired cues. Here, we hypothesized that the dynorphin/KOR system mediates blast-induced aversion/dysphoria. We evaluated this by pharmacologically antagonized KOR activation to block adverse blast-induced behavioral outcomes. We used a well-established pneumatic shock tube that models battlefield-relevant open-field blast forces generated by detonation of high explosives. Male mice were pretreated with vehicle (saline) or the selective KOR antagonist norbinaltorphimine (norBNI) prior to repetitive (3x) sham (anesthesia only) or blast exposure followed by behavioral testing at the one-month timepoint. KOR antagonism did not block blast-induced increase in loss of righting reflex or acute weight loss. Conversely, KOR antagonist pretreatment prevented blast-induced conditioned aversion, hyperarousal, social deficit, and anxiety/risk-taking/disinhibition but not sensorimotor deficits when tested one-month post sham/blast exposure. Our results show that KOR antagonist norBNI inhibited blast-induced affective, but not sensorimotor deficits in blast exposed mice. Together, these data suggest a new potential treatment strategy targeting the KOR system to prevent some chronic neuropsychological symptoms experienced by individuals with blast-related mTBI.

Title: Sex-dependent differences in hippocampal expression of Cytochrome P450 1B1 in penetrating traumatic brain injury.

Authors: *E. LIDIN[1], M. K. SKOLD[1,2], M. ANGÉRIA[1], J. DAVIDSSON[3], M. RISLING[1]; [1]Dept. of Neurosci., Karolinska Institutet, Stockholm, Sweden; [2]Dept. of Neuroscience, Section of Neurosurg., Uppsala Univ., Uppsala, Sweden; [3]Div. of Vehicle Safety, Dept. of Mechanical and Maritime Sci., Gothenburg, Sweden

Abstract: Abstract Hippocampal dysfunction contributes to multiple traumatic brain injury sequala. Female rodents' outcome after injury is superior to male which has been ascribed the neuroprotective sex hormones 17β-estradiol and progesterone. Cytochrome P450 1B1 is an oxidative enzyme influencing the neuroinflammatory response by creating inflammatory mediators and metabolizing neuroprotective 17β-estradiol and progesterone. In this study, we

aimed to determine how penetrating traumatic brain injury influences hippocampal Cytochrome P450 1B1 mRNA expression and if sex-dependent differences exist. 64 adult Sprague Dawley rats equally divided by sex were subjected to penetrating traumatic brain injury or sham-surgery and assigned survival times of 1-, 3-, 5- or 7 days. mRNA in-situ hybridization was performed to quantify Cytochrome P450 1B1 mRNA in hippocampal subregions and immunohistochemical analysis to verify protein colocalization. Cytochrome P450 1B1 mRNA expression was greatest in CA2 irrespective of sex. 3-, 5- and 7 days post-injury, expression in CA2 was reduced in male rats subjected to penetrating traumatic brain injury compared to those receiving sham-surgery. Females subjected to penetrating traumatic brain injury instead exhibited increased expression in all CA subregions 3 days post-injury, the only time point expression in CA2 was greater in females than in males. Immunohistochemical analysis confirmed Cytochrome P450 1B1 protein in all hippocampal subregions. Following penetrating traumatic brain injury, Cytochrome P450 1B1 mRNA expression exhibits sex-dependent differences. Females displayed a more urgent but brief regulatory response than males. This indicates there may be sex-dependent differences in Cytochrome P450 1B1 activity, possibly influencing inflammation and neuroprotection in penetrating traumatic brain injury.

Title: Gut Microbiome Depletion in Adolescence Modifies Behaviour, Bone Development, and Neuropathology in a Rodent Model of Repetitive Mild Traumatic Brain Injury

Authors: M. SGRO[1], Z. KODILA-JONES[2], K. WONG[1], C. LI[1], R. D. BRADY[1], G. R. YAMAKAWA[1], ***R. MYCHASIUK**[1];
[1]Neurosci., Monash Univ., Melbourne, Australia; [2]Neurosci., Monash Univ., Melbouren, Australia

Abstract: It is well recognized that the gut microbiome plays an integral role in optimal brain development and function. Recent literature demonstrates that mild traumatic brain injury (mTBI) alters the gut microbiome and the brain-gut axis, leading to persistent neuroinflammation. However, there has been no investigation into the effects that the microbiome may have on adolescent mTBI pathophysiology. Given that studies have

demonstrated that chronic antibiotic administration depletes the gut microbiome, antibiotic administration is a non-invasive means by which the microbiome can be manipulated within the context of mTBI. We therefore investigated the effects of microbiome depletion on behavioural recovery, bone development, and neuropathology following repetitive mTBI in adolescence. Specifically, adolescent rats (39F:40M) were administered an antibiotic cocktail or placebo in their drinking water for 14 days. The rats were then randomly assigned to receive 3 mild TBIs (RmTBI) or sham injuries followed by a behavioral test battery to examine functional recovery. The battery included rotarod for motor function, the elevated plus maze (EPM) for anxiety-like behaviour, the hot/cold plate for pain sensitivity, and play plus temperament scoring for social behaviour. We used micro-computed tomography (μCT) to examine bone volume, bone density, and femur length. Finally, immunohistochemistry was used to investigate changes in perineuronal net integrity, as well as microglia activation within the prefrontal cortex. Analyses of fecal samples demonstrated that antibiotic administration effectively depleted the gut microbiome. Three-way ANOVAs with sex (Female/Male), treatment (Antibiotic/Standard), and Injury (RmTBI/Sham) as factors were run. We found that microbiome depletion and RmTBI differentially modified motor, anxiety-like, pain, and social behaviours, in a sex-dependent manner. In addition, we found sexually dimorphic changes in adolescent bone development. For example, female femur length was reduced in response to both RmTBI and microbiome depletion (but not when combined), while male femur length was only restricted by microbiome depletion. Finally, using a triple label for Wisteria floribunda agglutin, parvalbumin neurons, and IBA1, we demonstrate alterations to perineuronal net integrity surrounding parvalbumin interneurons and microglia activation that are dependent upon injury, microbiome depletion, and sex. These results suggest that the microbiome modulates recovery from RmTBI and may be an efficacious therapeutic target for neurotrauma if the treatment is differentially formulated for males and females

Title: Traumatic brain injury alters gut-derived peripheral serotonin signaling in mice

Authors: *N. M. MERCADO, G. ZHANG, Z. YING, F. GOMEZ-PINILLA;
Dept of Integrative Biol. & Physiol., UCLA, Los Angeles, CA

Abstract: Most efforts to understand the pathology of traumatic brain injury (TBI) have been centered on the brain, ignoring the role played by systemic physiology in TBI and limiting understanding of the dimensionality of pathogenesis and treatment efficacy. Gut-derived serotonin (5-HT), which interacts with gut microbiota and various tissues throughout the body under the regulatory action of the enteric nervous system (ENS), is emerging as a major regulator of whole body homeostasis and energy balance. We are devoting major efforts to understand the action of TBI on systemic function via regulation of peripheral 5-HT signaling. Male C57BL/6J mice were subjected to a mild fluid percussion injury (FPI; 1.5-1.7 atm) and compared to sham animals. Mice were sacrificed 1, 3, or 7 days following FPI. Reverse-transcription qPCR was used to examine gene expression changes following TBI in intestine, liver, and adipose tissue. Systemic 5-HT levels were measured in blood by ELISA and visualized in colon using immunofluorescence. In the ENS, neuronal markers *Chat* and *Nos* were transiently downregulated in the duodenum and colon following TBI. In the colon, alterations in genes related to synthesis and degradation of 5-HT were observed in TBI mice vs sham, favoring an overall 5-HT downregulation. Colonic 5-HT expression corroborated these findings, showing a significant decrease in 5-HT fluorescence intensity at 7 days post-TBI. Blood 5-HT levels were also significantly decreased in TBI mice compared to sham at this time point. Furthermore, we detected alterations in 5-HT-associated gene expression in downstream tissues after TBI: namely, upregulation of 5-HT receptor *Htr2a* in liver and adipose, and upregulation of lipogenesis marker *Srebp1* in liver. Our findings suggest that TBI alters peripheral 5-HT homeostasis by lowering systemic 5-HT levels, a change which has the potential to impact whole body energy balance and gastrointestinal function. In all, these data highlight the importance of building an integrative view of the role of systemic physiology in TBI pathogenesis, and we posit that a thorough understanding of the dimensionality of peripheral TBI pathology is necessary for the design of effective treatments.

Title: Loss of bHLH Transcription Factors Decreases Glioblastoma Progression and Increases Survival

Authors: *B. MYERS[1], M. KEITH[2], R. ANDERSON[3], T. VUE[1];
[1]Neurosciences, Univ. of New Mexico Dept. of Neurosciences, Albuquerque, NM;
[2]Neurosciences, [3]Undergraduate Pipeline Network, Univ. of New Mexico Hlth. Sci. Ctr., Albuquerque, NM

Abstract: Loss of bHLH Transcription Factors Decreases Glioblastoma Progression and Increases SurvivalGlioblastoma (GBM) makes up about 50% of primary brain tumors and survival has not increased over the last 30 years, with less than 5% of patients surviving past 5 years of diagnosis. The lethality of GBM is likely due to high degree of inter- and intratumoral heterogeneity and the presence of key neurodevelopmental transcription factors such as ASCL1 and OLIG2, which have been shown to be present in the majority of GBMs. Functionally, these basic-helix-loop-helix (bHLH) transcription factors form heterodimers with E-proteins (E47/TCF4) and bind to DNA to regulate gene transcription. Previously, we showed in patient-derived GBM xenograft (PDX-GBM) that ASCL1 binds to promoter and enhancer regions of cell cycle, mitotic, and chromatin organization genes, as well as neurodevelopmental transcription factors including that of *OLIG2*. Similarly, in this study we showed that OLIG2 is able to bind to the majority of ASCL1 target genes, including the promoter and/or enhancer regions of both *ASCL1* and *OLIG1/2* loci, illustrating a potential redundant and/or feed-forward function between these two bHLHs in GBM. It has been proposed that the presence of ASCL1 and OLIG2 contribute to the neural stem cell-like properties of these cancer cells, which may be responsible for the increased treatment resistivity and high recurrence rate of GBMs in patients. However, to date the combinatorial roles of these two bHLHs in GBM are as of yet untested in vivo in the brain. Remarkably, we found that the loss of ASCL1 or OLIG2 alone slows tumor progression but is not enough to stop tumor growth entirely in a glioma mouse model in which tumors are induced from glial progenitors in the brain of immune competent mice. In contrast, the combined loss of both ASCL1 and OLIG2 completely prevents tumor growth and results in 100% survival of mice up to 6 months. These research findings illustrate the need for a better understanding of the combinatorial function of ASCL1 and OLIG2 as well as their shared downstream targets as they could lead to the development of novel therapeutics for patients suffering from GBM.

Title: Autophagy Dysregulation Exaccerbates NeuroInflammation Following Experimntal TBI in Mice

Authors: *N. HEGDEKAR[1], C. SARKAR[1], R. M. RITZEL[1], S. BUSTOS[1], M. HANSCOM[2], D. J. LOANE[2], A. FADEN[1], M. M. LIPINSKI[1];

Abstract: The autophagy-lysosomal pathway serves an important role in cellular homeostasis and protection against neurodegeneration. Recently autophagy has been also implicated in regulation of immune and inflammatory responses. Specifically, high levels of autophagy flux - the progress of substrates through autophagic compartments leading to their delivery and degradation in the lysosomes - are generally associated with anti-inflammatory, and inhibition of flux with pro-inflammatory phenotypes. To determine if autophagy may be involved in modulation of neuroinflammation after traumatic brain injury (TBI), we assessed the levels of autophagy in resident microglia and infiltrating macrophages following moderate controlled cortical impact (CCI) in mice. Our data demonstrated accumulation of autophagosomes and inhibition of autophagy flux specifically in the activated microglia and infiltrating macrophages starting by day 1 and continuing through day 28 post-CCI. Our immunofluoresnce studies in transgenic *Cx3Cr1-GFP* microglial and *Ccr2-RFP* monocyte reporter mice confirmed inhibition of autophagy flux and demonstrated that while both activated resident microglia and infiltrating macrophages are affected, inhibition of autophagy is much more prominent in macrophages. Our FACS analysis demonstrated that immune cells with inhibited autophagy flux after CCI expressed increased levels of pro-inflammatory markers, including IL-1β and TNF-α, as compared to corresponding immune cells with normal levels of autophagy. Furthermore, inhibition of autophagy flux correlated with impaired phagocytic function, indicating microglial/macrophage dysfunction. These trends persisted through day 28- post CCI, suggesting that autophagy flux impairment following TBI has long-term consequences. *In vitro* experiments in IMG microglial and RAW macrophage cell lines demonstrated that inhibition of autophagy can potentiate pro-inflammatory activation induced by lipopolysaccharide (LPS) treatment. Our *in vivo* studies further support the importance of autophagy in inflammation regulation. Mice with microglia/macrophage-specific knockout of the autophagy gene *Beclin1* (*Beclin1-flox/LysM-Cre*) showed increased expression of pro-inflammatory gene and protein markers, and in particular, marked exacerbation of innate immune responses, including activation of the NLRP3 inflammasome and the type I IFN pathways and performed worse than *LysM-Cre* controls on behavioral tasks after CCI. Overall, these findings indicate that impairment of autophagy in microglia/macrophages exacerbates neuroinflammation after TBI and contributes to functional deficits.

Title: Protein kinase C δ is a molecular mechanism for headache in a mouse model of migraine

Authors: *Y. HE[1], R. O. MESSING[2], Z. J. WANG[3];
[1]Oklahoma State Univ., Tulsa, OK; [2]Univ. of Texas, Austin, Austin, TX; [3]BPS, Univ. Illinois, Chicago, IL

Abstract: Migraine is one of the most common neurological disorders characterized by recurrent attacks of typically throbbing and unilateral headaches, affecting up to 20 % of the population worldwide. Despite the high prevalence and severity of this primary headache disorder, it remains to be a challenge to fully understand and treat migraine headaches. By characterizing and validating a mouse migraine model, this study aimed to investigate the functional contribution of PKC isoforms in migraine. In this study, we identified the presence of migraine-like ongoing pain in mice after chronic intermittent treatment with nitroglycerin (NTG). The peptide antagonist of calcitonin gene related peptide (CGRP) α-CGRP (8-37), but not topiramate nor sumatriptan, effectively blocked ongoing pain and elicited pain relief-induced CPP in NTG-treated mice. Prominent activation of PKCδ was observed in chronic NTG-treated mice. Functional inhibition of PKCδ significantly attenuated ongoing spontaneous pain in chronic NTG-treated mice. Furthermore, we recapitulated the NTG-triggered migraine behavior in wild-type, but not in PKCδ-null mice. In response to repeated administration of NTG, ongoing spontaneous pain was not developed in mice lacking the specific PKC isoform. This study identified the presence of ongoing pain in mice treated with nitroglycerin, a known human migraine trigger that closely resembles the common manifestation of spontaneous migraine attacks in humans. These findings demonstrated a critical regulatory role of PKCδ in migraine pathophysiology, which may offer new pharmacological targets for anti-migraine treatment.

Title: Effects of respiratory-gated auricular vagal afferent nerve stimulation (RAVANS) on the modulation of cardiovagal response to trigeminal somatosensory stimulation in migraine patients

Authors: M. HYMAN[1], R. BARBIERI[4,2], R. R. EDWARDS[5,6], N. HADJIKHANI[1,6], R. GOLLUB[3,6,1], V. NAPADOW[1,6,5], *R. G. GARCIA[3,6];

Hosp., Charlestown, MA; [4]Dept. of Electronics, Information and Bioengineering, Politecnico di Milano, Boston, Italy; [5]Dept. of Anesthesiology, Perioperative and Pain Med., Brigham and Women's Hosp., Boston, MA; [6]Harvard Med. Sch., Boston, MA

Abstract: Background & Aims: Hypersensitization of the brainstem trigeminal sensory complex may underlie impaired sensory processing and decreased cardiovagal regulation in patients with migraine. Recently, our group has developed a novel respiratory-gated transcutaneous auricular vagus nerve stimulation technique (RAVANS taVNS) aimed at the regulation of key brainstem nuclei involved in trigeminal somatosensory processing and autonomic activity. As taVNS has shown promise for episodic migraine in clinical trials, we evaluated the impact of RAVANS on modulation of cardiovagal response to trigeminal afference in episodic migraine patients. **Methods**: We enrolled 16 interictal episodic migraine patients (35.8±13.4 yrs, 15 F) and 16 age- and sex-matched healthy controls (36.0±13.7 yrs). Subjects received exhalatory-gated RAVANS and sham stimulation in a randomized, crossover design study. Aversive air-puff stimuli (14-sec ON and 20-sec OFF, 11 reps) were administered to the right supraorbital forehead (ophthalmic (V_1) trigeminal division) before and after a 6-min period of RAVANS or sham stimulation at the left cymba concha. Cardiac pulse was recorded, and a point process model calculated instantaneous estimates of the high-frequency power component of heart rate variability (HF-HRV), a measure of cardiovagal response. Peri-stimulus plots were obtained by averaging HF-HRV epochs temporally aligned with respect to stimulus onset (Fig. 1). The average HF-HRV power over the 5 seconds of pre-stimulus time was used as a baseline. **Results**: Migraineurs showed increased HF-HRV during forehead air-puff stimulation post-RAVANS compared to pre-RAVANS (p=0.04, Fig. 1). No significant changes in HF-HRV were observed when comparing post vs pre-RAVANS in healthy subjects, nor post vs pre-sham in either group. **Conclusion**: RAVANS effectively increased cardiovagal response to trigeminal sensory stimulation in migraineurs, which may constitute both an adaptive mechanism for the processing of trigeminal afference and a potential biomarker for clinical efficacy in this population.

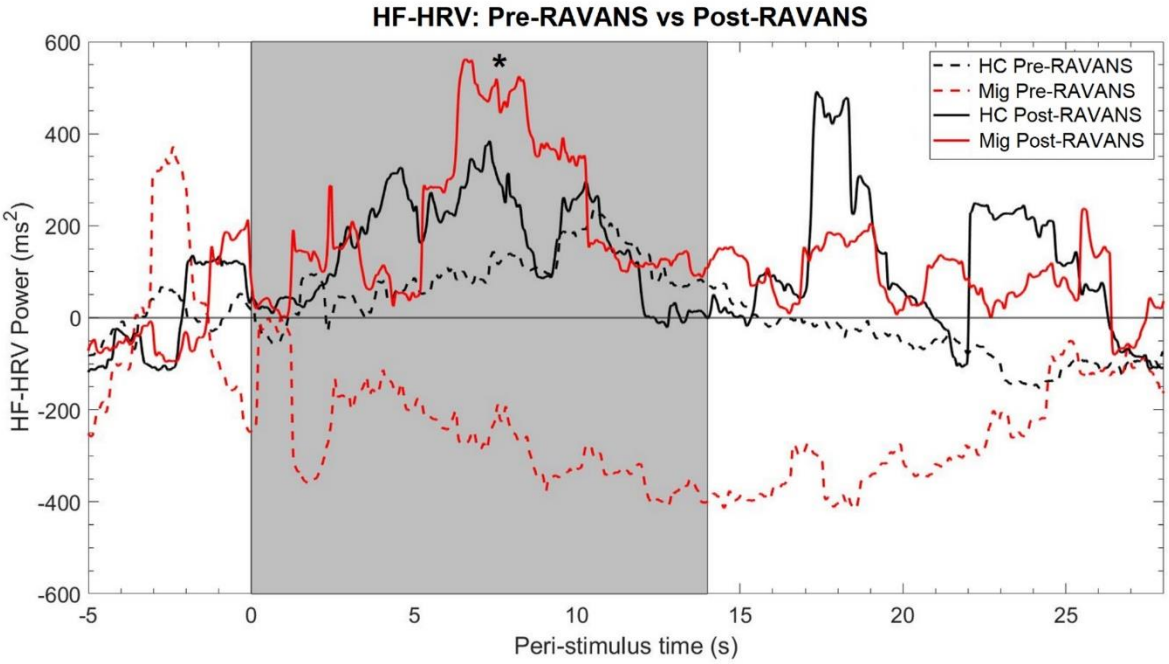

Figure 1. Peri-stimulus plot for HF-HRV changes during air-puff stimulation pre- and post-RAVANS in healthy controls (HC) and migraineurs (Mig)

Title: Prophylactic Administration of Hsp90 Inhibitor 17-AAG Limits Onset of Trigeminal Facial Allodynia and Improves Blood Brain Barrier Integrity in KCl Model of Episodic Headache

Authors: *S. PALOMINO[1], A. LEVINE[1], J. WAHL[1], E. LIKTOR-BUSA[1], J. STREICHER[1], T. M. LARGENT-MILNES[2];
[2]Pharmacol., [1]Univ. of Arizona, Tucson, AZ

Abstract: Blood-brain barrier (BBB) homeostasis is integral to the health and maintenance of the central nervous system. Dysregulation of the blood brain barrier has been associated with certain neuroinflammatory disease states such as stroke, Alzheimer's, and epilepsy. Migraine is the 3rd most prevalent disease in the world and the 6th ranked disease associated disability. Despite this fact there is limited data on blood brain barrier function and integrity during migraine states. Previously published data has shown that cortical spreading depression (CSD), a phenomenon related to migraine with aura, causes onset of trigeminal facial allodynia in rodents and compromises the physical integrity of the blood brain barrier. The neurogenic theory of migraine suggests both vascular and inflammatory components contribute to the pathology. Hsp90 inhibitors have been shown to have anti-inflammatory effects as well as neuroprotective action at the blood brain barrier in disease states such as stroke. In this study we observed the effects of Hsp90 inhibitor 17-AAG in a rodent model of KCl induced cortical spreading depression to assess pain outcome and barrier integrity and function. To investigate if Hsp90 inhibitors impacted the outcome of facial allodynia caused by cortical spreading depression we used a well characterized model of migraine with aura induced by cortical injection of KCl (1M, 0.5uL). Using immortalized mouse brain endothelial cells, Hsp90 inhibition with 17-AAG mitigated reductions in trans-endothelial electrical resistance induced by KCl. 17-AAG also decreased paracellular uptake of radiolabeled sucrose under the same conditions. Moreover, 17-AAG preincubation led to tight junction reorganization of claudin-5 in ICC images of Bend3 cells. In situ brain perfusions evaluated the effects of Hsp90 inhibition on the blood brain barrier 90 minutes post CSD. Results showed increased sensitization to pain with increasing doses of 17-AAG, however, at a moderate dose 17-AAG decreased the number of animals affected by cortical spreading depression. 17-AAG improved blood brain barrier integrity invitro and invivo. Studies are ongoing at this time to determine how 17-AAG application will affect sumatriptan activity.

Title: The role of dural immune cells and blood vessels in a preclinical mouse model of migraine.

Authors: *L. BALCZIAK[1], M. CONRAD[1], W. CHO[3], A. KUBURAS[1], M. W. CHAPLEAU[2], A.-S. WATTIEZ[1], A. F. RUSSO[1];

Abstract: Migraines are the leading cause of disability in the US and affect around 1 billion people worldwide. Symptoms include pain, photophobia, nausea and vomiting. The neuropeptide calcitonin gene-related peptide (CGRP) is a key mediator of migraine and drugs that block CGRP action are now being used to prevent migraine. However, the mechanism by which CGRP causes migraine remains unknown. It is thought that the site of migraine pain originates in the dura mater, specifically the trigeminal afferent endings around blood vessels and immune cells. CGRP released in this region from trigeminal neurons may cause dysregulation in the meningeal environment and cause sensitization of nearby afferents. Since CGRP causes vasodilation, immune cell activation and nociception, it is critical to parse out which effect may drive migraine. We previously showed that CGRP's systemic vascular effect isn't necessary for the migraine-like symptoms of light aversion. The current focus is on local dural vasculature and resident immune cells. We use a preclinical mouse model of migraine measuring migraine-like symptoms of light aversion (photophobia) and periorbital allodynia (pain) induced by CGRP. We found that $Kit^{+/-}$ mice with reduced mast cells may have a lower magnitude of CGRP-induced light aversion compared to controls. These mice and those that overexpress the CGRP receptor subunit hRAMP1 in monocyte lineage are currently being tested with periorbital von Frey. In vivo awake two-photon microscopy macrophage morphology is being investigated in the meninges along with meningeal blood vessel diameter. Additional work is being done to determine whether IP CGRP changes fluctuating serum cytokine levels during the normal behavioral testing window. This research should give insight into the potential interaction with the mouse dural immune system and meningeal vessels in a preclinical model of migraine to help flesh out understanding of CGRP's peripheral effects.

Title: The Local Field Potential Change in Migraine Headache

Authors: *Z. WANG, Q. LIN, Y. B. PENG;
Psychology, The Univ. of Texas At Arlington, Arlington, TX

Abstract: Migraine is a recurrent primary headache disorder and has been ranked as the second leading cause of disability and sixth prevalence disease with up to 1 billion patients worldwide. However, the pathophysiology of migraine headache remains not fully understood. The ***purpose*** of this study is to determine differential local field potential (LFP) changes, a neurophysiological tool to investigate the combined neuronal activity, from multiple selected brain regions related to migraine-relevant pain networks, by a well-established migraine model, the intraperitoneal (i.p.) injection of nitroglycerin (NTG). The ***hypothesis*** is that these brain areas, which are involved in different orders of neurons in trigeminovascular system and pain processing, will exhibit different response patterns to migraine attacks. In this study, LFPs from the anterior cingulate cortex (ACC, related to emotional processing), posterior nucleus of the thalamus (Po), trigeminal ganglion (TG), and primary visual cortex (V1M) (involved in trigeminovascular system) were simultaneously recorded, during the light aversion behavior in freely-moving animals. Four electrodes were implanted into these brain areas in Sprague-Dawley rats (n=11). After one-week recovery, LFPs were firstly recorded for 30 minutes as the baseline, then NTG was injected (i.p. 10 mg/kg), and continued recording for four hours. Light aversion behavior test, which was performed for 30 minutes, the percentage of time in dark box was then calculated, was measured one day before the recording as the baseline, and immediately after NTG injection. The control group rats (n=10) received i.p injection of vehicle solution. The raw data of LFP was processed by power spectrum analysis in MATLAB. The powers of delta (0.1-3 Hz), theta (3-7 Hz), alpha (7-12 Hz), beta (12-30 Hz), and gamma (30-100 Hz) bands were normalized by the average of the baseline. A mixed analysis of variance (ANOVA) was implemented to test the difference of LFP and behavior changes between NTG and control groups. The results indicated that: Overall, the relative change of LFP powers for delta, theta, alpha, beta, and gamma bands were increased significantly ($p < .05$) after NTG injection (n=11) in the ACC, Po, TG, and V1M simultaneously in contrast to the control group (n=10). The light aversion test showed a significant elevation of time spent in the dark box in the NTG group ($p < .05$). In conclusion, NTG-induced migraine has significant LFP intensity in various related brain regions, indicating potential parameters for predicting migraine.

Title: Enhanced CGRP and PACAP signaling in trigeminal ganglion neurons in mouse models of chronic migraine and post-traumatic headache

Authors: *Z. GUO, K. CZERPANIAK, J. ZHANG, Y.-Q. CAO;
Washington Univ. in St. Louis, SAINT LOUIS, MO

Abstract: Numerous studies indicate that calcitonin gene-related peptide (CGRP) and pituitary adenylate cyclase-activating polypeptide (PACAP) signaling pathways contribute to migraine pathophysiology. Both CGRP and its receptors are abundantly expressed in primary afferent neurons in trigeminal ganglia (TG). Under normal condition, endogenous CGRP activates/sensitizes nociceptors through paracrine signaling. However, whether repeated headache episodes alter the relative contributions of autocrine versus paracrine CGRP signaling, or the overlap between CGRP and PACAP signaling in TG neurons have not been investigated. In this study, we used EGFP signal in heterozygous CGRP$\alpha^{EGFPf/+}$ mice to define TG neurons that express endogenous CGRP. TG neurons that exhibit functional CGRP and/or PACAP receptors were identified by CGRP- and/or PACAP-evoked intracellular Ca^{2+} increase. This allowed us to reveal the relationship between CGRP-responsive (CGRP-R), PACAP-responsive (PACAP-R) and CGRP-expressing neurons in mouse TG under normal and disease states. Under normal condition, most CGRP-R TG neurons did not express CGRP, indicating that paracrine CGRP signaling predominates. After repeated nitroglycerin (NTG, a reliable migraine trigger in migraineurs) administration, there was a significant increase in CGRP-R neurons in mouse TG but not DRG, supporting its relevance to chronic migraine. The percentage of CGRP-R neurons were increased in both $EGFP^+$ and $EGFP^-$ cells, suggesting that both autocrine and paracrine CGRP signaling are enhanced in TG neurons during chronic migraine. In $EGFP^+$ TG neurons that express endogenous CGRP, repeated NTG led to several fold increase in the number of neurons that respond to both CGRP and PACAP (CGRP-R&PACAP-R), suggesting that the release of endogenous CGRP can be enhanced by both CGRP and PACAP signaling pathways under chronic migraine condition. The numbers of CGRP-R, PACAP-R as well as CGRP-R&PACAP-R neurons were also increased by mild traumatic brain injury (mTBI). Low-dose interleukin-2 treatment, which the behavioral sensitizations related to chronic migraine and post-traumatic headache (PTH), also blocked the increase in both CGRP-R and PACAP-R TG neurons in mouse models. Taken together, our findings suggest that enhanced CGRP and PACAP signaling in TG neurons may play important role in the pathophysiology of chronic migraine and post-traumatic headache. Inhibition of both CGRP and PACAP signaling in TG neurons may be more effective in treating chronic migraine and post-traumatic headache than targeting individual signaling pathways.

Title: Transient receptor channel 4 (TRPC4) small-molecule inhibition alleviates migraine-like behavior in mice

Authors: *C. F. COHEN, S. LEE, T. BERTA;
Anesthesiol., Univ. of Cincinnati Col. of Med., Cincinnati, OH

Abstract: Migraine is a common neurological disorder that is estimated to affect 15% of the world population, making it the third most prevalent disease worldwide. Yet migraine underlying mechanisms are poorly understood, and few treatment options exist for this disorder. Transient receptor potential channels are important mediators of itch and pain and are emerging therapeutic targets. We have recently demonstrated the role of the transient receptor potential channel 4 (TRPC4) in itch and how blockade of TRPC4 reduced psoriatic-itch and skin inflammation, potentially through inhibition of calcitonin gene-related peptide (CGRP) release from peripheral sensory neurons. Because release of CGRP from peripheral sensory neurons is a major mechanism of migraine, we asked whether TRPC4 is involved and may therefore represent a therapeutic target in migraine. First, we assessed whether TRPC1-7 are expressed in trigeminal peripheral sensory neurons innervating the head. We found a significantly higher expression of TRPC4 transcripts in trigeminal ganglia (TG) compared to other members of the TRPC family. Furthermore, we showed by immunohistochemistry that the majority of TRPC4 positive neurons in TG also expressed CGRP. Second, we used a well-characterized mouse model of migraine consisting of repeated injections of nitroglycerin (NTG), 10 mg/kg, to assess the therapeutic effect of the small-molecule inhibitor ML-204, a specific TRPC4 antagonist. Notably, mice injected with NTG developed mechanical hypersensitivity mimicking symptoms observed in migraineurs. Assessments of mechanical sensitivity by von Frey filaments showed that intraperitoneal injections of ML204 (40 μg per animal) significantly alleviated NTG-evoked mechanical hypersensitivity compared to vehicle control injections in both male and female mice ($n=5$-6/group; $p < 0.05$). Third, we explored the potential mechanism underlying this alleviation and found a significant decrease of CGRP protein levels in blood of both male and female mice treated with ML-204 ($n=5$-6/group; $p < 0.05$). Using sensory neuron cultures, we confirmed that activation of TRPC4 by Englerin A (a specific TRPC4 agonist) evoked rapid CGRP release, which was significantly reduced by ML-204 ($n=4$/group; $p < 0.05$). Collectively, our findings identify TRPC4 in DRG and TG neurons as a mediator of CGRP release and NTG-evoked migraine. Since a TRPC4 antagonist is already in clinical trials, we expect that this study will rapidly lead to novel and effective clinical treatments for millions of patients suffering from migraine.

Title: The role of glucocorticoids in repetitive stress-induced migraine-like behaviors in mice

Authors: *Y.-Y. HU[1], R. SOUZA[2], C. K. MCINTYRE[3], G. O. DUSSOR[4];
[2]Sch. Behav and Brain Sci., [1]Univ. of Texas at Dallas, Richardson, TX; [3]Sch. Behav and Brain Sci., Univ. Texas at Dallas, Richardson, TX; [4]Behavioral and Brain Sci., Univ. of Texas At Dallas, Richardson, TX

Abstract: Stress is one of the most common precipitating factors in migraine and it is identified as a trigger in nearly 70% of migraine patients. The nervous system responds to stressors by activating neuroendocrine mechanisms, like inducing glucocorticoid release to change behaviors. Although it has adaptive value, migraine headache may be an adverse consequence of this glucocorticoid response. We have shown previously that repeated restraint stress in mice (3 days, 2 hours each day) evokes migraine-like behavioral responses as well as priming to the nitric oxide donor sodium nitroprusside (SNP). In the present study, we used CD-1 male and female mice to investigate the effect of glucocorticoids on these restraint stress-induced migraine-like behaviors. To examine the role of glucocorticoids, we gave subcutaneous injections of metyrapone, an inhibitor of glucocorticoid synthesis, 30 minutes prior to each restraint stress exposure. Metyrapone attenuated both the initial restraint stress-induced migraine-like behaviors and priming to SNP in both male and female mice. These results indicate that migraine-like behaviors in this model are dependent on normal synthesis of corticosterone (CORT). To further investigate the role of glucocorticoids in this model, and to test whether CORT injections alone can mimic restraint stress-induced migraine-like behaviors, we administered subcutaneous injections of either 10mg/kg, 20mg/kg doses of exogenous CORT, or vehicle for 3 consecutive days in the absence of restraint stress. Daily CORT injections led to migraine-like behaviors although the pattern of response was different from restraint stress. Restraint stress induced facial hypersensitivity 24 hours after the last day of restraint, but CORT alone did not induce facial hypersensitivity until 72 hours after the last injection. Moreover, CORT injections did not cause any pain-like facial expressions. During the SNP-induced priming phase, CORT injection group and stress groups both showed facial hypersensitivity. Neither CORT injection group nor the restraint stress group showed any pain-like facial expression during the priming phase. These data indicate that corticosterone plays an important, but not exclusive role in the behavioral responses to repeated stress. Together, these results reveal that glucocorticoids are critical for the development of migraine-like behavioral responses following repeated stress in mice. Better understanding of where, when, and how glucocorticoids influence the nervous system in the

context of stress may provide important information for how stress contributes to migraine and may lead to new therapeutic approaches.

Title: Low-dose interleukin-2 reverses chronic headache-related behavioral and cellular sensitization

Authors: *J. ZHANG[1], K. CZERPANIAK[1], Z. GUO[1], X. LIU[1], J. UNSINGER[2], R. HOTCHKISS[2], Z. QIN[3], Y. CAO[1];

Abstract: Chronic headache disorders, including chronic migraine and post-traumatic headache (PTH), affect a large population and cause debilitating pain, with limited treatment options. Although a large body of work indicates that many pro-inflammatory immune cells contribute to headache pathophysiology, the involvement of the immuno-suppressive regulatory T (Treg) cells in the chronification of headache disorders remains unknown. Here, we used two mouse models to examine the potential therapeutical effect of Tregs in chronic headache disorders. In a mouse model of chronic migraine, repeated nitroglycerin (NTG, a reliable trigger of migraine in patients) increased the number of CD3+ T cells in the trigeminal ganglia (TG) without altering the number of Treg cells, suggesting a loss of balance between immune activation and suppression. Low-dose interleukin-2 (ld-IL2) treatment preferentially expanded the endogenous Treg cells in peripheral tissues, including the dura and TG. This completely reversed NTG-induced persistent facial skin hyper-sensitivity in both male and female, inbred and outbred mice. Importantly, the basal nociceptive responses were not altered by ld-IL2, and tolerance was not observed. The therapeutic effect of ld-IL2 was abolished by Treg cell depletion and was recapitulated by the adoptive transfer of Treg cells, indicating that endogenous Treg cells mediate the effects of ld-IL2. Ongoing experiments focus on elucidating the molecular mechanisms underlying ld-IL2's beneficial effects. In a mouse model of mild traumatic brain injury (mTBI), ld-IL2 treatment 1 week post-injury not only accelerated the resolution of behavioral sensitization related to acute PTH, but also prevented the development of hyperalgesic priming related to chronic PTH. Moreover, starting ld-IL2 treatment 5 weeks post-

injury effectively reversed mTBI-induced hyperalgesic priming, suggesting that delayed ld-IL2 treatment may be effective for both acute and chronic PTH. At cellular level, ratiometric Ca2+ imaging analysis revealed that repeated NTG and mTBI
significantly increased the number of TG neurons that respond to neuropeptides CGRP and PACAP (calcitonin gene-related peptide and pituitary adenylate cyclase-activating polypeptide). This was completed blocked by ld-IL2 treatment, suggesting that ld-IL2 reverses chronic headache-related behaviors through inhibition of peripheral sensitization. Collectively, the present study identifies Treg cell as a promising target and ld-IL2 as a potential therapy for chronic migraine and PTH with a mechanism of action distinct from the existing treatment options.

Title: Efficacy of a Dual ENKephalinase Inhibitor in a preclinical stress-induced migraine model

Authors: *H.-R. MEI[1], T. OUIMET[2], H. PORAS[2], G. O. DUSSOR[1];
[1]Behavioral and Brain Sci., Univ. of Texas At Dallas, Richardson, TX; [2]Pharmaleads, Paris, France

Abstract: Migraine is the 2nd most disabling disease worldwide. The current treatments for migraine are triptans, NSAIDs, CGRP signaling inhibitors and antiemetics, but many people with migraine do not get adequate relief from any of the currently-available therapeutics. While opioids show efficacy for migraine, their use could lead to medication overuse headache or transformation from episodic to chronic migraine. To determine whether the endogenous opioid system could potentially be utilized as a migraine therapeutic approach, we tested the efficacy of an Dual ENKephalinase Inhibitor (DENKI) (PL37) in a preclinical model of migraine. We have shown previously that repetitive restraint stress (2 hours per day, 3 consecutive days) induces mechanical hypersensitivity and grimace responses as well as priming to the nitric oxide donor sodium nitroprusside (SNP; 0.1 mg/kg). Facial and hindpaw mechanical thresholds were measured using von Frey filaments and grimace scores were evaluated by observation of mouse facial expressions. We tested PL37 at two different phases of this preclinical model. On day 2 post-stress, either i.v. (10 mg/kg) or p.o. (20 mg/kg) PL37 significantly attenuated the stress-

induced facial and hindpaw hypersensitivity, as well as facial grimace responses, while no effect was observed in the vehicle group. Additionally, both i.v. (10 mg/kg) and p.o. (20 mg/kg) PL37 given one hour prior to SNP (0.1 mg/kg, i.p.) on day 14 post-stress significantly reduced SNP-induced facial and hindpaw hypersensitivity. To test whether opioid receptors mediate these effects, mice were pretreated with the peripherally-restricted opioid antagonist naloxone methiodide (5 mg/kg, s.c.) 30 min prior to PL37, which blocked the effects of this compound. Studies are currently underway to test the efficacy of additional opioid receptor antagonists to further elucidate which opioid receptor mediates the efficacy of PL37 in this model. These data demonstrate that inhibiting enkephalinase in the periphery is effective in treating migraine-like behavior via activation of opioid receptors. Peripheral targeting of endogenous opioid signaling may be an effective novel therapeutic strategy for migraine that lack the negative effects commonly associated with centrally-acting opioids.

Title: Calcitonin gene-related peptide 1 receptor blockade in the amygdala inhibits pain-related behaviors and neuronal activity in a chronic neuropathic pain model

Authors: *P. PRESTO[1], V. NEUGEBAUER[1,2,3];
[1]Pharmacol. and Neurosci., [2]Ctr. of Excellence for Translational Neurosci. & Therapeut., [3]Garrison Inst. on Aging, Texas Tech. Univ. Hlth. Sci. Ctr., Lubbock, TX

Abstract: The amygdala has emerged as a key player in the emotional-affective aspects of pain and pain modulation. The laterocapsular region of the central amygdala nucleus (CeLC) is defined as the “nociceptive amygdala” due to its high content of neurons that process pain-related information. The CeLC is the target of the spino-parabrachio-amygdaloid pain pathway, which is the major source of calcitonin gene-related peptide (CGRP) . Therefore, CGRP acting on CGRP1 receptors is an important molecular marker of the CeLC. Changes in CeLC neurons

have been observed in pain models and synaptic plasticity in the CeLC has been linked to pain-related behaviors. CGRP has been shown to be involved in peripheral and spinal mechanisms and in pain-related synaptic plasticity in the amygdala. However, the role of CGRP-mediated plasticity in the amygdala in neuropathic pain behaviors remains to be determined. Here we tested the hypothesis that the CGRP1 receptor is involved in neuropathic pain-related amygdala plasticity and that blockade of this receptor can inhibit neuropathic pain behaviors. Sensory and affective behaviors were measured in adult chronic neuropathic rats (4 weeks after spinal nerve ligation, SNL). For blockade of the CGRP receptor, a selective CGRP1 receptor antagonist (CGRP 8-37) was administered stereotaxically into the CeLC by microdialysis. Inhibition of the CGRP1 receptor reduced emotional responses to noxious stimuli (audible and ultrasonic vocalizations) and mechanical hypersensitivity (hindlimb withdrawal reflexes). Tonic aversive aspects of pain relief by CGRP 8-37 were detected in the conditioned place preference (CPP) test. In brain slices containing central amygdala corticotropin releasing factor (CeA-CRF) neurons from neuropathic rats, multiphoton imaging showed that CGRP1 receptor blockade reduced calcium signals evoked by electrical stimulation of presumed PB input. Together these findings may suggest that CGRP1 receptors in the CeLC are involved in neuropathic pain-related plasticity and contribute to nociceptive and emotional-affective pain responses. CGRP1 receptors in the amygdala may serve as a therapeutic target for pain relief.

Title: Subacute silencing of HMGB1 in the amygdala inhibits pain-related behaviors in a rat model of chronic neuropathic pain

Authors: *R. JUNELL[1], P. PRESTO[1], I. PONOMAREV[1,2], V. NEUGEBAUER[1,2,3];
[1]Pharmacol. and Neurosci., [2]Ctr. of Excellence for Translational Neurosci. & Therapeut., [3]Garrison Inst. on Aging, Texas Tech. Univ. Hlth. Sci. Ctr., Lubbock, TX

Abstract: Chronic pain is a pervasive health care issue that affects a significant portion of the global population each year. An intricate interplay between sensory, cognitive, and emotional-affective dimensions forms the highly complex experience of pain, presenting a challenge to

identifying effective treatment options. Maladaptive neuroplasticity is a key contributor in the transition from acute to chronic pathological pain, and mechanistic investigation of this transition is of particular interest for the potential discovery of new therapeutic strategies. This transition may be associated with neuroimmune mechanisms in the brain, which have yet to be elucidated. The amygdala is a limbic structure that has emerged as a key player in the emotional-affective aspects of pain and pain modulation. The role of neuroimmune signaling in the amygdala in chronic pain states is an important knowledge gap. High motility group box 1 (HMGB1) is a "proinflammatory" molecule that is involved in pain-related crosstalk between neurons and glia in the spinal cord, though its role in the amygdala in pain states has yet to be explored. Here we tested the hypothesis that HMGB1 is involved in pain-related amygdala plasticity and that inhibition of this molecule can reduce neuropathic pain behaviors. Transcriptomic analysis using RNA-Seq and validation using qPCR showed that HMGB1 was upregulated in the central nucleus of the amygdala (CeA) of adult chronic neuropathic rats (4 weeks after spinal nerve ligation, SNL). HMGB1 siRNA (pooled AAV vector) was injected stereotaxically into the right CeA of adult male and female rats as either a pretreatment (2 weeks before) or posttreatment (1 week after) to SNL surgery. Sensory and affective behaviors were measured 4 weeks after SNL. HMGB1 silencing ameliorated anxiety-like behaviors (open field test and elevated plus maze), increased mechanical withdrawal thresholds (von Frey test and tissue compression with calibrated forceps), and reduced emotional-affective responses (audible and ultrasonic vocalizations) in the posttreatment but not pretreatment group. mRNA analysis of right CeA tissues using qPCR after behavioral testing showed upregulation of HMGB1 expression in the pretreatment group compared to sham controls, indicating recovery of HMGB1 at the chronic stage. Together these findings suggest that HMGB1 in the amygdala contributes to the transition from acute to chronic neuropathic pain, and that inhibition of this molecule at a subacute time point may serve as a potential therapeutic target for neuropathic pain relief.

Title: Optogenetic silencing of amygdala CRF neurons inhibits anxiety-like behaviors at the acute stage of a rat neuropathic pain model

Authors: *V. NEUGEBAUER, M. MAZZITELLI, V. YAKHNITSA;
Texas Tech. Univ. Hlth. Sci. Ctr., Lubbock, TX

Abstract: The amygdala plays a critical role in the emotional-affective component of pain and in pain modulation. The central nucleus of amygdala (CeA) serves as the major output nucleus of the amygdala. Changes in different subsets of CeA neurons have been observed in pain models and neuroplasticity in the CeA has been linked mechanistically to pain-related behaviors in different pain conditions. While CeA neurons containing corticotropin releasing factor (CRF) have been implicated in affective disorders and pain modulation, their role in different pain conditions and at acute versus chronic stages are not well understood. Here we focused on the effects of optogenetic silencing of CeA-CRF neurons on pain related behaviors in the acute phase of the neuropathic condition. Sensory and affective behaviors were measured in adult neuropathic rats (1 week after spinal nerve ligation, SNL). For optogenetic silencing of CRF neurons, a Cre-inducible viral vector (DIO-AAV) encoding enhanced Natronomonas pharaonis halorhodopsin (eNpHR3.0) was injected stereotaxically into the right CeA of transgenic Crh-Cre rats (original breeding pairs kindly provided by Dr. Robert Messing, UT Austin). Animals were allowed to recover for channel expression. For wireless optical stimulation of eNpHR3.0 expressing CeA-CRF neurons, an LED optic fiber was stereotaxically implanted into the right CeA in order to deliver yellow (590 nm) light in neuropathic rats. Optical silencing of CeA-CRF neurons ameliorated anxiety-like behaviors (elevated-plus maze and open-field tests) but effects on mechanical withdrawal thresholds (von Frey test and tissue compression with calibrated forceps) and emotional-affective responses (vocalizations) did not reach significance in the acute phase of the neuropathic pain model. These findings suggest that CRF neurons in the CeA contribute to certain neuropathic pain associated behaviors at the acute stage.

Title: Differential pain-related changes in PB- and PAG-projecting amygdala CRF neurons in a neuropathic pain model

Authors: *T. KIRITOSHI[1], V. NEUGEBAUER[1,2,3];
[1]Pharmacol. & Neurosci., [2]Ctr. of Excellence for Translational Neurosci. & Therapeut.,
[3]Garrison Inst. on Aging, Texas Tech. Univ. Hlth. Sci. Ctr., Lubbock, TX

Abstract: The central nucleus of the amygdala (CeA) plays a key role in pain modulation and pain-related emotional-affective aspect of pain. The CeA contains a high level of corticotropin releasing factor (CRF)-expressing neurons that project to wide brain areas including key pain modulatory regions in the brainstem such as the parabrachial area (PB) and periaqueductal gray (PAG). Our recent study revealed that manipulation of CeA-CRF neurons can modulate neuronal activity in the spinal cord and pain-related behaviors. However, functional differences as well as pain-related cellular and synaptic changes in projection-defined CeA-CRF neurons remain to be determined. Here we sought to determine any differences between PB- and PAG-projecting CeA-CRF neurons in a neuropathic pain model using cell-type specific retrograde labelling and slice patch-clamp recording. Retrograde Cre-dependent adeno-associated viral vectors AAVrg-hSyn-DIO-EGFP and AAVrg-FLEX-tdTomato were stereotaxically injected into the PB and PAG, respectively, of transgenic Crh-Cre rats (original breeding pairs kindly provided by Dr. Robert Messing, UT Austin) to identify PB- and PAG-projecting CeA-CRF neurons in brain slices. Whole-cell patch clamp recordings were obtained from retrogradely labeled CeA-CRF neurons in brain slices from sham control and neuropathic rats (1 week after L5 spinal nerve ligation, SNL model). In current clamp mode, neuronal excitability was measured by injecting depolarizing currents. In voltage clamp mode, excitatory and inhibitory postsynaptic currents (EPSCs and IPSCs) were evoked by electrical stimulation of the basolateral amygdala (BLA) or presumed PB input. We found increased excitability in both PB- and PAG-projecting CeA-CRF neurons in the SNL model compared to sham control. The amplitude of EPSCs were increased in projection-undefined CeA-CRF neurons but changed differently in PB- and PAG-projecting CeA-CRF neurons in the SNL model. These results suggest that CeA-CRF neurons undergo differential changes in pain conditions depending on their projection targets.

Title: Differential effects of mGluR2 and mGluR3 on the modulation of CeA-CRF containing neurons in an arthritic model of pain

Authors: *M. MAZZITELLI[1], P. CONN[2], V. NEUGEBAUER[1];
[1]Texas Tech. Univ. Hlth. Sci. Ctr., Lubbock, TX; [2]Ctr. for Neurosci. Drug Discovery, Vanderbilt Univ., Nashville, TN

Abstract: The amygdala is critically involved in the regulation of emotional-affective components of pain and in pain modulation. The central nucleus of amygdala (CeA) serves major output functions and receives nociceptive information via the external lateral parabrachial nucleus (PB). The CeA contains the highest density of extra-hypothalamic corticotropin releasing factor (CRF), which is implicated in several neuropsychiatric disorders. CeA-CRF containing neurons project to other brain regions involved in behaviors and pain. Gi/o-coupled group II metabotropic glutamate receptors (mGluR2 and 3) are expressed in different brain regions, including the amygdala. Their activation can decrease neurotransmitter release and regulate synaptic plasticity, but effects of the modulation of group II mGluR subtypes on CeA-CRF neurons remain to be determined. Here, we address this knowledge gap in an arthritic pain model. Brain slice physiology was performed to determine the effects of a group II mGluR agonist (LY379268 disodium salt), a positive allosteric modulator (PAM) selective for mGluR2 (LY487379 hydrochloride), and the combination of a group II mGluR agonist (LY379268) with a negative allosteric modulator (NAM) selective for mGluR2 (VU6001966) on CeA-CRF neurons. To visualize CRF neurons, a Cre-inducible viral vector expressing red fluorescent protein (mCherry) was injected into the CeA of transgenic Crh-Cre rats (original breeding pairs kindly provided by Dr. Robert Messing, UT Austin). A viral vector coding channelrhodopsin 2 (ChR2) fused to enhanced yellow fluorescent protein under the control of CaMKII promoter was injected into the PB for optical activation of glutamateric inputs to CeA-CRF neurons. Whole-cell patch-clamp recordings in brain slices from normal and arthritic rats (5-6 h postinduction of a kaolin/carrageenan-monoarthritis) were used to investigate neuronal excitability, monosynaptic excitatory postsynaptic currents (EPSCs), and glutamate-driven inhibitory postsynaptic currents (IPSCs) evoked from PB inputs. Application of LY379268 decreased neuronal excitability and EPSCs and IPSCs in the arthritis condition. Application of LY487379 resulted in decreased EPSCs, whereas selective activation of mGluR3 (combination of LY379268 with VU6001966) mimicked the effects of the group II mGluR agonist on the modulation of CeA-CRF neurons in pain. These results suggest that mGluR2 and 3 have different roles in controlling functions and pain-related changes of CRF neurons in the amygdala, providing important insights into the subtype-specific roles, which may help identify appropriate therapeutic strategies for pain management.

Title: Opposing effects of kappa and mu opioid receptors on amygdala CRF neuronal activity in a rat neuropathic pain model

Authors: *G. JI[1], T. KIRITOSHI[1], V. YAKHNITSA[1], E. NAVRATILOVA[2], F. PORRECA[2], V. NEUGEBAUER[1];
[1]Texas Tech. Univ. Hlth. Sci. Ctr., Lubbock, TX; [2]Pharmacol., Univ. of Arizona Col. of Med.,, Tucson, AZ

Abstract: Chronic pain states have been consistently associated with a loss of the conditioned pain modulation response. Clinical evidence suggests that the amygdala plays a key role in maintaining descending pain facilitation in chronic pain patients. The amygdala is a major site of opioid receptor and the origin of major corticotropin-releasing factor (CRF) containing pathways in the brain, and CRF is a key player in emotional pain-related responses. We have shown that microinjection of a kappa opioid receptor (KOR) agonist into the right central nucleus of the amygdala (CeA) elicits allodynia whereas a mu opioid receptor (MOR) agonist as analgesic effects. We hypothesize that MOR and KOR in the CeA elicit opposing effects on CRF neurons. In this study, we tested effects of KOR and MOR ligands on neuronal activity by measuring synaptically evoked calcium signals in CeA-CRF neurons in rat brain slices with a multiphoton system. To measure calcium signals in CeA-CRF neurons, CRF-cre rats (original breeding pairs kindly provided by Dr. Michael Burman, Univ. of New England) were injected with AAV5-Syn-Flex-GCaMP7s into the right CeA 5-6 weeks before brain slices were obtained to allow viral vector mediated expression of a fluorescent calcium sensor. Sham or SNL surgery was performed one week after viral vector injection. A multiphoton system (Intelligent Imaging Innovations, Inc., 3i, Denver, CO) was used to record calcium transients evoked by electrical stimulation of the dorsomedial fiber tract containing presumed axons from the parabrachial area. The 2-photon (2P) excitation light was generated by a mode-locked Ti:Sapphire laser (920 nm, model Mai-Tai DeepSee, Spectra-Physics, Santa Clara, CA, USA). CeA-CRF neurons that responded to synaptic stimulation were further analyzed. Fluorescent activity and background ($\Delta F/F0$) were analyzed using SlideBook 6 (3i, Denver, CO, USA). Multiphoton imaging of CeA-CRF neurons in SNL rats showed that synaptically evoked calcium signals were decreased by a MOR agonist (DAMGO, 1 μM) or a KOR antagonist (nor-BNI, 1 μM). A KOR agonist (U-69593, 1 μM) alone had no clear effects. Effects of DAMGO were blocked by co-application of U-69593 but enhanced by co-application of nor-BNI. The data show that KOR and MOR ligands elicit opposing effects on synaptically evoked activity of CeA-CRF neurons in a rat neuropathic pain model. These results may suggest that dual action drugs with KOR antagonist/MOR agonist activity could be explored as a novel therapeutic strategy for neuropathic pain.

Title: Kappa opioid receptor blockade reduces pain-like behaviors and restores inhibition of amygdala CRF neurons in a functional pain model in rats

Authors: *Z. GRIFFIN[1], V. A. YAKHNITSA[1], M. HEIN[1], E. NAVRATILOVA[2], F. PORRECA[2], V. NEUGEBAUER[1];
[1]Texas Tech. Univ. Hlth. Sci. Ctr., Lubbock, TX; [2]Univ. of Arizona Col. of Med., Tucson, AZ

Abstract: Chronic pain is observed in conditions related to identifiable injury as well as in functional pain syndromes (FPS), including fibromyalgia, irritable bowel syndrome, and migraine, in which the pain cannot be attributed to tissue pathology. The amygdala is an important contributor to pain-related emotional-affective conditions and pain modulation. The central nucleus of amygdala (CeA) is also a major site of opioid receptors. Activation of kappa opioid receptors (KOR) in the CeA has been shown to generate pain-like behaviors, enhance neuropathic pain behaviors, and disinhibit corticotropin releasing factor (CRF) expressing CeA neurons. Similar adverse effects can also be induced by the endogenous KOR agonist-dynorphin. Here we tested the hypothesis that blockade of KOR signaling with a KOR antagonist (nor-binaltorphimine, nor-BNI) in the right CeA inhibits pain-like behaviors by restoring inhibitory control of CRF neurons in the CeA in a rat model of FPS. The FPS model was induced by morphine priming for 7 days (using subcutaneously implanted mini osmotic pumps) followed 2 weeks later by one hour of restraint stress on two consecutive days. The control group received morphine without stress. For behavioral experiments, animals were implanted with microdialysis probes into the right CeA 5 days prior to testing. Brain slice electrophysiology was used to determine the effects of nor-BNI on CeA-CRF neurons. To visualize CRF-expressing neurons in CeA we used CRF-Cre rats (original breeding pairs kindly provided by Dr. Michael Burman, Univ. of New England). AAV5-ChR2-CaMKII-eYFP was injected into the right lateral parabrachial area (LPB) to allow optical activation of glutamatergic synaptic inputs to CeA neurons. Administration of nor-BNI into the right CeA decreased vocalizations evoked by noxious mechanical stimuli and anxiety-like behaviors in elevated plus maze test. Whole-cell patch-clamp recordings of CRF-positive and CRF-negative CeA neurons revealed that in the FPS model, nor-BNI increased optically and electrically evoked inhibitory synaptic currents (IPSCs) from LPB, while decreasing neuronal excitability (frequency-current F-I relationship). Nor-BNI also decreased spontaneous and miniature IPSCs frequency, but not amplitude. The data suggest

that blockade of KOR signaling in a rodent model of FPS reduces pain-like behaviors and restores synaptic inhibition of CRF-CeA neurons through a presynaptic mechanism of action.

Title: SK2-channel dysfunction in central nucleus of amygdala in chronic neuropathic pain. Evidence for epigenetic modifications

Authors: *V. YAKHNITSA, *V. YAKHNITSA, J. M. THOMPSON, V. NEUGEBAUER, K. PRUITT;
Texas Tech. Univ. Hlth. Sci. Ctr., Lubbock, TX

Abstract: Neuroplasticity in the central nucleus of amygdala (CeA) is linked to pain behaviors, and increased CeA activity contributes to emotional-affective aspects of pain. Small conductance calcium activated potassium (SK2) channels are expressed in the amygdala and inhibit neuronal excitability by mediating afterhyperpolarization, shunting excitatory transmission, and enhancing inhibitory synaptic transmission. Western blotting and RT-PCR reveal decreased levels of SK2 subunit protein and mRNA in the CeA in neuropathic pain, suggesting pretranscriptional SK2 channel downregulation. Chronic pain, stress, and cognitive impairment can induce epigenetic changes such as DNA methylation. Here we test the hypothesis that SK2 gene promoter methylation alters expression of SK2 channels in CeA neurons in chronic neuropathic pain. Audible and ultrasonic vocalizations and mechanical thresholds (von Frey) were measured in neuropathic rats (left L5 spinal nerve ligation model, SNL) and in sham controls 4 weeks after surgery. SNL rats showed increased vocalizations and reduced withdrawal thresholds compared to sham rats. Whole-cell patch-clamp recordings of CeA capsular neurons revealed that in the SNL model apamin-sensitive medium afterhyperpolarizations (mAHP), mediated by SK2 channels, were decreased while neuronal excitability (frequency-current F-I relationship) was increased. Right amygdala tissue was removed and homogenized for DNA extraction. The methylation profile of SK2 gene promoter region was assessed by bisulfite sequencing methods.

Overall, low methylation levels were observed in both SNL and sham rats, however increased methylation of CpG island of SK2 promoter region in the CeA was detected in SNL group. Interestingly, methylated CpG sites identified in the SNL rat CeA samples were different from those seen in the sham rats. A total of 11 CpG sites ranging from position -832 to -383 relative to the transcription start site of SK2 gene were methylated in SNL rats. Only 3 sites at these positions were found to be methylated in the sham rat CeA (-759, -676, and -383). We also found differential DNA methylation within consensus sequences of transcription factor binding sites across the methylated CpGs in SNL as compared to sham group. The data demonstrate loss of SK2 channel function in CeA in neuropathic pain. Methylation changes in the pain model suggest reduced gene expression by epigenetic mechanisms. Nevertheless, further studies are needed to determine the effect of DNA methylation on transcription factor binding to these differentially methylated transcription regulatory regions and their role in modulating the expression of SK2 gene.

Title: Dissecting a neural substrate for stress-induced analgesia

Authors: *C. DIAZ[1], B. CHEN[3], F. WANG[3], K. M. FRANKS[2];
[2]Neurobio., [1]Duke Univ., Durham, NC; [3]MIT, Boston, MA

Abstract: Affective modulation of pain is an important mechanism for selecting appropriate behavior given different contexts. As an adaptive mechanism, it can aid an animal in surviving a life-threatening situation. Stress-induced analgesia (SIA) is such a phenomenon in which an affective state of high stress, induced by such stimuli as predator odor, produces analgesia to noxious stimuli. Previous studies of SIA have shown that stressful stimuli increase freezing behavior and decrease nociceptive responses, a readout of analgesia. Furthermore, SIA was shown to critically depend on the central amygdala (CeA). CeA is known to have a multitude of roles in processing emotional responses to pain and fear. We recently described a distinct population of CeA neurons that are activated by general anesthetics (CeA_{GA}). Optogenetically stimulating CeA_{GA} neurons produces robust analgesia[1]. Furthermore, we have found that CeA_{GA}

cells receive strong projections from a region called the amygdala-piriform transition zone (AmPir), and this region is known to be activated by predator odor[2]. Here we show that the predator odor 2MT reduces nociceptive behavior and increases freezing behavior, functioning as a model of SIA. Additionally, we have found that exposure to the predator odor 2MT activates many fear regions in the brain, including CeA, specifically CeA_{GA}, and AmPir, through calcium imaging and cFos expression. Future work will dissect this AmPir-CeA_{GA} circuit and its function in SIA, providing novel insights into the neural circuits mediating the interplay between stress and pain, and advance our understandings of how emotions modulate pain.

Title: Divergent opioidergic brainstem pathways that mediate pain-breathing interaction

Authors: *S. LIU[1,2], M. YE[1], G. M. PAO[1], S. M. SONG[2], J. JHANG[1], H. JIANG[2], J. KIM[1], S. J. KANG[1], S. HAN[1];

Abstract: Breathing and pain perception seem to be unrelated critical brain functions, yet they influence each other. Severe pain induces hyperventilation, whereas paced slow breathing alleviates pain perception. However, a neural circuit-based understanding of pain-breathing interaction is lacking. Here we report that *Oprm1* (μ-opioid receptor)-expressing neurons in the lateral parabrachial nucleus (PBL) are crucial for regulating breathing, pain, and their interaction. The PBL^{Oprm1} activity is tightly correlated with the breathing rhythm, and noxious stimuli simultaneously elevate both. Manipulating PBL^{Oprm1} activity collectively modulates breathing rhythm and negative affects, such as pain and anxiety. Furthermore, we find that the association of pain and breathing is mediated by two non-overlapping but reciprocally connected *Oprm1* subpopulations in the core and shell of the PBL, which diverge to the central amygdala and

medullary respiratory center, respectively. These results uncover the role of the parabrachial opioidergic pathways in regulating basal respiratory rhythm and pain-breathing interaction.

Title: Mapping CNS correlates of pain processing, opioid tolerance, and pain processing in the tolerance setting

Authors: *S. J. CHHAYA, A. I. BASBAUM;
Dept Anat., Univ. of California San Francisco, San Francisco, CA

Abstract: Tolerance to opioid analgesics is not only a clinical problem that impedes effective pain management, but it may also be a mechanism of sensitization in chronic pain. Previous studies demonstrated that long-term exposure to opioids induces a state of latent sensitization in neurons of the spinal cord and brain, which may manifest as hypersensitivity in the tolerant state and even post withdrawal. This study aims to assess alterations in the patterns of neuronal activity in opioid tolerance and after acute noxious stimulation in morphine-tolerant mice. Using a $Fos^{2A\text{-}iCreER}$ mouse line with the TdTomato Cre reporter Ai14, once stable tolerance has been established, we injected 4-hydroxytamoxifen (4-OHT) in TRAP2 (Targeted Recombination in Active Populations) mice, which then triggers activity-dependent genetic labeling of neurons throughout the brain and spinal cord. Cre-recombination induced by 4-OHT drives TdTomato expression in active cells when the immediate early gene *c-fos* is induced. Activated neurons are thus permanently TdTom+. Groups of male and female adult TRAP2:Ai14 mice were made tolerant with a subcutaneous (s.c.) implant of a 25mg morphine or placebo pellet. Acute morphine analgesia and tolerance to 10mg/kg morphine sulphate injection s.c. was measured using the tail immersion test, before and 3 days after pellet implantation. 4-OHT i.p. was injected 7 days later, so as to capture neuronal populations active in morphine-tolerant mice and pellet-implanted controls. Seven days later the mice received 2% formalin/10µl injection into the hindpaw. Ninety minutes later the mice were euthanized, and tissue processed for Td-tomato and immunoreactive Fos, which marks neurons “active” in the tolerant state and in response to the formalin in the tolerant state, respectively. Whole brain and spinal cord were immunostained and

cleared using iDISCO (Immunolabeling-enabled 3-Dimensional Imaging of Solvent-Cleared Organs) followed by quantification of TdTom+ and Fos+ cells using light-sheet and confocal imaging and ClearMap for analysis of 3D datasets. Preliminary results show unique patterns of activity in response to formalin in tolerant compared to non-tolerant mice, in several areas of the brain involved in pain modulation, notably the periaqueductal gray. Ongoing studies are also comparing the patterns of neuronal activity manifest in the opioid tolerant CNS with patterns generated in different chronic pain conditions, with the eventual goal of mapping anatomical regions and circuits that contribute to opioid- and opioid tolerance-dependent mechanisms of chronic pain development.

Title: Resolving Delta Opioid Receptor Distribution and Function in Pain Neural Circuits

Authors: *W. MCCALLUM[1], D. WANG[2], A. SHUSTER[2], D. J. BERG[2], S. LOW[2], G. SCHERRER[1,3];

Abstract: Resolving Delta Opioid Receptor Distribution and Function in Pain Neural Circuits
The delta opioid receptor (DOP) is an attractive drug target to develop novel opioid analgesics with fewer side effects, compared to mu opioid receptor (MOP) agonists such as morphine. However, the mechanisms of action of DOP and MOP within neural circuits remain poorly understood due to the lack of genetic tools to investigate the neurons that express each receptor. To address this issue, we generated knockin mouse lines in which we targeted the *Oprd1* and

Oprm1 genes that encode DOP and MOP to express the DNA recombinases Cre or Flp. Here, we describe the characterization of *Oprd1*^{Cre} mice. To identify CNS neurons with Cre activity in adult mice, we first used intracranial and spinal injections of AAV5-CAG-FLEX-GFP or intravenous (iv) injections of AAVPHP.eB-CAG-FLEX-GFP. To examine *Oprd1* expression in DRG neurons, we made iv injections of AAVPHP.S-CAG-FLEX-GFP to *Oprd1*^{Cre} mice. We also crossed *Oprd1*^{Cre} mice with Ai14 (Rosa26 LSL-tdTomato) and *Oprd1*^{GFP} mice to compare the *Oprd1* expression fate map (*Oprd1* lineage) and *Oprd1* expression pattern in the adult mouse. In the brain, we found that the Cre activity distribution pattern in *Oprd1*^{Cre} mice is consistent with the known expression pattern of DOP in wildtype mice, for example with GFP+ layer II/III and V cortical neurons, basolateral amygdala neurons, and striatal neurons. In the spinal cord, we observed GFP+ neurons throughout the grey matter, including in the ventral horn, and with a particularly high density at the ventral border of lamina II inner, confirming our recent findings (Wang et al., Neuron, 2018). In DRG, these studies revealed the remarkably dynamic expression of DOP through embryonic development, during which considerably more neuronal types express *Oprd1*, including peptidergic C nociceptors that express *Oprm1*, before DOP expression is extinguished in these cells postnatally. Thus, in the adult DRG, Cre activity is largely restricted to mechanosensory neurons, as evidenced by the presence of tdTomato+ and GFP+ large diameter DRG neurons with axons that project both to spinal laminae III-IV and to medullary cuneate and gracile nuclei through the dorsal column pathway. Collectively, our data establish and validate the utility of *Oprd1*^{Cre} mice to investigate and manipulate DOP-expressing neurons, and begin to define the temporal and spatial characteristics of *Oprd1* and *Oprm1* (co)-expression for elucidating the functional organization of the opioid system.

Abstract: Opioid analgesics are critical for acute and chronic pain management, but important side effects—including tolerance, constipation, respiratory depression, and abuse liability—limit their safety and utility. To provide patients with safer analgesic options, it is critically important to identify of new pharmacotherapeutic strategies to treat pain. Activation of μ-opioid receptors (MORs) in central and peripheral nociceptive pathways mediates opioid analgesia and their critical side effects. Antinociception can also be achieved via selective enhancement of GABAergic signaling at ionotropic GABAA receptors. α2 and α3 subunit-containing GABAA receptors (α2/α3GABAA), which are co-expressed with MORs in dorsal horn spinal pathways important to nociceptive transmission, can be selectively targeted with novel imidazodiazepine positive allosteric modulators (PAMs), such as MP-III-024, which produces antinociceptive effects with limited behavioral disruption. MP-III-024 co-administered with morphine produces synergistic antinociceptive and anti-hyperalgesic effects. In this study, we evaluated whether MP-III-024/morphine co-administration produces sub-additive or synergistic effects in behavioral tests sensitive to morphine side effects. Herein we report that co-administration of MP-III-024/morphine at a 0.94/1 ratio (synergistic in models of antinociception) produced sub-additive effects in morphine-induced hyperlocomotion and in measures of behavioral disruption in food-maintained operant responding. Ongoing studies are evaluating the effects of MP-III-024/morphine co-administration on tolerance in the hot plate test and in conditioned place preference. These experiments are the first comprehensive preclinical analyses of a dual MOR-α2/α3GABAA pharmacotherapy strategy which may increase the therapeutic window between desirable opioid analgesic effects and side effects.

Title: Sex Differences in Vapor Fentanyl Self-administration Outcomes in Mice With Chronic Neuropathic Pain

Authors: *M. CENTENO[1], R. JABAKHANJI[2], J. M. COX[4], D. SURMEIER[5], A. V. APKARIAN[3];
[1]Northwestern Univ., Chicago, IL; [2]Dept. of Physiol., [3]Northwestern Univ. Feinberg Sch. of Med., Chicago, IL; [4]Physiol., Northwestern university, Chicago, IL; [5]Prof. Dept. Physiology/ NUIN, Northwestern Univ. Dept. of Physiol., Chicago, IL

Abstract: Due to technical difficulties, we have little knowledge regarding the interaction between opioid
dependence and opioid induced pain relief in rodent models of chronic pain. A knowledge gap that
critically impacts on mechanistic studies which would importantly impact on clinical decisions regarding the current opiate epidemic. Here, following methods described by Moussawi et al. 2021,
we constructed a noninvasive mouse self-administration using fentanyl vaping. With this set-up we
could study neuropathic mice regarding pain and opioid consumption (reinforcement, extinction, reinstatement, motivation) over multiple months.
Mice (n=20), 50% female, were operated for spared nerve injury (SNI, 50%) or sham. Three months
later they were exposed to self-administered fentanyl vapor. Initial dose of fentanyl was 5.0 mg/ml, which was decreased to 2.5 mg/ml in later sessions. Daily (2 hour), fixed ratio (FR1,5,10, 5
days/FR) was followed with extinction, reinstatement, and progressive ratio regiments. The procedure was repeated for the lower dose fentanyl. Active and inactive nosepokes (AN, IN), and
vape puff numbers (reward) were monitored. We also quantified constipation by counting poops/vaping
exposure. Tactile allodynia was also monitored once/week, at the termination of a FR sequence.
Mice learned to discriminate AN from IN with first exposure and maintained constant rate of reward
consumption across increasing FRs. They exhibited signs of dependence: high rates of AN during
reinstatement, in early phase during extinction, and high motivation by completing most PR episodes. Main group difference was in female SNI who showed lowest AN across varying FRs and
lowest discrimination ratio (AN-IN)/AN+IN) (2-way ANOVAs, significant interaction by sex and type
of injury, $p<0.05$). Unexpectedly, we also observed that fentanyl vaping induced, besides hyperalgesia on the uninjured paw, complete reversal of tactile allodynia for the SNI paw which persisted for more than a week and was more prominent in female SNI. Constipation was less in

males throughout extinction, indicating higher stress with fentanyl abstinence (2-way ANOVA, significant interaction by sex and type of injury, $p<0.05$).
Fentanyl vaping provides an ideal environment to study opiate exposure in chronic pain. Our results
challenge current concepts and suggest important sex dependence of opiate addiction and opiate pain
relief in chronic pain.

Title: Adenylyl cyclase 1 involvement in chronic pain and morphine tolerance in mice

Authors: A. DOUCETTE[1], K. JOHNSON[1], A. EDWARDS[1], A. VERDI[1], R. MCFARLAND[1], V. J. WATTS[2], ***A. KLEIN**[1];
[1]Univ. of Minnesota, Duluth, MN; [2]MCMP, Pudue Univ., W Lafayette, IN

Abstract: Chronic opioid use for pain management leads to tolerance and dosage escalation, potentially increasing substance dependence. Upregulation of adenylyl cyclase activity has been previously implicated in opioid tolerance and opioid induced hyperalgesia and chronic pain. The objective of this study was to examine the potential adenylyl cyclase isoforms involved in these processes in the peripheral and central nervous system. We also tested the hypothesis that a reduction in adenylyl cyclase 1 (AC1) activity would attenuate morphine tolerance and hypersensitivity, and inflammatory pain using murine models. Mice were subjected to twice daily treatments of saline, 15 mg/kg morphine, for 5 days. dorsal root ganglia (DRG) and spinal cord (SC) were collected from mice in each treatment group for Quantitative PCR. mRNA expression of adenylyl cyclase (*Adcy*) 1, 2, 3, 5, 6, 8; Epac 1 (*Rapgef 3*) and Epac 2 (*Rapgef 4*); and PKA subunits A and B (*Prkaca and Prkacb*) were compared to vehicle controls. Morphine tolerance (15mg/kg, sc, 5 days and 10-40mg/kg escalation over 4 days) and opioid-induced hypersenstivity were assessed after intrathecal administration of an AAV9 viral vector encoding a *s*hort-hairpin RNA (shRNA) of *Adcy1* (AAV9-GFP-U6-m-Adcy1-shRNA) and compared to viral controls (AAV9-GFP-U6-m-scrambl-shRNA). Behavioral testing such as open field testing,

rotarod testing, burrowing, thermal and mechanical paw withdrawal latencies were also tested after injection. Systemic administration of an AC1 inhibitor, ST 034307 was also tested during chronic morphine administration. Morphine induced hypersensitivity was attenuated after Adcy1 shRNA or pharmaceutical inhibition of AC1. Loss of Adcy1 activity decreases morphine tolerance and opioid-induced hypersensitivity, which could form the basis for novel therapeutics in the future.

Title: Inhibition of Spinal Cord Hsp90 Enhances Src Kinase and Protein Kinase C signaling to Increase Opioid Anti-Nociception

Authors: *J. BOWDEN[1,2], J. STREICHER[1];
[1]Univ. of Arizona, Tucson, AZ; [2]Inst. of Publ. Hlth., United States Army Vet. Corps, Aberdeen Proving Ground, MD

Abstract: Chronic pain remains a huge social and economic burden in the world. With few safe treatment options, many physicians turn to opioid analgesics. These medications are not without serious side effects including respiratory depression and addiction. Ultimately this has led to an opioid addiction crisis, emphasizing the need to find new ways to improve opioid therapy and decrease side effects. One such research area is the signal transduction cascades evoked by opioid receptor activation, which could be modulated to enhance pain management while decreasing side effects. Previously, our lab discovered that the molecular chaperone protein Heat shock protein 90 (Hsp90) plays a key role in mu opioid receptor signal transduction. When inhibiting Hsp90 in the spinal cord through intrathecal (IT) administration of 17-N-allylamino-17-demethoxygeldanamycin (17-AAG) in mice we observed a significant increase in morphine anti-nociception, which could enable an opioid dose-reduction strategy. Two targets, Src Kinase and Protein Kinase C were hypothesized to be upregulated by 17-AAG treatment. CD-1 mice were treated with 0.5 nmol 17-AAG or vehicle IT. After 24 hours, mice were treated with 10 nmol of the Src kinase inhibitor Src-I1 or vehicle IT, followed by 3.2 mg/kg morphine and a tail

flick assay was performed. This was repeated using 1 nmol of the PKC inhibitor GO6983. The enhanced anti-nociceptive effects seen with 17-AAG were completely abolished in the inhibitor groups, suggesting that Hsp90 inhibition enhances Src and PKC signaling to lead to enhanced opioid pain relief. Interestingly, the group that did not receive 17-AAG but did receive Src-I1 also showed a decrease in the anti-nociceptive effects of morphine, suggesting a role for Src in the opioid receptor pathway at baseline. A post-surgical paw incision pain model showed similar results. The PKC activator phorbol myristate acetate (PMA) at a 0.1 nmol dose produced a drastic increase in antinociception. Initial analysis by Western blot shows the two signaling kinases to be upregulated by 17-AAG treatment and suggests a pathway that includes ERK downstream of both. Analysis via immunohistochemistry of mice treated with 17-AAG and the potent mu agonist DAMGO showed significant increases in Src and PKC phosphorylation. Initial co-staining suggests that Src may be upregulated in different cells depending on treatment. CRISPR knockdown of the Src Kinase also blocked enhanced antinociception in tail flick behavior. These findings have helped elucidate two key molecular mechanisms by which Hsp90 regulates opioid signaling and enhances opioid antinociception, creating potential targets to improve opioid treatment.

Title: Anatomical tracing of cerebello-thalamo-cortico-striatal connections

Authors: *J. HENNESSEY[1], C. CHEN[2], I. A. SAVTCHOUK[1];
[1]Biomed. Sci., [2]Neurosci., Marquette Univ., Milwaukee, WI

Abstract: The cerebellum is crucial for the execution of complex and fine motor behavior, and damage to the cerebellum can lead to severe motor deficits. Perhaps unexpectedly, the cerebellum also has important non-motor-related functions, including contributions to higher cognition and emotional regulation. Damage to the cerebellum in humans can result in Schmahmann Syndrome (Cerebellar Cognitive Affective Syndrome), deficits in social interactions, linguistic processing, executive function, and reward processing, and obsessive-compulsive disorders. It has even been suggested that cerebellar abnormalities are fundamental

to the development of autism spectrum disorders. Although it is of broad clinical and scientific interest to understand the contributions of the cerebellum to non-motor cognitive function, pre-clinical animal models appropriate for studying non-motor aspects of the cerebellar function are rare.The cerebellum is known to be extensively connected to the cerebral cortex via thalamic and pontine nuclei. Various regions of motor and non-motor cerebral cortex send information to the cerebellum, the cerebellum performs computations, and the cerebellum in turn projects disynaptically back to the same regions of cortex, forming a closed loop of information processing. Recent anatomical studies indicate cerebellar interconnection with the cortical-basal ganglia-thalamus loops. While the exact connectivity is not precisely known, motor and non-motor thalamic regions are involved: MD, VA, VL, VM, anterior intralaminar nuclei and centromedial/parafascicular nuclei. It is hypothesized some of these cortical-striatal-cerebellar loops are essential to not only motor cerebellar function, but also to higher-order functions like cognition, emotion, and reward anticipation.To better describe these subcortical connections, we performed anatomical tracing of projections from the deep cerebellar nuclei (DCN) of the cerebellum to motor and non-motor thalamic regions. This is achieved through unilateral stereotaxic injections of an adeno-associated viruses into the DCN of adult female mice, causing an expression of fluorescent markers in infected neurons. Similarly, we used retrograde AAV injections to the thalamus to back-label the DCN efferents. Neuronal connections to thalamic nuclei were subsequently reconstructed via two-photon imaging of 350 µm slices. Projections from the interposed nucleus were of particular interest, as this set of nuclei has previously been shown to be involved in cognitive functions relating to habit formation.

Title: Requirement of the Cerebellum-Thalamo and Cerebellum-Thalamo-Striatal projection on the execution of a simple or complex trajectory movement

Authors: *R. D. CONTRERAS-LÓPEZ, E. DÍAZ-HERNÁNDEZ, J. O. RAMÍREZ-JARQUÍN, F. TECUAPETLA;
Inst. de Fisiologia Celular, Mexico, City, Mexico

Abstract: The cerebellum and basal ganglia are implicated in motor control through parallel circuits and recently, through subcortical cerebellar-thalamo-striatal (Cb-Th-Str) communication, although this last scarcely explored. This study aimed to characterize the communication properties of the Cb-Th-Str and its role in motor control. For this purpose, we mapped the thalamic nuclei that project to the dorsal striatum and receives synaptic projections from the cerebellum. We observed that the cerebellum communicates with the dorsal striatum through ventral and intralaminar nuclei. Whole-cell recording showed a high probability (80%) of Cb-Th-Str connection, with no difference in synaptic properties between dorsal lateral (DLS) and dorsal medial (DMS) striatum. Interestingly, when performing whole-cell recordings on CB-Th-DLS projections, which were located in ventral lateral (VL), ventral medial (VM), central medial (CM), central lateral (CL), and parafascicular (Pf) nuclei, our results revealed that the PF was the principal relay for cerebellar projections to DLS. Next, to evaluate the contribution of these communications on motor control, mice were trained to execute a simple trajectory movement (reaching 8 mm), followed by a complex trajectory movement (reaching >4 mm and returning to the start position). Then, we conducted optogenetic silencing of cerebellar-thalamic synapses in the relay nuclei of the thalamus (VL, CL, and Pf) or in the di-synaptic communication (Cb-Th-DLS). In the simple trajectory movement, Cb-VL silencing resulted in longer displacement during the reaching movement, while CL silencing increased movement velocity. Interestingly, Cb-Th-DLS silencing showed no effects. To contrast the di-synaptic Cb-Th-DLS role in the acquisition and late training of a complex trajectory movement, we conducted optogenetic silencing of the aforementioned synapses during the first three days of acquisition of the complex trajectory movement and late in training. The silencing of Cb-Th-DLS communication early and late in the acquisition of the complex trajectory impaired the performance, inducing longer displacements in the reaching movement and incomplete trajectories in the returning movement. Our results suggest that the cerebellum establishes significant disynaptic connections with the striatum through thalamic nuclei. We suggest that the Cb-Th-DLS connection may not be required during the execution of a simple trajectory movement, but it has an important role during the early and late phase of the acquisition of a complex trajectory movement, likely due to the seriation of the movements in the complex trajectory demanded.

Title: Motor and reward-related signaling in the cerebellar-nigral-striatal pathway

Authors: *J. YOSHIDA[1], M. OÑATE[1], V. LOVALLO[1], L. KHATAMI[1], S. G. KEE[1], Y. ISOMURA[2], F. NADIM[3], K. KHODAKHAH[1];

Abstract: The basal ganglia play a central role in voluntary movement and reward-dependent learning. The dopaminergic projections from the substantia nigra pars compacta (SNc) to the dorsal striatum (DS) are an essential pathway in these processes. The cerebellum also contributes to motor control and motor learning, but has been historically considered to work independently of the basal ganglia. We have recently found that the deep cerebellar nuclei (DCN, the main output of the cerebellum), send monosynaptic excitatory projections to the SNc. Additionally, optogenetic stimulation of the DCN-SNc projections induced dopamine release in the striatum, indicating that this pathway could contribute to the basal ganglia function. To understand the functional nature of this connection, using calcium signals as a proxy for neural activity, we recorded this pathway during simple behaviors. Fiber photometry recordings showed that the DCN-SNc projections were activated when the animal initiated a movement such as moving a lever. The DCN-SNc activity was bilateral even with unilateral (e.g. lever) movement. Thus, the DCN-SNc projections have bilateral motor-associated activity. We then used a Pavlovian learning task to examine the DCN-SNc activity in response to randomly-assigned rewards of different quantity and quality. These data indicated that the DCN-SNc activity also has a reward-associated component that is larger with higher reward value. Simultaneous recordings of the DCN-SNc projections and the SNc-DS dopaminergic projections showed a correlation between the activities of both pathways with reward value. However, the SNc-DS dopaminergic population activity was similar in shape to the derivative of the activity of the DCN-SNc pathway, indicating that the dopaminergic neurons may be sensitive to the change in the rate of input from the cerebellum to the SNc. These findings suggest a potentially important role for the cerebellum in how SNc dopaminergic neurons process movement and reward-related learning.

Title: Mid-lateral cerebellar complex spikes encode multiple independent reward-related signals during reinforcement learning

Authors: *N. SENDHILNATHAN[1], A. E. IPATA[1], M. E. GOLDBERG[2];
[1]Columbia Univ., New York, NY; [2]Columbia Univ., NEW YORK, NY

Abstract: Although the cerebellum has been implicated in simple reward-based learning recently, the role of complex spikes (CS) and simple spikes (SS), their interaction and their relationship to complex reinforcement learning and decision making is still unclear. Here we show that in a context where a monkey learned to make novel visuomotor associations, classifying CS responses based on their SS properties revealed distinct cell-type specific encoding of the probability of failure after the stimulus onset and the monkey's decision. In a different context, CS from the same cerebellar area also responded in a cell-type and learning independent manner to the stimulus that signaled the beginning of the trial. Both types of CS signals were independent of changes in any motor kinematics and were unlikely to instruct the concurrent SS activity through an error based mechanism, suggesting the presence of context dependent, flexible, multiple independent channels of neural encoding by CS and SS. This diversity in neural information encoding in the mid-lateral cerebellum, depending on the context and learning state, is well suited to promote exploration and acquisition of wide range of cognitive behaviors that entail flexible stimulus-action-reward relationships but not necessarily motor learning.

Title: Direct Purkinje cell connections onto parabrachial neurons allow the cerebellum to influence multiple forebrain regions and bidirectionally control reward

Authors: *C. CHEN, L. NEWMAN, A. STARK, K. BOND, W. REGEHR;
Harvard Med. Sch., Boston, MA

Abstract: In addition to its well-known contributions to motor control and motor learning, the cerebellum is involved in executive function, emotional regulation, anxiety, and language. Here we investigate how the cerebellum could regulate these processes. We find that suppressing

cerebellar Purkinje cell (PC) firing excites regions implicated in such functions, including the amygdala, the basal forebrain, and the septum. Retrograde tracing experiments revealed that the classic cerebellar outputs from the deep cerebellar nuclei (DCN) do not project to these regions, but that the parabrachial nucleus (PBN) does. We find that PCs directly and tonically inhibit neurons in the PBN, and that suppressing PC firing elevates PBN activity. Using selective suppression of ongoing PC to PBN inhibition, c-Fos labelling, and trans-synaptic tracing we show that PCs inhibit PBN neurons that project to widely to many forebrain regions. We find that suppressing PC-PBN is aversive, in contrast to the well-established rewarding PC-DCN pathway. We conclude that the PC to PBN pathway is an important but underappreciated output pathway that could allow the cerebellum to influence many nonmotor behaviors.

Title: Developmental contribution of dentate nuclei in flexible cognitive behavior

Authors: *T. LYLE, S. SHIPLEY, J. ESPINOZA, J. VERPEUT;
Psychology, Arizona State Univ., Tempe, AZ

Abstract: While the neocortex is predominantly studied for autism pathology, recent evidence has identified decreased connectivity between deep cerebellar nuclei (DCN) and distal cortical regions (e.g., frontal, parietal) associated with theory of mind networks. For clinical interventions to attenuate higher-order (e.g., flexible cognitive behavior) deficits found in autism, additional research identifying neural structure function and influence on neuronal circuits during development is required. Unfortunately, little research has studied the relation between aberrant DCN circuity and cognitive behavior. We have hypothesized that typical maturation of the cerebello-neocortical circuit is required to relay input into distal neocortical regions for cognitive behaviors.
Previously, manipulation of Purkinje cells using chemogenetics, Designer Receptors Exclusively Activated by Designer Drugs (DREADDs) has elucidated cerebellar influence on cognitive behavior. Specifically, bilateral inhibition of crus I Purkinje cells (PC) has been shown to impair choice accuracy during an evidence-accumulation decision task and reversal ability in a water Y-maze task. The cerebellum may influence cognition through bidirectional loops between

cognitive regions (e.g., prelimbic and infralimbic cortex) and cerebellar crus I/II, which have been traced using neurotropic viruses. To further this data, we seek to understand the cerebello-thalamo-cortical circuit by analyzing the influence of dentate nuclei during flexible cognitive behavior.
Our objective is to analyze DCN influence on flexible cognitive behavior and neural structure in juvenile mice. PCs project to distal forebrain regions through the DCN, which form dense perineuronal nets at the end of critical periods, suggesting a possible influential neural circuit in early life. To investigate associative functions of crus I projecting PCs to the dentate nucleus, we will use the Gi-coupled hM4Di retro-DREADD (rAAV2-hSyn-DIO-hm4Di(Gi)-mCherry) to drive expression in PC specific, Pcp2 cre mice. Animals will have access to the DREADD ligand clozapine-N-oxide (CNO; 10 mg/kg) in drinking water from postnatal day 21-35. Resulting cognitive behavior will be analyzed using a touch screen pairwise visual discrimination task. Flexible cognition will be tested by reversing the correct stimuli. Post-sacrifice, neural structure in neocortical regions receiving input from the dentate nucleus will be analyzed for dendritic complexity, spine density, and maturation. Using this paradigm, we seek to identify dentate nuclei influence on distal neocortical circuits and flexible cognitive behavior.

Title: Social memory deficit gated by dysregulation of the cerebellar vermis

Authors: O. CHAO[1], S. PATHAK[1], H. ZHANG[1], G. J. AUGUSTINE[2], J. M. CHRISTIE[3], H. TANIGUCHI[4], ***Y.-M. YANG**[1];

Abstract: Social recognition memory is a key determinant of social behavior. It integrates cognition into social interaction to distinguish between familiar and novel conspecifics. The cerebellum emerges as an important contributor to social functions. For example, reduced activity of Purkinje cells (PCs), in part due to over-inhibition from molecular layer interneurons (MLIs), is a common cerebellar phenotype in various mouse models of autism. Yet, how the cerebellum transforms the abnormal local activity to the global deficit in social behavior remains elusive. To this end, we selectively increase the excitability of MLIs to suppress PC firing with

chemo- and optogenetic approaches in the central vermis of the mouse cerebellum. The chemogenetic perturbation impairs animals' social recognition memory without affecting their sociability, anxiety, motor coordination or object recognition. The optogenetic interference during distinct phases of the social recognition test highlights the cerebellar engagement in the retrieval, but not encoding, of social information. Functional mapping with an immediate early gene product (c-Fos) following the social recognition test reveals a significant reduction in the interregional correlations and a network shift from medial prefrontal cortex (mPFC) and hippocampus-centered to amygdala-centered modules by the chemogenetic manipulation. The social recognition task-induced expression of phosphorylated TrkB receptor for brain-derived neurotrophic factor (BDNF) in the mPFC and hippocampus is inhibited by the optogenetic stimulation, indicating a potential role of BDNF signaling in the brain network shift. Transsynaptic neuronal tracing illustrates hierarchical projections from the central cerebellum to the sub/cortical structures. Collectively, our results suggest that the cerebellum organizes the neural matrix required for social memory.

Title: Effects of rodent optogenetic theta burst stimulation of the lateral cerebellar nucleus on prelimbic cortex physiology

Authors: *P. ABBOTT[1], K. L. PARKER[2];
[2]Dept. of Psychiatry, [1]Univ. of Iowa, Iowa City, IA

Abstract: Evidence continues to accumulate suggesting the cerebellum’s involvement in non-motor processing. Through wide-reaching polysynaptic connections the cerebellum can influence regions of the cerebral cortex that are involved in cognitive processes. Because of this, the cerebellum is being studied as a therapeutic node for treating cognitive dysfunction in disorders such as schizophrenia, autism spectrum disorder, and major depression. Intermittent theta burst stimulation (iTBS) in particular has been delivered to the cerebellum of healthy and psychiatric patients to influence cognitive functioning. One brain region known to be involved in cognition that is likely manipulated by cerebellar stimulation is the medial frontal cortex (MFC). Literature has shown that evoked cerebellar activity can produce observable changes in the rodent prelimbic cortex (PrL), a subregion of the MFC, across a range of physiological measures including electrophysiology and neurotransmitter detection. However, little is known about

plasticity effects in the PrL after theta burst stimulation of the cerebellum. In this ongoing work, the lateral cerebellar nucleus (LCN) of rats is stimulated using optogenetic theta burst stimulation to focus on measures of electrophysiology and dendritic properties. Multi-site local field potential (LFP) recordings were performed in the rat brain during theta burst stimulation, with an optrode placed in the LCN for simultaneous recording and stimulation. After 10 sessions of intermittent theta burst stimulation, brains were collected for dendritic spine analysis in the prelimbic cortex. It is hypothesized that LCN stimulation will result in changes to both LCN and PrL LFP dynamics and lead to altered quantities and morphological qualities of dendritic spines in the PrL. Results are pending and will have important implications for the administration of cerebellar theta burst stimulation in the clinic as a treatment of brain disorders that present with frontal cortical dysfunction. Knowledge of the mechanisms of plasticity underlying brain stimulation remains an important research avenue in order to deliver the most optimal symptom-focused treatment of brain disorders.

Title: The role of Nurr1 in the circadian fluctuations in the number of tyrosine hydroxylase expressing midbrain dopamine neurons

Authors: *J. B. EELLS, H. S. PARTINGTON, J. M. TRUE;
Anat. & Cell Biol., East Carolina Univ. Sch. of Med., Greenville, NC

Abstract: Alterations in dopamine neurotransmission from midbrain dopamine neurons contribute to symptoms of addiction, depression, schizophrenia, and Parkinson's disease. All of these diseases have a strong circadian component and previous data has also observed fluctuations in dopamine neurotransmission across the circadian cycle, including the number of neurons actively expressing tyrosine hydroxylase (TH). The current study investigated how deficits in Nurr1, an essential transcription factor for expression of the dopamine phenotype and expression of TH during development, affect the circadian fluctuations in TH expression. Additionally, we describe a transgenic mouse model with Cre recombinase expression under control of dopamine transporter (DAT) and yellow fluorescent protein (YFP) Cre reporter which, when combined with immunofluorescence, can be used to differentiate between "current" DA neurons (TH^{+}/ YFP^{+}) and "former" dopamine neurons (TH^{neg}/YFP^{+}). The Nurr1 wild-type (+/+) mice showed circadian cycling of dopamine neuron numbers, with a significantly greater number (~2-fold increase) of dopamine neurons in both the substantia nigra pars compacta and ventral

tegmental area at circadian time (CT) 0 (when lights come on) than CT12 (lights go out). In contrast, the Nurr1-null heterozygous (+/-) mice did not show a circadian cycling of the dopamine phenotype, as no differences in the numbers dopamine neurons were observed between CT0 and CT12. Additionally, the +/- mice had significantly fewer dopamine neurons at CT0 but not at CT12 as compared to +/+ mice. Using the DAT cre/YFP reporter mice, we found, at birth, ~95% of all YFP^+ neurons were TH^+. Comparisons, at CT0 and CT12 across development, found no difference at 21 days of age (CT0: 88.07 ± 1.95% and ZT12: 86.79% ± 7.75%), but a significant difference at 35 days (CT0: 89.36 ± 0.25% and ZT12: 75.0 ± 5.26%) and 60 days of age (CT0: 87.15 ± 4.1% and CT12: 75.08 ± 3.70%). These data demonstrate the capability of visualizing "current" and "former" dopamine neurons and show an essential role for Nurr1 in regulating the number of "current" dopamine neurons across the circadian cycle. Since aging, stress, toxins, and inflammation can reduce Nurr1 expression, these perturbations could have a similar effect on the circadian cycling of the dopamine phenotype and potentially contribute to neurologic and neuropsychiatric symptoms associated with dopamine neurotransmission.

Title: Nigral GPR55 receptors stimulate motor behavior through modulation of GABA release.

Authors: J. AVALOS-FUENTES[1], F. PAZ-BERMÚDEZ[1], *B. FLORAN[2];
[1]Ctr. de Investigación y de Estudios Avanzados del IPN, MEXICO, Mexico; [2]Ctr. de Investigación y de Estudios Avanzados del IPN, Mexico DF, Mexico

Abstract: Previously we reported that orphan GPR55 receptors stimulate [^{3}H]-GABA release at striato-nigral terminals. Here we study if intra-nigral activation of GPR55 with their endogenous agonist lysophosphatidylinositol (LPI) stimulates motor behavior through stimulation of GABA release and activation of GABA A postsynaptic receptors. LPI (20 µM) induced contralateral turning when intra-nigrally injected. The gradual increase has a maximum of 8±1 turns/min at 10 min after injection. A previous ten min injection of CID 16020046 (10 µM), a GPR55 antagonist, prevents turning induced by LPI. To test if the effect of LPI was mediated by indirect activation of presynaptic striato-nigral D1 receptors, we blockade them by previously injecting the D1 antagonist SCH 23390 (1µM), which itself did not induce turning either did not modify LPI induced circling remaining at 10 min at 8±2 turns/min. Finally, to test if the effect of LPI was mediated by modulation of GABA release, we blockade GABA A postsynaptic receptors by

intranigral injection of bicuculline (15 µgrs/µl). Bicuculline does not modify motor behavior; however, it prevents almost totally turning elicited by LPI. These data indicate that stimulation of nigral presynaptic GPR55 receptors stimulates motor behavior through modulation of GABA release.

Title: Striatal acetylcholine and dopamine fluctuations maintain a constant temporal relationship in vivo

Authors: *A. C. KROK[1], P. MISTRY[1], Y. LI[2], N. X. TRITSCH[1];
[1]Neurosci. Inst., New York Univ. Sch. of Med., New York, NY; [2]State Key Lab. of Membrane Biol., Peking Univ. Sch. of Life Sci., Beijing, China

Abstract: It is widely believed that there exists a steady state, basal tone of neuromodulators like acetylcholine (ACh) and dopamine (DA) that is periodically interrupted by phasic increases or decreases signaling salient events that need to be attended to, acted on or learned from. Here we employ a combination of techniques to simultaneously monitor cholinergic interneuron activity in vivo, as well as ACh and DA levels with dual color fiber photometry. We show that extracellular ACh levels in the dorsal striatum of mice constantly undergo large fluctuations several times a second, even during quiet wakefulness. We show that these fluctuations are driven by coordinated spiking of cholinergic interneurons. These fluctuations grow larger in amplitude during movement, in phase with acceleration, and are comparable in time course and magnitude to phasic ACh responses typically associated with reward. Importantly, these ACh fluctuations maintain a specific temporal relationship to striatal DA levels across behavioral contexts. These findings question the existence of a basal tone for ACh and DA, and suggest that phasic increases and decreases in ACh and DA are not uniquely associated with reward and salient behavioral events. Rather, our data indicate that striatal DA and ACh signaling is consistently and intrinsically structured, forcing a reconsideration of our understanding of modulation of neural activity and behavior by ACh and DA.

Title: Acute dopamine modulation of PKA in the dorsal striatum during locomotion

Authors: *L. MA[1], O. P. JAIDAR[2], J. B. DING[3], T. MAO[4], H. ZHONG[5];
[1]Oregon Hlth. & Sci. Univ., portland, OR; [2]Stanford Univ. Sch. of Medicine,, Palo Alto, CA; [3]Neurosurg., Stanford Univ. Dept. of Neurosurg., Palo Alto, CA; [4]Vollum Institute/Oregon Hlth. & Sci. Univ., Portland, OR; [5]Vollum Institute, L474, Portland, OR

Abstract: Acute dopamine modulation of PKA in the dorsal striatum during locomotion
Lei Ma[1], Omar Pedro Jaidar Benavides[2], Jun Ding[2], Tianyi Mao[1], and Haining Zhong[1,*]1. Vollum Institute, Oregon Health & Science University, Portland, Oregon, 972392. Department of Neurosurgery and Department of Neurology and Neurological Sciences, Stanford University School of Medicine, Palo Alto, CA, 94305
Dopaminergic inputs to the dorsal striatum play essential roles for locomotion. The effects of dopamine are thought to be mediated by its modulation of medium spiny neuron (MSN) excitability through pathways that involve cAMP/protein kinase A (PKA). However, little is known about the dynamics of PKA signaling in MSNs following dopamine activation *in vivo*. The precise contribution of PKA to dopamine related physiological functions also remains to be determined.
These questions have not been addressed in part due to the lack of effective techniques to monitor real-time PKA activity in neuronal populations in behaving mice. By combining an optimized genetically-encoded PKA sensor, tAKARα, with two-photon fluorescence lifetime imaging microscopy (2pFLIM), we have recently established PKA activity imaging with single-cell resolution in the cortex of head-fixed behaving mice. By performing 2pFLIM imaging of tAKARα via a gradient-index (GRIN) lens, we now extend such PKA imaging capability to the striatum, and have successfully observed PKA activity in striatal neurons at subcellular resolutions in defined neuronal types during locomotion.
To determine how dopamine modulates PKA activity in MSNs in the direct and indirect pathways (dMSNs and iMSNs, respectively), we performed PKA imaging in these neuronal types in response to optogenetic stimulation of dopaminergic axons in the dorsal striatum. We found that optogenetic release of dopamine in the dorsal striatum leads to cell type-specific dopamine responses. Our ongoing work will further assess whether PKA activity is regulated by

locomotion and aim to provide mechanistic understanding of how PKA activity affects neuronal functions and animal behavioral outcomes.

Title: Synaptic mechanisms underlying the regulation of striatal excitability by the neuronal glutamate transporter EAAC1

Authors: *M. A. PETROCCIONE, L. D'BRANT, N. AFFINNIH, H. CHESBRO, S. ZAHID, A. SCIMEMI;
Biol., Univ. At Albany - SUNY, Albany, NY

Abstract: Non-functional mutations of the gene encoding the neuronal glutamate transporter EAAT3 (EAAC1 in mice) are associated with obsessive compulsive disorder (OCD). This neuropsychiatric disorder is associated with hyperactivity in the striatum, which is one of the brain regions where EAAC1 is most abundantly expressed. While EAAC1 is expressed at both glutamatergic and GABAergic synapses in other brain regions, the role of EAAC1 at striatal synapses is still poorly understood. Our lab has previously shown that EAAC1 increases the expression of D1-dopamine receptors in striatal medium spiny neurons (MSNs) by limiting the activation of group I metabotropic glutamate receptors (mGluRI). By doing so, it limits the execution of stereotyped grooming behaviors. Here, we show that EAAC1 limits dendritic length, spine diameter and synaptic inhibition only in D1-MSNs. The frequency and amplitude of miniature EPSCs are increased in D1-MSNs of $EAAC1^{-/-}$ mice, as is the quantal size of GABAergic miniature IPSCs. By using optogenetics, we show that only a subset of inhibitory synapses are responsible for these effects. NEURON compartmental models show that these effects allow EAAC1 to reduce the offset and gain of the firing output of D1-MSNs. Together, these findings highlight the importance of EAAC1 in controlling synaptic transmission in the striatum, with potential long-range implications for understanding the synaptic and circuit basis of OCD.

Title: VMAT2 availability in Parkinson's disease with rapid eye movement sleep behaviour disorder

Authors: *M. VALLI[1,2], S. CHO[1,4], C. URIBE[1], M. MASELLIS[5], R. CHEN[6], A. MIHAESCU[3], A. STRAFELLA[1];

Abstract: Objective: To use [^{11}C]DTBZ PET imaging to explore vesicular monoamine transporter 2 (VMAT2) availability in Parkinson's disease (PD) with and without rapid eye movement sleep behaviour disorder (RBD). **Background:** RBD is a condition marked by the lack of normal skeletal muscle atonia during REM sleep, resulting in dream enacting behaviours. RBD is one of the strong prodromal clinical predictors of PD. Molecular imaging evidence shows that PD with RBD (PD-RBD+) show lower dopamine transporter activity within the caudate and putamen compared to PD without RBD (PD-RBD-). However, the characterization of the VMAT2, an index of nigrostriatal dopamine innervation, has been rarely explored in PD patients with RBD. **Design/Methods:** We enrolled 15 PD-RBD+, 15 PD-RBD- and 15 age matched healthy controls (HC) for the [^{11}C]DTBZ PET imaging study. This technique measures VMAT2 availability within striatal regions of interest (ROI). Mixed effect model was used to compare the radioligand binding of VMAT2 between the three groups for each striatal ROI, while co-varying for sex, cognitive and depression scores. The fixed factors in this model were group and ROI hemisphere (i.e., left vs. right ROI), while participants were kept as a random factor. Significant level was set at $p<0.05$ (Bonferroni corrected). **Results:** Significant main effect was observed within the caudate, putamen, ventral striatum, external globus pallidus, internal globus pallidus, and substantia nigra. Specifically, we observed that both PD-RBD+ and PD-RBD- group had lower VMAT2 availability compared to HC. **Conclusions:** Our findings reveal that both PD patient subgroups have lower VMAT2 availability relative to HC—which reflects denervation within the nigrostriatal pathway. There is limited indication that VMAT2 contributes differently to PD patients with RBD relative to PD patients without RBD. Future studies are encouraged to explore other underlying neural mechanisms contributing to RBD in PD patients.

Abstract: The cerebellum's theoretical role in cognitive processes such as language is based on indirect evidence of deficits in patients with cerebellar damage or non-invasive stimulation studies. Here, we present electrophysiological activity recorded from the scalp and cerebellar dentate nucleus (DN) during a semantic priming task. Recordings were obtained in eight patients (mean age 58 ± 8.2; 6 males) enrolled in a clinical trial of DN Deep Brain Stimulation (DBS) to treat upper extremity motor impairments following middle cerebral artery stroke (3 left hemisphere, 5 right hemisphere). Patients viewed 3 to 6 blocks of 100 serially-presented prime-probe pairs in a low-expectancy condition (19% related prime-probe words) followed by a high expectancy condition (73% related prime-probe words). Continuous activity was recorded from 36 scalp electrodes and 8 DBS contacts embedded in the contra-lesional DN. Event-related potentials time locked to onset of the probe word showed the classic N400 component at central-parietal sites that was larger for unrelated pairs relative to related pairs, indicative of greater semantic processing requirements for unprimed words. Time frequency analysis demonstrated increased gamma power (35-45hz) in the same time window after onset of related compared to unrelated probes, consistent with prior studies in neurologically normal adults. Coherence between DN and the contralateral parietal region following onset of related and unrelated probe words was evident in both the high and low expectancy conditions in the 8-15 Hz range. In contrast, coherence between DN and ipsilateral frontal regions in most patients was more specific to unrelated probes in the high expectancy condition during the early semantic processing window of 200-400ms post-onset. This may represent cross-network mismatch between semantic content and predictive models generated by the cerebellum. To our knowledge, these data represent the first evidence of cognitive task-related activity recorded directly from the human cerebellum.

Coherence between left DN and Scalp in High expectancy condition from one subject. Coherence between DN and ipsilateral Frontal areas evident during Unrelated probe.

Title: Amplitude modulated high-frequency stimulation elicits asynchronous axonal spiking activity

Authors: *B. BARRA[1], R. KUMAR[2], C. GOPINATH[1], R. GAUNT[1], M. CAPOGROSSO[1], L. E. FISHER[1];

Abstract: Regaining sensory feedback is a priority for people with limb amputation, and electrical stimulation of the peripheral nerves can reproduce sensory percepts that feel like they emanate from the prosthetic limb. However, subjects often describe these sensations as unnatural. Traditional electrical stimulation paradigms activate neural structures using charge-balanced rectangular pulses at frequencies lower than 100 Hz. This simplistic approach elicits synchronous responses in all recruited fibers. It has recently been hypothesized that unnatural synchronicity in peripheral neural activity is responsible for several negative effects of electrical stimulation, such as the production of unnatural sensory percepts in amputees (e.g., tingling), and muscle fatigue during functional electrical stimulation in people with spinal cord injury or stroke. Here, we propose a non-conventional stimulation paradigm that consists of an amplitude-modulated, high-frequency (AM-HF) sinusoidal stimulation waveform. We combined computational and experimental approaches to show that AM-HF stimulation produces asynchronous firing in populations of nerve fibers. First, we modeled a set of parallel multicompartmental axons derived from the standard Hodgkin-Huxley formalism and we inserted them in an infinite homogeneous space. All axons were contained within a space of 100 um2 and two ideal current sources were oriented parallel to the axons and placed at 1 mm from the center of the bundle. We computed the responses of the modeled axons to stimulation using the NEURON simulation environment. Our computational model highlighted that the AM-HF waveform induced pseudo-stochastic firing in each axon. Moreover, we found that different axons fired asynchronously during AM-HF stimulation and that the firing rate was modulated by stimulation parameters. Second, we validated the computational results by delivering AM-HF stimulation in an anesthetized cat animal model. We stimulated with AM-HF through a multi-contact cuff (Ardiem Medical) wrapped around the sciatic nerve, while recording with 2 micro-electrode arrays (Blackrock Microsystems, Utah) implanted in the L6 and L7 dorsal root ganglia. Our experimental results corroborated the findings of our computational study: the recorded action potentials mostly occurred asynchronously and were robustly modulated by stimulation parameters. These results represent an important step towards the development of biomimetic stimulation strategies that could be applied in several clinical applications such as for the restoration of sensory feedback.

Title: Comparison of coordination in residual limb muscle reflexes and sensory percepts evoked by epidural stimulation of the lumbosacral spinal cord in trans-tibial amputees

Authors: *D. SARMA[1], B. BARRA[2], A. C. NANIVADEKAR[3], B. PETERSEN[3], R. BOSE[3], E. HELM[2], M. BONINGER[2], M. CAPOGROSSO[4], L. E. FISHER[2], D. J. WEBER[1];

Abstract: In the lower limbs, bilaterally coordinated spinal reflexes are evoked by sensory inputs from the foot and ankle. These reflexes largely mediate the transitions between phases of gait as well as managing stability after unexpected perturbations like slips and trips. Without these sensory inputs, lower-limb amputees experience approximately double the annual incidence of falls compared to able-bodied individuals. Lumbar epidural spinal cord stimulation (eSCS) is an intervention that can modify dysregulated lower-limb sensorimotor function and augment residual motor capacity. In two below knee amputees, eSCS was delivered through 2-3 percutaneously implanted (<30 days) commercial 16-electrode leads (Boston Scientific) over the L1-L3 spinal cord and dorsal roots. eSCS was delivered at pulse widths of 0.2 to 1ms at 1-50Hz across amplitudes ranging from 0.1mA to 6mA. Throughout stimulation, myoelectric responses were recorded bilaterally using surface electromyographic (EMG) electrodes over eight major muscles on both the intact and residual limb. Compound muscle action potentials (CMAPs) were derived from the stimulation-triggered average responses generated for each stimulation parameter. The subjects reported the location and quality of any elicited sensations using a custom graphical user interface. CMAP amplitudes increased with increasing stimulation amplitudes. Muscles innervated in more rostral segments, i.e. the quadriceps, of the spinal cord showed higher activity during stimulation from rostral contacts, while muscles innervated in more caudal spinal segments, i.e. lateral gastrocnemius, showed higher activity during stimulation from caudal contacts. Across all electrodes, 3-5 synergies, aligned to anatomical groups, could be calculated from the evoked CMAPs. For higher-frequency stimulations, we noticed that stimulation from caudal contacts evoked percepts in the phantom foot. This was correlated to an increased EMG response in all muscles. We also observed a higher EMG activity whenever the reported sensation was centered on the anterior part of the sole. This correlation persisted strongly for all muscles. In order to develop a clinically relevant stimulation protocol that effectively restores foot and leg sensations, the normal activity of the leg muscles needs to be preserved within a physiological range. These preliminary results show that evoked sensory percepts are linked to lower-limb myoelectric reflex responses. Further work is needed to decompose this relationship to understand the predictive power of coordinated muscle activation on evoked sensation as well as how to selectively modulate both independently.

Engin., Univ. of Wisconsin, Madison, WI; [4]Neuronoff Inc., Cleveland, OH; [5]Dept. of Mechanical Engin., Carnegie Mellon Univ., Madison, WI; [6]Mechanical Engieering, Carnegie Mellon Univ., Pittsburgh, PA; [7]Dept. of Biomed. Engin., Case Western Reserve Univ., Cleveland, OH

Abstract: Implanted neural stimulation devices, known as bioelectronic medicines, electroceuticals, or neuromodulation therapies, are being used to treat a variety of disorders. One increasingly prevalent application of neural stimulation is the treatment of chronic pain through electrical stimulation of the spinal cord or dorsal root ganglion (DRG). Compared to spinal cord stimulation (SCS), DRG stimulation has shown improved efficacy but also an increased complication rate. This is potentially due to a complex insertion procedure where the lead is steered laterally from the epidural space and through the vertebral foramen, as well as the need to implant a pulse generator resulting in the complete system having multiple potential failure points.

To meet the need for a simpler and minimally invasive neuromodulation system, we have previously developed an injectable electrode system, referred to as the Injectrode, that can be delivered through a needle and conforms to the target neuroanatomy. We demonstrated that an Injectrode can have similar impedances and charge injection properties to conventional neuromodulation electrodes and can be used for neural stimulation. Here, we expand upon our previous work by demonstrating a procedure for minimally invasive delivery of the Injectrode to the DRG from a lateral approach performed under fluoroscopy guidance. We also compared thresholds for sciatic nerve activation between stimulation with the Injectrode and a conventional DRG stimulation electrode.

Experiments were performed in 40-50kg swine to assess delivery and function of the Injectrode

in a clinically-relevant animal model. Gold or platinum Injectrodes were delivered under fluoroscopic guidance through a transforaminal approach, while conventional DRG electrodes (St. Jude Medical) were inserted through the epidural anterograde approach normally used for DRG lead placement. Placement was confirmed with cone beam computed tomography (CBCT). To compare function, evoked compound action potentials (ECAPs) were recorded from cuff electrodes placed on the sciatic, tibial, and common peroneal nerves and used to compute recruitment curves for activation of Aβ fibers.
Our results demonstrate minimally invasive delivery of the Injectrode in a swine model with clinically-relevant spine anatomy. We also show similar thresholds for recruitment of Aβ fibers between stimulation applied through the Injectrode and conventional DRG electrodes. By reducing invasiveness of the neuromodulation system and complexity of the surgical procedure, the Injectrode fills an unmet need for less invasive neuromodulation electrodes that can stimulate complex neural targets.

Title: Modelling recruitment of afferents in the dorsal root ganglion for somatosensory neuroprostheses

Authors: *J. FAROOQUI[1,2], A. C. NANIVADEKAR[3], M. CAPOGROSSO[4], S. F. LEMPKA[6], L. E. FISHER[5];
[1]Program in Neural Computation, Carnegie Mellon Univ., Pittsburgh, PA; [2]Rehab Neural Engin. Labs, [3]Bioengineering, [4]Dept. of Neurosurg., [5]Physical Med. and Rehabil., Univ. of Pittsburgh, Pittsburgh, PA; [6]Dept. of Biomed. Engin., Univ. of Michigan, Ann Arbor, MI

Abstract: Electrical stimulation of the dorsal root ganglion (DRG) is a promising intervention to restore sensory feedback in the missing limb for individuals with amputations. Epineural electrodes, placed on the surface of the DRG, are an attractive tool for such stimulation due to their stability and reduced likelihood of causing tissue damage, as compared to penetrating electrodes which pierce the neural tissue. Our recent work has shown that DRG stimulation delivered via epineural macroelectrodes can achieve a similar degree of selectivity compared to stimulation delivered via penetrating microelectrodes.
In this work, we developed a computational model of an L6 DRG populated with multicompartment models of pseudounipolar Aα and Aβ neurons, to probe the mechanisms of selectivity for stimulation delivered via epineural and penetrating electrodes. Our model replicated the realistic geometry of DRG neurons and realistic distributions of neuron fiber types and diameters within the DRG. We then used this model to simulate stimulation with experimentally relevant parameters.
Our results indicate that the unique geometry and spatial organization of DRG neurons may lead to different activation sites during stimulation applied by epineural and penetrating electrodes. Specifically, stimulation via epineural electrodes results in greater recruitment at the initial segment of the stem axon, adjacent to the cell body, while stimulation via penetrating electrodes preferentially recruits T-junctions. Combined with the varying density of initial segments and T-junctions near the epineural and penetrating electrodes, these recruitment differences can explain the similar selectivity observed experimentally between the epineural macroelectrodes and the penetrating microelectrodes. Further, our results suggest different recruitment properties between Aα and Aβ neurons, especially via epineural electrodes, which could suggest a possible approach for evoking different modalities of sensations.

Engin., Case Western Reserve Univ., Cleveland, OH

Abstract: Neurostimulation of the spinal cord and, more recently, the dorsal root ganglion (DRG) is being increasingly used as a neuromodulation therapy for chronic pain. These neurostimulation methods likely provide pain relief through the gate control theory of pain, where the activation of Aβ fibers inhibit the transmission of nociceptive signals in the spinal cord. DRG stimulation relieves pain in precise dermatomes, but the implant procedure is more challenging because the leads need to be steered laterally into the foramen. The implant procedure may be simplified by using a more flexible and conformal electrode. In this study, we tested the Injectrode as an alternative electrode for DRG stimulation. The Injectrode comprises a conducting polymer that is injectable, cures in place, and conforms to a neural target. We injected the Injectrode onto the L6 and L7 DRG in 4 anesthetized cats either through a burr hole in the lamina or a partial laminectomy. DRG stimulation comprised of biphasic pulses with a pulse width of 80, 150, or 300 μs using either the Injectrode or a stainless steel electrode. We recorded evoked compound action potentials (ECAPs) from the sciatic, tibial, and common peroneal nerves. We measured ECAP thresholds and recruitment rates and calculated their conduction velocity. We also compared the electrochemical impedance spectra of the Injectrode and stainless steel electrode in vivo. Here we show that DRG stimulation using the Injectrode can excite primary afferents with conduction velocities ranging from 13-120 m/s, corresponding to Aα, Aβ, and Aδ fibers. The Injectrode had similar or lower ECAP thresholds than the stainless steel electrode. The threshold for evoking ECAPs from Aβ fibers were 90.9 ± 42.9 nC for the Injectrode and 100.0 ± 32.3 nC for the stainless steel electrode ($p < 0.05$). Larger diameter fibers were activated at lower amplitudes (Aα, Aβ, then Aδ). The Injectrode had similar recruitment rates as the stainless steel electrode. At 50% of the maximum stimulation amplitude, ECAPs from Aα and Aβ were most prevalent (in 100% and 75% of trials respectively), with very few ECAPs from Aδ fibers (5.4% of trials). Impedances for both the Injectrode and stainless steel electrode were similar at higher frequencies (>1 kHz) and <1 kΩ. At low frequencies (<100 Hz), the impedance of the Injectrode was lower and more resistive than the stainless steel electrode. The Injectrode can excite primary afferents, notably Aβ fibers, when used for DRG stimulation. The Injectrode can be implanted using a simple technique while achieving similar activation to conventional electrodes, making it a worthy candidate for DRG stimulation or other neuroprosthetic applications.

Title: Effects of Lumbosacral Spinal Cord Stimulation on Balance and Gait after Trans-tibial Amputation

Authors: *B. A. PETERSEN[1], A. C. NANIVADEKAR[2], D. SARMA[1], R. BOSE[1], E. HELM[4], M. BONINGER[1], P. J. SPARTO[1], D. J. WEBER[2], L. E. FISHER[3];
[2]Bioengineering, [3]Physical Med. and Rehabil., [1]Univ. of Pittsburgh, Pittsburgh, PA; [4]UPMC, Pittsburgh, PA

Abstract: Individuals with a lower-limb amputation can experience a wide range of functional impairments and, critically, a higher risk of falls than the average population. Sensory feedback is crucial to making necessary postural corrections, and the lack of sensory feedback from the prosthesis likely contributes to these functional deficits. In this study, we use lumbosacral spinal cord stimulation (SCS) to generate sensations that are perceived to emanate from the missing limb and use those sensations to provide feedback from the prosthesis. The aim of this study is to evaluate the effects of sensory feedback on balance and gait. Two SCS leads were implanted percutaneously in the epidural space of an individual with a trans-tibial amputation, targeting the ipsilateral lumbosacral spinal cord. Psychophysical experiments were completed to determine appropriate stimulation parameters to evoke and control sensations in the missing limb. During standing and walking, plantar pressure signals for the corresponding area of the prosthesis triggered stimulation. Tests of balance (Sensory Organization Test, SOT) and gait (Functional

Gait Assessment, FGA) were performed with and without stimulation. In the SOT, participants stand on a force platform while either visual or somatosensory feedback are altered. Equilibrium scores indicate a participant's ability to stay within a normative 12° of anteroposterior (AP) sway. The FGA is a 10-item clinical measure of stability during gait. We utilized the electrode that most reliably evoked sensation in the missing limb, specifically the lateral forefoot. There were no changes in composite equilibrium scores or FGA scores with the addition of sensory feedback, however stimulation did improve performance on the most challenging SOT conditions (platform sway with altered vision or platform sway without vision) and tandem walking. With platform sway and altered vision, AP excursion and area of sway decreased with stimulation. With platform sway and no vision, AP excursion increased, however path length and equilibrium score improved. For both conditions, AP stability improved more than mediolateral stability. Notably, baseline scores for this participant were comparable to able-bodied levels and ceiling effects of these measures may be a confounding factor. The participant's balance performance varied widely across trials with stimulation, indicating the need for more training prior to assessment. In addition, these outcome measures may not be sufficiently sensitive to characterize the effects of impaired sensation in this population, and therefore, may not be able to detect changes due to the addition of sensory feedback.

Title: Restoring sensations by percutaneous spinal cord stimulation in people with lower limb amputation

Authors: *R. BOSE[1], A. C. NANIVADEKAR[2], B. PETERSEN[1], D. SARMA[1], E. OKOROKOVA[6], S. J. BENSMAIA[7], E. HELM[3], M. BONINGER[4], D. J. WEBER[2], L. E. FISHER[5];

Abstract: Sensory feedback is crucial for tasks involving the lower limbs such as balance and gait. People with lower-limb amputation lack feedback from the missing limb, and often experience abnormal gait patterns, impaired balance, lack of reflexive muscle activity, and are more prone to falling. A major goal of our research is to restore sensory feedback via lower limb prostheses by electrically stimulating sensory nerve fibres in the spinal cord that project from the missing limb. Importantly, for this technique to be effective, the restored sensations should be stable across days and, ideally, they should be perceived as 'natural' (e.g. touch or movement) rather than paresthetic (e.g. electrical buzzing). In this context, we evaluated (1) the locations and focality of percepts evoked by stimulating the ipsilateral lumbosacral spinal cord, (2) the stability of these percepts over 4 weeks, and (3) the perceptual quality (i.e modality and intensity) of these percepts.We implanted two or three 16-contact spinal cord stimulation (SCS) leads in the epidural space of the lumbosacral spinal cord in two human subjects with transtibial amputation over a period of 29 days. We delivered stimulation through monopolar and multipolar combination of contacts over a wide range of stimulation parameters (e.g. amplitude, frequency) and recorded the location, modality, and intensity of the evoked sensations. We also conducted standard psychophysical assessments to measure the just noticeable difference and threshold for evoking a percept.In both subjects, lumbosacral SCS elicited sensations localized to the ankle and foot of the missing limb along with sensations in the residual limb. The threshold for evoking sensations in the missing limb decreased over time but was always higher than the threshold for evoking sensation in the residual limb. A majority of percepts evoked in Subject 1 were described as naturalistic while Subject 2 reported a majority of percepts as paresthetic. There was substantial lead migration with Subject 1, but changes to the surgical approach minimized migration for Subject 2, and the evoked percepts displayed greater stability over the 29-day implant period. We demonstrated that percutaneous SCS can elicit sensory percepts in the missing limb for the two people with lower-limb amputation. The stability of the sensations was also improved by the surgical procedure of anchoring the SCS leads. We plan to recruit additional subjects and perform closed-loop experiments to observe potential improvements in balance and gait over a longer timescale.

Abstract: Cochlear implants (CIs) use an intra-cochlear multi-electrode array to electrically activate auditory neurons and have restored hearing in hundreds of thousands of deaf individuals. However, the fundamental performance of the CI has not significantly improved for over 25 years; it is generally accepted that this lack of improvement is due to the physical limitations of the electrode-nerve interface. Current spread resulting from multiple factors limits the number of effective independent channels, which in turn limits performance in the use cases of speech-in-noise and music perception. One strategy to overcome this limitation is to directly stimulate fibers of the auditory nerve. The development of a novel auditory prosthesis, an Auditory Nerve Implant (ANI), is presented in which a penetrating electrode array is directly inserted into the auditory nerve between the cochlea and the brainstem. The ANI system uses a commercially available cochlear stimulator from MED-EL but replaces the existing macro-electrode array and lead with a penetrating micro-electrode array and helically coiled lead tailored to the dimensions of the human auditory nerve. The ANI electrode array is a modified Utah Slanted Electrode Array consisting of 15 shanks in a 3x5 grid. Linearly increasing electrode shank lengths (0.5 mm - 0.9 mm) across the array allow stimulation across the auditory nerve cross-section. The helical lead improves mechanical performance (as measured by bend and tensile testing) such that it complies with mechanical standards for cochlear electrode leads. The design of the electrode array, the lead, and the insertion tool were optimized through human cadaver studies. Two surgical approaches, translabyrinthine and retrosigmoid, were proposed and their viabilities were confirmed via intraoperative experiments. Initial acute experiments in cats and non-human primates have demonstrated successful stimulation of the auditory nerve based on recordings of electrically evoked auditory brainstem responses (eABRs). Chronic non-human primate and cat experiments are currently in process to assess the long-term safety and stability of the ANI. Insertion testing will be performed using the modified ANI insertion tool and a nerve phantom model to verify the safety and proper insertion of the modified electrode array. Finally, the data collected from preclinical safety studies of chronically implanted cats and non-human primates will be used to seek regulatory approval for a clinical trial.

Title: Simulation study of a novel auditory nerve implant: model and expected percepts

Authors: *A. P. HEILLER[1], K.-H. DYBALLA[2], D. KIPPING[2], B. RICHARDSON[3], T. LENARZ[2], A. J. OXENHAM[1], W. NOGUEIRA[2], H. H. LIM[1];

Abstract: An intracranial auditory prothesis that targets the auditory nerve between the cochlea and brainstem (auditory nerve implant, ANI) is currently being developed across five institutions and two medical device companies (MED-EL and Blackrock Neurotech). The overall goal of the ANI is to improve hearing performance over current hearing treatment options. The ANI will be directly implanted into the auditory nerve with the aim of achieving more focused activation and greater transmission of auditory information to the brain compared to current cochlear implants. The ANI consists of a MED-EL stimulator attached to a Utah Slanted Electrode Array (USEA; developed by Blackrock Neurotech) with 15 electrodes in a 3x5 configuration. A spatial model of the auditory nerve cross-section was created to mimic the anatomical organization of the fibers, overall shape, and diameter of the auditory nerve. Two tonotopic frequency organizations were tested: an ideal 2.25 turn spiral like the tonotopy observed in the cochlea and a randomized tonotopy. These 2D models of the auditory nerve fibers were translated into 3D by extending each fiber in a third dimension. The tips of the USEA were placed within these fibers based on the expected positioning of the ANI in future patients. A computational model of the neuronal activation based on cochlear implant stimulation was employed by applying an electrical current at the electrode tips to simulate excitation profiles of the auditory nerve fibers. These excitation

profiles were converted into vocoded stimuli to test the expected percepts of the ANI in 10 normal-hearing listeners to determine the potential performance of the device. The main outcomes measured with these stimuli were threshold, dynamic range, loudness balancing, and pitch ordering. The excitation profiles showed a variety of shapes ranging from single frequency peak with a narrow spread of activation to multiple peak frequencies with broader spread of activation. Threshold and loudness balancing levels were determined for each of the simulated electrodes for each of the listeners. The loudness-balanced stimuli were used in the pitch-ordering task under two conditions: no level roving and 2 dB level roving. The results of the pitch-ordering tasks indicated that it was possible to map the simulated electrodes to the appropriate frequency bands, even with the multiple frequency peaks observed on some electrodes. The results of these studies will aid in the future development of perceptual tasks for the ANI clinical trial.

Title: Characterization of electrically-evoked auditory brainstem responses in rhesus monkey, cat, and guinea pig produced by stimulation via a novel auditory nerve implant using the Blackrock Utah array

Authors: *I. SONDH[1], G. M. GHOSE[1], L. A. JOHNSON[1], L. VERDUN[1], D. J. WARREN[2], W. M. THOMAS[2], L. RIETH[3], M. LEBER[4], F. SOLZBACHER[2,4], S. ZUNIGA[1], M. ADAMS[1], H. H. LIM[1];

Abstract: The cochlear implant (CI) is an effective neural prosthetic capable of restoring hearing in those with severe to profound hearing loss. However, CI users have reduced performance in noisy environments and music perception. A major cause for these deficiencies is the poor electrode-neural interface due to the bony cochlear wall, which causes unwanted current spread across the frequency coding of the cochlea. Recent studies have shown that direct stimulation of the auditory nerve could help overcome these limitations and activate a greater number of

frequency channels of information. Therefore, our group is developing and testing a new auditory nerve implant (ANI) in several animal models. To demonstrate successful activation of the auditory system using the ANI, acute experiments were performed in the cat (n=4) and rhesus monkey (n=2) using a 3x5 Utah Slanted Electrode Array (USEA) developed by Blackrock Neurotech. The USEA was implanted in the auditory nerve via a translabyrinthine surgical approach. Needle electrodes placed in the scalp and mastoid areas were used to record the electrically-evoked auditory brainstem response (eABR). In both species, multiple component waves of the eABR were observable, indicating strong activation of auditory brainstem structures. Using different stimulation sites on the array resulted in changes in the eABR waveform, suggesting activation of different nerve fiber groups per site. The amplitude of the eABR waves increased with applied current level and the latency of eABR peaks decreased, showing progressively stronger recruitment of nerve fibers. Guinea pig studies were also performed to support the findings in our cat and monkey studies. Because the smaller skull of the guinea pig prevented usage of the USEA, we utilized a 16-site single-shank probe developed by NeuroNexus. In addition to the eABR, invasive recordings of multi-unit activity were collected, through a 32 site 2-shank probe placed along the tonotopic axis of the central nucleus of the inferior colliculus (ICC). The ICC recordings in response to stimulation corroborated the eABR recordings; only certain groups of ICC neurons (i.e., only those tuned to certain frequency ranges) were activated, depending upon stimulation site. This supports the assertion in the cat and monkey studies that changes in the eABR waveform were due to recruitment of different frequency fiber groups. Future experiments will involve chronic implantation in 2 NHPs, with eABRs being measured periodically to track stability, functionality, and safety of the device. We then seek to translate to the clinical setting and ultimately provide a solution for patients who are not eligible for a CI.

Title: Dynamic Epiretinal Stimulation Improves Shape Discrimination in People with Blindness

Authors: B. CHRISTIE[1], R. SADEGHI[2], *A. KARTHA[3], S. LEE[4], A. CASPI[5], F. TENORE[1], R. KLATZKY[6], G. DAGNELIE[3], S. BILLINGS[1];

Abstract: Different neural targets along the visual pathway can be stimulated to elicit flashes of lights known as phosphenes that can be used as feedback for people with blindness. The information delivered by a single phosphene is limited, so phosphene presentations are often spatially combined through electrode array stimulation to maximize real-time visual understanding of one's environment. In theory, stimulating electrodes that form a specific shape within an array should elicit phosphenes in the same shape, given that the retina and primary visual cortex (V1) are retinotopic. However, it is not typically that simple: when multiple electrodes are stimulated simultaneously, phosphenes tend to merge together in an uninterpretable way (Bosking et al. 2018). To address this, a recent study demonstrated that shapes could be "drawn" by sequentially stimulating electrodes in V1 (Beauchamp et al. 2020). To evaluate if this technique would be successful when the retina is the neural target, we conducted a similar study in people with epiretinal microelectrode arrays.
We conducted experiments with two subjects with retinitis pigmentosa. These individuals had previously been implanted with the Argus II retinal prosthesis, which consists of a 6x10 electrode array (Luo et al. 2016). We ran a two-alternative forced choice (2-AFC) discrimination task in which subjects were asked to respond if an arrow-shaped simulation on the array was pointing to the left or to the right. These arrow-shapes were created by stimulating three electrodes that evoked phosphenes which were perceived as similar in size, shape, and brightness by the subjects. We ran this test with either "static" stimulation (all electrodes were stimulated simultaneously for 200 ms) or "dynamic" stimulation (electrodes were sequentially stimulated, each for 200 ms with no temporal gap in between).
Our results indicate that dynamic stimulation outperforms static stimulation when discriminating arrow direction. When performing the test with dynamic stimulation, both subjects got 19/20 trials correct. When performing the task with static stimulation, one subject achieved only 4/20 correct and the other 8/20 correct. Interestingly, one subject originally found it impossible to make a judgment until we used electrodes that elicited similar phosphene shapes and sizes.
Our next steps are to recruit additional subjects and to test dynamic stimulation with more complex shapes, such as letters of the alphabet. Our preliminary findings demonstrate that an epiretinal prosthesis can produce coherent simple shapes with a dynamic stimulation paradigm, demonstrating their functionality to restore rudimentary vision.

Title: Wearable Sensors Detect Impaired Balance and Coordination in LBSL During Remote, Home-Based Assessments

Authors: *A. SMITH FINE[1], J. GOODMAN[2], B. R. TURK[3], A. J. BASTIAN[5], A. FATEMI[4], J. KELLER[2];
[1]Kennedy Krieger Inst. / Johns Hopkins, Baltimore, MD; [2]Kennedy Krieger Inst., Baltimore, MD, MD; [3]Neuroscience, Kennedy Krieger Inst., [4]Neurol., Johns Hopkins Univ., Baltimore, MD; [5]KKI & Johns Hopkins, Baltimore, MD

Abstract: Objective The objective is to identify neuromotor measures that can detect disease severity in the disease leukoencephalopathy with brainstem and spinal cord involvement and lactate elevation (LBSL). LBSL is a rare neurologic disorder with motor impairment due to biallelic mutations in *DARS2,* which encodes mitochondrial aspartyl tRNA synthetase. There are white matter changes in the cerebrum, cerebellum, pyramidal tracts and dorsal columns, resulting in ataxia and spasticity. There are no targeted therapies for LBSL. Methods The study analyzes cross-sectional data from wearable sensors and clinical scales used to assess walking and balance in LBSL and age-matched control participants' homes through video conferencing. Outcomes include parameters obtained from a wearable accelerometer system for gait and static postural sway in 4 standing conditions and the Scale for the Assessment and Rating of Ataxia (SARA). Measures were collected on two consecutive days in a subset of participants for the reliability analysis. Results A total of 8 LBSL participants and 8 controls were included in the study, age range 5 - 23 years. There is good reliability of remotely collected gait measures (intra-class correlation coefficient 0.86-0.99) and sway measures (intra-class correlation coefficient 0.53-0.96) among participants. LBSL participants have a slower stride velocity (1.11±.03 vs. 1.02±.03m/s) and shorter stride length (1.11±.02 vs. 1.05±.02m) than their control counterparts. Lateral step variability, which indicates variability in walking step width, is increased for LBSL participants (5.6±0.6 vs. 3.7±0.4cm). During standing conditions with the eyes closed and feet together, LBSL participants had anteroposterior sway instability covering a much greater area than controls (2.1±0.6 vs. 0.3±0.1 m^2/s^4). These variables correlate strongly with the SARA (r=0.6-0.9). Conclusions Virtual collection of data in the home using wearable sensors is a reliable and sensitive means for detecting gait and balance abnormalities LBSL patients. Distinct gait and balance abnormalities measured in the LBSL patients are related to clinical ratings of ataxia severity. This work will address the unmet need to establish quantitative outcome measures in the natural history of LBSL.

Title: Wearable Inertial Measurement Units Demonstrate Strategy and Performance Differences During Individual Ice Dance Steps

Authors: *S. G. YING[1], Y. S. TARUI[1], A. V. JOYCE[1], A. G. YING[1], C. DUGAN[1], A. T. JOYCE[1], V. A. YE[1], M. E. DUGAN[1], N. S. YING[1], C. F. JOYCE[1], D. DUGAN[1], S. PAN[1], M. BRAMANTE[1], E. GEMINIANI[2], S. H. YING[1];
[1]Deeper Edge, Norwood, MA; [2]Boston Children's Hosp., Boston, MA

Abstract: Background:The ability to continuously identify and quantitatively rate motor activity in patients with movement disorders could provide a more granular view of disease activity for clinical management or clinical trials. Our objective was to demonstrate the feasibility of collecting and classifying movement data efficiently from stereotyped ice dance patterns and to demonstrate that meaningful conclusions could be drawn from the data. Ultimately, this approach could be used to develop a training set for a machine-learning algorithm to detect, classify, and analyze movements from a continuous data stream. Methods:Three ice skaters each performed three patterns of the Dutch Waltz, a basic ice dance pattern. Noitom Perception Neuron wearable inertial measurement units (IMUs) were used to collect movement data, and video recordings were used to verify accurate execution of steps. Traces were visualized according to step classification, and were compared to average traces using Pearson's product-moment correlation coefficient. Classification utility was illustrated using a receiver operator

characteristic curve. Skating quality was visualized using Fourier analysis. Results:The ice dance pattern data from a limited subset of sensors clearly showed it was possible to visually differentiate general features in an ice dance pattern as well as skater-specific differences. Correlation analysis showed that individual movements were more likely to be correlated with a template step of the same classification vs a different classification. Receiver operator characteristic analysis of classification utility using a personalized template demonstrated an area under the curve up to 0.915. Moreover, hip instability observed on video could be detected in the waveform of the traces and on Fourier analysis as high-frequency hip oscillations. Conclusion: Our results show it is feasible to collect data from wearable motion sensors during ice dance pattern dances. Moreover, the data are grossly reproducible; they correspond to identifiable physical features in the dance and identify performance features that are meaningful for coaching and also suggest a different strategy for performance. Although classification of steps in a single individual could be robust, generalized classification may be optimized either by using an individualized template or by using different features. It will be essential to examine a wider range of individuals to understand the spectrum of individual variation and learning trajectories, as well as to gather a complete training set for an automated movement recognition algorithm to recognize a greater variety of movements.

Title: Effects of transcutaneous spinal direct current stimulation applied during walking rehabilitation on spinal reflex modulation, reflex behavior and walking function

Authors: *K. A. HAWKINS[1], D. D. FULLER[1], D. J. CLARK[3,2], E. J. FOX[1,4];

Abstract: Spinal cord injury (SCI) alters the excitability of spinal circuits below the injury, affecting motor output and reflex modulation in a manner that contributes to walking dysfunction. Studies of neuromodulatory electrical stimulation approaches demonstrate beneficial effects on spinal motor output; however, these approaches can be painful, have unwanted side effects or require invasive procedures. In contrast, transcutaneous spinal direct current stimulation (tsDCS) uses a non-invasive, low-dose current applied with an affordable, commercially available device. Importantly, tsDCS can modulate spinal reflexes, increase corticospinal excitability, and influence spinal processing of sensory inputs. Therefore, tsDCS may enhance the responsiveness of these circuits to synaptic inputs associated with task-specific rehabilitation. We tested the hypothesis that a single session of tsDCS applied during walking rehabilitation (tsDCS+walk), compared to sham stimulation during rehabilitation (sham+walk), induces improvement in spinal modulation. We also examined changes in reflex behavior and walking function after 16 sessions. Eight individuals with chronic motor incomplete SCI (6 male, 31-62 years, speed 0.07-0.83 m/s, 6 wheelchair dependent) completed two single-day, random-ordered sessions of either tsDCS+walk (anodal tsDCS, 2.5 mA, 30 min) or sham+walk. Spinal modulation was assessed through post-activation depression (PAD) of the soleus Hoffman (H) reflex, elicited supine with a 1 ms pulse to the tibial nerve. PAD was calculated as the percent reduction in amplitude of a second H reflex stimulated 1 second after the first. Four participants had recordable reflexes. PAD increased an average of 10.5±7.2% with tsDCS+walk with all 4 demonstrating improvement compared to 1 of 4 improving after sham+walk (average change -6.2±8.5%). Participants were randomized to receive 16 sessions of tsDCS+walk or sham+walk. Session goals were 30 minutes of treadmill and 10 minutes of overground walking at high intensity. Pre- and post-training, we completed a double-blind assessment of reflex behavior (clonus subscale of the Spinal Cord Assessment Tool for Spastic Reflexes) and walking function (walking speed). Clonus improved in 2 of 4 receiving tsDCS+walk compared to 1 of 4 in sham group. Speed gains exceeded the minimal clinically important difference (>0.13 m/s) in 3 of 4 receiving tsDCS+walk and 1 of 4 in the sham group. In a small cohort, greater gains were evident with tsDCS+walk versus sham+walk. Outcomes suggest this non-invasive stimulation may have beneficial effects on spinal modulation and clinical outcomes, warranting further investigation.

Title: Vector coding technique to quantify arm swing coordination during walking in individuals with Parkinson's disease

Authors: *M. ARCODIA, J. CHUNG, J. J. JEKA, H. REIMANN, R. G. BURCIU;
Kinesiology & Applied Physiol., Univ. of Delaware, Newark, DE

Abstract: Although reduced arm swing amplitude is a common motor feature of Parkinson's disease (PD) it is unclear if swing coordination between arms is also impaired during gait. A better characterization of arm swing coordination is crucial because coordination between body segments during gait can be an indicator of a healthy functioning system. Limb coordination is commonly assessed in the time domain, however, vector coding of interlimb segments in angle-angle space can describe different relationships not observed in the time domain. Therefore, the aim of this study is to evaluate arm swing coordination in individuals with PD and healthy older adults during gait using vector coding and circular statistics. Twenty-one healthy older adults (11 female, 63.28 +/- 9.86 yrs) and eleven individuals with PD (3 female, 59.72 +/- 9.38 yrs) participated in the study. Individuals with PD were tested off antiparkinsonian medication (>12h withdrawal). Participants performed a 2-minute walking task up and down a corridor (7.6m) for three conditions: preferred walking speed, preferred walking speed with a cognitive task of counting backwards by threes, and a faster walking speed. Participants wore an APDM Opal inertial measurement unit set consisting of a sensor strapped to the participant's lumbar spine, sternum, left and right wrist, and left and right foot. Angular velocities around the medial-lateral axis were extracted from both wrists and used to calculate the coupling angle at each point of the gait cycle in the vector coding approach. Circular variance of the coupling angle was calculated at each point of the gait cycle, then averaged across the gait cycle. As a secondary analysis the correlation between the angular velocity time series at each wrist was calculated. For both outcome variables a two-way ANOVA was performed to analyze effects of group and condition. Results show that individuals with PD have a higher circular variance of the coupling angle and lower correlation coefficients between arms than healthy older adults during the cognitive task condition further suggesting that individuals with PD lack arm swing coordination during gait with a dual task. Therefore, arm swing coordination may serve as an additional assessment of PD and a target for mobility goals that can be addressed in a clinical setting.

Title: Determination of chief features in clinician observational gait analysis

Authors: *S. SETHI, J. SCHIERLMANN, I.-C. LEE, H. HUANG;
UNC/NCSU Joint Dept. of Biomed. Engin., Raleigh, NC

Abstract: Observational gait analysis (OGA) is an important skill for clinicians when evaluating gait abnormality. However, various factors such as patient height or fitness may inadvertently affect clinician judgment. Consequently, little is known about which objective gait features they rely on during OGA. To answer these questions, we propose a novel method to (1) identify what body areas clinicians gaze at to diagnose gait abnormality, (2) investigate the difference in OGA skill between individuals with different levels of clinical experience, and (3) determine what factors affect their accuracy.

To answer these questions, the motion of three unilateral above-knee amputees and a healthy control walker were utilized to build three biological motion models through principal component analysis. For each amputee model, we meshed the gait features between the amputee and control walker to build 6 videos that displayed synthesized point-light walking motion. We varied the weight of gait features from 0 to 100% in 20% increments, beginning with amputee gait at 0% and ending with healthy gait at 100%. These videos were used to test the accuracy in judging the range of gait abnormality for two groups of participants—experienced raters with at least 2 years of clinical experience, and inexperienced raters. Gaze was recorded with an eye tracker system as participants watched 10 trials of video sets generated from each amputee.

All participants fixated on the left side of the pelvis most overall ($p < 0.05$), and the more experienced participants fixated on the left shoulder more than the inexperienced participants ($p < 0.05$). No other factors were found to influence gaze. Regarding accuracy, Amputee A (K-3 level) was the easiest for all participants to rank ($p < 0.05$); Amputee B, which was the same K-level as Amputee C (K-4) but possessed much less joint asymmetry, was significantly more difficult to rank ($p < 0.05$). More experienced participants were more accurate in rating Amputee B than inexperienced participants ($p < 0.05$). However, we did not find a difference in accuracy based on experience when rating the other amputees. Moreover, participants consistently ranked walkers with very abnormal gait (0% and 20% control walker motion) more accurately than walkers very close to normal motion (60%, 80%, and 100% control walker motion; $p < 0.01$). These results indicate that hip motion is the most common feature that was used by both groups in judging gait abnormality. Furthermore, the clinicians may gain greater accuracy by evaluating shoulder motion. Overall, the degree of gait abnormality is the largest factor affecting accuracy.

Title: Effect of Aging on Cortical Activity in Response to Sensory Organization Test

Authors: *Y. HU[1], A. BISHNOI[1], L. ZIEGELMAN[2], M. E. HERNANDEZ[1];
[1]Kinesiology and Community Hlth., [2]Neurosci., Univ. of Illinois Urbana-Champaign, Urbana, IL

Abstract: Decreased upright postural control ability is associated with aging, leading to a higher risk of falling, decreased mobility, decreased functional capacity and independence, and reduced ability to perform physical activities, thus reducing older adults' quality of life. Although previous evidence suggests cortical involvement in human postural control, it is unclear how aging affects functional cortical activity. The current study examined cortical electrical activity in response to sensory perturbations that challenge standing postural control. Cortical beta rhythm (13-30hz) activity at postural control-related areas (electrodes Fz, Cz, Pz) were measured by Electroencephalography (EEG) in older adults (OA) and young adults (YA). We hypothesized that 1) OA would demonstrate higher beta activities compare to YA; 2) there would be a significant age by condition interaction, in which YA would demonstrate increased beta activity with increased difficulty in a condition, while OA would not demonstrate any changes. In a cross-sectional study design, we examined 13 OA (71±6yrs; Sex: 7F/6M; BMI:25) and 10 YA (22±2yrs; Sex: 4F/6M; BMI:25). Participants completed baseline cognitive and motor testing before starting the clinical sensory organization test (SOT) on a Neurocom Clinical Research System. In SOT, participants completed 3 trials each of 6 conditions: Eyes open, Eyes closed, Eyes open sway-referenced surround, Eyes open sway-referenced platform, Eyes closed sway-referenced platform, Eyes open sway-referenced surround and platform. The participants were instructed to maintain upright balance without taking steps throughout each condition. The results of linear mixed effect models analysis revealed age ($p<0.05$), condition ($p<0.01$), and electrode effects ($p<0.05$), and age by condition interaction ($p<0.01$). In addition, post hoc analysis confirmed the interactions between age and condition. We found statistically significant higher beta power in OA compares to YA. Moreover, while YA increased beta power as condition difficulty increased, OA demonstrated the opposite behavior. Larger beta depression associated with eye-close conditions was also found in OA in comparison to YA. This study suggests aging altered cortical engagement in postural control of standing balance tasks,

indicating potential cortical hyperactivity and higher voluntary control in response to sensory balance perturbations in OA.

Title: Reducing the midline tremor with deep brain stimulation improves gait and balance in essential tremor patients

Authors: *Y. CHOI[1], B. YACOUBI[1], A. CASAMENTO-MORAN[1], S. DELMAS[1], B. WILKES[1], C. W. HESS[2], A. SHUKLA[2], M. OKUN[2], K. FOOTE[2], D. VAILLANCOURT[1,2,3], E. CHRISTOU[1,2];

Abstract: Although more than 40% of Essential Tremor (ET) patients exhibit balance and gait impairments, the relation to their tremor remains unclear. Here, we compared tremor at various body locations during balance and gait tasks between healthy controls (HC) and ET patients undergoing deep brain stimulation treatment (ET DBS) and examined how neurostimulation effects tremor and performance in these tasks. Seventeen ET DBS and 17 age-and sex-matched HC performed a postural balance task (quiet standing task with eyes open) and an overground walking task at their preferred speed. We quantified tremor (4-8 Hz acceleration power) during the gait and balance tasks using wearable sensors (APDM) located at the wrists (upper limb), ankles (lower limb), chest (upper trunk), and lumbar area (lower trunk). We focused on sway path length and stride length variability for postural balance and gait performance, two variables that relate to the fall risk. ET DBS exhibited significantly greater sway path length and stride length variability relative to HC ($p<0.003$). Their tremor was greater at the lower limb and lower trunk during the postural balance task ($p<0.05$), and at the upper limb and lower trunk during the gait task relative to HC ($p<0.03$). During the postural balance task, neurostimulation significantly reduced sway path length ($p=0.01$) and lower trunk tremor ($p=0.03$). During the gait task, neurostimulation significantly reduced stride length variability ($p=0.04$). The reduction in sway path length significantly associated with a reduction in upper trunk tremor ($R^2=0.24$, $p=0.03$),

whereas the reduction in stride length variability strongly associated (R^2=0.79, p=0.001) with a reduction in both upper trunk (part r = 0.4) and upper limb tremor (part r = 0.3). Our study provides novel evidence that DBS may effectively improve gait and balance performance in ET patients by reducing trunk (midline) tremor. Trunk tremor may be an indicator of midline tremor, often associated with cerebellar degeneration, and its reduction may improve trunk control an essential component for balance and gait performance.

Title: Associations between neural correlates of imagined walking and community mobility: preliminary results from the Mind in Motion study

Authors: *V. SHAH[1], T. FETTROW[1], C. HASS[1], D. FERRIS[1], P. RUETER-LORENZ[2], D. CLARK[1], T. MANINI[1], R. SEIDLER[1];

Abstract: Studies have shown associations between functional brain activity and lab-based gait measurements, where increased brain activity is associated with better gait performance. Traditionally, gait performance in laboratory settings has been quantified via gait speed, step length, and step duration. However, direct associations between functional brain activity and community mobility have been rarely examined. Community mobility is complex as it is done in an uncontrolled environment with significant temporal variability. Data from the Mind in Motion study were used to characterize brain activity and associations with community mobility data. Actigraphy and MRI data were collected from 6 younger adult (20-33 yrs old) and 7 older adult (71-86 yrs old) volunteers. We used functional magnetic resonance imaging (fMRI) to record brain activity during walking motor imagery (WMI) on increasingly difficult uneven terrain. fMRI during a N-back (NB) spatial working memory task was also collected. The NB task increased in difficulty when the number of spatial targets to recall increased. Community mobility data was collected via a hip-worn ActiGraph accelerometer, worn over approximately a 2-week period. Mean cadence measures were calculated for valid wear-days (>5 hrs/day of wear

time). A voxel-wise analysis [p(uncorrected) < 0.005, k= 10] was used to identify the correlations between functionally active brain regions during the highest difficulty of the WMI/NB tasks and mean cadence of community walking. Voxel-wise results of WMI revealed a negative correlation in the right inferior temporal lobe, and positive correlations in left inferior temporal lobe, and right superior and left middle frontal gyri. For NB, we found a negative correlation in the left inferior temporal lobe. We are continuing data collection to further investigate brain-behavior correlations of mobility and will perform group-wise correlations that will highlight potential connection between brain aging and community mobility. We also plan to determine correlations of brain structure and connectivity to community mobility. Overall, our preliminary results suggest that lower brain activity in the frontal lobe during walking could result in lower cadence in community mobility, but more data are needed to confirm this relationship. Title: Association of balance recovery mechanisms with brain structural integrity in older adults with mild cognitive impairment

Authors: *L. N. KANNAN[1], T. S. BHATT[2], O. A. AJILORE[3];
[1]Physical Therapy, Univ. of Illinios, Chicago, CHICAGO, IL; [2]Physical Therapy, Movt Sci., [3]Univ. of Illinois at Chicago, Chicago, IL

Abstract: Background: Older adults with mild cognitive impairment (OAwMCI) exhibit subtle balance control and gait deficits which are predominantly associated with brain pathologies such as impaired white matter integrity (WMI) and reduced gray matter volume (GMV). However, the relationship between balance recovery mechanisms and neural substrates in OAwMCI remains unknown. This study thus aimed to explore the associations of volitional (self-initiated) and reactive balance (in response to an external perturbation) control with WMI and GMV. **Methods:** Twelve OAwMCI (MoCA 18-25/30, > 55 years) were examined on the limits of stability test (LOS, volitional balance via Equitest), stance perturbation test (SPT, reactive balance via ActiveStep treadmill), and underwent MRI. Forward movement (frequently performed functional activity of daily living) - LOS was quantified by maximum excursion

(maximum ability to shift one's center of gravity toward the theoretical limit [MXE-%]) and directional control (amount of movement exhibited towards the target to the movement away from the target [DCL-%]). Slip-like (prevalent type of accidental falls) perturbations -SPT was quantified by postural stability (shortest distance of the COM motion state, i.e., its position and velocity, to the theoretical boundary). WMI was quantified by fractional anisotropy (FA, movement of water molecules directionality) and GMV measured in mm^3. **Results:** For LOS, reduced forward MXE was significantly ($p<0.05$) associated with lower FA in left ($R^2=0.48$) and right ($R^2=0.71$) corticospinal tract, left ($R^2=0.46$) and right ($R^2=0.47$) corticothalamic tract, left ($R^2=0.60$) and right ($R^2=0.68$) frontopontine tract, left ($R^2=0.68$) and right ($R^2=0.77$) cingulum, anterior commissure ($R^2=0.67$), and corpus callosum ($R^2=0.65$). Reduced forward DCL was significantly ($p<0.05$) associated with reduced GMV in the left cerebellum ($R^2=0.45$), brainstem ($R^2=0.52$), left ($R^2=0.39$), and right ($R^2=0.46$) thalamus. For SPT, reduced postural stability ($p<0.05$) was significantly associated with reduced FA in the right corticospinal tract ($R^2=0.61$) and right frontopontine tract ($R^2=0.50$). Reduced postural stability was significantly ($p<0.05$) associated with reduced GMV in the brainstem ($R^2=0.69$) and right cerebellum ($R^2=0.66$). **Conclusion:** Our results indicate that structural brain integrity influences stability control in OAwMCI for both volitional and reactive balance tasks, which may share some common cortico-subcortical motor pathways and relay centers. Results also show that the integrity of descending pathways from cortical attentional centers could influence stability control for both tasks.

Title: Use of Erasmus Ladder to assess performance after pharmacological or neurological challenge

Authors: *D. MURPHY, P. LEACH, M. ARNOLD, A. THOMAS, A. NELSON;
Biogen, Cambridge, MA

Abstract: Neurodegenerative diseases and acute injuries to the brain can impair motor and cognitive performance. Relatively high-throughput, quantitative assessment of motor performance in rodents (i.e., RotaRod or open field activity) can capture gross motor dysfunction, but fine-tuned assessment (i.e., gait analysis or horizontal ladder performance) is time consuming and often scored subjectively. We have been working with the Erasmus ladder, a semi-automated behavioral apparatus to assess motor performance and associative motor learning in mice. The Erasmus ladder is able to capture left and right stepping patterns of mice as

they cross a horizontal ladder. To understand how the Erasmus Ladder could yield sensitive and quantitative measures of motor performance we assessed performance of mice on the Erasmus Ladder following surgical or pharmacological manipulations that have been shown disrupt coordinated movement. Stepping responses and the lateral distribution of step types were captured at each time point. Experiment 1 examined the effect of ethanol (0 or 2.5g/kg, IP) 30 minutes prior to ladder assessment in C57BL/6J male mice. Ethanol-induced performance consisted of a global increase in errors compared to performance after vehicle administration. Experiment 2, in contrast, examined performance of C57BL/6J male mice after induction of a severe unilateral cortical infarct (DH-MCAO). In our experiment, a unilateral stroke selectively impaired performance on the contralateral side of the body relative to the damaged brain regions, leaving performance on the ipsilateral side indistinguishable from sham-stroke performance. These studies are consistent with previously published studies that suggest that the Erasmus Ladder is a useful tool to measure of motor performance in mice that is sensitive widespread motor impairments but is also able to differentiate unilateral impairments, such as those caused by unilateral insult such as stroke or traumatic brain injury.

Title: Differences in postural control strategies after ankle and knee injuries, measured by concurrent motor evoked potential responses in leg muscles from the motor cortex during single limb stand on firm and foam surfaces

Authors: *N.-H. KO, C. SANO, H. CLEMENTI;
Physical Therapy, California State University, Fresno, Fresno, CA

Abstract: About 52-60% of individuals with anterior cruciate ligament (ACL) injuries reported a history of ankle injuries. Biomechanical and neurophysiological changes have been reported after both injuries, indicating impaired sensorimotor control in lower extremities (LE). Some have speculated a potential link between chronic ankle instability (CAI) and ACL injuries; however, this has not been studied in multimodal approaches. We recruited three individuals: no injury (C01, F, 27yrs), ankle sprains (A01, F, 24yrs), and ACL injuries (K01, F, 25yrs). We asked them to perform single limb stand (SLS) on a firm and foam surface and measured 1) a degree of sways, 2) muscle activity, and 3) corticospinal excitability from the motor cortex. Muscle activity was recorded from tibialis anterior (TA), peroneus longus (PL), vastus lateralis

(VL), and semitendinosus (ST) using surface EMG. Motor evoked potentials (MEPs) of TA and non-targeted muscles (PL, VL, ST) were measured using transcranial magnetic stimulation during SLS tasks. Results were the comparisons of C01's dominant leg to A01 and K01's affected leg. K01 showed the lowest sway scores for both firm and foam surfaces. The EMG data showed that C01 dominantly activated TA (mean_28.8uV) and PL (15.2uV), A01 mainly activated PL (8.69uV), K01 dominantly activated PL (25.85uV) and TA (14.4uV) during SLS_foam. The average peak-to-peak MEPs of TA was the greatest in K01 (1598.2±344.5uV), followed by A01 (955.5±307.5uV) and C01 (192.8±80.8uV) during SLS_foam. When non-targeted muscle MEPs were normalized by TA MEP trial-by-trial, C01 showed 4 times amplified MEPs in VL on average, while A01 had similar degrees of corticospinal excitability in all muscles. K01 showed 1.3 times amplified MEPs in PL only while corticospinal excitability in VL and ST were mostly turned off. Each individual's different control strategies are not explicitly demonstrated by task performance and/or degrees of muscle activation. Measuring concurrent MEPs of non-targeted muscles may provide information on corticospinal recruitment patterns as cortical motor maps of those muscles overlap. C01 VL's amplified MEP may reflect flexibility and its ability to control instability as dynamic control increases corticospinal excitability. With CAI, the neuromuscular system may explore ways to stabilize the LE, recruiting all muscles synergically while PL plays a role in planting the ankle on the surface. Finally, an individual with both CAI and ACL injuries co-contracts TA and PL, stiffening the leg and avoids synergic use of VL and ST, which lacks flexibility to instability. These approaches may help explore a potential link between CAI and ACL injuries.

Title: Anticipatory and compensatory postural adjustments during perturbed standing in individuals with traumatic brain injury

Authors: *A. VEERUBHOTLA, N. EHRENBERG, O. IBIRONKE, R. PILKAR;
Kessler Fndn., West Orange, NJ

Abstract: Anticipatory postural adjustments (APA) and compensatory postural adjustments (CPA) are two types of postural mechanisms employed to achieve balance and prevent falls during perturbations. APA are the neuromechanical responses generated prior to the predictable

perturbations and their goal is to minimize the impact of the imminent perturbations. CPAs, on the other hand, are the postural responses generated after the onset of a perturbation to stabilize the body and achieve equilibrium. Failure to employ these defense mechanisms in response to perturbations can lead to postural instability and a potential fall. Traumatic brain injury (TBI) diminishes the ability to sense the environmental perturbations and impairs the ability to generate essential responses such as APA and CPA. Weakened ability to generate APA may need much larger CPA responses during perturbation to maintain stability. This could be an unattainable demand due to the neuromuscular pathology after a TBI. The generation of APA and CPA responses to perturbations is unclear in TBI populations. The objective of the current investigation is to understand APA and CPA generation post TBI and evaluate the effectiveness of a novel computerized feedback-based balance intervention to improve APA-CPA generation and functional balance. In this study, we examined APA and CPA responses during predictable and unpredictable perturbations to the base of support in healthy control (n=5) and TBI (n=10,) on a programmable platform during upright standing. Additionally, TBI-Intervention (TBI-I, n=3) group performed 16-sessions (4 days/week for 4 weeks) of balance intervention with visual and auditory feedback. The APA/CPA responses to predictable and unpredictable perturbations were derived using tibialis anterior electromyography outcomes (amplitude, reaction time) from 300ms before and after the perturbation onsets, respectively. The functional balance outcomes included Berg balance scale (BBS), and timed-up and go (TUG). The design and outcomes of the proposed study present a novel way of understanding critical factors behind balance dysfunction and falls after a TBI. Understanding APA and CPA generations during base of support perturbations is extremely vital as many of the environmental perturbations during everyday activities involve modifications to the base of support conditions. This study provides valuable knowledge based on APA and CPA generation which is a key to designing strategies to improve balance dysfunction and prevent falls post TBI.

Title: Peripheral and central factors in age-related difference in balance control

Authors: *H. PARK, A. BAKSHI, J. R. LACKNER, P. DIZIO;
Ashton Graybiel Spatial Orientation Lab., Brandeis Univ., Waltham, MA

Abstract: To study age differences in the interplay among multi-level factors in a balancing task, we used a visual inverted pendulum (VIP) task requiring continuous stabilization of stance-like pendular biomechanics without mechanical loading and postural reflexes, and we simulated altered strength and reflex delay. The participants were 30 younger adults (YA) and 26 older adults (OA). They used a joystick to control an animated beam and bob pivoting about its base. The VIP was programmed as an undamped pendulum (0.27 Hz); the joystick accelerated the pendulum proportionately to its deflection (K_J). Subjects were instructed to keep the VIP at a visible upright reference line (0^o) and avoid visible $\pm 60^o$ "fall" boundaries. When a fall occurred, the VIP was instantly reset to upright and the subject restarted the trial by pressing a thumb button. Every subject experienced all combinations of two joystick gains (K_J =0.025, 0.05) and three delays (0, 0.03, 0.06 s). We analyzed the effects of age and joystick gain and delay on whole-trial variables reflecting overall performance (number of falls, variance of pendulum angular position and velocity) and joystick command strategy (incidence of inactivity, anticipatory adjustments, reactive corrections, and reactive errors driving the pendulum toward a fall). We found significant main effects of age, gain, and delay, as well as an age x gain interaction on the number of falls. There were significantly more falls in OA than YA, in the longer delay conditions, and in the higher gain setting. OA fell significantly more as joystick gain increased but YA did not. No significant age interactions were found for the other variables. We also analyzed periods of imminent falling, where the pendulum was leaning and moving toward a fall boundary, categorized by whether a fall or a successful recovery (crossing the upright) occurred. We compared the incidence of corrective and destabilizing commands for the two outcomes as a function of time before an unavoidable fall. The time of unavoidable falling was defined as the future point where, given the initial velocity, the maximum correct joystick deflection could not prevent reaching the fall boundary. We found significantly more and earlier corrections for recovery than falling, and fewer and earlier destabilizing commands. The differences were significantly larger for YA than OA. The results indicate: 1) a central balancing mechanism compensates for the simulated increases in sensorimotor delays better in YA than OA but equally well to simulated strength changes in YA and OA; 2) a critical, age-dependent error in periods of imminent falling is the decision to move toward or away from the fall boundary.

Title: Regional modulation of the ankle plantarflexors during standing perturbations is attenuated following concussion

Authors: J. W. COHEN[1], T. D. IVANOVA[2], *S. GARLAND[3];
[1]Collaborative Program in Musculoskeletal Hlth. Res., [2]Fac. of Hlth. Sci., [3]Western Univ., London, ON, Canada

Abstract: Balance deficiencies are one of the most commonly reported physical symptoms following a concussion. However, the underlying mechanisms of how balance is affected is relatively unknown. In a previous study, we observed that healthy participants respond to directionally induced perturbations by regionally modulating the activity of their ankle plantarflexors. The findings suggested that the central nervous system activates motor units within different regions of the ankle plantarflexors in response to standing perturbations in different directions. Fourteen participants (7 participants within 6 weeks of concussion (return to play stage 3) and 7 age and sex matched healthy controls; mean age 21.8 yrs; 4 females and 3 males per group) participated in an investigation to determine whether the ankle plantarflexor muscles of participants with concussion were modulated according to perturbation direction during unilateral standing perturbations of 1% body mass. High-density surface electromyography (HD-sEMG) was used to determine the amplitude and barycenter of the muscle activation. The barycenter, defined as the weighted mean of the maximal root mean square amplitude across columns and rows, was used to evaluate the medio-lateral (X) and proximo-distal (Y) shifts of muscle activity within the three plantarflexor muscles. In the healthy controls, the HD-sEMG amplitude of the medial gastrocnemius (MG) and lateral gastrocnemius (LG) modulated with the perturbation directions (MG and LG $p < 0.01$, partial $\eta^2 > 0.500$; one-way repeated-measures ANOVAs), however participants with concussion did not modulate the amplitude of their plantarflexor muscles ($p > 0.05$). The barycenter in the LG and the soleus was also modulated across the perturbation directions for healthy controls (LG: $p < 0.01$, partial $\eta^2 = 0.767$ for X coordinates; soleus: $p < 0.01$, partial $\eta^2 = 0.913$ for X&Y coordinates; one-way repeated-measures ANOVAs). No significant modulation of barycenters of all three muscles was observed in participants with concussion ($p > 0.05$) with the magnitude of the barycenter shift being significantly lower in the concussion group compared to healthy controls ($p < 0.05$, Cohen's $d > 1.2$ (values range from 1.2 to 2.9); one-way ANOVA). Further, the relative contribution of MG activation compared to the total gastrocnemii activation was significantly lower in participants with concussion ($p < 0.05$, Cohen's $d = 0.85$; one-way ANOVA). The findings suggest that the responses of the central nervous system are attenuated following concussion at return to play stage 3, and may not be able to meet the demands required for balance during perturbation tasks.

Minimizing energy costs while walking has been widely accepted for gait regulation. Whereas energy optimization characterizes average gait patterns, there have been rare attempts to reconcile/accommodate gait variability into the explanation. Given that motor redundancy allows individuals to perform tasks reliably while varying in particular ways, to achieve energy optimization, it is of interest to determine how the task goal-irrelevant and goal-relevant variability is regulated. In this study, we investigated how unilateral transfemoral amputees regulate step and stride variability based on the task to achieve energy economy. Nine unilateral transfemoral amputees walked on a treadmill at speeds of 0.6, 0.8, 1.0, 1.2, and 1.4 m/s using their daily passive prosthesis. We applied goal equivalent manifold (GEM) based control to calculate the step-to-step and stride-to-stride variability that were decomposed into goal-relevant and goal-irrelevant manifold during treadmill walking. To quantify the energy economy, the energy recovery rate was calculated based on potential energy and kinetic energy. We found amputees exhibited greater variability along the goal-relevant manifold compared to the goal-irrelevant manifold ($p<.001$) and with less energy recovery rate compared to healthy adults (at least 20% less at faster walking speeds). There was a negative relationship between energy recovery rate and goal-irrelevant variability. Moreover, compared to the standard deviation measurements, the variability decomposed using GEM reflected the amputees' preferred walking speed and the limitation of the passive prosthetic devices. Amputees found a clever way to explicitly exploit the task redundancy and regulate step/ stride variability that was tuned to the goal equivalent manifold. The exploitation of inherent task redundancy allows them to receive potential benefits from motor variability in achieving energy economy. Our findings highlight the limitations of passive prosthetic legs and brings a new perspective motivating the development of powered prosthetic limbs to take into account the task variability allowing

variability distributed along the task space while minimizing variability that interferes with the task goal.

Title: Probiotics Improve Recovery of Hippocampal Memory Following Disruption from High-Fat Diet

Authors: *S. EL-HULU[1], H. NABI[1], T. J. SCHOENFELD[2];
[2]Psychological Sci., [1]Belmont Univ., Nashville, TN

Abstract: Prolonged high-fat diet (HFD) consumption during adulthood reliably leads to physiological markers of obesity, damage to the hippocampus in the brain, and impairments to spatial memory; however, rescuing these physiological and psychological changes by probiotic therapy is underexplored. Probiotics show some rescue effects of memory impairments, but also do switching back to control diet. Therefore, it is difficult to know whether probiotics, or simply avoiding HFD consumption, is important for restoring good memory as aging progresses. To test this, 16 adult Long-Evans male rats were tested on three different one-trial memory tests: novel object recognition (NOR), novel object location (NOL), and spatial working memory on the radial arm maze (RAM) in a longitudinal design. Performance on each memory test was ascertained at the beginning of the experiment to obtain baseline measurements, following 6 weeks of HFD (60% calories from fat), and weekly during a recovery phase after being switched back to a control and healthy diet. In addition to observing memory changes, metabolic markers of blood leptin and glucose were taken at each time point. To see if probiotic treatment during the recovery phase aided in memory restoration, rats were randomly assigned to two treatment groups following 6 weeks of HFD: the probiotic group (n = 8), syringe-fed diluted Chobani Greek non-fat yogurt daily, and the control group (n = 8), fed the same yogurt but filtered to remove bacterial strains. Results show that HFD significantly impairs memory performance across all rats. During the recovery period, although all rats somewhat improved performance over the course of 4 weeks, the probiotic group had faster recovery, with significantly greater performance across all tests by week 4. Although behavioral recovery was different, blood glucose and leptin levels decreased similarly across both groups during recovery. Together the data suggest that HFD impairs memory performance broadly during adulthood and that return to a healthy diet can rescue these effects. However, pairing with probiotic therapy can hasten the recovery processes, suggesting another brain benefit to the use of probiotics.

Title: Acute Exercise Reduces Anxiety and Restores Stress-induced Detriments to Spatial Working Memory

Authors: *J. DAVIS[1], B. MOORE[1], T. J. SCHOENFELD[2];
[2]Psychological Sci., [1]Belmont Univ., Nashville, TN

Abstract: Many rodent studies highlight the impact of chronic aerobic exercise paradigms broadly on cognition, affect, and stress resilience. Despite the common belief that real-time exercise serves as an important stress-coping mechanism in humans, the ability of acute exercise to counteract the effects of stress in rodents has not been explored. In our experiment, adult male Long-Evans rats (n = 8) were habituated for hours at a time to exercise cages containing running wheels to develop a liking towards wheel running without the chronic experience of running. Then, a within-subjects experimental design was used where all rats were tested for spatial working memory on a radial arm maze (RAM) and anxiety-like behavior on an elevated plus-maze (EPM) following either brief exposure (15 minutes) to a running cage or an empty cage after acute music stress (15 minutes) or none. For spatial working memory, acute running did not affect performance at baseline, however acute running did significantly improve performance when preceded by acute music stress ($p < .01$). On the EPM, acute running did reduce anxiety-like behavior at baseline ($p < .01$), but acute music stress prevented these anxiolytic effects. Blood samples were taken to measure corticosterone levels following all four conditions, suggesting that both acute running and music stress increase plasma corticosterone and is unlikely to explain behavioral results. Lastly, effects of acute running alone on optimistic decision-making were examined through the replication of a cognitive bias experiment. Using the RAM, both rough- and smooth-sandpaper textured arms were paired with appetitive or aversively bitter reward, respectively. Once rats learned the sandpaper-reward associations, they were tested on a spectrum of ambiguous sandpaper textures to determine biased behavior in a positive or negative direction, following either brief acute running (15 minutes) or none. It is expected that acute exercise will bias RAM behavior on ambiguous trials in expectation of a positive reward. Overall, results show that rats can be used to model the stress-coping actions of “going for a run” and that brief bouts of running can affect behavior in real time and partially reverse the negative effects of stress on anxiety, performance, and decision-making.

Title: The Impact of Suppressing Adolescent Hippocampal Neurogenesis on Adult Anxiodepressive Behavior and Stress

Authors: *N. JOHNSON[1], R. LARIVEE[1], T. J. SCHOENFELD[2];
[2]Psychological Sci., [1]Belmont Univ., Nashville, TN

Abstract: Various stressors during the adolescent period can affect development of the brain and have long-lasting impacts on behavior. Specifically, adolescent stress impairs hippocampal neurogenesis and produces increased risk for anxiety, depression, and a dysregulated stress response in adulthood. In order to model the functional effects of reduced hippocampal neurogenesis during adolescence, a transgenic neurogenesis ablation rat model was used to suppress neurogenesis only during the adolescent period and test anxiodepressive behaviors and stress physiology during adulthood, when neurogenesis would be normalized again. Wildtype and GFAP-TK rats (n = 8-9) were given valganciclovir during the first two weeks of adolescence (4-6 weeks old) and injected with bromodeoxyuridine (BrdU) to measure cell proliferation throughout treatment. Starting in young adulthood (13 weeks old), blood was sampled at various time points following acute restraint stress to measure negative feedback of the HPA axis stress response and rats were tested on a battery of anxiodepressive tests (elevated plus-maze, novelty-suppressed feeding, forced swim test, sucrose preference test) at baseline and following acute restraint stress. Hippocampal tissue was additionally analyzed to measure doublecortin in the dentate gyrus to quantify relative neurogenesis during young adulthood and hippocampal volume using Nissl-based stereology to determine long-lasting impacts of neurogenesis arrest during adolescence on hippocampal structure in adulthood. Overall, results show the impact that suppressing neurogenesis has on risk for increased anxiety-like behavior, depressive behavior, and healthy stress physiology and adds further evidence to the dangers of early-life aversive experiences on brain development and behavior.

Title: Behavioral sex differences after predator scent stress exposure

Authors: *P. TORRES-CARRILLO[1], Y. B. VIDAL-DE LA O[2], D. B. PAZ-TREJO[3], L. D. OCHOA-DE LA PAZ[4], H. SANCHEZ-CASTILLO[5];
[1]Univ. Nacional Autónoma De México, Ciudad de Mexico, Mexico; [2]Univ. Nacional Autónoma De México, Ciudad DE Mexico, Mexico; [3]Univ. Nacional Autonoma de Mexico, Mexico City, Mexico; [4]Univ. Nacional Autónoma de México, Mexico city, Mexico; [5]Univ. Nacional Autonoma De Mexico. Fac Psicologia, Mexico City, Mexico

Abstract: The higher prevalence in females to develop stress related disorders could be explain by sex differences in neuroendocrine and behavioral responses to stress, under this explanation, the females have showed more impairment than males, however there is not enough evidence to support that hypothesis. Additionally, the lack of evidence about mechanisms which females had more impairment is explained because most neural and behavioral studies not included females, however, the pattern suggest that stressed males have downregulation on neural activity while stressed females have not alter or have upregulation of neural activity. Such facts support the idea of sex specific stress effects on behavior. The aim of this study was to compare female and male responses to an acute stressor vs. no-stress condition: Predator Scent Stress (PSS) was used as a stress model. Male and female Wistar rats 12 weeks old were used and randomly distributed in a PSS and control group (n=10 per group). Animals of the PSS group were exposed for 10 minutes in an exposure box that contained a bottle with scent tag impregnated with predator urine, whereas the control group only was exposed to the container without the predator urine. Behavior was assessed with novel object recognition (NOR), Barnes maze (BMT), open field (OFT), saccharin preference (SPT), and forced swim (FST) tests 24 hours after the stressor exposure. The results obtained in NOR showed that PSS groups had highest latencies to explore the novel object for the first time. In the BMT's results the PSS induced higher latencies and errors than control groups, but PSS females had more errors than PSS males. Further, in the SPT's results shows that PSS-induced lower preference for saccharin than control groups. Also, PSS females had a higher consumption of liquid in comparison with PSS and control males. Additionally, in FST PSS males increase immobility time than control groups while PSS exposed females decreases. On the other hand, PSS groups exhibited anxiety-like behaviors in OFT. PSS females spend lower time in the central area than PSS males. Also, PSS groups had a lower locomotor activity than control groups. Finally, PSS groups had an increase of time spend immobility and grooming in the OFT. This suggests that PSS induced impairment on memory in females and males but not in the same way. Also, PSS induced anhedonia, a depression-like behavior. Additionally, PSS induced anxiety-like behaviors in OFT. Those impairments could be associated with sex-specific alterations in areas important for learning and memory like the prefrontal cortex and hippocampus and for areas mediating mood and anxiety such amygdala.

Title: Alpha 2-adrenergic mechanism in stress induced decision-making

Authors: *C. TURNER, V. VISOCKIS, Y. CHUDASAMA;
Natl. Inst. of Mental Hlth., Bethesda, MD

Abstract: The α2A-adrenergic receptor is closely associated with stress. In fact, systemic administration of yohimbine, an α2A receptor antagonist increases stress in rats and humans as measured through autonomic physiological responses (Johnston and File, 1989. Pharmacol Biochem. Behav. 32:151-156). In rats, it also leads to impulsive decision-making (e.g., Sun et al. 2010, Biol. Psychiat. 67:649-656). Moreover, the stress response is associated with significant increases in noradrenaline (NA) in the hippocampus (Tanaka et al. 1982. Pharmacol. Biochem. Behav. 16:315-319), and dopamine (DA) in the prefrontal cortex (Thierry et al. 1976. Nature. 263:242-244), which might stimulate the cortex to drive risky behaviors contributing to pathological tendencies towards gambling, substance abuse, and other high-risk behaviors. Here, we explored this possibility by combining a pharmacological stressor, FG7142 with adrenergic agonists and antagonists. We first trained rats on an operant touchscreen decision-making task in which rats chose between two visual stimuli. Responses to the 'safe' stimulus always resulted in the delivery of a certain reward (50µl sucrose). Responses to the 'risky' stimulus resulted in the delivery of an uncertain reward (10µl 75% of the time, and 170µl 25% of the time). The left and right positions of the visual stimuli were determined pseudorandomly. When given a systemic 4 mg dose of FG7142, the rats shifted their baseline strategies by increasing their choice of the safe stimulus and hence the certain reward. In addition, these animals showed long response latencies indicating a slow or deliberated response. In contrast, the co-administration of FG7142 and yohimbine made the rats riskier since these animals not only preferred the option that delivered the uncertain reward but also increased the speed of responding. In comparison, the combination of FG7142 and guanfacine, an α2A receptor agonist, had little impact on the animals' behavior. These data indicate that stress together with acute activation of the noradrenergic system may worsen or trigger risky behaviors observed in both clinical and non-clinical populations. Further studies will examine the combined effects of stress and dopamine stimulation on risky decision-making.

Title: Profiling individual behavioral differences in zebrafish across time using the novel tank test.

Authors: *N. RAJPUT, J. W. KENNEY;
Wayne State Univ., Detroit, MI

Abstract: Social gatherings can be fun for one person, but awkward, for another. Such individual variations in behavior are common, but how they arise is poorly understood. Individuality in behavior is known to be influence by environmental and biological factors. To better understand differences in behavior, we have analyzed zebrafish swim behavior during exploration of a novel tank. When exposed to a novel environment, zebrafish exhibit a variety of exploratory behaviors. To assess these behaviors, we automatically captured three-dimensional swim patterns using depth-sensing cameras. We recorded swim behavior from 400 animals (4-6 months of age) from four commonly used inbred strains (AB, TU, TL, and WIK) and both sexes to study the influence of sex and genetics on behavioral variability. Markerless tracking of the fish was done using a deep learning approach (DeepLabCut) to identify fish posture. To identify postures, we analyzed 200000 video frames. We found that fish posture stratifies into approximately 11 different clusters. Additionally, our analysis of behavioral parameters found that fish behavior stratifies into 5 distinct clusters. Finally, we found that clustering membership is consistent over time and is influenced by strain and sex. With this exploratory study, we provide new insight into the effects of sex and strain on individual behavioral differences in zebrafish.

Title: Rapid Shifts in the Spectral Dynamics of the Medial Prefrontal Cortex and Hippocampus during Nonspatial Memory for Sequences of Events in Rats

Authors: *A. GARCIA[1], M. JAYACHANDRAN[1], R. P. VERTES[2], T. A. ALLEN[1];
[1]Psychology, Florida Intl. Univ., Miami, FL; [2]FAU/Ctr Complex Systems, Boca Raton, FL

Abstract: A fundamental feature of episodic memory is the ability to remember a sequence of events as they occurred over time, which depends on interactions between the medial prefrontal cortex (mPFC) and the hippocampus (HC; e.g., Jayachandran et al., 2019, *Cell Rep*; Eichenbaum 2017, *NatNeurosci*). While the HC is thought to represent information according to spatiotemporal contexts, mPFC is thought to support the rapid retrieval of information relevant to an action or decision. Nevertheless, how the two structures interact in support of memory for sequences of events is not well understood. Here, we performed simultaneous local field potential (LFP) recordings in mPFC (targeting the prelimbic cortex) and HC (targeting dorsal CA1) using NeuroNexus silicon probes. LFPs in dorsal CA1 have shown to engage theta (5-11Hz) and beta (15-30Hz) during odor sequence memory, with beta activity related to the sequential context (Allen et al. 2016, *JNeurosci*). Here, we expected that mPFC-HC neural dynamics would have complementary spectral modes that reflect the rapid shifting of cognitive processes necessary to perform the sequence memory task. To look at this, we tested five rats (3 females, 2 males) on a sequence memory task with two sequences composed of four unique odors located in nose ports at opposite ends of a linear maze (Side 1, Sequence 1: A_1-B_1-C_1-D_1; Side 2, Sequence 2: A_2-B_2-C_2-D_2). Rats demonstrated sequence memory by holding for >1sec for in sequence odors or withdrawing prior to 1sec for out of sequence odors in order to receive a small water reward. LFPs from mPFC and HC were analyzed using perievent power spectral densities and by looking at coherence between these two regions. We divided our analysis into several epochs including running up to the port, sampling the odor, executing a decision, and receiving the reward. In the spectrograms, we observe strong theta power while running towards the port in HC (and to a lesser degree as the animal poked in the port), strong delta (1-4Hz) power in mPFC around poking behaviors, and strong beta power in both mPFC and HC during odor sampling. Likewise, we observed strong mPFC-HC coherence in all bands, but the task-related modulations were dominated by increased coherence in delta and beta bands during sequence memory. Beta coherence levels seem to be related to performance accuracy, reflecting the olfactory nature of the task. These results indicate that mPFC-HC interactions are highly dynamic and rapidly cycle through multiple modes of rhythmic operation in the delta, theta, and beta bands, reflecting the multiple cognitive stages necessary in memory for sequences of events.

Title: Examining Sex and Estrous Cycle in Memory for Sequences of Events in Rats

Authors: *P. LANGIUS[1], M. JAYACHANDRAN[1], F. PAZOS REGO[2], R. P. VERTES[3], T. A. ALLEN[1];
[1]Psychology, Florida Intl. Univ., Miami, FL; [2]Educ. and Human Develop., Univ. of Miami, Miami, FL; [3]FAU/Ctr Complex Systems, Boca Raton, FL

Abstract: A fundamental feature of episodic memory is the ability to remember a sequence of events as they occurred in time. While rodent studies have examined sex and estrous cycle in spatial and episodic-like memory tasks, little is known about these biological variables in memory for sequences of events. Here, we investigated the role of sex (female/male) and estrous cycle in rats during training and testing phases of an odor sequence memory task (Jayachandran et al., 2019, *Cell Reports*). Rats (10 females, 10 males) were trained on an odor-based sequence memory task composed of two sequences each with four unique odors, delivered in two ports at opposite ends of a linear track. Training occurred over several weeks. First, rats were trained to poke in a nose port and hold for 0-1.2s with an adaptive rule (+10ms for correct trials) for a small water reward on Side1. Second, rats were trained to poke for 1.2s on Side2. Third, time was reduced to 1s, and rats were required to alternate between sides for rewards. Fourth, A_1 and A_2 odors were added to acclimate rats to the odor delivery. Fifth, a second pair of odors were added (Side1, Sequence1: A_1-B_1; Side2, Sequence2: A_2-B_2) forcing rats to poke in the port twice in a row for rewards. Sixth, repeated odors were added (A_1-A_1) which provided a reward for withdrawing prior to 1s. 1s became a decision threshold where rats responded to in sequence odors by holding in the port for >1s and out of sequence odors for <1s. Seventh and eighth, the sequence lengths were extended to three (Side1, Sequence1: A_1-B_1-C_1; Side2, Sequence2: A_2-B_2-C_2) and four odors (Side1, Sequence1: A_1-B_1-C_1-D_1; Side2, Sequence2: A_2-B_2-C_2-D_2). Sequence memory was demonstrated in the last phase when rats responded to both in and out of sequence odors accurately, summarized by a sequence memory index (SMI). Performance across training phases was analyzed by sex and estrous cycle (proestrus, estrus, metestrus, and diestrus) determined by the cellular composition of a vaginal lavage. Results did not show any sex differences in asymptotic sequence memory performance, similar to what we observed in humans performing an analogous task (Reeders et al., 2021, *LearnMem*). Across the estrous

cycle, proestrus and estrus had higher SMI compared to metestrus and diestrus. Some notable observations during training include: females acquired hold times faster; male rats transitioned to new phases faster; female rats had longer pokes, while males had more short pokes (<200 ms). These results indicate that sex differences are evident in training but not testing phase of sequence memory in rats and that the estrous cycle is related to small differences in performance in females during the testing phase.

Title: Laboratory-based Spatial Memory Testing in the Aged Minipig and Domestic Pig

Authors: *L. M. ALLEN[1], M. N. MOUSSA[1], A. DELGADO[1], M. AGUIAR[1], K. LEE[2], T. J. JAROME[3], T. A. ALLEN[1];
[1]Dept. of Psychology, Florida Intl. Univ., Miami, FL; [2]Univ. of Missouri, Columbia, MO; [3]Virginia Tech., Blacksburg, VA

Abstract: Pig (*Sus scrofa*) biology is similar to humans in multiple ways, such as fat distribution, hair coverage, and several organ systems including skin, lung, cardiovascular, metabolic, pancreatic, and gastrointestinal. The pig genome is three times closer to the human genome than that of the mouse (Walters and Prather, 2013, *Advancing Swine Models for Human Health and Diseases*). As such, pigs have been used in translational biomedical research for more than 40 years. However, pigs have rarely been used in behavioral neuroscience, and could benefit translational neurological research on disorders such as age-related cognitive decline and Alzheimer's Disease. As part of a larger strategy in establishing the pig model for translational behavioral neuroscience, we have been developing multiple laboratory-based cognitive/behavioral tasks for pigs. Here we present data from Minnesota minipigs and domestic pigs (mixed-breed) each of which present distinct advantages for neuroscience. For example, the minipig has a more manageable weight across their lifespan, while the domestic pig has a more accessible frontal cortex. Specifically, subjects were minipigs (National Swine Resource and Research Center) or domestic pigs (Wallister Pork) that differed by age (0.5-6.5yrs) to assess viability and differences across cohorts in a classic spatial delayed alternation paradigm. The spatial alternation task is a staple in rodent behavioral neuroscience and responsible for much of

what is known about the neurobiological mechanisms of learning and memory. Spatial memory was tested in a large, fully automated T-maze (17' x 13') with a start box, choice points, automatic rewards (flavored pellets), and return arms separated by guillotine doors. First, we tested the ability for pigs to acquire spatial memory by assessing trials to criteria (3 days at >75% accuracy). We found that younger domestic pigs (n=6, 0.5-1.5yrs) reached criteria quickly over 7 training sessions. By contrast, the older minipigs (n=2, 1.5 & 6.5yrs) demonstrated shallower learning curves: the 1.5yr minipig required 12 training sessions, while the 6.5yr counterpart needed 18 sessions. Next, we tested spatial working memory by introducing various randomly presented delays (5, 60, 120, and 240 sec) which provides a memory decay function. Here, we found that younger pigs performed well declining from 95-63% accurate across delays, while aged minipigs had a slight decrease in overall performance, but similar decay rate from 85-60% accurate across delays. We are continuing to test aged minipigs in order to see if spatial memory differences vary as a function of age, or reflect other cohort differences.

Title: Neuronal Representations in Medial Prefrontal Cortex during Nonspatial Memory for Sequences of Events

Authors: *M. JAYACHANDRAN[1], A. VASALLO VELIZ[1], S. LEYVA[1], R. P. VERTES[2], T. A. ALLEN[1];
[1]Psychology, Florida Intl. Univ., Miami, FL; [2]FAU/Ctr Complex Systems, Boca Raton, FL

Abstract: Memory for sequences of events facilitates organization of episodic experiences into serial or ordinal associations representing the flow of events that have occurred. It is established that hippocampus (HC) is essential for formation (e.g., Fortin et al., 2002, *NatNeurosci*) and representation of sequential context (Allen et al., 2016, *JNeurosci)*. We recently showed that specific cell populations in medial prefrontal cortex (mPFC) differentially contribute to retrieval strategies in sequence memory (Jayachandran et al., 2019, *Cell Rep*). Yet, how individual mPFC neurons respond while processing sequence memory is not fully understood. We expect mPFC activity to be related to the sequential context, ordinal position, and accuracy aspects of the task.

Specifically, mPFC neurons should encode features with a temporal pattern complementing CA1 dynamics. Here, rats were trained to remember two sets of four odor sequences (Side 1, Sequence 1: A_1-B_1-C_1-D_1; Side 2, Sequence 2: A_2-B_2-C_2-D_2) presented at opposite ends of a linear track. Rats demonstrated sequence memory in both sequences by holding their nose in the port for >1s for in sequence odors, and withdrawing prior to 1s for out of sequence odors for a water reward. We recorded ~200 neurons during the task in five rats (2 males, 3 females) using NeuroNexus silicon probes with a 2x4 tetrode pattern targeting prelimbic cortex and dorsal CA1. Single mPFC neurons were isolated offline, and their spike times analyzed across task variables (odors, positions, sequential context, and accuracy) in temporal analysis windows aligned to poking behaviors (poke in/out). Results showed that ~30% of mPFC neurons were related to position, sequential context and accuracy, but not odors. Moreover, mPFC spike activity changed around poking behaviors with ramping-like changes in firing rates. These response patterns generalized between sequences, and were thus nonspatial. In addition, local field potential dynamics reliably show a patterned dominance of HC theta (5-11Hz) running up to the port, mPFC delta (1-4Hz) around poking behaviors, and mPFC and HC coherent beta (15-30Hz) during odor sampling. We next looked within spike-phase relationships in these spectral bands and observed mPFC spikes are often entrained to local delta around poking behaviors, and phase entrained to beta and theta related to trial accuracy (Symanski et al., 2021, *bioRxiv*). The spiking dynamics raise interesting questions about the supremacy of different rhythmic mechanisms governing mPFC neuronal integration during processing epochs related to sequence memory. Overall, the results are consistent with sequence memory as a mPFC-HC based process.

Title: Optogenetic stimulation of nucleus reuniens of the thalamus elicits frequency and projection specific changes in medial prefrontal cortex and ventral hippocampus activity

Authors: T. D. VIENA[1], B. SETLOW[2], F. D. LUBIN[3], R. P. VERTES[4], T. A. ALLEN[1]; [1]Dept. of Psychology, Florida Intl. Univ., Miami, FL; [2]Dept. of Psychiatry, Univ. of Florida, Gainesville, FL; [3]Dept. Neurobiol, Univ. Alabama Birmingham, Birmingham, AL; [4]Ctr. for Complex Systems and Brain Sci., Florida Atlantic Univ., Boca Raton, FL

Abstract: Abnormal synchronization in the prefrontal-hippocampal circuit is a hallmark of several neuropsychiatric disorders. Anatomically, nucleus reuniens (RE) projects to both the medial PFC (mPFC) and hippocampus (HC), including a population of neurons that simultaneously project to both structures (Viena et al., 2020, *Hippocampus*). Previous work has demonstrated the involvement of RE in cognitive tasks that require mPFC-HC interactions, and importantly, involvement in the rhythmic activity of the mPFC-HC system in the theta (5-11Hz) and delta bands (1-4Hz; Dolleman-van der Weel et al., 2019, *LearnMem*). One current hypothesis is that RE is responsible, in part, for mediating coordinated interactions within the mPFC-HC network in support of cognition. It is unclear, however, which RE neurons are capable of modulating mPFC-HC rhythms. We tested this capacity using an optogenetics/AAV-retrograde strategy to differentially activate RE neurons that project to mPFC or ventral CA1. Rats received bilateral retrograde AAV injections of channelrhodopsin (ChR2) in prelimbic cortex (n=5) or vCA1(n=4), while control rats received non-ChR2 injections (n=5). All rats were implanted with stainless-steel electrodes bilaterally in mPFC and vCA1 to record local-field potential (LFP) and unit activity, and an optrode above RE for LED-based blue light stimulations. Recordings occurred in an open field maze during free behavior. ChR2 infected RE neurons were stimulated with square pulses or sine waves at frequencies known to be intrinsic to RE neurons (Viena et al., 2021, *BehavBrainRes*; 1, 2, 4, 8, 20, 50Hz; 5 min blocks each). When stimulated at these frequencies, the resultant LFP rhythm included the stimulated frequency superimposed on the intrinsic activity of experimental rats but not in controls. The strongest effects were in pathway targeted regions (i.e., RE⇒mPFC or RE⇒vCA1). This effect was present in mPFC and vHC when we applied sine waves, but it was weaker or absent with pulses. Compared to controls, overall delta rhythms were enhanced in vHC, and overall theta rhythms were enhanced in mPFC. Consistent with glutamatergic projections from RE, we observed single neurons in downstream targeted areas (mPFC) that were directly activated by blue light activation of ChR2 in RE. In combination, findings demonstrate that activation of RE⇒mPFC or RE⇒vCA1 pathways can elicit frequency and projection-specific changes in mPFC and vHC activity. Our findings support the idea that RE influences the activity of mPFC-HC system, potentially by sustaining synchronous changes in these target regions to support higher-order cognitive processes associated with mPFC-HC interactions.

Title: Dual medial prefrontal cortex and hippocampus projecting neurons in the paraventricular nucleus of the thalamus of rat

Authors: *G. E. RASCH, T. D. VIENA, T. A. ALLEN;
Cognitive Neurosci., Florida Intl. Univ., Miami, FL

Abstract: The paraventricular nucleus (PVT) of the midline thalamus is a critical integration site and contributes to emotional memory, context learning, reward seeking, and feeding behavior (e.g., Do-Monte et al., 2015, *Nature*). The diversity of its functions is supported by its anatomical connections to both cortical and subcortical regions, including medial prefrontal cortex (mPFC), central/basal nuclei of amygdala, and hippocampus (HC) (Vertes & Hoover, 2008, *Comparative Neurology*). While studies have shown that PVT neurons project to mPFC and HC separately, it is not known whether these come from the same or different cell populations. Previous investigations show single and dual mPFC and HC projecting neurons in the nucleus reuniens (RE) (Viena et al, 2020, *Hippocampus*). Using a dual retrograde adeno-associated viral approach, we sought to identify neuronal populations within PVT that project to medial prefrontal cortex (mPFC), ventral HC (vHC) and/or neurons with collaterals to both regions. Simultaneous bilateral injections were delivered targeting mPFC deep layers V/VI (0.4μL of AAVr-CAG-TdTomato) and ventral CA1 regions of vHC (0.5 μL of AAVr-CAG-GFP) in four rats. Quantification of retrogradely labeled neurons was performed in four levels throughout the anteroposterior axis of PVT. Results showed that PVT contains a population of neurons that simultaneously project to mPFC and vHC (~2%), with no significant differences in the prevalence of this population across the anteroposterior axis. Next, we examined the calcium binding protein expression in these cells. We previously showed that the distribution of calcium binding proteins calretinin (CR) and calbindin (CB) cells segregate throughout the nuclei of the midline thalamus including PVT. We found that dual mPFC-vHC projecting cells in PVT did not express either CR nor CB, however, CR^+ and CB^+ immunopositive PVT cells were spatially segregated into random clusters surrounding dual projecting PVT cells. Generally, dual mPFC-vHC projecting cells in PVT share the characteristics found in RE. This newly identified PVT cell population that projects to both mPFC and vHC forms a unique circuit that may, like RE, may provide a synchronization mechanism for coordinating mPFC-vHC activity but for cognitive functions more associated with PVT.

Title: Reducing Seizure and Behavior-Related Hypersynchrony of the Hippocampal Theta Rhythm Caused by Chronic Exposure to Lead (Pb^{2+})

Authors: *N. W. SCHULTHEISS[1], J. L. MCGLOTHAN DZIEDZIC[2], T. R. GUILARTE[2], T. A. ALLEN[3];
[2]Envrn. Hlth. Sci., [3]Dept. of Psychology, [1]Florida Intl. Univ., Miami, FL

Abstract: Pb^{2+} is a NMDA receptor antagonist, and exposure during brain development can cause permanent intellectual impairments and social, emotional, and behavioral dysregulations. Pb^{2+} exposure is also a risk factor for schizophrenia (SZ) and epilepsy (Epi). Pb^{2+} neurotoxicity exhibits significant comorbidity SZ and Epi; biomarkers for Pb^{2+} exposure correlate to SZ incidence and symptom severity; and Pb^{2+} exposure exacerbates seizures and worsens cognitive and sensorimotor deficits in experimental models of SZ. Childhood Pb^{2+} exposure reduces parvalbumin-positive GABAergic interneurons (PVGIs) in prefrontal cortex (PFC) and hippocampus (HC), a hallmark of schizophrenia. These fast-spiking PVGIs are integral to thetarhythmic HC synchronization (6-10 Hz), that in turn coordinates gammafrequency neuronal interactions (25-120 Hz). As we have recently demonstrated, developmental Pb^{2+} exposure causes hypersynchrony of the HC theta rhythm and gamma oscillations, potentially arresting functional coupling between HC and PFC. Pb^{2+} exposure also increased absence seizures marked by synchronous discharges with a theta fundamental frequency (Schultheiss et al., 2020, bioRxiv 181149). It is a provocative possibility that cortical SWDs entrain intrinsic HC mechanisms of rhythmogenesis, contributing to learning and memory deficits. At present there are no effective treatment strategies for theta hypersynchrony.We analyzed local field potential recordings (LFPs) from control and Pb^{2+}-exposed rats (Schultheiss et al. 2020b, BehavNeurosci) to test whether 7,8dihydorxyflavone (DHF), a TrkB-mimetic and common dietary supplement, can ameliorate theta hypersynchrony. Following baseline sessions, rats were given daily DHF injections (5 mg/kg) for 2 weeks. After controlling for locomotion, theta was normalized to DHF(-) values in control rats. Distributions of theta power for Pb^{2+}-exposed rats showed that DHF markedly reduced theta hypersynchrony ($t(286) = 10.64$, $p = 1.68x10^{-22}$), and a 2 x 2 ANOVA revealed a significant interaction of Pb^{2+} x DHF ($F(1,608)=20.0$, $p=9.1x10^{-6}$). This suggests a possible avenue to improve neurocognitive function in millions of people using a safe, inexpensive supplement. We also found that absence seizures were abolished by the antiepileptic drug ethosuximide (50-200 mg/kg). Complementing DHF, blocking absence seizures in children could reduce neurotoxic effects of Pb^{2+}. We propose that developmental Pb^{2+} neurotoxicity shares pathophysiological mechanisms with SZ and absence epilepsy, defining a distinct neurophysiological endophenotype underlying similar patterns of cognitive impairment across conditions.

Title: Dual-projecting cells linking thalamic and cortical communication routes between the medial prefrontal cortex and hippocampus

Authors: *M. SCHLECHT, M. JAYACHANDRAN, G. E. RASCH, T. A. ALLEN; Florida Intl. Univ., Miami, FL

Abstract: Interactions between the agranular medial prefrontal cortex (mPFC) and hippocampus (HC) play a major role in basic cognitive and behavioral functions, especially those related to memory-based decision making (e.g., Dolleman-van der Weel, 2019, *LearnMem;* Eichenbaum, 2017, *NatNeurosci*). Dysfunction in mPFC-HC have been specifically implicated in several neurological disorders including schizophrenia, epilepsy, frontotemporal dementia, and Alzheimer's disease. Although HC projects directly to mPFC, return projections go through an intermediary region. In memory, the ventral midline thalamus (vmThal) and parahippocampal cortex constitute major communication pathways in mPFC-HC interactions. These thalamic and cortical routes of communication between mPFC and HC provides the interface for executive functions, working memory, and long-term memory integration. While the anatomy of the thalamic and cortical pathways in the mPFC-HC circuitry have been explored in detail elsewhere, it is not known about whether the afferent regions shared by vmThal, lateral entorhinal cortex (LEC), and perirhinal cortex (PER) arise from the same or different (non-overlapping) cell populations. Here, we sought to determine whether these two regions share cell-specific inputs that could activate patterns in both routes simultaneously. To do this we used a dual fluorescent retrograde tracing approach using cholera toxin subunit-B conjugated with Alexa Fluorophores (CTB-488 and CTB-594) with injections targeting vmThal (0.3 µL of CTB) and the parahippocampal region (LEC/PER; 0.5 µL of CTB) in rats. Retrograde cell body labeling was examined in key regions of interest within the mPFC-HC system including: (1) mPFC, specifically anterior cingulate cortex (ACC), dorsal and ventral prelimbic cortex (dPL, vPL), and infralimbic cortex (IL); (2) medial and lateral septum (MS, LSd, LSi, LSv); (3) subiculum (Sub) along the dorsal-ventral and proximal-distal axes; and (4) medial and lateral entorhinal cortex (MEC, LEC). Results showed that dual vmThal-LEC/PER-projecting cell populations are found in MS, ventral Sub, and the shallow layers II/III of MEC and LEC.

Interestingly, we did not find any dual vmThal-LEC/PER-projecting cells in mPFC or in the cornu ammonis (CA) subfields of the HC. Therefore, mPFC and HC activity is sent to vmThal and parahippocampal cortex via non-overlapping projection cell populations from HC proper. These newly described dual vmThal-LEC/PER-projecting cell populations in MS, ventral Sub, and LEC are in a unique position to simultaneously influence both the cortical and thalamic mPFC-HC pathways.

Title: Locating the midline thalamus in humans using diffusion weighted imaging for the investigation of neurological disorders

Authors: *P. C. REEDERS[1], A. T. MATTFELD[1], T. A. ALLEN[1,3,2];
[1]Dept. of Psychology, [2]Dept. of Envrn. Hlth. Sci., Florida Intl. Univ., Miami, FL; [3]Ctr. for Complex Systems and Brain Sci., Florida Atlantic Univ., Boca Raton, FL

Abstract: The midline thalamus coordinates activity in higher-order cortico-thalamic-cortical networks, most notably those that involve the agranular medial prefrontal cortex and medial temporal lobe. At a basic level, the midline thalamus is critical to cognition at the intersection of executive and memory function. At the clinical level, midline thalamic pathology is associated with several neurological disorders including Alzheimer's disease, epilepsy, drug addiction, mood disorders, and others. In Alzheimer's disease (AD), neurofibrillary tangles are present in the thalamus, which target the midline nuclei, when symptoms are most severe (Braak & Braak, 1991, *Acta Neuropathol*, p. 261-268). Based on specific patterns of anatomical connectivity in rodents and macaques, four midline thalamic nuclei have been identified including paratenial nucleus (PT), paraventricular nucleus (PV), rhomboid nucleus (RH), and the nucleus reuniens (RE). However, almost nothing is known about the midline thalamic nuclei in humans *in vivo*. This is due, in part, to the difficulty in identifying the limbic thalamus with current imaging technologies. Here, we sought to identify the midline thalamus *in vivo* by using probabilistic tractography and *k*-means clustering with diffusion weighted imaging data. Thalamic nuclei were clustered and sorted based on connectivity profiles (cortical and subcortical targets). This approach revealed a midline thalamic cluster that is well connected to the agranular medial prefrontal cortex and medial temporal lobe and located directly adjacent the third ventricle. This pattern was identified as the human midline thalamus. We created two masks for human midline

thalamus dividing a dorsal midline thalamic mask, which includes the PV and PT, from a ventral midline thalamic mask, which includes the RH and RE. These divisions are important because dorsal and ventral midline thalamus are known to contribute to different cognitive functions in rodents. Ultimately, this connectivity-based identification and segmentation method can be used to help characterize neurological brain pathologies by investigating alterations in the quantified structural connectivity between the midline thalamus, medial temporal lobe, and medial prefrontal cortex region. We are currently examining these patterns across stages of Alzheimer's disease.

Title: Theta synchronized stimulation increases hippocampal excitability in humans

Authors: *J. E. KRAGEL[1], S. M. LURIE[1], M. J. SCHATZA[4], E. B. BLACKWOOD[4], E. A. CHUNG[1], C. ZELANO[2], S. U. SCHUELE[2], J. F. DISTERHOFT[3], A. S. WIDGE[4], J. L. VOSS[1,2];
[1]Med. Social Sci., [2]Neurol., [3]Physiol., Northwestern Univ., Chicago, IL; [4]Psychiatry, Univ. of Minnesota, Minneapolis, MN

Abstract: Theta oscillations organize memory processing across cortico-hippocampal networks to support memory function. The phase of theta dictates the flow of information to and from the hippocampus, with sensory inputs optimally timed to arrive at the trough of hippocampal theta. Modulation of hippocampal activity timed to the ongoing theta rhythm would provide a framework to causally assess a behavioral role of theta and develop stimulation-based techniques to restore memory function. However, phase-locked stimulation of hippocampal networks and resulting neurophysiological changes have not been characterized in humans. Here, we used a phase-locking algorithm to drive direct electrical stimulation (DES) of the lateral temporal cortex, a node of the hippocampal network. Network-targeted stimulation was timed to the trough of invasively recorded hippocampal theta oscillations (N=2 participants). After 30 minutes of phase-locked DES, evoked potentials in the hippocampus increased in amplitude (both $p = .01$, permutation tests). In addition, we assessed changes in synchronization between the hippocampus and the stimulation site using the debiased weighted phase lag index. Phase-locked stimulation increased theta synchrony (4 - 8 Hz, participant one, $p = .01$; participant two,

p = .04, permutation tests) during rest. Taken together, these preliminary findings suggest that theta-phase synchronized stimulation is an effective means to modulate hippocampal excitability and network strength, providing a pathway to modulate hippocampal-dependent behaviors.

Title: Effects of closed-loop phase-locked stimulation on cortico-hippocampal connectivity in rats

Authors: *E. SONG[1], A. ALPERS[1], K. WARNER[1], M. SCHATZA[1], C. WEISS[2], H. S. WIRTSHAFTER[2], J. F. DISTERHOFT[2], J. L. VOSS[3], A. S. WIDGE[1];
[1]Univ. of Minnesota, Minneapolis, MN; [2]Northwestern Univ. - Chicago, Chicago, IL; [3]Med. Social Sci., Northwestern Univ., Chicago, IL

Abstract: The hippocampus (HPC) and its interactions with broader brain networks are essential for memory processing. In rats, temporal association cortex area 2 (TE2), a region that is dorsally adjacent to the perirhinal cortex, communicates with the HPC and plays an important role in recognition memory. Synchronization of local field potentials (LFP) has been linked with network functions throughout the brain. Here we report that a novel phase-locked stimulation algorithm developed by our group can alter LFP synchronization within the hippocampal network. The effects of the phase-locked stimulation were examined in three ways: 1) TE2->HPC synchrony, 2) synchrony among HPC subfields, and 3) acute and cumulative effects of multiple daily sessions. Long Evans rats were implanted with a 32-channel silicon probe in the dorsal hippocampus and an 8-channel microwire bundle with a stimulating wire in TE2. Neural signal was recorded while rats were behaving in an open field and performing a touch screen memory task in an operant chamber. We demonstrated that phase-locked stimulations in TE2, locked to specific stages of the theta/alpha oscillation in the hippocampus, could increase or decrease the coherence in the theta-alpha band throughout the network. Specifically, 100µA 90µs biphasic pulses delivered to TE2 at 0º or 90º phases of a hippocampal 6Hz oscillation increased and decreased, respectively, the TE2-HPC coherence. The efficacy of different current intensities, phase degrees and oscillation frequencies were also examined. Our results suggest

that a single 30min phase-locked stimulation session could induce changes in coherence and that a 30min session of stimulation daily over the course of 2-3 weeks could potentially lead to sustained changes in coherence between the TE2 and the HPC. The data also support that the synchronization of the subfields within the HPC can be altered following closed-loop stimulation. For instance, the coherence between the dentate gyrus and the CA1 was increased after stimulation. Additionally, we measured effects of stimulation on memory using a spatial object recognition memory task (paired associate learning). Behavioral effects of the phase-locked stimulation are currently being evaluated. This study, to our best knowledge, is the first to demonstrate that closed loop stimulation can causally manipulate frequency-specific coherence in hippocampal networks and thus potentially improve learning and memory. The present work provides important insights and therapeutic potential in treating patients with memory disorders.

Title: Hippocampal potentials evoked by network-targeted stimulation vary by theta phase

Authors: *S. M. LURIE[1], J. E. KRAGEL[1], E. SONG[4], M. SCHATZA[4], S. U. SCHUELE[2], J. F. DISTERHOFT[3], A. S. WIDGE[4], J. L. VOSS[1];
[1]Med. Social Sci., [2]Neurol., [3]Physiol., Northwestern Univ., Chicago, IL; [4]Psychiatry, Univ. of Minnesota, Minneapolis, MN

Abstract: Although stimulation targeting the hippocampus indirectly via its network can impact hippocampal memory function, the mechanisms governing its effects are not fully understood. For example, though CA3 excitability and entorhinal connectivity vary with hippocampal theta phase (Hasselmo et al. 2002), it is not known whether phase has an impact on network stimulation efficacy. To address this question, we tested whether corticocortical evoked potential (CCEP) amplitude in the human hippocampus varies according to local theta phase at the time of stimulation. Intracranial local field potential data were collected from individuals with epilepsy undergoing medically necessary stereotactic electroencephalographic recording (sEEG) (n = 7 participants, 23 hippocampal sEEG contacts). Biphasic bipolar direct electrical stimulation (1Hz, 5mA) was delivered via sEEG contacts in the lateral-temporal node of the hippocampal network.

Lateral-temporal stimulation consistently yielded CCEPs in ipsilateral hippocampus with distinct early (N1) and late (N2) negative components. We hypothesized that N1 and N2 amplitudes would vary periodically with local theta phase at stimulation onset. Further, we hypothesized that stimulation would evoke maximum component amplitude when delivered at theta trough and minimum component amplitude at peak. After estimating theta phase at stimulation for each trial and electrode, we performed circular-linear analysis to determine if component amplitude varied continuously according to phase. There was significant circular-linear correlation between theta phase and mean amplitude during both N1 ($P<0.002$) and N2 ($P<0.01$; computed via permutation testing). Control analyses on stimulation-free epochs indicated that the periodic stimulation effects were not merely due to a relationship between phase and future amplitude. Contrary to our hypothesis, N2 amplitude was significantly greater in peak trials than trough trials, an effect which persisted even after correcting for the stimulation-free amplitude predicted by phase at stimulation onset ($P<0.02$). These findings suggest that local theta phase predicts the magnitude of evoked hippocampal response by stimulation of lateral temporal afferents. Comparative analyses of phase-based variation in hippocampal responses to network-targeted stimulation in the Long-Evans rat will also be discussed (see also Song et al., SFN 2021). These findings are relevant to understanding mechanisms for control of hippocampal function via network-targeted stimulation.

Title: Functional connectivity between the temporal association cortical area 2 and the hippocampus in rats

Authors: *A. ALPERS[1], E. SONG[1], K. WARNER[1], C. WEISS[2], J. DISTERHOFT[2], J. L. VOSS[3], A. S. WIDGE[1];
[1]Psychiatry, Univ. of Minnesota, Minneapolis, MN; [2]Dept Physiol., Northwestern Univ. Med. Sch., Chicago, IL; [3]Med. Social Sci., Northwestern Univ., Chicago, IL

Abstract: Temporal association cortical area 2 (TE2) in rats is homologous to the lateral temporal cortex in humans and is implicated in episodic memory functions. Human lateral cortex has been used as a location for network-targeted stimulation to indirectly influence the

hippocampus. Thus, mapping connectivity of TE2 to hippocampus in rats is important for developing a rodent model for human network-targeted stimulation. TE2 is known to connect to the perirhinal cortex, but its exact connections to the hippocampus are not well known. The objective of this study was to determine if TE2 in rats is functionally connected to the hippocampus, and if so, where. We electrically stimulated TE2 in one hemisphere in Long Evans rats (n=6, 3M/3F) using 0.1 ms biphasic (300 µa) pulses at a frequency of 10 Hz for four minutes, then stained slices for the immediate early gene *c-fos* 60 min following the stimulation. We found that stimulation in area TE2 leads to strong *c-fos* activation in the dentate gyrus (DG) throughout the length of the hippocampus, both dorsally and ventrally. This expression starts from -2.16 AP behind bregma to -6.12 AP. In addition, we found *c-fos* activation in the dorsal and ventral CA1 and CA3 subfields, though it did not fluoresce as brightly as in the DG. This evidence of connectivity was consistent in the hemisphere that was stimulated, but not in the contralateral hemisphere. We also recorded neural data from the hippocampus (both DG and CA1) at -5.3 AP while electrically stimulating TE2 and found low-frequency activity synchrony between TE2 and these areas. Altogether, this evidence suggests that area TE2 in the rat is ipsilaterally connected to the dentate gyrus, CA1, and CA3 hippocampal subfields. We posit, based on previous studies as well as preliminary analysis of the timing of stimulation data, that TE2 connects first through the perirhinal and entorhinal cortex, then to the hippocampal subfields starting with DG and then to CA1 and CA3. This has important implications in studies of the memory system, especially as TE2/temporal cortex is well positioned as a target to noninvasively modulate the hippocampus in human patients.

Abstract: Hippocampal memory processing can be influenced via network-targeted stimulation to locations of the broader hippocampal network, providing indirect impact on hippocampal activity and associated memory processing. To understand the physiological basis of such effects we use rats to examine different stimulation protocols, e.g. we report in this session that stimulation of temporal Area TE2 phase-locked to the LFP at 0^{o} significantly increases coherence of TE2-hippocampal activities. We validated a paired-associate learning (PAL) task using the Bussey-Saksida touch-screen apparatus. We use a Latin square design to test four different stimulation patterns. This requires four sets of unique stimuli to test the effects of four different stimulation procedures. Given that most studies use only one set of visual stimuli we tested the responsivity of young adult Long Evans rats to four different sets of visual stimuli. The following sets were used (shown are the rewarded positions planned for each stimulus; during any trial one correct, one blank, and one incorrect image/position pairs are presented among the three panels of the touchscreen). Rats were first trained to respond to images in order to retrieve a sucrose pellet reward. Most rats (9 of 12 in cohort 1; 6 of 8 in cohort 2) gradually increased their percentage of correct responses during the different training phases. Rats that were slow to master the initial steps of training continued to have trouble on each successive step. A threshold of 7 sessions per training step differentiated learners from slow learners. After the pairwise discrimination (PD) task, a pilot group of 7 rats continued PD training using stimuli from either Set 3 or Set 4. Rats increased their responding (GT 60 trials) and accuracy (GT 60%) for both sets over 4 sessions, i.e. the new stimuli were differentiated by the rats. No obvious sex differences in responding were noted. These findings will be useful for experiments that involve testing multiple interventions on episodic-like memory, including for our own experiments using phase-locked stimulation.

Title: Examining hippocampal sharp-wave ripple-locked activation in language networks

Authors: *A. MISHRA[1,2], S. AKKOL[1,2], N. MARKOWITZ[1,2], E. ESPINAL[1,2], A. D. MEHTA[2,1], S. BICKEL[1,2,3];

Abstract: Hippocampal sharp-wave ripples (SWR) may serve as a conductor of cortical regions to foster the encoding and retrieval of stored memories. Prior studies showed SWR locked cortical activation in a variety of tasks, but their involvement in reactivating cortical language networks is unknown. To investigate this, we employed a list-learning task where participants were presented with twelve semantically unrelated words, structured in either a set of three sentences or in a randomized word list. After a mathematical distractor task, participants were asked to verbally recall words that they remembered. We obtained intracranial EEG recordings in four patients undergoing treatment for intractable epilepsy that graciously volunteered their time. We identified candidate hippocampal SWR by filtering in a 70-180Hz ripple band before isolating SWR that showed correct physiological form. We found that SWR activity peaked after the onset of verbal response in the recall portion of the task ($p < 0.05$ for 800ms after recall onset). To examine reactivation in the language network, we then isolated electrodes that exhibited selective increase of high-frequency activity (HFA, 60-160Hz) during listening to the sentence trials (n = 55 contacts), word list trials (n = 53), or non-selective activation in both (n = 76). During recollection of words, the identified language regions exhibited response ripple-locked reactivation in preferred recall trials (sentence selective contacts in recall sentence trials, randomized word areas in recall randomized word trials, significant time-bins from -50 to 150ms). Further, we found a sustained HFA increase following SWRs in both conditions in the lateral anterior temporal cortical regions (n = 218) which correlated with HFA activation in all language-responsive areas. Our results extend previous findings from the visual domain to the language network in that task specific cortical networks show co- (or re-) activation with hippocampal SWRs.

Title: Theta-gamma phase-amplitude coupling and the fMRI BOLD signal

Authors: *P. F. HILL[1], D. X. WANG[2], M. D. RUGG[3], A. D. EKSTROM[1], D. R. KING[3], B. C. LEGA[4];
[1]Univ. of Arizona, Tucson, AZ; [2]Southern Methodist Univ., Dallas, TX; [3]Ctr. for Vital Longevity, Univ. of Texas at Dallas Ctr. for Vital Longevity, Dallas, TX; [4]Neurosurg., UT Southwestern Med. Ctr., Dallas, TX

Abstract: Local changes in the fMRI blood-oxygen-level dependent (BOLD) signal are typically equated with commensurate changes in gamma-band activity. However, the electrophysiological dynamics underlying inter-regional BOLD connectivity remain under explored. Phase-amplitude coupling (PAC) has been advanced as a candidate mechanism for coordinating local brain activity across different spatial scales. We examined whether the strength of task-evoked cortico-hippocampal phase coherence and theta-gamma PAC differentially predict variance in functional BOLD connectivity between the same cortico-hippocampal ROIs. Fifteen neurosurgical patients implanted with depth electrodes performed a verbal free recall task while electrophysiological activity was recorded simultaneously from hippocampal and neocortical sites. The same patients performed a similar version of the task during a later fMRI session. Local and cross-regional subsequent memory effects were computed for both imaging modalities as patterns of brain activity predictive of later free recall. Cross-regional phase coherence and PAC between pairs of cortico-hippocampal contacts was computed for theta [slow (2-4 Hz), fast (4-8 Hz)] and gamma [low (30-70 Hz), high (70-150 Hz)] frequencies and contrasted according to subsequent memory status. BOLD connectivity was computed between the same cortico-hippocampal ROIs as the contrast between beta-series correlations for subsequently remembered and forgotten study items. Linear-mixed effects modeling revealed that intra-regional measures of theta-gamma PAC predicted significant variance in neocortical BOLD activity independently of local increases in theta and gamma power. Estimates of cross-regional phase coherence between slow theta oscillations measured in the hippocampus and lateral prefrontal cortex predicted significant variance in BOLD connectivity between the same regions. By contrast, cross-regional PAC measured between hippocampal theta and cortical gamma did not reliably co-vary with BOLD connectivity between cortico-hippocampal ROIs. Follow-up analyses confirmed that the relationship between cross-regional PAC and BOLD connectivity was not moderated by hemisphere, long axis location of the hippocampal seed, lobar location of the cortical target, or the direction of task-evoked BOLD connectivity. Taken together, these results suggest that theta-gamma PAC contributes to local measures of BOLD activity but does not provide a reliable index of cross-regional BOLD connectivity. This has important implications for interpreting cortico-hippocampal interactions obtained from different imaging modalities.

Title: Frequency-dependent response to intracranial theta-burst stimulation of anterior-temporal and posterior-medial divisions of the human hippocampal-cortical network

Authors: *M. S. HERMILLER[1], U. R. MOHAN[1], M. SPERLING[2], R. GORNIAK[2], A. SHARAN[2], G. A. WORRELL[3], B. M. BERRY[3], B. C. JOBST[4], K. DAVIS[5], R. E. GROSS[6], B. C. LEGA[7], S. DAS[5], J. Med., Atlanta, GA; [7]UT Southwestern Med. Ctr., Dallas, TX

Abstract: Hippocampal interactions with a widespread set of brain regions, including the medial temporal, ventromedial prefrontal, lateral parietal, dorsal thalamus, precuneus and posterior medial cortex, give rise to a distributed hippocampal-cortical network (HCN). Theta-band activity is the putative neural mechanism that coordinates interactions between the hippocampus and the HCN, facilitates interregional communication, provides content for binding into memory, and supports recreation of content during retrieval. Proposed anatomical and functional subsystems of the HCN, the anterior-temporal (AT) and posterior-medial (PM) subnetworks, have been proposed to support specific memory processes. Anatomically, perirhinal and parahippocampal cortices show preferential connectivity with anterior and posterior hippocampus, respectively. Additionally, there is evidence of distinctions in theta-band activity in the human hippocampus, with low theta frequencies (~2-4 Hz) more prominent in the anterior hippocampus, and higher theta (~5-8 Hz) in the posterior hippocampus. Here, we tested the hypothesis that the AT and PM subnetworks would respond preferentially to brain stimulation delivered at different theta frequencies. We analyzed human electrocorticographic recordings from neurosurgical epilepsy patients (N=20) collected while systematically delivering direct electrical theta-burst stimulation varying in theta frequency (i.e., 3,4,5,6,7,8 Hz). We measured the amplitude and frequency of narrowband oscillations before and after stimulation events in recording electrodes placed in the AT (128 electrodes) and PM (50 electrodes) subnetworks. We found that electrodes in the AT exhibited power in lower theta-frequencies (~2-4 Hz) following stimulation relative to pre-stimulation, whereas electrodes in the PM showed an increase in higher theta (~5-8 Hz) power following stimulation. These results indicate that the AT and PM subdivisions of the human HCN respond differently to theta-burst stimulation, possibly related to the endogenous theta oscillations identified in the anterior versus posterior hippocampus. Our findings provide insight into how brain stimulation may be used to target endogenous network oscillations and motivate future interventions for therapies utilizing brain stimulation to treat disorders and impairments with an associated disruption in network oscillatory activity.

Title: Combined Prenatal Nicotine and THC Exposure via E-Cigarettes Alters Maternal Factors and Behavioral Development in Rats

Authors: K. R. BREIT[1], C. G. RODRIGUEZ[2], S. HUSSAIN[2], A. RUIZ[2], *J. THOMAS[2]; [1]Behavioral Teratology, West Chester Univ., West Chester, PA; [2]San Diego State Univ., San Diego, CA

Abstract: Nicotine and cannabis are two of the most commonly consumed drugs among pregnant women, often consumed via e-cigarettes. An estimated 5-14% of women report using e-cigarettes during their pregnancy, partly due to the assumption that e-cigarettes are safer than traditional smoking routes. However, the consequences of prenatal e-cigarette use with either drug, or the combination, are not well understood. This study exposed pregnant Sprague-Dawley rats to nicotine (36 mg/mL), tetrahydrocannabinol (THC; 100 mg/mL), the combination, or a vehicle (propylene glycol) via e-cigarettes daily from gestational days 5-20, mimicking the first and second human trimesters. Maternal blood samples were collected throughout the pregnancy at multiple time points to measure drug and metabolite levels, as were core body temperatures. Pregnant dams exposed to combined nicotine and THC had lower plasma nicotine and cotinine levels than those exposed to nicotine alone; similarly, the combined exposure group also had lower plasma THC and THC metabolite levels than those exposed to THC alone, illustrating pharmacokinetic interactions. Prenatal nicotine exposure gradually reduced basal core body temperatures during pregnancy, whereas exposure to THC alone decreased temperatures only during the drug exposure sessions. Despite these physiological effects, no changes were observed in food or water intake, weight gain, or basic litter outcomes. One sex pair of offspring per litter were used to separately examine motor development, activity levels, anxiety-related behaviors, and learning and memory. The combination of prenatal exposure to nicotine and THC delayed early sensorimotor development, and although nicotine and THC separately impaired later motor

coordination, the combination produced more severe motor deficits. In contrast, primarily unique effects of prenatal nicotine and THC were seen on other tasks. For example, prenatal exposure to nicotine reduced locomotor activity but increased fine motor activity in the open field, increased time spent in the open arms, and impaired visuospatial learning acquisition on the Morris water maze. In contrast, prenatal exposure to THC produced subtle and sex-dependent changes in both open field activity and anxiety-related behaviors (increased anxiety). These data suggest that combined exposure to prenatal exposure to low-moderate nicotine and THC elicits both unique and interactive effects on dams and offspring. These data can help identify risks and improve education for pregnant mothers about prenatal e-cigarette use. Supported by TRDRP 28IP-0026.

Title: Select roles for ERK1/2 signaling in MGE-derived cells

Authors: *S. KNOWLES[1], J. S. MARTINEZ-FUENTES[1], K. REES[1], A. AFSHARI[1], M. HOLTER[1], K. NISHIMURA[1], G. LI[2], T. R. ANDERSON[2], J. NEWBERN[1];
[1]Arizona State Univ., Tempe, AZ; [2]Univ. of Arizona-College of Med. Phoenix, Phoenix, AZ

Abstract: The canonical RAS/RAF/MEK/ERK1/2 (ERK1/2) pathway is a highly conserved signaling cascade found in nearly all cells which is activated by diverse extracellular signals during development. Dysregulated ERK1/2 signaling is involved in multiple neurodevelopmental syndromes, particularly the RASopathies and select genetic forms of Autism Spectrum Disorder (ASD). It remains unclear which cell types are driving cognitive dysfunction in each of these disorders. The consequences of reduced ERK1/2 on the development and basic functions of MGE-derived GABAergic interneurons and glia are poorly understood. Here, we used a conditional genetic approach to specifically delete the principal ERK1/2 components *Mapk3/Erk1* (*Erk1*$^{-/-}$) and *Mapk1/Erk2* (*Erk2*$^{fl/fl}$) from MGE progenitors or GABAergic interneurons. Loss of ERK1/2 in progenitors definitively reduces glial number in the anterior commissure. We determined that ERK1/2 is not required for the establishment of cortical

GABAergic interneuron number or the expression of parvalbumin, a marker for a large subset of interneurons. However, our data reveal that ERK1/2 is necessary for the expression of SST, a marker of ~30% of cortical interneurons. We also examined the effects of a hyperactive *caMEK1* allele on SST neuron specification. Due to well established roles of ERK1/2 in activity-dependent development, we then tested whether the GABAergic neuron response to *in vivo* stimulation was altered by loss of ERK1/2. We found that ERK1/2 deleted GABAergic neurons exhibit deficits in FosB expression following chemogenetic stimulation. Interestingly, 1 week of chemogenetic stimulation led to a partial rescue of SST expression in ERK1/2 deleted neurons. Injection of a Cre-dependent AAV9-CAG-RFP into the neonatal somatosensory cortex was used to examine whether the development of dendritic complexity relies upon ERK1/2 signaling. Overall, our data highlight the important roles of ERK1/2 in the development and maturation of cortical GABAergic circuitry.

Title: Loss of p120-catenins leads to progressive hydrocephalus and cortical heterotopia in the developing mouse brain.

Authors: *J. RAKOTOMAMONJY[1], K. ZANG[2], Y.-G. NG[3], L. REICHARDT[4], A. CHENN[5], A. D. GUEMEZ-GAMBOA[6];
[1]Physiol., Northwestern University, Feinberg Sch. of Medici, Chicago, IL; [2]Physiol., [3]UCSF, San Francisco, CA; [4]Simons Fndn., New York, NY; [5]LabCorp, Raleigh-Durham, NC; [6]Physiol., Nortwestern University, Feinberg Sch. of Med., Chicago, IL

Abstract: Members of the p120-catenin subfamily of catenins are crucial components of the cadherin-catenin cell adhesion complex as they stabilize cadherins at the cell surface. The p120-catenin subfamily consists of four members encoded by four independent genes. These four genes can be divided in 2 monophyletic groups: one containing ARVCF (*ARVCF*) and p120-catenin (*CTNND1*); the other comprising δ-catenin (*CTNND2*), and p0071 (*PKP4*). Previous work has shown that both p120-catenin and δ-catenin were crucial for proper dendritic spine, arborization, and synapse development. However, little is known about ARVCF and p0071 functions in the brain. Here, we investigated the role of evolutionarily related p120-catenin and

Arvcf in cortical development. To do so, we used stand-alone constitutive *Arcvf* and dorsal forebrain-specific *Ctnnd1* knockout (KO) mouse models, as well as a combination of both in order to assess their potential functional redundancy. Our results show that only the double KO mice exhibit reduced viability. Apicobasal polarity and cell junctions are disrupted in radial glia, resulting in formation of rosette-shaped heterotopias appearing as early as E16.5 and impaired postnatal cortical lamination. Moreover, p120/ARVCF double KO results in failed ependymal cell differentiation with loss of ciliated cells from the ventricular surface, potentially promoting development of hydrocephalus. Thus, our results suggest that p120-catenin and Arvcf have redundant functions during the neurogenic and gliogenic phases of cortical development.

Title: Maternal Western-Style Diet Decreases Social Engagement in Japanese Macaques

Authors: *A. MITCHELL[1], S. KHAMBADKONE[3], G. DUNN[4], H. GUSTAFSSON[2], E. L. SULLIVAN[2];
[1]Behavioral Neurosci., [2]Psychiatry, Oregon Hlth. and Sci. Univ., Portland, OR; [3]Psychiatry and Behavioral Sci., John Hopkins Univ., Baltimore, MD; [4]Univ. of Oregon, Eugene, OR

Abstract: The CDC reports that almost 30% of women in the US were diagnosed with maternal obesity in 2019. Maternal obesity is associated with increased risk of offspring neurodevelopmental disorders such as Autism Spectrum Disorder (ASD) and Attention Deficit Hyperactivity Disorder (ADHD). Although characterizations of the behavioral phenotypes underlying these disorders are becoming increasingly accurate, less is known about their neurodevelopmental origins. Increasing evidence from both epidemiological and preclinical animal models suggests that maternal overnutrition alters fetal neurodevelopment in ways that impair socio-emotional control in offspring. Impairments in socio-emotional control often result in social deficits, however the effects of mWSD on social development has not been examined in the macaque. The present study utilizes Japanese macaques to investigate the impact of maternal Western-Style Diet (WSD) (high in saturated fat and simple sugars) on offspring social behavior during novel peer introductions during the periweaning period. Our results suggest that maternal

WSD (mWSD) decreases social engagement in offspring, where mWSD offspring display decreases in the percentage of initiate proximity to the novel peer (β = -.37, p =.024). Significant increases in maternal IL-12 from exposure to the WSD (β =.33, p<.000) mediated decreases in initated affiliative contact observed in mWSD offspring (IL-2◊affiliative contact β= -.65, p < .000). We also found that maternal IL-12 were also associated with the decreased iniated proximity mWSD offspring (IL-12◊proximity β = -.35. p = .041). Interesting, alterations in offspring social behavior were also related to prepregnancy levels of leptin and glucose regulation (as assessed by glucose area under the curve). These results indicate that maternal exposure to an obesogenic diet prior to and during pregnancy influences fetal brain development in ways that lead to decreased social engagement.

[5]Pediatrics, Univ. of Nebraska Med. Ctr., Omaha, NE

Abstract: Mitochondrial oxidative phosphorylation supplies ATP to the brain except during early development and periods of starvation when neurons require ketone bodies produced by astrocytes or the liver for beta-oxidation and ATP synthesis. Beta-oxidation of long-chain fatty acids (LCFAs) depends upon the carnitine transferase system composed of carnitine palmitoyltransferase (CPT). CPT catalyzes the carnitine-dependent entry of long-chain acyl-Coenzyme A into the mitochondria matrix. Acylcarnitine production is important for membrane composition, protein synthesis and function, antioxidant production and cholinergic neurotransmission. Human CPTII deficiencies cause neurodevelopmental abnormalities, however, little is known about the mechanisms of brain-specific metabolic deficiencies. We present a zebrafish model system to investigate CPTII function in vertebrate brain and body development. Translation (TB) and splice-blocking (SB) morpholinos were used to knockdown

CPTII expression in wildtype (WT) TuAB zebrafish. Scrambled morpholino-injected (SC) and uninjected TuAB (WT) zebrafish served as controls. At 5days post-injection, morphological, lipid deposition and behavior experiments were performed. Standard length in TB and SB fish decreased by 128.2± 17.9μM and 316.7± 48.2μM compared to SC fish, respectively ($p \leq 0.01$, $n < 50$, ±SEM). Distance to rump in TB and SB fish decreased by 168.5 ± 24.6μM and 534.5 ± 80.1μM compared to SC fish, respectively ($p \leq 0.0001$, $n < 50$, ±SEM). Distance between eyes in SB fish decreased by 48.5± 8.4μM compared to SC fish, respectively ($p \leq 0.001$, $n < 50$, ±SEM). Standard length, distance to rump, distance between eyes were not significantly different for WT and SC injected fish ($p > 0.05$, $n > 50$). SB exhibited significantly higher percentages of fish with curved tails (38%), cardiac edema (20%), and abnormal yolk sacs (10%) than SC and WT fish. Lipid deposition was more concentrated in the liver, swim bladder, and yolk sac in TB and SB fish compared to WT and SC fish. LC-MS/MS analyses demonstrated in SB and TB fish a significant difference in lipids and acylcarnitine modifications. Behavior analyses showed that freezing duration, bursting movement, and duration of burst movement were significantly different in TB and SB fish compared to WT and SC fish ($p \leq 0.01$, $n < 70$). Immunohistochemistry and electrophysiological experiments will determine differences in network formation. This vertebrate model system serves to inform our understanding of the role of long chain fatty acid β-oxidation in neurodevelopment and how dysfunction of metabolic cell-signaling contributes to neurodevelopmental pathologies.

Abstract: Investigation of a recurrent splice site mutation in mitochondrial methionyl-tRNA formyl transferase (MTFMT) using cellular and a novel mouse model.Author: Sukanniya Kaneshamoorthy[1], Spencer Belnap[1,], Raj Gupta[1], Preethi Swaminathan[1], C4RCD Research Group[1, 2], Vinodh Narayanan[1,2], Sampathkumar Rangasamy[1,2] 1) Neurogenomics Division, Translational Genomics Research Institute (TGen), Phoenix, AZ2) Center for Rare Childhood Disorders (C4RCD), Translational Genomics Research Institute (TGen), Phoenix AZMutation in the MTFMT gene is identified to cause combined oxidative phosphorylation deficiency and Leigh syndrome. We recently identified a recurrent homozygous nonsynonymous mutation in *MTFMT* c. 626C>T, in three children from two unrelated families through whole-exome sequencing (WES) analysis. Although *MTFMT* mutations are established as a cause of LS and combined oxidative phosphorylation, the underlying molecular mechanisms of disease pathogenesis remain poorly understood. To understand the mitochondrial dysfunction in MTFMT mutation, we studied patient-derived fibroblast cells from homozygotes (probands) and six heterozygotes (carriers) from the two families. RNA sequence analyses revealed differentially expressed mitochondrial genes that separated affected patients and unaffected controls. We also found that glutaminase, a vital enzyme that helps in the conversion of glutamine to glutamate, is highly expressed in homozygous patients. This result indicates the activation of a compensatory metabolic pathway in homozygous patients due to the primary oxidative phosphorylation deficiency. MTFMT homozygote cells displayed elevated levels of mitochondrial reactive oxygen species (mROS) and decreased mitochondrial membrane potential, as measured by fluorimetry assay. Western blot analysis of OXPHOS complexes from the homozygous MTFMT mutant patient fibroblast cells revealed complex I and IV deficiency compared to heterozygotes and control cells. In collaboration with Jackson labs, we have created heterozygous MTFMT-Mut-Hum (mutant MTFMT with c. 626C>T variant human exon 4). Breeding of these heterozygous resulted in successful generation of homozygous MTFMT-Mut-Hum animals that recapitulate the mitochondrial protein synthesis defect. Our preliminary analysis signifies a consistent decrease in the level of nuclear-encoded CI subunit (NDUFB8) and mitochondrial encoded CIV subunit (MTCO1) in the mutant mice compared to the control mice. Our results demonstrate that loss of function MTFMT (c. 626C>T) mutation leads to altered mitochondrial homeostasis and energy metabolism.

Title: The Slc6a8$^{y/Y389C}$ rat model of creatine transporter deficiency reveals behavioral disorder, altered brain metabolism, muscle atrophy and altered motor function

Authors: *L. DURAN-TRIO[1], G. FERNANDES-PIRES[1], D. SIMICIC[2], J. GROSSE[2], C. ROUX-PETRONELLI[1], S. BRUCE[1], P.-A. BINZ[1], C. SANDI[2], C. CUDALBU[2], O. BRAISSANT[1];
[1]UNIL-CHUV, Lausanne, Switzerland; [2]EPFL, Lausanne, Switzerland

Abstract: Creatine is an organic compound used as fast phosphate energy buffer to recycle ATP, important in tissues with high energy demand such as muscle or brain. Creatine is taken from the diet or endogenously synthetized by the enzymes AGAT and GAMT, and specifically taken up by the transporter SLC6A8. Deficit in the endogenous synthesis or in the transport leads to Cerebral Creatine Deficiency Syndromes (CCDS). CCDS are characterized by brain creatine deficiency, intellectual disability with severe speech delay, behavioral troubles such as attention deficits and/or autistic features, epilepsy and motor dysfunction. Among CCDS, the X-linked creatine transporter deficiency (CTD) is the most prevalent with no efficient treatment so far. Different mouse models of CTD were generated by doing long deletions in the *Slc6a8* gene showing reduced brain creatine and cognitive deficiencies or impaired motor function. Our recently described *Slc6a8$^{y/Y389C}$* knock-in (KI) rat model of CTD holds an identical point mutation found in patients with reported lack of transporter activity. KI males showed brain creatine deficiency, increased urinary creatine/creatinine ratio, cognitive deficits, autistic-like traits, motor dysfunction and muscle atrophy. *Slc6a8^{Y389C}* KI rat fairly enriches the spectrum of CTD models and provides new data about the pathology, being the first animal model of CTD carrying a point mutation.

Title: Effect of Post-Infectious Hydrocephalus on the Developing Ventricular-Subventricular Zone Stem Cell Niche

Authors: *J. HERMAN[1], M. MARTLAND[1], S. KALARIA[1], Y. WANG[1], F. MANDINO[2], A. MEZGER[1], E. M. LAKE[2], P. H. VERARDI[1], J. C. CONOVER[3];

Abstract: Congenital hydrocephalus, a common birth defect affecting 1 in 1000 infants, is characterized by expansion of the cerebroventricular system. One common cause of this disorder is infection, resulting in post-infectious hydrocephalus (PIH). PIH can occur following maternal infection during pregnancy, resulting in viral and inflammatory exposure to the developing fetal and neonatal brain. Our group is interested in the effects of PIH on the ventricular-subventricular zone (V-SVZ), which includes an active stem cell niche present throughout development and then retained only along the lateral wall of the lateral ventricles postnatally. V-SVZ stem cells populate the developing brain with newly generated neurons and glial cells, including multi-ciliated ependymal cells which are generated through the process of ependymogenesis. A monolayer of ependymal cells then lines the ventricles providing a protective barrier and fluid/solute exchange system, and, via motile cilia, laminar flow of cerebrospinal fluid at the ventricle surface. Here, we present a novel mouse model of PIH using intracerebroventricular injections of influenza or a non-virulent component of influenza (neuraminidase) at two specific timepoints: embryonic day 16, prior to the development of the ependyma, and neonatal at postnatal day 4, following completion of the ependymal monolayer. Influenza and neuraminidase alone were found by immunohistochemistry to target ependymal cells and induce PIH in approximately 60% of mice injected postnatally as observed by serial section analysis of the lateral ventricles or by 11.7T MRI. Ependymal denudation and accompanying astrogliosis were noted along the expanded ventricle surface based on immunohistochemical analysis. This model will be used to assess inflammatory regulation in the development of PIH and V-SVZ repair mechanisms, as well as the niche's capacity for continued neurogenesis over time.

Title: Evaluating the impact of gestational ethanol consumption on adult immune function and addiction-like behavior.

Authors: *P. KOZAN, B. O. GLEESON, K. L. RONALD, P. D. RIVERA;
Dept. of Biol., Hope Col., Holland, MI

Abstract: In the United States, one in twenty babies are born with fetal alcohol spectrum disorder (FASD). FASD is commonly associated with maternal alcohol consumption during pregnancy that results in offspring with physiological and behavioral deficits that are mediated by immune dysfunction. Previous studies in rodents have found that gestational ethanol exposure leads to increased inflammatory responses and deficits in cognitive and social behaviors. Additionally, enhanced immune signaling can lead to an increase in addiction-like behavior in rodents. However, studies have not characterized the impact of gestational alcohol on adult addiction-like behaviors, as it relates to systemic immune dysfunction. Therefore, to assess the impact of gestational ethanol on adult immune function and subsequent addiction-like behavior, we used WT C57BL/6J dams (PND50) and bred them with WT C57Bl/6J males. Dams were then checked for plugs daily and drinking-in-the-dark (DID) occurred at gestation day (GD) 10-14. At PND 4 and 10, pups were removed from their litter to record ultrasonic vocalizations (USVs). Preliminary results suggest a sex by treatment effect in the number of USVs emitted from pups (PND4). Offspring from dams that previously consumed EtOH during GD 10-14, appear to vocalize more than water controls. Offspring matured to adulthood and addiction-like behavior was assessed via DID. Mice (PND60-70) were sacrificed 90 minutes after DID test day. Plasma and brain samples were then collected to examine systemic inflammatory cytokines in plasma via ELISAs and microglia and Fos (Iba1+) via IHC, respectively. Taken together, we hope to understand the impact of gestational EtOH exposure on physiological development, adult immune function, and addiction-like behaviors. Future experiments will replicate this process using other drugs of abuse, such as morphine.

Title: Autism spectrum disorder heterogeneity modeled in iPSC-derived telencephalic organoids

Authors: *A. JOURDON[1], J. MARIANI[1], F. WU[1], D. CAPAUTO[1], S. NORTON[1], A. AMIRI[1], J. SCHREINER[1], L. TOMASINI[1], A. ABYZOV[3], F. M. VACCARINO[1,2];

Abstract: Autism spectrum disorder (ASD) exhibits heterogeneity in clinical presentation and genetic studies have not yet identified a convergent etiology for the spectrum. Using induced pluripotent stem cell (iPSC)-derived brain organoids, we modeled in this study the alterations in the formation of the telencephalon between 18 idiopathic ASD individuals and their unaffected first-degree family members as controls. Differences in cellular composition and cell type-specific gene expression were evaluated by single-cell RNA-sequencing (scRNA-seq) during the first 3 months of organoid neural differentiation over a longitudinal time course. More than a hundred scRNA-seq samples were collected and integrated in the study presented here. This large-scale dataset allowed us to investigate the sources of variation influencing human neurogenesis in the organoid system over multiple genetic backgrounds and culture batches. Using correlation analysis, we showed how different patterns of gene expression in progenitor cells, such as canonical signaling pathway activity in radial glia, were associated with the propensity to generate different subtypes of excitatory and inhibitory lineages of the telencephalon. We observed that on average organoids generated from ASD probands did not present a specific cell type composition compared to control individuals, although differential gene expression revealed cell type-specific alterations in genes associated with neural patterning, cell division, cortical neurogenesis and synaptogenesis. We investigated the biological effect of macrocephaly (larger head circumference) on ASD probands gene expression, and propose head circumference as a clinical variable susceptible to drive the heterogeneity of ASD phenotypes observed in organoids. This suggests that macrocephaly could be a potential stratifying factor in large clinical or genetic studies of ASD. Altogether, the research presented here aims to understand the heterogeneity of human brain development across individuals and establish how large single-cell omics study on patient-derived organoids could decipher the etiologies behind neurodevelopmental disorders.

Title: Human induced pluripotent stem cell-derived neuronal and brain organoid models of SLC6A1-related neurodevelopmental disorder

Authors: *M. C. VARELA, T. N. THENSTEDT, J. G. VALDIVIESO, M. D. UHLER, J. M. PARENT;
The Univ. of Michigan, Ann Arbor, MI

Abstract: Epileptic encephalopathies and other neurodevelopmental disorders are linked to variants in the *SLC6A1* gene which encodes for the most abundant GABA transporter in the brain, GAT-1. GAT-1 is responsible for the reuptake of GABA at the synapse and, in the cortex, is expressed primarily in inhibitory neurons. Loss of GAT-1 function results in epilepsy and cognitive delays, however how GAT-1 haploinsufficiency affects early cortical development in humans remains unclear. In this study, we use both 2D and 3D human induced pluripotent stem cell (iPSC)-derived models to test the hypothesis that GAT-1 LOF alters inhibitory neuron development and subsequent network formation. We first reprogrammed human foreskin fibroblasts into iPSCs with concurrent CRISPR/Cas9 gene editing targeted to generate out-of-frame insertions or deletions in the *SLC6A1* gene. We generated several *SLC6A1* heterozygous (Het) null, compound heterozygous (KO), and isogenic control (WT) iPSC lines which were differentiated into 3D cortical and ventral organoids using our novel self-organizing single rosette spheroid (SOSRS) model. We also generated 2D induced GABAergic neurons (iGNs) using an inducible expression system driving the human ASCL1 and DLX2 transcription factors. We used a combination of immunocytochemistry and RT-qPCR of SOSRS cultured for 2-36 weeks or iGNs for 1-4 weeks to investigate interneuron development and specification. Because loss-of-function *SLC6A1* variants are predicted to increase ambient GABA levels in early brain development, and ambient GABA levels influence the migration of developing interneurons, we also fused cortical and ventral SOSRS to investigate interneuron migration and integration into the cortex. Both our 2D and 3D models displayed the expected GABAergic and mature neuronal marker expression and morphology. We found a marked reduction of GAT-1 expression in the KO iGNs and SOSRS ranging from 6.7 ± 2.0% to 28.2 ± 11.5% of WT, while GAT-1 expression in the Het lines was partially reduced, ranging from 23.4 ± 16.5% to 56.4 ± 33.4% of WT (n=3 lines each). We observed a potential delayed migration phenotype in mutant *SLC6A1* ventral SOSRS compared to controls, with the KO SOSRS displaying severely decreased neuronal migration, and Hets showing an intermediate degree of decreased migration. Our findings suggest that *SLC6A1* complete loss of function, and to a lesser extent haploinsufficiency, impairs GABAergic cell migration and likely alters subsequent network formation. Further investigation into this phenotype could provide early treatment targets for *SLC6A1*-related neurodevelopmental disorders.

Title: Parallel RNA-seq and ChIP-seq in iPSC-derived cortical organoids identify important regulators of neuronal development in ASD

Authors: *S. NORTON[1], J. MARIANI[1], A. JOURDON[1], D. CAPAUTO[1], L. TOMASINI[1], J. SCHREINER[1], A. PANDA[2], Y. WANG[2], F. WU[1,3], A. ABYZOV[2], F. VACCARINO[1]; [1]Yale Univ., New Haven, CT; [2]Mayo Clin., Rochester, MN; [3]Fred Hutchinson Cancer Res. Ctr., Seattle, WA

Abstract: Autism spectrum disorders (ASD) exhibit high variation between patients, with more severe disorder correlated with larger head size (macrocephaly) relative to the general population (normocephaly). Cortical organoids derived from induced pluripotent stem cells (iPSC) provide an effective model of early brain development (Mariani 2015, Amiri 2018) and allow for the retrospective study of neurodevelopment in individuals with ASD. We derived iPSC lines from six nine macrocephalic and five normocephalic ASD probands along with their respective, unaffected fathers (total, XX14 subjects). We differentiated these lines into cortical organoids and analyzed gene expression over a developmental timeline from neural stem cells to cortical neurons by RNA sequencing. In parallel we mapped gene regulatory elements (enhancers) location and activity by histone modifications (ChipIP-seq) and open chromatin (ATAC-seq) at various stages of development. Putative enhancer elements defined from ChIP-seq analyses against four histone marks were linked to physically interacting gene promoters to identify likely cis-activators and repressors of gene expression. Such elements can harbor DNA sequence mutations that may impact their activity. Genes that significantly covary with head size and ASD diagnosis are expressed in excitatory neuron (EN) and inhibitory neuron (IN) lineages, indicating divergent lineage trajectories in macrocephalic vs normocephalic ASD. We highlight a set of enhancer elements that are likely regulators of genes for EN and IN lineages implicated in ASD, including NEUROD2, NEUROD6, DLX5, and FOXG1. Our strategy allows to construct a gene regulatory network of early brain development in typical development and developmental disorders such as ASD.

Abstract: Fragile X syndrome (FXS) is a neurodevelopmental disorder, characterized by intellectual disability and sensory deficits, caused by epigenetic silencing of the *FMR1* gene and subsequent loss of its protein product, fragile X mental retardation protein (FMRP). Delays in synaptic and neuronal development in the cortex have been reported in FXS mouse models, however, the main goal of translating lab research into pharmacological treatments in clinical trials has been so far largely unsuccessful, leaving FXS a still incurable disease. Here, we generated 2D and 3D in vitro human FXS model systems based on isogenic *FMR1* knock-out mutant and wild-type human induced pluripotent stem cell (hiPSC) lines. Phenotypical and functional characterization of cortical neurons derived from FMRP-deficient hiPSCs display altered gene expression and impaired differentiation when compared with the healthy counterpart. FXS cortical cultures show increased proliferation of GFAP positive cells, likely astrocytes, increased spontaneous network activity and depolarizing GABAergic transmission. Cortical brain organoid models show increased proliferation of glial cells, and bigger organoid size. Our findings demonstrate that FMRP is required to correctly support neuronal and glial cell proliferation, and to set the correct excitation/inhibition ratio in human brain development.

Title: Proteomics of Δ^9-tetrahydrocannabinol (THC) impact on cortical development in health and schizophrenia with iPSC-derived cerebral organoids

Authors: B. ALURAL[1], B. BALL[1], J. ANG[1], H. THORPE[2], S. D. SHERIDAN[3], R. H. PERLIS[3], J. KHOKHAR[2], J. GEDDES-MCALISTER[1], *J. LALONDE[1];

Abstract: The primary psychoactive compound of cannabis, Δ^9-tetrahydrocannabinol (THC), causes depression of glutamate signaling and functional changes in the brain as a result of its interaction with cannabinoid receptor type 1 (CB_1) receptors. Neuroimaging studies have also identified structural changes in regular cannabis users. Given these findings, an important question concerns the impact that THC exposure may have on the growth and organization of neuronal cells during the prenatal stages of brain development. Study of cerebral cortex formation at the cellular and molecular levels has been largely limited to non-human models in the past; however, the possibility of using human-induced pluripotent stem cells (hiPSCs) that can be differentiated as 3-dimensional organoids now offers the opportunity to investigate baseline and dynamic changes in a human-like neural system. Here, we used cerebral organoid models derived from different hiPSC lines in conjunction with proteomics and imaging methods to profile the impact of THC exposure. Since previous studies established that cannabis-use rates and diagnosis of cannabis use disorder are more frequent in schizophrenia (SCZ) patients than non-patient groups, and that a connection between cannabis and first-episode psychosis exists for a subgroup of vulnerable patients, we also searched for possible differences specific to this neuropsychiatric disorder. First, we present characterization of the 6 hiPSC lines (3 SCZ patients and 3 healthy control individuals) used in our study, including their culture as cerebral organoids

alongside the expression of CB receptors (CB_1 and CB_2) and other common markers. Second, we report the completed quantitative proteomic analysis of our 6 hiPSCs lines matured for 125 days as organoids where we identified 37 proteins with significant difference in abundance between healthy control and SCZ specimens or resulting from THC application to the maturation culture media. Finally, we highlight ongoing efforts at understanding the connection between specific proteins that we found to be affected by THC, in particular those that are predominantly expressed in synaptic terminals. Together, our efforts provide tantalizing insights about the impact of THC on neuron biology during prenatal stages of cerebral cortex development, as well as possible connections to psychosis.

Abstract: Schizophrenia (SCZ) is a neuropsychiatric disorder caused by the interaction between genetic and environmental factors. SCZ individuals exhibit cognitive deficits, positive (psychosis, hallucinations and delusions) and negative symptoms (depression, avolition and anhedonia), as well as reduced gray matter volume. Microanatomical analyses suggest this phenomenon occurs due to diminished dendritic spine density, which likely happens as a result of exaggerated synaptic pruning. It has already been shown that the classical complement cascade and CX3CL1/CX3CR1 pathway play a direct role in this process, triggering synaptic

engulfment by microglia. Taking into account that pre-natal infection acts as an environmental risk factor for SCZ, this work aims at analyzing synaptic pruning-related modulators (complement components and CX3CL1) production employing induced pluripotent stem cells (iPSCs)-derived astrocytes from both healthy control (HC) and SCZ individuals (n = 5) after stimulation with TNF-α. All experiments were conducted in accordance with the Helsinki Declaration and approved by an IRB. The present results indicate that CX3CL1 transcripts are increased in SCZ-derived astrocytes relative to HC-derived astrocytes, while the classical complement components (C1q, C3 and C4) display similar expression levels across both phenotypes. Further validation indicates that secreted CX3CL1 levels mirror its transcript expression pattern, thus confirming the increased CX3CL1 production in SCZ astrocytes upon TNF-α stimulation. In order to verify whether SCZ astrocytic secreted CX3CL1 stimulates higher synaptic engulfment by microglia, HC induced microglial-like cells (iMGs) were incubated with astrocyte conditioned media (ACM) from both phenotypes, under non-stimulated (N.S.) or TNF-α stimulated conditions and in the presence or absence of the CX3CR1 antagonist (AZD 8797) for up to 24 h with CM-Dil-labeled synaptoneurosomes. Surprisingly, TNF-α HC ACM, N.S. SCZ ACM and TNF-α HC ACM exposure lead to lower synaptoneurosomal phagocytic engulfment by iMGs relative to N.S. HC ACM. In addition, pre-treatment with AZD 8797 enhances synaptic phagocytosis only in iMGs exposed to N.S. HC ACM, with no changes observed in other conditions. Since secreted cytokines can impact microglial phagocytic capacity, we analyzed cytokine expression in HC and SCZ astrocytes stimulated with TNF-α. Interestingly, TNF-α and IL-6 mRNA levels are elevated in stimulated SCZ astrocytes relative to HC astrocytes. Altogether, these results indicate that SCZ astrocytes secreted factors impair HC iMG synaptic engulfment.

Title: Loss-of-function variants in the schizophrenia risk gene SETD1A alter neuronal network activity in human neurons through cAMP/PKA pathway

Authors: S. WANG[1], J.-R. VAN RHIJN[1], I. AKKOUH[2], N. KOGO[1], N. MAAS[1], A. BLEECK[1], E. LEWERISSA[1], K. WU[1], C. SCHOENMAKER[1], S. DJUROVIC[2], H. VAN BOKHOVEN[1], T. KLEEFSTRA[1], N. NADIF KASRI[1], D. SCHUBERT[1];
[1]Radboud UMC, Nijmegen, Netherlands; [2]Oslo Univ. Hosp., Oslo, Norway

Abstract: <META NAME="author" CONTENT="王 珊">**Abstract** Heterozygous loss-of-function (LoF) mutations in *SETD1A*, which encodes a subunit of histone H3 lysine 4 methyltransferase, have been shown to cause a novel neurodevelopmental syndrome and increase the risk for schizophrenia. To study the effect of decreased SETD1A function in human cells, we generated excitatory/inhibitory neuronal networks from human induced pluripotent stem cells with a *SETD1A* heterozygous LoF mutation (*SETD1A*$^{+/-}$). Our data show that *SETD1A* haploinsufficiency resulted in altered neuronal network activity, which was mainly characterized by an overly synchronized network. In individual neurons, this network phenotype was reflected by increased somatodendritic complexity and elevated synaptic connectivity. We found that this network phenotype was strongly driven by *SETD1A* haploinsufficiency in glutamatergic neurons. In accordance with the functional changes, transcriptomic profiling revealed perturbations in gene sets associated with schizophrenia, synaptic transmission and glutamatergic synaptic function. At the molecular level, we identified specific changes in the cAMP/PKA pathway pointing toward a hyperactive cAMP pathway in *SETD1A*$^{+/-}$ neurons. Finally, using pharmacological experiments targeting the cAMP pathway we were able to rescue the network deficits in *SETD1A*$^{+/-}$ cultures. In conclusion, our results illuminate key molecular, cellular and network abnormalities resulting from *SETD1A* haploinsufficiency and demonstrate a potential link between SETD1A and the cAMP-dependent pathway in human neurons.

Abstract: Post-tetanic potentiation (PTP) is a form of short-term synaptic plasticity that occurs in part due to an increase in the number of readily releasable vesicles at the active zone. Clustering of the active zone structure is inversely correlated with the presence of filamentous actin (F-actin). The calyx of Held is a large high-fidelity synapse located in the medial nucleus of the trapezoid body (MNTB) in the auditory brainstem. The calyx of Held contains a dense layer of presynaptic F-actin that is organized by the potassium channel Kv3.3 and facilitates endocytosis of presynaptic vesicles. We hypothesized that tetanic stimulation would result in reorganization of the F-actin structure in the presynaptic terminal, allowing the accumulation of additional vesicles at active zones and thus PTP. Initial confocal microscopy studies of rat brain slices containing the MNTB showed that in seconds after stimulation with potassium chloride, F-actin intensity near active zones decreased, while active zone size increased. Here, we report the use of three-dimensional stimulated emission depletion (3D STED) super resolution microscopy to reconstruct the presynaptic terminal before and after electrical stimulation of calyx of Held synapses. We found that F-actin likely depolymerizes 20-40s seconds after stimulation, concomitant with the expansion of docked vesicle pools. After 20 more seconds, the F-actin likely repolymerizes even as the number of docked vesicles continues to increase, suggesting that actin contributes to PTP through two separate mechanisms: (1) depolymerization in order to make space for active zone machinery and perhaps for recycling/reserve pool activity and (2) repolymerization, perhaps to coordinate endocytosis and the replenishment of vesicle pools. Since tethering by F-actin is known to coordinate complexes of vesicles and mitochondria in the calyx of Held, we plan to use electron microscopy to determine if there are changes in mitochondrial size, structure, or proximity to docked vesicles following tetanic stimulation. This study uses cutting-edge microscopy techniques to capture dynamic, activity-induced structural changes in the calyx of Held synapse that contribute to its rapid and sustained synaptic transmission.

Abstract: Neuroadaptations within glutamatergic terminals from the medial prefrontal cortex (mPFC) that synapse onto dendritic spines of medium spiny neurons in nucleus accumbens (NAc) are thought to be important for learning in animal models of drug addiction. Many studies used western blot assays to assess molecular alterations in synapses that were obtained from whole brain areas regardless of the afferent source of these synapses. We developed an optimized flow cytometry of synaptoneurosomes (FCS) protocol for analyzing protein and phosphorylation alterations in individual synaptoneurosomes from identified afferent sources – synaptoneurosomes contain sealed presynaptic and postsynaptic elements of a synapse. First, YFP-expressing AAV was injected into the PFC and the expressed YFP protein was transported over 6-8 weeks to label PFC-specific presynaptic endings in the nucleus accumbens core (NAcc). On test day, we injected each rat with 20 mg/kg cocaine (IP) and placed them in a novel environment to induce cellular and synaptic activation. We dissected the NAcc at 0, 5, 10, 30 and 60 min following the injection. We prepared synaptoneurosomes and confirmed their size and structure using electron microscopy and nanoparticle tracking analysis. We labeled the synaptoneurosomes with commercially available antibodies against candidate synaptic activation markers, such as Arc, CaMKII (protein and phosphorylation-specific), ribosomal protein S6 (protein and phosphorylation-specific) and calcineurin (protein and phosphorylation-specific). We then used our FCS protocol to quantify these molecular elements selectively in PFC-NAc synaptoneurosomes labeled with YFP. We found increased ribosomal S6 protein (but not phosphorylation) at 5-60 min and increased calcineurin at 5 and 10 min. We did not observe significant alterations in the Arc, CaMKII protein or phosphorylation at any of these time points. We validated the increases of ribosomal protein S6 and Calcineurin proteins in NAc synapses

using immunoelectron microscopy. Chloral hydrate anesthesia before cocaine injections will be used to demonstrate neuronal activity-dependence of cocaine-induced synaptic increases in S6 and calcineurin proteins. We propose that S6 and Calcineurin can be markers of synaptic activation *in vivo*. Our FCS-based approach is a rapid technique for discovery of synaptic plasticity alterations in small amounts of tissue obtained from single rats.

Title: Synaptosomal vs cytosolic microRNAs and synapse function in Alzheimer's disease

Authors: *E. ORLOV[1], P. GOWDA[2], P. H. REDDY[3], S. KUMAR[4];
[1]Texas Tech. Univ., Luboock, TX; [2]Texas Tech. Univ. Hlth. Sci. Ctr., Luboock, TX; [3]Dept. of Intrnl. Med., Texas Tech. Univ. Hlth. Sci. Ctr., Lubbock, TX; [4]TTUHSC, Lubbock, TX

Abstract: Synaptosomal vs cytosolic microRNAs and synapse function in Alzheimer's disease Erika Orlov[1], Prashanth Gowda[1], P. Hemachandra Reddy[1-5], Subodh Kumar[1],1. Internal Medicine Department, 2. Neuroscience & Pharmacology, 3. Neurology, 4. Public Health Department, 5. Speech, Language and Hearing Sciences, School Health Professions, Texas Tech University Health Sciences Center, Lubbock, TX, 79430 USA.
Introduction: The purpose of our study is to understand the role of synaptosomal microRNAs (miRNAs) in Alzheimer's disease (AD) progression. MiRNAs have been discovered in nerve terminals, synaptosomes, and synaptic vesicles in recent research. However, in AD, it is unclear if any specific miRNA is localized at the synapse. If so, are synapse miRNAs expressed differentially in the cytosol? What function do synaptosomal miRNAs play in synaptic activity

and neurotransmission in AD? **Methods:** To address these intriguing questions, synaptosomal and cytosolic fractions were separated from AD and healthy control postmortem brains. Synaptosomal fractions were confirmed by transmission electron microscopy, qRT-PCR and immunoblotting of synaptic proteins. Next, we performed the global affymetrix microarray analysis of synaptosomal and cytosolic miRNAs in both AD patients and healthy controls. Transcriptome Analysis Console V.4 was used to compare miRNAs data in four different ways: 1) AD synaptosome vs AD cytosol, 2) healthy control (HC) synaptosome vs HC cytosol, 3) AD cytosol vs HC cytosol, and 4) AD synaptosome vs HC synaptosome. **Results:** In different comparisons, some miRNAs tended to display very significant ($P<0.0001$) and high fold changes variance (+/- 200-fold) in their expression levels. Validation analysis on a large number of postmortem brain samples revealed that certain possible miRNAs were consistent across all samples in various comparisons. The potential miRNAs were further validated on APP transgenic (Tg2576), Tau transgenic (P301L) and wild type mice. MiRNAs were categorized as synaptosomal or cytosolic based on their existence and/or expression levels. In comparison to healthy controls, synaptosomal and cytosolic miRNAs were found to be dysregulated in AD patients. Further, Gene Ontology Enrichment and Ingenuity Pathway Analysis of synaptosomal miRNAs showed the involvement of these miRNAs in nervous system development, cell junction organization, and synapse assembly formation.
Conclusions: This is the first study to distinguish synapse miRNA candidates from cytosolic miRNAs based on their localization and expression levels and their possible roles in AD. **Key words:** Synapse, MicroRNAs, Synaptosomes, Cytosol, Synaptic activity

Title: Presynaptic vesicles can provide membrane to enlarge boutons following LTP

Authors: *L. KIRK[1], D. HANKA[1], K. ZATYKO[1], T. M. BARTOL, JR[3], T. J. SEJNOWSKI[4], K. M. HARRIS[2];
[2]Ctr. for Learning and Memory, [1]Univ. of Texas at Austin, Austin, TX; [3]CNL-S, [4]Salk Inst., La Jolla, CA

Abstract: Long term potentiation (LTP) is the sustained increase in evoked response following the delivery of high frequency stimulation. In the hippocampus, LTP is the cellular correlate of learning and memory. There are many ultra-structural changes that occur at hippocampal synapses several hours after LTP. Most of this work has focused on changes in postsynaptic structures. However, less is known about presynaptic structural changes. We showed that two hours following LTP there is a significant drop in the reserve pool of synaptic vesicles, with a larger drop occurring at boutons that contain mitochondria. Previous work demonstrated that boutons are enlarged following LTP (Chereau et al., 2017). We hypothesized that the vesicles lost following LTP contribute their membrane to the enlarged boutons. Serial section electron microscopy was used to reconstruct presynaptic boutons and their components from CA1 stratum radiatum in hippocampal slices that received either control or TBS resulting in LTP. We expanded the suite of Neuropil Tools, built in the Blender environment, to measure surface areas of presynaptic boutons. We found that as the nondocked presynaptic vesicle pool decreased 2 hours following LTP, presynaptic boutons were enlarged with substantial increase in membrane surface area. Furthermore, the membrane from approximately 50% of the lost vesicles was sufficient to account for the growth in bouton surface area. We have analyzed the inter-bouton membrane area and found that its expansion was not sufficient to account for the rest of the vesicle membrane. Hence, we are currently analyzing other internal membrane bound organelles (mitochondria, SER, and endosomes) within the bouton to determine where the other 50% of vesicle membrane surface area may have gone.

Title: Dendritic signaling pathways underlying endocannabinoid-mediated inhibitory bouton growth

Authors: *L. J. HERSTEL, H. HU, D. L. H. KRUIJSSEN, C. J. WIERENGA;
Cell Biology, Neurobio. and Biophysics, Dept. of Biol., Utrecht Univ., Utrecht, Netherlands

Abstract: Coordination between excitation and inhibition is essential for proper functioning of neuronal circuits. Inhibitory synapses can locally control the activity of excitatory inputs by their constructive placement on the same dendrite. We recently discovered that excitatory and

inhibitory plasticity is regulated at the synaptic level. By repeated stimulation of excitatory synapses, the formation of a nearby inhibitory bouton onto the same dendrite can be triggered. Our findings show that this process is mediated by the production of the endocannabinoid 2-arachidonoylglycerol (2-AG) which activates axonal cannabinoid type 1 (CB1) receptors. Spine stimulation failed to induce inhibitory bouton growth in presence of the cannabinoid receptor type 1 (CB1R)-antagonist AM251. In addition, we found that excitatory synaptic plasticity was affected by manipulations of the endocannabinoid system. Structural long-term plasticity of excitatory synapses was completely abolished by increasing 2-AG concentration via preventing degradation, whereas average spine growth was accelerated after AM251 application. These results might indicate a role for postsynaptic CB1 receptors in mediating excitatory synapse strengthening. We also explored the local dendritic signaling mechanism that underlies this coordinated inhibitory plasticity. We found that N-methyl-D-aspartate receptor (NMDA) receptor activation is required, but not sufficient, to induce bouton growth. We hypothesized that additional activation of metabotropic glutamate receptor 5 (mGluR5) is necessary. We used two-photon microscopy to image crossings between CA1 pyramidal cell dendrites (labeling via a patch pipette) and GFP-labeled GABAergic axons in organotypic hippocampal slices of GAD65-GFP mice (of both sexes, dissected at P6-8, used at DIV10-21). We stimulated multiple dendritic spines close (<10 um) to the crossing axon using two-photon glutamate uncaging (30x @0.5Hz) paired with somatic postsynaptic depolarization (0 mV, 100 msec). Pharmacological blockade of mGluR5 throughout the experiment with 2-Methyl-6-(phenylethynyl)pyridine (MPEP) did not prevent bouton growth, indicating that inhibitory bouton growth is independent of mGluR5 activation. Our results help to further unravel the activity-dependent signaling pathways that regulate coordination between excitatory and inhibitory synapses within dendrites.

Title: Rab11 activity is required for proper localization of FasII and PIP2 at glutamatergic synapses

Authors: *I. SMITH[1], J. PRESTON[2], F. L. LIEBL[2];
[1]Southern Illinois Univ. Edwardsville, East Alton, IL; [2]Southern Illinois Univ. Edwardsville, Edwardsville, IL

Abstract: Neural plasticity is an activity-dependent process that relies on vesicular transport of proteins like cell adhesion molecules (CAMs) and endocytic proteins at the synapse. Rab GTPases are a family of proteins that are critical to the membrane trafficking of vesicles. In particular, Rab11 plays a role in trafficking proteins from the recycling endosome to the plasma membrane thereby influencing synaptic localization of synaptic proteins. We have found that when Rab11 is constitutively active in neurons, there is an increase in synaptic Fasciclin II (FasII) and a decrease in the colocalization of Endophilin A (EndoA) and Dynamin, two endocytic proteins. In contrast, when a dominant negative Rab11 is expressed in neurons, we observe the opposite phenotype. In order construct a more comprehensive model of Rab11 function in neurons, we knocked down Rab11. While we found no significant changes in protein levels of FasII, EndoA, Glutamate Receptor IIC (GluRIIC), and the active zone protein Bruchpilot, there was a significant reduction in synaptic Phosphatidylinositol 4,5 biphosphate ($PI(4,5)P_2$) levels. Collectively, these data will deepen our understanding of how Rab11 may contribute to the synaptic vesicle cycle and synaptic plasticity.

Title: The retrotransposon copia at the Drosophila neuromuscular junction

Authors: *P. G. M'ANGALE, A. SIMKIN, A. LEMIUEX, T. THOMSON, V. BUDNIK; Neurobio., Univ. of Massachusetts Med. Sch., Worcester, MA

Abstract: Copia is an abundant retrotransposon found in *Drosophila melanogaster*. It is found as a full length or spliced form and we hypothesize that copia may play a significant role at the Drosophila neuromuscular junction. Copia was found enriched together with Arc1 in extra-cellular vesicles derived from S2 cells. From RNA-sequencing data coupled with digital PCR, we determined that copia has several full-length forms that are found in differing abundancy in the Drosophila larval brain or body wall muscles. We also show that, in the Drosophila larval brain, the short-spliced form (copia Gag) is highly abundant compared to the full-length version. From bacterially expressed copia Gag, we found that the resultant capsids were heterogeneous in size with most capsids within the 60 to 100 nm range. We will perform RIP-seq, or RT-qPCR to

establish the interactome of copia and perform electrophysiological recordings in copia RNAi flies to establish the physiological role of this retrotransposon.

Title: Three-dimensional analysis of excitatory synapses in CA1 hippocampus reveals distinct populations of synaptic spinules and excitatory presynaptic boutons

Authors: A. YURINA, A. GORE, A. YUKEVICH-MUSSOMELI, ***M. NAHMANI**;
Univ. of Washington – Tacoma, Tacoma, WA

Abstract: Synaptic spinules are thin finger-like projections from one neuron that become fully embedded within the presynaptic or postsynaptic compartments of another neuron. While spinules are an evolutionarily conserved and relatively common feature of synapses across the animal kingdom, their specific function(s) remain unknown. This lack of understanding for what spinules “do” is mostly a reflection of their small size and the consequent difficulty in quantifying their abundance and 3D ultrastructure using previously available techniques. Recent focused ion beam scanning electron microscopy (FIBSEM) image volume analyses have demonstrated that spinules are embedded within ~ 25% of excitatory boutons in mammalian primary visual cortex (V1), yet the diversity of spinule sizes and ultrastructural relationship to their boutons across brain regions remain unclear. To begin to uncover the function of synaptic spinules, we sought to determine the abundance, origins, and 3D ultrastructure of spinules embedded within excitatory presynaptic boutons in mammalian CA1 hippocampus and compare these boutons with synaptic boutons bereft of spinules. Accordingly, we three-dimensionally reconstructed every excitatory presynaptic bouton (n = 138) along with their embedded synaptic spinules (if present; n = 122) and postsynaptic densities (PSDs, n=159) within a 5 nm^3 isotropic (7.68 x 10.24 x 5.33 µm) FIBSEM image volume from the CA1 hippocampus of an adult male rat. Surprisingly, we find that ~74% of excitatory boutons in this volume contain at least one spinule, suggesting that they are fundamental components of excitatory synapses in CA1. Moreover, synaptic spinules can be clearly differentiated into two groups: small clathrin-coated spinules, and 18 - 42X larger spinules without clathrin. Our analyses also reveal that a majority

of synaptic spinules in CA1 emanate from adjacent axons (60.5%), postsynaptic spines (38.1%), and adjacent (non-synaptic) spines (24.5%), with little variation in the volume, surface area, or bouton penetration distance across these spinule types. Yet interestingly, spinule-bearing boutons (SBBs) are 2.5X larger in volume and have 1.6X larger PSDs than boutons without spinules (non-SBBs), suggesting that SBBs are more stable and active than their non-SBB counterparts.

Title: Curcumin's mechanistic effects on neuroblastoma and glioblastoma

Authors: *K. ZHAI[1], M. SHAKIBAEI[2], D. BUSSELBERG[1];
[1]Physiol. and Biophysics, Weill Cornell Medicine-Qatar, Doha, Qatar; [2]Ludwig-Maximilian Univ. Munich, Munich, Germany

Abstract: Curcumin, a major constituent of the turmeric (*Curcuma longa*) plant, is a polyphenolic compound with antioxidant, neuroprotective, and anticancer activities. As a natural compound with the potential to overcome the challenges of conventional anticancer therapies, curcumin was clinically trialed as a supportive therapy in several types of common malignancies. However, studies on curcumin and cancers of the nervous system remain sparse. Two such cancers are glioblastoma (GBM), an astrocyte-derived central nervous system malignancy, and neuroblastoma (NB), a peripheral nervous system tumor derived from neural progenitor cells. As such, this study critically reviews the recent literature on curcumin’s mechanistic effects on GBM and NB. Preclinical results indicate that curcumin inhibits PI3K/Akt/mTOR-dependent proliferation, induces apoptosis, and reduces cell migration and invasion in GBM cells. Similarly, curcumin’s anti-NB effects are mediated through apoptotic induction, cell cycle arrest, and mitochondrial dysfunction. These anticancer activities underscore curcumin’s potential as a therapeutic agent in cancers of the nervous system. However, while curcumin is clinically safe, its bioavailability and blood-brain barrier permeability remain important considerations on the path toward clinical trials in GBM and NB.

Title: Flavonoids of Cannabis sativa limit glioblastoma survival and invasion by inhibiting TrkB signaling

Authors: *J. HOLBORN, C. GAGE, B. ALURAL, A. WALCZYK-MOORADALLY, C. PERRIN, N. JONES, T. AKHTAR, J. LALONDE;
Mol. and Cell. Biol., Univ. of Guelph, Guelph, ON, Canada

Abstract: Glioblastoma multiforme (GBM) is the most common and aggressive type of adult brain cancer. These tumours can occur in any region of the central nervous system and average survival time of patients after diagnosis is less than two years. This poor prognosis is attributable to the fact that GBM cells can rapidly invade into brain, a feature that is very difficult to attack with current treatment options. Better understanding of the molecular basis of GBM invasion, as well as how this phenomenon could be neutralized without damaging surrounding healthy cells, is therefore critically needed to develop more effective therapies. Abnormal neurotrophin signaling via the Tropomyosin receptor kinase B (TrkB) receptor is increasingly seen as an important factor in various types of brain tumour, including GBMs, and accumulating evidence suggest that targeting this pathway may be a valid strategy to limit the growth, proliferation, and/or motility of aggressive cancer cells. While screening for novel modulators of receptor tyrosine kinase (RTK) signaling, our group unexpectedly found that cannflavins—a class of flavonoid molecules that accumulates in the *Cannabis sativa* (*C. sativa*) plant—can prevent TrkB activation. This surprising finding motivated us to closely examine the impact of cannflavin A and cannflavin B against GBM biology. Here, we first present evidence that each type of flavonoid limits TrkB activation by Brain-Derived Neurotrophic Factor (BDNF) in dissociated mouse cortical neurons and human immortalized GBM cells (A172 and U87). Next, we report *in vitro* cytotoxicity experiments showing that inhibition of TrkB signaling by cannflavins sharply decreases viability of GBM cells by promoting programmed cell death. Finally, we show that a low, sub-toxic concentration of cannflavins is sufficient to significantly decrease the capacity of GBM cells to invade in the Boyden Chamber and spheroid migration assays. Together, our results suggest that targeting TrkB receptors with cannflavins can produce desirable anticancer effects against GBM cells by limiting molecular processes that support invasion and survival.

Title: Microglia derived olfactomedin-like 3 promotes primary mouse brain endothelial cell angiogenesis

Authors: R. G. TOEDEBUSCH, L. M. JOSEPH, C. A. LUCCHESI, L. A. WITTENBURG, ***C. TOEDEBUSCH**;
Univ. of California, Davis, CA

Abstract: Microvascular proliferation is a hallmark feature of glioblastoma multiforme (**GBM**), a uniformly lethal brain tumor. To date, anti-angiogenic therapies have targeted vascular endothelial growth factor (**VEGF**), the most abundant angiogenic factor in GBM. However, anti-VEGF therapy has proven ineffective for mitigating neoangiogenesis and improving patient survival, suggesting that VEGF-independent mechanisms of angiogenesis contribute to GBM progression. In recent years, a novel secreted protein, olfactomedin-like 3 (**OLFML3**), has been shown to promote tumor progression of several non-CNS cancers via increased angiogenesis. Preliminary data from our laboratory has demonstrated *Olfml3* expression in mouse brain endothelial cells (**EC**s) and microglia, the most abundant tumor invading immune cell type. However, the effect of exogenous OLFML3 and endogenous *Olfml3* on mouse brain EC angiogenesis remains unknown. Therefore, this study aimed to test the following two hypotheses: 1) Microglia-derived OLFML3 promotes primary mouse brain EC angiogenesis, and 2) EC-derived *Olfml3* is required for angiogenesis. To determine if OLFML3 was sufficient to induce angiogenesis, we exposed primary mouse brain ECs to human recombinant OLFML3 (**rhOLFML3**). rhOLFML3 (10 ng/mL) increased several phases of angiogenesis, including EC proliferation (CellTiter Glo; $p<0.0001$), migration (Boyden Chamber; $p=0.0375$) and differentiation tested via tube formation assay (total tubes, $p=0.009$; loops, $p=0.0011$; branching points, $p=0.0022$) relative to mock treated cells. To elucidate the contribution of microglia derived OLFML3, ECs were exposed to conditioned medium (**CM**) from immortalized isogenic control or *Olfml3* knockout microglial cells. All phases of angiogenesis were reduced in ECs exposed to CM from *Olfml3* knockout microglia (proliferation, $p=0.0035$; migration, $p=0.0016$; differentiation: total tubes, $p=0.0421$; branching points, $p=0.0467$). To determine if endogenous *Olfml3* is required for angiogenesis**,** primary ECs were transfected with a control, non-targeting,

or *Olfml3*-targeted siRNA which resulted in a 60% reduction in *Olfml3* mRNA. Proliferation (p=0.4773), migration (p=0.1430), and differentiation (total tubes, p=0.1431; loops p=0.1687; branching points pp=0.1788) were not altered following knockdown of EC *Olfml3*. Together, these data demonstrate that exogenous OLFML3 promotes primary mouse brain EC angiogenesis, but EC derived *Olfml3* may not be necessary. Importantly, microglial-derived *Olfml3* may be necessary for microglia-induced neoangiogenesis, providing a complementary, precise target for GBM patients.

HILLMAN[3], C. A. SCHEVON[4], D. S. PETERKA[6], P. CANOLL[1]; [1]Pathology & Cell Biol., [3]Biomed. Engin., [4]Neurol., [5]Neurosurg., [6]Zuckerman Inst., [2]Columbia Univ., New York, NY

Abstract: Recent studies have revealed that crosstalk between glioma cells and the brain microenvironment is a crucial regulator of cancer initiation and progression. We previously described a glioma model in Thy1-GCaMP6f mice that shows spontaneous seizure activity at the infiltrative margins of the tumor. Here, we used 2-photon imaging in awake Thy1-GCaMP6f mice to further characterize neuronal activity at the single cell level, both spontaneously and during whisker stimulation. AZD8055, a competitive dual mTORC1/2 inhibitor, has been shown to not only be a key regulator of neuronal excitability but also have anti-tumor effects in mouse models of glioblastoma. We have previously shown that AZD8055 suppresses neuronal hyperactivity in acute slices of this tumor model, yet little is known of its direct in-vivo effect on neuronal activity at the glioma border. At surgery, Thy1-GGaMP6f mice had glioma cells containing an mCherry fluorophore injected below the cortical surface prior to implantation of the cranial window. To investigate the impact of mTORC1/2 inhibition on neuronal activity,

imaging was performed before and after gavage of AZD8055 100mg/kg. In our imaging fields at the tumor border, we observed an intermingling of tumor cells and excitatory neurons. Our studies revealed that neuronal activity, as measured by thresholded peaks of somatic calcium events, is increased in response to whisker stimulation. Administration of AZD8055 reduced the rate of somatic calcium events in both the whisker stim and no stim conditions. To better understand how neuronal activity changes as a function of distance to tumor cells in the local microenvironment we utilized tumor cell mCherry signal to calculate a tumor burden score for each neuron. Our analysis revealed the rate of somatic calcium events increased as neuronal tumor burden scores increased, in both whisker stimulation and no stimulation conditions. Furthermore, this analysis illustrated that AZD8055 administration blunted this relationship. Lastly, we observed focal discharges of high amplitude synchronous calcium events, less than $500um^2$ in space and less than 1 second in time. These discharges were largely composed of neuropil fluorescence and were spatially concentrated to the high tumor burdened areas. Our ongoing analyses are aimed at further understanding the effects of mTOR inhibition on glioma-induced alterations in neuronal activity, neuronal synchrony, and whisker stimulus-evoked responses at the tumor margin. This study revealed that glioma cells have very local effects on neuronal activity at the infiltrative margin, and that these effects can be modulated by inhibition of mTOR signaling.

Title: Evaluation of fMRI Resting-State Functional Connectivity Following Resection of Brain Gliomas

Authors: *A. J. SCHROEDER[1], Y. CHEN[1], T. M. STEPHENS[2], I. F. DUNN[2], H. YUAN[1]; [1]Stephenson Sch. of Biomed. Engineering, Gallogly Col. of Engin., The Univ. of Oklahoma, Norman, OK; [2]Dept. of Neurosurg., The Univ. of Oklahoma Hlth. Sci. Ctr., Oklahoma City, OK

Abstract: Surgical resection is a mainstay of human glioma treatment. Extent of resection positively correlates with overall and progression-free survival, but resecting tumor-infiltrated brain tissue carries risk of inducing neurological deficits. However, it is increasingly recognized that the functional anatomy of the human neocortex is plastic. Functional connectivity of perilesional regions compared to that of corresponding contralateral regions has been implicated as a predictor of neurological outcome (Tarapore et al., 2012). Resting-state functional magnetic resonance imaging (fMRI) is an effective tool for identifying connectivity between tumor tissue and specific eloquent regions of the brain (Wongsripuemtet et al., 2018). To further our understanding of using fMRI to guide tumor resection, we evaluated whether fMRI could assess altered functional connectivity of perilesional tissue after surgery. Resting state fMRI data were obtained from nine subjects following glioma resection. Data analysis was conducted following our prior protocol (Yuan et al., 2017), using customized AFNI scripts. Spatial coregistration to anatomical images was performed for each fMRI dataset. The first five volumes of each run were excluded to allow the signal to reach steady state. Key processing steps were bandpass filtering (0.005-0.1 Hz), censoring data points with excessive motion (root mean square of 3D displacement > 0.3 mm) and smoothing using a Gaussian kernel (full width at half maximum = 6 mm). Functional connectivity of perilesional regions versus corresponding contralateral regions was evaluated via seed-based analysis, and further classified as having increased, decreased, or neutral connectivity. One subject was excluded due to excessive motion artifacts and another due to technical error resulting in echo-planar imaging data not covering the entire brain. In the remaining subjects, fMRI data allowed for identification of perilesional regions with altered connectivity compared to corresponding contralateral regions. In this study, we showed that fMRI resting state functional connectivity was able to identify regions of altered connectivity in patients following glioma resection, which is consistent with a previous report using magnetoencephalographic imaging (Tarapore et al., 2012). Future investigations could attempt to correlate the reorganization of functional connectivity to long-term neurological outcome. Patients may benefit from a more aggressive surgical strategy that accounts for predicted functional recovery after surgery. fMRI could become a valuable tool in the prediction and management of functional recovery.

Abstract: Glioblastoma (GBM) is the most common primary brain tumor in adults, with few available therapies and a 5-year survival rate of 7.2%. Hence, strategies for improving GBM prognosis are urgently needed. The translocator protein 18kDa *(*TSPO) plays crucial roles in essential mitochondria-based physiological processes and is a validated biomarker of neuroinflammation, which is implicated in GBM progression. TSPO is located in the outer mitochondrial membrane and binds cholesterol through its C-terminal domain. One frequent single-nucleotide polymorphism (SNP) rs6971, which changes the alanine 147 into threonine (Ala147Thr) has been found in the C-terminal domain of the TSPO region and dramatically alters the affinity with which TSPO binds drug ligands. High *TSPO* gene expression is associated with reduced survival in GBM patients; however, the relation between the most frequent *TSPO* genetic variant and GBM pathogenesis is not known. The present study retrospectively analyzed the correlation of the *TSPO* polymorphic variant rs6971 with overall and progression-free survival in GBM patients using three independent cohorts. *TSPO* rs6971 polymorphism was significantly associated with shorter overall survival and progression-free survival in male GBM patients but not in females in a well curated Cleveland Clinic Foundation cohort of 441 patients. We observed similar trends in two other independent cohorts. These observations suggest that the *TSPO* rs6971 polymorphism could be a significant predictor of poor prognosis in GBM, with a potential for use as a prognostic biomarker in GBM patients. These results reveal, for the first time, a biological sex-specific relation between rs6971 *TSPO* polymorphism and GBM.

Title: Autonomic nerve distribution predicts prostate cancer outcome

Authors: S. DWIVEDI[1], J. HALL[1], S. SHRESTHA[1], T. CHAPHEKAR[2], M. BAUTISTA[1], *A. KRISHNAN[1];
[1]Univ. of Saskatchewan, Saskatoon, SK, Canada; [2]Univ. of Tennessee, Knoxville, TN

Abstract: Recent studies demonstrated that autonomic nerves contribute to prostate cancer progression. For example, denser innervations of autonomic nerves are associated with high-grade tumors and a higher proliferation index. In particular, increased parasympathetic innervation was shown to promote disease recurrence. However, there is no data available on the spatial and temporal distribution of sympathetic and parasympathetic fibers, and their relation to each other, in prostate tumors, which is critical to understand their individual contribution to cancer and stromal cell metabolism. In this study, we examined the differential distribution of sympathetic and parasympathetic nerves in eight clinical samples of prostate tumors and corresponding adjacent normal tissues and correlated the findings with the associated clinical data. The samples were procured from Alberta Cancer Research Biobank following the guidelines approved by the Biomedical ethics committee. We used tyrosine hydroxylase and choline acetyltransferase staining to distinguish sympathetic and parasympathetic fibers, respectively, in these samples. We also determined the relative distribution of adrenergic beta and cholinergic muscarinic (M) receptors in these clinical samples. Our initial analysis revealed that higher sympathetic nerve density at the tumor site is associated with the development of metastasis. We also found a differential distribution pattern for adrenergic beta receptors. For example, beta 2 is highly expressed in cancer cells, while both beta 2 and beta 3 are expressed in stromal cells, indicating that sympathetic nerves promote both cancer and stromal cell metabolism. We found higher expression of M3 receptors in cancer cells while the tumor microenvironment showed the expression of both M1 and M3. Similar to sympathetic nerves, parasympathetic nerves were also abundant in high-grade tumors. Altogether, our result suggests that individual distribution of sympathetic and parasympathetic nerves and their receptors may have prognostic applications in prostate cancer. Detailed studies using a large set of samples are warranted for further validation.

Title: Physical activity is associated with changes in functional connectivity metrics across the lifespan

Authors: *V. KUMAR, S. LACEY, K. SATHIAN;
Penn State Col. of Med., Hershey, PA

Abstract: Physical activity has been associated with improved brain health and cognitive function across the lifespan. However, this characterization has focused largely on describing the effects of physical activity in maintaining the structural integrity of the aging brain. Consequently, its impact on functional connectivity (FC) that reflects information transfer amongst distributed neuronal assemblies, and underlies complex cognitive functions, remains unclear. Here, we examined the relationship between levels of physical activity and FC patterns in resting-state magnetoencephalography (rs-MEG) and resting-state functional magnetic resonance imaging (rs-fMRI) data across the lifespan. Physical activity and energy expenditure (PAEE), rs-MEG, and rs-fMRI data of 540 participants were obtained from the Cambridge Centre for Ageing and Neuroscience repository (http://www.mrc-cbu.cam.ac.uk/datasets/camcan/). In rs-MEG data, we investigated FC dynamics using the global coherence metric that quantifies the degree of synchrony amongst distributed neural oscillations. Two-way ANOVA with factors of age (7 levels: age deciles from 18-88 years) and PAEE (2 levels: High and Low) revealed significant effects of both age [$F(6,539) = 8.92$, $p < 0.001$] and physical activity [$F(1,539) = 6.48$, $p = 0.01$] on α-band (8-12 Hz) global coherence, with no significant interaction [$F(6,526) = 1.05$, $p = 0.389$]. Overall, the low physical activity group showed higher α-band global coherence than the high physical activity group. In rs-fMRI data, we evaluated the graph-theoretic measure of network segregation i.e., the degree to which networks share connections among one another. We constructed a functional connectivity matrix based on a 264-node functional atlas (Power et al., Neuron, 72:665-678). Mediation analysis revealed that physical activity positively mediated the age/network-segregation relationship for the default-mode network [$\beta = 0.0003$, $p_{fdr} = 0.024$] and the fronto-parietal task network [$\beta = 0.0003$, $p_{fdr} = 0.009$] but negatively mediated the ventral attention network [$\beta = -0.0002$, $p_{fdr} = 0.05$]. Our results suggest that physical activity affects the processes that manifest in α-band global coherence and impacts the within- and between-network correlations that are characteristic of segregated and specialized organization. Furthermore, our findings indicate that FC metrics indexed by rs-MEG and rs-fMRI are sensitive indicators of the brain's response to physical activity.

Title: Sex differences in age-related false alarm and differential temporal and frontal responses during non-emotional working memory retrieval

Authors: *S. STROTHKAMP[1], L. BROSTER[2], B. AGHAYEEABIANEH[2], A. ANDERSON[2], D. K. POWELL[2], G. JICHA[1], Y. JIANG[2];
[1]Univ. of Kentucky Col. of Med., Lexington, KY; [2]Univ. of Kentucky, Lexington, KY

Abstract: Inaccurate and prolonged working memory retrieval is hallmark of mild cognitive impairment (MCI) induced by Alzheimer's disease (AD) and related dementia pathologies. Increased false memory retrieval has been reported in normal cognitive aging (e.g. thinking a car in a parking lot is your car when it is not). It is unclear why there are more men in the US suffering from MCI (early stage of dementia), while AD disproportionally affect women. Here we test the hypothesis that sex differences in brain aging have differential effects on brain volumes and network associated working memory performance in preclinical cognitively intact older adults.
Forty-four (44) cognitively normal older adults (25 women; mean age 77), from the University of Kentucky ADC cohort, participated in the Bluegrass Working Memory Task inside the 3T Siemens magnetic resonance imaging (MRI) Scanner. The task is a 11-min modified delayed match-to-sample task (Jiang et al., 2016). A false alarm was defined as identifying a non-match visual object as a match target held in memory. MRI data was analyzed using Free Surfer. Spearman correlation and linear regression analyses were performed to test the hypothesis.
The mean false alarm rate in males was 3.74%, and 4.03% in females (no sex differences). Mean reaction time during false alarms (FA_RT) in men was 657 ms, and in women 792 ms (no sex differences, $p>0.05$). False alarm rate was negatively correlated with brain volumes in frontal and temporal regions. We observed significant correlations in FA_RT in all subjects in frontal and temporal regions. However, when subjects were separated by sex, FA_RT in males significantly correlated positively with frontal regions (e.g. rostral middle frontal gyrus and fontal pole) only while FA_RT in females correlated positively with temporal regions (e.g. transverse temporal gyrus).
We found that cognitively healthy older men and women made similarly rate of false alarm in working memory retrieval. However, the older men were significantly faster than women in false memory retrieval and involves differential cortical mechanisms. False alarm memory retrieval is

associated with decreased frontal volumes in older men but decreased temporal volumes more often in older women.

Abstract: Aging is a major risk factor for neurodegenerative diseases that impose tremendous burdens on people and societies. To understand trajectories of neurological aging in a primate, we generated one of the most comprehensive brain transcriptional datasets to date in a unique population of free-ranging, behaviorally phenotyped rhesus macaques (*Macaca mulatta*). We profiled bulk-tissue transcriptomes from 15 brain regions of 36 adult macaques (20 female, 16

male) and profiled single-nucleus transcriptomes from the dorsolateral prefrontal cortex (dlPFC) of 24 adult females spanning the natural age distribution. We then modeled transcriptomic data using linear mixed models that control for genetic relatedness among animals while controlling for sex and other technical and biological variables. We demonstrate that age-related changes in both the level and variance of gene expression occur in genes previously associated with neural functions and neurological diseases. Genes that are differentially expressed in diagnosed cases of Alzheimer's disease, for instance, are significantly associated with genes that change in both the mean and variance of expression in older ages. We also show that, of 8 distinct cell types, oligodendrocytes are the only cell type to significantly increase in proportion with age in the dlPFC. We identified, however, numerous cell-type-specific changes in expression, including decreases in expression of synaptic signaling-related genes in excitatory neurons, decreases in expression of genes regulating the modulation of excitatory postsynaptic potential in astrocytes, and increases in expression of genes related to proinflammatory responses in microglia. Finally, given existing evidence showing that elevated disease and mortality risk are caused in part by social adversity, we test if macaque dominance ranks—a proxy for social adversity—accelerate the effects of aging in the brain. We show that higher social status in females is associated with younger relative transcriptional ages, providing a link between the social environment and aging in the brain. Taken together, our findings lend insight into biological mechanisms underlying brain aging and indicate promising directions for improving social gradients in neurological health

Abstract: It is recognized that the microbiota in host's gut communicate with the CNS impacting the neurolipidome and brain health. A proposed mechanism for this communication is short chain fatty acids (SCFAs), neuroactive metabolites from the fermentation of carbohydrates in the colon and caecum. The literature demonstrates that SCFAs are beneficial for improving host health but emerging evidence from our work suggest these enteric metabolites can cause neural inflammation associated with altered neurolipidome. We exposed Long Evans rats to an acute dose of SCFAs consisting of 500mg/kg of acetate, propionate, and butyrate (60:20:20 molar ratio) for 7 days via IP injection. After the injection period, animals were sacrificed, and frozen brain samples used to assess the neurolipidome using UHPLC-RPC30-HESI-HRAM/MS-MS and DESI-MS. To compare animal results to in vitro, SH-SY5Y neuroblastoma cells were treated with the same ratio of SCFAs in equivalent molarity. The cell lipidome was assessed using UHPLC-RPC30-HESI-HRAM/MS-MS, Flow Cytometry, STED, Cytation3, and Seahorse XF. We observed cells arrest in cell cycle progression, increased mitochondrial mass, hyperfusion and fragmentation, decreased respiration and ATP production, with SCFA induced alterations to the neurolipidome. Trauma/neurodegenerative diseases have been linked to modified lipid compositions within the brain. Alterations were observed in sphingolipids, phospholipids, plasmalogens, neutral lipids, and mitochondrial lipids in both rat brain and cell line. Both increases and decreases in phospholipids included saturated (16:0,18:0), monounsaturated (16:1,18:1), and polyunsaturated (20:4,22:6) fatty acid lipid composition. These alterations have the potential to affect lipid membrane stability, fluidity, and inflammation. This inluded plasmalogen species, which are important in oxidation and oxidative stress. Triglycerides were significantly impacted by the treatment resulting in a lowered concentration. While considered for fat storage and energy only, recent research has been shown that TGs can impact cognition within the brain, making them now relevant to diseases such as Alzheimer's disease. Observed alterations in mitochondrial specific lipids cardiolipin and acyl-carnitine can have energy and functional implications that are connected to neurological disorders within the brain. This study aims to understand how metabolites change the lipid composition within brain. This could lead to an understanding of how susceptible an organism may be to neurological health consequences or disorders following acute exposure to SCFAs.

Care Syst., Portland, OR

Abstract: Cerebrospinal fluid (CSF), a clear colorless fluid, is one of the two discrete fluid compartments of the brain along with interstitial fluid (ISF). CSF, together with ISF, plays a key role for the removal of solutes and metabolic wastes from the brain interstitium. Regulation of CSF dynamics is crucial to optimize the central nervous system (CNS) health, and impaired CSF circulation can potentially contribute to CNS diseases such as Alzheimer's disease. Therefore, understanding the mechanisms driving CSF movement, and interventions that influence its resultant removal of waste products from the brain is of high scientific and clinical impact. Pulsatile CSF movement is driven by pressure changes in CNS vascular system due to cardiac pulsation and respiration. Since pulsatile CSF dynamics is sensitive and synchronous to respiratory movements, we are interested in identifying potential integrative therapies such as yogic breathing to regulate and enhance CSF dynamics, which has not been reported before. We investigated the pre-intervention baseline data from our ongoing randomized controlled trial studying the impact of long-term practice of yogic breathing on CSF dynamics. The purpose of this study is to study the immediate modulation of pulsatile CSF velocity waveforms at the level of foramen magnum during four yogic breathing practices versus spontaneous breathing using a non-invasive magnetic resonance imaging (MRI) approach. In examinations of 18 healthy participants (eight females, ten males; mean age 34.9 ± 14 (SD) years; age range: 18-61 years), we discovered immediate increase (16% - 28%) in cranially-directed velocities of instantaneous-CSF velocities during yogic breathing compared to spontaneous breathing, with most statistically significant increase during deep abdominal breathing (28%, p=0.0008). In addition, cardiac pulsation was the primary driver of CSF during all breathing conditions except during deep abdominal breathing when there was a comparable contribution of respiration and cardiac

pulsation, which suggests respiration can be the primary driver for pulsatile CSF depending on individual differences in breathing depth and location. Since increased pulsatile CSF dynamics is suggested to increase brain's waste clearance through increased mixing and diffusion, we hypothesize that a potential underlying mechanism for the benefits of sustained training yogic breathing is its impact on pulsatile CSF dynamics, in turn removal of solutes from the brain. Further work is needed to confirm this hypothesis in healthy young and aged brain, and neurological conditions such as Alzheimer's disease.

Title: Synaptic Integrity in Cognitive SuperAgers

Authors: R. TAEFI, K. HAYNES, I. A. AYALA, *E. TAEFI, C. B. SWOPE, M. E. FLANAGAN, T. GEFEN, E. ROGALSKI, M. M. MESULAM, C. GEULA;
Mesulam Ctr. for Cognitive Neurol. and Alzheimer's Dis., Northwestern Univ. Feinberg Sch. of Med., Chicago, IL

Abstract: Decline in memory is a normal characteristic of aging. However, there is an alternative trajectory that resists the cognitive changes of normal aging. Our center has been engaged in investigations of a subset of individuals over the age of 80 with performance on tests of episodic memory equal to or better than individuals 20-30 years their junior. We have used the term "SuperAger" to refer to such individuals. SuperAgers show larger cortical volumes, less ApoE4, more von Economo neurons, and fewer instances of Alzheimer's disease (AD) pathology than their cognitively average peers. Synaptic loss is one of the strongest correlates of cognitive decline in the normal elderly and in AD. The purpose of this study was to investigate whether greater synaptic integrity is a characteristic of SuperAger brains. The status of synaptic proteins in individuals with a range of cognitive performance was studied. We examined the levels of the presynaptic protein synaptophysin and the postsynaptic density protein 95 (PSD-95) in fresh frozen tissue homogenates of the middle frontal gyrus (MFG) and the superior temporal gyrus (STG) of SuperAgers, cognitively average elderly, and AD patients ($N \geq 3$ per group)

using Western blot analysis and specific antibodies. Optical densities of bands were determined using the Image J software, and synaptic protein levels were expressed as percentage of the housekeeping protein GAPDH. As expected, levels of synaptic proteins were decreased in AD brains when compared with controls (0-31%). Interestingly, results indicated higher levels of synaptophysin in MFG (21%), and of PSD-95 in STG (51%) in SuperAgers when compared with cognitively average elderly. While preliminary, these findings suggest that enhanced integrity of cortical synapses, assessed through levels of synaptic proteins, may contribute to the SuperAging phenotype.

Title: Increased Neural Heterogeneity after 30 minutes of Aerobic Exercise in Older Adults.

Authors: *J. PURCELL[1], J. WON[1], L. R. WEISS[1], A. ALFINI[2], D. CALLOW[1], J. C. SMITH[1]; [1]Univ. of Maryland, College Park, MD; [2]Johns Hopkins Univ., Baltimore, MD

Abstract: Background: As one progresses into old age, there is a higher risk of decreased physical and cognitive health. Although there is a growing body of work demonstrating that aerobic exercise can help improve neural function, the specific mechanisms of improvement are not well understood, especially immediately after exercise. One hypothesized mechanism is that a single session of exercise can lead to increased local neural heterogeneity within brain regions important for separating neural signals (Suwabe et al. 2018) including the hippocampus and cerebellum (Cayco-Gajic and Silver 2019). To date, no study has examined differences in local neural heterogeneity following a single bout of exercise in older adults. **Hypothesis:** There will be relatively high levels of neural heterogeneity (i.e., less similarity of adjacent neural signals) after 30 minutes of aerobic exercise within both the hippocampus and cerebellum. **Methods:** 32 physically active, right-handed older adults (ages, 55-85 years) participated in a within subject randomized crossover design. We employed a novel analytic technique termed General Heterogeneity Regression which concatenates several distinct fMRI runs together (resulting in about 30 minutes of fMRI data per time point/subject) with the goal of producing a reliable and reproducible measure of local neural heterogeneity. We compared the whole brain neural heterogeneity after 30 minutes of moderate intensity aerobic exercise (stationary bike) relative to 30 minutes of rest. **Results:** Aerobic exercise was associated with higher heterogeneity in the left

hippocampus, bilateral lingual gyrus, left anterior cingulate, and cerebellum (bilateral Crus 1 and 2, bilateral vermis, right I-IV, and left VI), confirming our hypothesis. These results were both reliable (whole brain permutation-based threshold-free cluster enhancement corrected, two-way $p<0.05$), and replicable (split-half reproducibility intra-class correlations > 0.4). **Significance:** These findings provide support for the hypothesized mechanism that after just 30 minutes of aerobic exercise there are higher levels of activation heterogeneity within regions that play an important role in separating similar neural signal patterns. These findings further suggest that a single bout of aerobic exercise may lead to improvements on tasks for which pattern separation is important, such as associative learning (Cayco-Gajic and Silver 2019) and cognitive control (Abrahamse et al. 2016). Future work will investigate exercise induced changes in neural heterogeneity as a possible mechanism of improved neural health in older adults at risk for or with a neurodegenerative disease.

Title: Neurophysiologic consequences of knocking out $GABA_A$ receptors containing the α4 subunit in mice

Authors: *P. GARCIA, T. Z. CASSIM, M. GRAVES, M. T. MANSOURI;
Columbia Univ. Med. Ctr., New York, NY

Abstract: Introduction: The GABA Type A receptor ($GABA_AR$) is important for mediating unconsciousness in clinical anesthesia. Monitoring of neurophysiologic signals via the electroencephalogram (EEG) during anesthesia can help identify characteristic patterns in sleep, general anesthesia, and coma. Burst suppression is a discontinuous EEG pattern typically seen with administration of excessive anesthesia but can also be observed in older patients that are receiving usual doses of analgo-sedative medication. Previously we have demonstrated subtle differences in burst features that depend of the anesthetic used (propofol vs sevoflurane). **Objective:** Here we examine the role of a specific subtype of $GABA_AR$ (α4-containing) in the relationship of drug choice and anesthetic dose with burst suppression. **Methods:** Age-matched, adult male (26-30 g) mice genetically manipulated to knock-out (KO) the *gabra4* gene and wild-

type (WT) littermates were used. Following the administration of isoflurane (1.5% - 2.5%, inhaled), propofol (150 mg/kg, intraperitoneal injection), ketamine/xylazine (K/X, 90/5 mg/kg, intraperitoneal injection) and ketamine (90 mg/kg, intraperitoneal), sub-dermal needle electrodes were applied and electrophysiology was recorded wirelessly using an OpenBCI™ Cyton board. The collected data were analyzed using custom scripts written in MATLAB. **Results:** We demonstrated that genetic ablation of GABRA4 results in discontinuous EEG patterns at a lower concentration of isoflurane than the WT control group. The results from intraperitoneal injection of other clinically used anesthetic agents was more variable. **Conclusion:** We conclude that there are important differences in thalamocortical neurophysiology mediated by α4-containing $GABA_A$Rs. These findings may be important to consider during the titration of analgo-sedative agents in clinical scenarios.

Title: Mediterranean diet adherence, gut microbiota, and Alzheimer's or Parkinson's disease risk: A systematic review

Authors: *R. J. SOLCH[1], J. O. AIGBOGUN[1], A. G. VOYIADJIS[1], G. M. TALKINGTON[1], R. M. DARENSBOURG[1], S. S. O'CONNELL[2], K. M. PICKETT[3], S. R. PEREZ[1], D. M. MARAGANORE[1];
[1]Dept. of Neurol., [2]Office of Academic Affairs and Provost, [3]Rudolph Matas Library of the Hlth. Sci., Tulane Univ., New Orleans, LA

Abstract: INTRODUCTION: There are no known cures for the two most prevalent neurodegenerative diseases, Alzheimer's disease (AD) and Parkinson's disease (PD). The Mediterranean diet (MeDi) has been associated with neuroprotection, but the mechanism of this effect is unknown. These benefits may be in part due to downstream effects of the modulated gut microbial composition. This systematic review aims to explore the modulatory effects of adhering to a MeDi on the gut microbiota in relation to AD or PD risk. **METHODS:** Following the preferred reporting items for systematic review and meta-analysis guidelines, a search from inception to November 2020 was conducted in PubMed, CINAHL, EMBASE, Web of Science, Global Health, Biological Abstracts, and Grey Literature Report databases. As the topic of gut

microbiota, Mediterranean diet and AD or PD has not been extensively studied, two searches for human studies were conducted: 1) (MeDi or Microbiota) and (PD or AD) and 2) MeDi and Microbiota. Screening of abstracts and full-texts, and completion of data extraction and quality assessments were independently completed by two authors. **RESULTS:** Of the 4,672 studies identified, 65 were eligible and included in this systematic review. These studies were further divided into five groups: MeDi and AD risk (n=5), MeDi and PD risk (n=2), MeDi and microbial composition or metabolomics (n=21), microbial composition or metabolomics and AD (n=7), and microbial composition or metabolomics and PD (n=30). Generally, adherence to the MeDi was associated with a lower risk of AD development, but was conflicting for PD risk. Additionally, those adhering to a MeDi had shifts in short-chain fatty acid producing bacteria. These changes were supported by metabolomics data showing increases in at least one short-chain fatty acid. Further, MeDi-associated bacteria shared commonalities between AD or PD microbiota changes. Eight genera and two species had an inverse relationship with MeDi and AD, and one family, eight genera and three species had an inverse relationship with MeDi and PD. **CONCLUSION:** MeDi may be a neuroprotective modifiable lifestyle factor through its effects on the gut microbial composition. However, as these associations were made mostly from observational studies, more interventional studies are needed to expand further our understanding of the relationship between MeDi, gut microbiota and AD or PD risk.

Title: Impact of early physical activity on feelings of depression during the COVID-19 pandemic

Authors: *N. K. KOZIEL LY[1], L. MOHAMUD[1], K. MATHESON[1,2], H. ANISMAN[1,2], M. J. CHEE[1];
[1]Neurosci., Carleton Univ., Ottawa, ON, Canada; [2]Royal Inst. of Mental Hlth. Res., Ottawa, ON, Canada

Abstract: Physical activity is important for promoting both metabolic and mental health. It is a vital aspect of body weight management, but it is also a form of active coping to manage stress, including that from lifestyle changes during the COVID-19 pandemic. While it is known that physical activity is related to reduced feelings of depression or anxiety, the objective of this study was to determine: 1) if physical activity at the onset of the pandemic predicted lower feelings of depression or anxiety over time, and 2) whether appraisals of stressful situations mediated this relationship. We surveyed 319 adults living in Canada or the United States during the COVID-19 pandemic to assess physical activity, stress appraisals, and mental health outcomes at two time points - May (T1) and October 2020 (T2). There was an overall decrease in physical activity at T2, which was attributed to a decrease in leisure-time physical activity (LTPA) but not on-the-job physical activity. Higher LTPA at T1 was associated with control-by-self appraisals of stressful situations (at T1 and T2), while lower initial LTPA was associated with appraisals of uncontrollability (at T1 and T2) and threat (at T2). Furthermore, lower initial LTPA was also associated with higher feelings of depression (at T2) but not anxiety. Hierarchical regression analyses demonstrated that stress appraisals of control-by-self, uncontrollability, and threat at T2 each uniquely contributed to feelings of depression at T2, over-and-above the contribution of T1 stress appraisals. Finally, while all three forms of stress appraisals at T2 were related to depression, only the appraisal of uncontrollability mediated the relationship observed between LTPA at T1 and depression at T2. In summary, physical activity during times of leisure in the early stages of the pandemic indirectly predicted subsequent feelings of depression 5 months later, reflecting the association between activity and being less likely to appraise stressful situations as uncontrollable. Although correlational, these data point to the possibility that physical activity may protect against worsened mental health outcomes during stressful periods like those associated with the COVID-19 pandemic.

Title: Early cell-type-specific transcriptomic changes in motor cortex of a C9orf72 ALS/FTD mouse model

Authors: *A. SPIEGEL[1,2], K. LEE[4], J. W. ANDERSEN[5], L. A. GOFF[3,1,2], S. P. BROWN[1,2]; [1]Solomon H. Snyder Dept. of Neurosci., [2]Kavli Neurosci. Univ., Seoul, Korea, Republic of; [5]Dept. of Neurobio., Harvard Med. Sch., Boston, MA

Abstract: Neurodegenerative diseases are characterized by the progressive loss of specific neuronal populations. In amyotrophic lateral sclerosis (ALS), for example, corticospinal and spinal motor neurons are particularly vulnerable to degeneration. Although genetic causes of ALS have been identified, the most common being a repeat expansion in the *C9orf72* gene, why certain cell types are particularly affected by these mutations remains poorly understood. We hypothesize that early functional changes in neurodegenerative diseases such as ALS are cell-type-specific, given the selective vulnerability of specific cell types in disease. We therefore asked whether we could identify cell-type-specific transcriptomic responses in a bacterial artificial chromosome (BAC) transgenic mouse model of *C9orf72* disease (Liu et al., 2016) during the first postnatal week. Specifically, this transgenic mouse model expresses the human *C9orf72* gene containing a hexanucleotide repeat expansion—a mutation that has been associated with ALS, frontotemporal dementia (FTD), and other neurodegenerative diseases. We performed single-cell RNA-seq on cells from the motor cortex from five wildtype and five *C9orf72* mice at P6-7. Using a generalized linear mixed model to identify genes differentially expressed across all cells with respect to genotype, we failed to identify any genes with differential expression. However, inclusion of cell type in this model revealed 220 genes differentially expressed in a cell-type-specific manner, including genes previously implicated in ALS. We further used nonnegative matrix factorization to identify patterns of gene expression that were differentially used with respect to genotype, again in a cell-type-specific manner. These analyses highlight the importance of transcriptomic analysis at single-cell resolution, enabling the detection of subtle cell-type-specific effects early in disease. They also provide a general workflow for identifying cell-type-specific signatures of disease in single-cell RNA-seq datasets.

Title: In-silico multi-factorial system stability to identify promising SOD1-G93A ALS mouse combination treatments

Authors: *S. BI[1], A. KRUEGER[2], A. LEE[1], C. MITCHELL[1];
[1]Biomed. Engin., [2]Physics, Georgia Inst. of Technol., Atlanta, GA

Abstract: Superoxide dismutase 1 glycine 93 to alanine (SOD1 G93A) transgenic mice exhibit mutations associated with amyotrophic lateral sclerosis (ALS). However, it is difficult to do high throughput combination treatment testing for ALS in-vivo. The primary study objective is to model combination therapy performance for ALS in-silico using "stability", equating to homeostasis, as the criterion for a successful treatment. Computational models of wild-type (WT) and SOD1 G93A (ALS) mouse physiological stability were developed using dynamic meta-analysis, mathematical optimization, and unsupervised machine learning. WT and ALS models were based on seven prominent regulatory mechanisms in ALS pathophysiology: apoptosis, bioenergetics, chemistry, excitotoxicity, inflammation, oxidative stress, and proteomics. Each ontology was divided into 2 aggregation schemes with opposite physiological functions. For both models, the gain values or "modulatory feedback" linking each mechanism to the system of dynamical derivatives were optimized using a genetic algorithm and validated using a separate experimental dataset. To simulate ALS treatment and re-stabilization, 2548 different combinations of gain parameters representing three-way treatments were examined. Mathematically, stability was defined as a treatment combination for which all real portions of the eigenvalues of the gain matrix were negative. Three different optimization algorithms and varying modulation bounds were tested to determine the effect size necessary to re-stabilize the ALS system. Increased bounds for modulation of the gain values led to an increased number of stabilized combinations for all treatment optimization algorithms used. For maximum effect sizes of 500%, 1000%, and 1500%, a maximum of 10, 24, and 50 combinations stabilized, respectively. The combinations that stabilized at smaller effect sizes continued to stabilize for larger maximum effect sizes. Combinations modulating gain values corresponding to anti-apoptosis, energy consumption, energy production, anti-inflammatory, and pro-proteomic factors stabilized most often. The identified treatment combinations, stability patterns, and effect sizes provide critical insight for experimental development and testing of translational ALS treatments and etiological hypotheses.

Title: Deciphering the mechanisms underlying the neuroprotective effect of glycolysis in ALS

Authors: *S. LOGANATHAN[1], H. E. BALL[1], M. E. MACIAS[1], M. L. TRAN[1], G. M. PETERSON[1], G. BIRCHAK[1,3], E. MANZO[1,4], D. C. ZARNESCU[1,2];

Abstract: Amyotrophic Lateral Sclerosis (ALS) is a progressive neurodegenerative disorder for which there is no cure. ALS affects upper and lower motor neurons leading to loss of motor coordination, irreversible paralysis, respiratory failure and eventually death within 2-5 years of diagnosis. TDP-43 pathology is observed in &gt97% of ALS cases. Our lab has developed a *Drosophila* model of ALS based on overexpression of human TDP-43 that recapitulates multiple disease aspects including cytoplasmic aggregates, neuromuscular junction (NMJ) abnormalities, reduced lifespan, and locomotor defects. Our lab has shown that glycolysis upregulation, specifically an increase in Phosphofructokinase-1 (PFK1; PFK in *Drosophila*), provides a compensatory, neuroprotective effect in *Drosophila* models of ALS based on TDP-43 proteinopathy. In this study we aim to understand the mechanisms underlying the neuroprotective effect of PFK overexpression (OE) in ALS. Recent findings from other groups show that PFK forms clusters at the synapses of *C. elegans* where it is required for synaptic vesicle (SV) cycling, and along with other glycolytic enzymes, forms Glycolytic bodies in yeast under stress, which is associated with increased glucose consumption and cell survival. In addition, pyruvate, the end product of glycolysis, was found to be increased in multiple ALS models. Interestingly, pyruvate has also been shown to have strong Reactive Oxygen Species (ROS) scavenging capacity, protecting mitochondrial membrane potential, and regulating cell metabolism. These findings led us to hypothesize that 1) PFK localization and/or Glycolytic body assembly are altered at ALS synapses 2) PFK OE mitigates TDP-43 dependent SV cycling deficit at the larval NMJ in Drosophila and/or 3) PFK OE mitigates oxidative stress by antioxidant activity of pyruvate. We began to test this hypothesis by using expansion microscopy, which shows that PFK forms puncta within *Drosophila* NMJs, in the context of TDP-43 OE. Furthermore, PFK clustering is observed in Drosophila primary motor neurons with TDP-43 proteinopathy. In addition, we used FM1-43, a membrane probe, and found that PFK OE rescues TDP-43 induced SV cycling deficits. We are currently testing if oxidative stress is altered under the conditions of PFK overexpression in several ALS models. Together, these

results suggest that PFK forms puncta at the synapse and mitigates TDP-43 induced SV cycling deficits. These findings may uncover novel therapeutic strategies for ALS.

Title: Spiking motoneurons effective connectivity as an early electrophysiological biomarker of amyotrophic lateral sclerosis

Authors: A. Y. ABDELAAL[1], M. H. MOUSA[2], M. GAMAL[4], M. I. KHALIL[1], S. M. ELBASIOUNY[3], ***S. ELDAWLATLY**[4,1];

Dept., German Univ. In Cairo, Cairo, Egypt

Abstract: Amyotrophic lateral sclerosis (ALS) is thought to be a multi-factorial disease involving both autonomous and non-autonomous cell mechanisms. Of the many pathways under examination, abnormalities in motoneuron (MN) excitability remain the most tightly linked to disease pathogenesis. Experimentally, abnormalities were found in MN electrical behavior long before clinical symptoms manifestation, which motivates the development of machine learning and statistical approaches that could detect irregular patterns in MN firing compared to normal firing behavior. In this work, we use machine learning methods to infer the effective connectivity among individual MNs from their spiking activity and use that as an early electrophysiological biomarker of ALS. Specifically, cross-correlograms computed from pairs of same-type MNs are used to construct effective connectivity graphs in which nodes represent MNs and directed edges represent connections. A machine learning classifier is then applied to discriminate between graphs representing ALS versus Wild-Type (WT). A high-fidelity computational model of the spinal MN pool was used in this study to simulate the spiking activity of type-identified MNs (S,

FR, and FF cell types) under WT and ALS conditions. In the simulations, MNs were activated via synaptic inputs using trains of monophasic pulses. Our results demonstrate that effective connectivity among MNs changes early in ALS. Applying the machine learning classifier to the obtained feature space resulted in average classification accuracies of 97 ± 5.1%, 94 ± 6.9 % and 93 ± 7.7 % for the FF, FR and S types graphs, respectively. Our analysis reveals that the accuracies obtained for different cell types are consistent with the simulated ALS conditions depending on cell-type vulnerability. These results provide evidence that MN effective connectivity could serve as an electrophysiological biomarker for early ALS diagnosis.

Title: Exploring optogenetic stimulation of the hypoglossal nucleus to preserve tongue structure and function in a mouse model of ALS

Authors: *B. STEALEY[1], K. OSMAN[1], J. WANG[2], C. HAXTON[1], T. E. LEVER[3], I. OZDEN[2];
[1]Univ. of Missouri, Columbia, Columbia, MO; [2]Bioengineering, Univ. of Missouri, Columbia, MO; [3]Otolaryngology - Head and Neck Surgery, Univ. of Missouri Columbia, Columbia, MO

Abstract: Impaired tongue function due to progressive degeneration of hypoglossal nucleus (HGN) neurons in amyotrophic lateral sclerosis (ALS) commonly progresses to dysphagia and increased risk of malnutrition, aspiration pneumonia, and feeding tube dependence. Importantly, there are currently no effective treatments to prevent or slow the progression of HGN degeneration. Here, we used a translational mouse model of ALS to develop a targeted excitatory optogenetic stimulation approach to preserve HGN neurons and prevent corresponding tongue atrophy and dysphagia.
We stereotaxically injected AAV5-hSyn-ChR2-eYFP (ChR2) into the HGN (4 WT, 4 SOD1-G93A mice) and implanted an optrode into the HGN 3 weeks post-injection. Opsin expression was confirmed in all mice by evoked HGN activity and tongue movement in response to optogenetic stimulation (40Hz, 50% duty cycle, 450nm). Tongue movements were also triggered by surface illumination of the tongue (6/8 mice), meaning the opsin spread to the distal

hypoglossal nerve. Post-mortem histological examination confirmed strong opsin expression in the HGN and hypoglossal nerve, thus demonstrating they can be reliably targeted for functional optogenetic stimulation.
Videofluoroscopic swallow studies (VFSS) revealed our surgical procedures had no significant effect on licking and swallowing function or survival ($p<0.05$) for WT or SOD1 mice compared to archived data from the same colony. To evaluate the effects of HGN optogenetic stimulation on behavior, we examined tongue function in real-time by assessing lick rate during voluntary drinking and monitoring local field potentials in the HGN. We found that lick rate can be modulated in a graded fashion by tuning the intensity of HGN optogenetic stimulation (n=4/4). We hypothesize that optogenetic stimulation alters lick rate by causing muscle stiffness; higher laser intensities generate more resistive force against tongue movement to cause slower licking. In conclusion, the HGN can be safely and reliably targeted for optogenetic stimulation. Optogenetic responses were strong and could evoke tongue movements. Therefore, optogenetic stimulation of the HGN holds promise as a targeted tongue resistance exercise program where the resistive force can be tuned by adjusting the laser intensity during drinking. Given that optogenetic stimulation has shown to promote axonal growth and proliferation in previous studies, we hypothesize controlled optogenetic stimulation of the HGN may significantly delay neuronal death and preserve licking /swallowing function, which if translatable, could prolong the survival of human ALS patients and enhance quality of life.

Abstract: Amyotrophic lateral sclerosis (ALS) is a progressive neurodegenerative disease that affects motor neurons in the spinal cord and brain. Based on pathological and genetic findings, ALS sits on a spectrum with frontotemporal dementia (FTD), a neurodegenerative disease that leads to the progressive degeneration of neurons in the temporal and frontal lobes of the brain.

Recently, several lines of evidence have suggested that Receptor interacting protein kinase 1 (RIPK1) activation may be causally linked to the pathophysiology of ALS and FTD. RIPK1 is a critical signaling protein that mediates inflammatory and cell death signaling. Loss of function mutations in *OPTN* and *TBK1* can lead to familial ALS/FTD and their deficiency causes hyperactivation of RIPK1 kinase activity. Genetic and pharmacological inactivation of RIPK1 rescues the increased RIPK1 activation and necroptosis in the spinal cords of $Optn^{-/-}$ mice. Additionally, TBK1 is a negative regulator of RIPK1 kinase activity by phosphorylation at T189 and the embryonic lethality of $Tbk1^{-/-}$ mice is rescued by genetic inactivation of RIPK1 kinase activity. Previous studies have suggested increased RIPK1 expression in $SOD1^{G93A}$ mouse models and ALS patient samples and while these data suggest activation of RIPK1 in the central nervous system (CNS) may mediate ALS disease progression, we sought to definitively elucidate the role of RIPK1 kinase activity in the $SOD1^{G93A}$ mouse model and in ALS patient-derived post-mortem samples. Using a mouse active CNS-penetrant RIPK1 inhibitor, we show that blocking RIPK1 kinase activity attenuates disease phenotypes in the SOD1 model of ALS and improves the age-dependent behavioral deficits in this mouse model. The role of RIPK1 kinase activity in this model is also assessed using a multi-omics approach. Furthermore, we demonstrate RIPK1 activity and expression is increased in sporadic ALS spinal cord and motor cortex samples relative to control. Based on our previous data we suggest that aberrant RIPK1 activation in various cell types in the CNS contributes to motor neuron loss in ALS.

Title: Spinal Muscular Atrophy (SMA) Differentially Reduces Cerebellar Structure and Axon Development in SMNΔ7 Mice: An MRI Study

Authors: *N. COTTAM, C. CHARVET, M. HARRINGTON, J. SUN;
Delaware State Univ., Dover, DE

Abstract: Spinal Muscular Atrophy (SMA) is an autosomal recessive disease that affects 1 in every 6,000-10,000 individuals at birth, making it the leading genetic cause of infant mortality. There are effective treatments for SMA, but not all patients respond to them, and their long-term effects are unclear. SMA is best defined by motor neuron dysfunction due to a depletion of ubiquitous survival motor neuron protein (SMN) in motor neurons, leading to their degeneration at the neuromuscular junction in the anterior horn of the spinal cord. However, due to the key roles of SMN in cellular function, a growing number of studies support that SMA is a multi-system disease. Moreover, the spinal cord has received much attention; but the cerebellum hasn't, even when widespread pathology has been reported in the cerebellum of SMA patients. Due to its important role in motor function, we performed an exploratory study to investigate it's development using the SMNΔ7 mouse model. Mouse genotypes were confirmed using a mass measurement and righting test. We acquired volumetric brain data using T2-weighted images from magnetic resonance imaging scans (dMRI) and segmentation. We found that cerebellar growth is significantly reduced in SMA-affected mice compared to wild type. Furthermore, the cerebella of late-stage SMA (P12, post-natal day 12) mice are differentially affected relative to other brain regions, despite an observed decrease in whole-brain volume in SMA. To further define SMA disease pathology in the cerebellum, we studied the tractography using diffusion tensor imaging (DTI) to quantify white matter pathway abnormalities in SMA. Inferior peduncular tracts and intracerebellar connections were significantly diminished by the disease in the P12 ex-vivo SMNΔ7 mice brain scans relative to wild type. To better understand whether these cerebellar effects are downstream pathologies or play an important role in disease development, future work will consist of similar analyses on P3-P4 mice brain scans, immunohistochemistry, and acquiring DTI metrics such as fractional anisotropy, radial, medial, and axial diffusivity at P3-P4 and P12. We conclude that cerebellar axonal development and concomitant white matter pathways are affected by SMA. A better basic understanding of these neurobiological abnormalities of SMA may lead to novel and more effective avenues for treatment.

Title: Serotonergic neuromodulation is impaired in a mouse model of spinal muscular atrophy

Authors: *N. DELESTRÉE, E. SEMIZOGLOU, J. G. PAGIAZITIS, A. VUKOJICIC, E. DROBAC, V. PAUSHKIN, G. Z. MENTIS;
Columbia Univ., New York, NY

Abstract: Spinal muscular atrophy (SMA) is a neurodegenerative disease due to deficiency of SMN protein and is characterized by motor neuron loss, muscle atrophy and impairment of motor function. Gait, posture and locomotion, which are largely influenced by both proprioception and neuromodulation, are altered in SMA patients. We previously reported that one of the earliest hallmark of the disease is the dysfunction and elimination of proprioceptive synapses mediated by the classical complement pathway. However, whether the neuromodulatory serotonergic system is affected in SMA, is not known.
To address this, we utilized the SMN-Δ7 mouse model of SMA and investigated the morphological and functional characteristics of the serotonergic (5-HT) synapses on spinal motor neurons. We found that 5-HT synaptic coverage is reduced by 25% as early as P4 in vulnerable (L1 and L5-MMC) but not resistant (L5-LMC) motor neurons in SMA and that this reduction progressed to ~55% in vulnerable motor pools of P10 SMA animals. We also found that the proportion of 5-HT synapses tagged by the complement protein C1q is increased in SMA mice, suggesting that the complement pathway is involved in 5-HT synapses pruning in SMA. Functionally, 5-HT is known to modulate the monosynaptic sensory-motor reflex mediated by proprioceptive synapses on motor neurons. Using an *ex vivo* brainstem-spinal cord preparation, we confirmed that stimulation of the brainstem reduces the amplitude of this reflex by 50% in P10 WT animals. However, while this modulatory effect was preserved in SMA animals in the resistant L5 segment, it was reduced by 90% in the vulnerable L1 spinal segment. Selective restoration of SMN in 5-HT neurons using a conditional inversion SMA mouse line, in which Cre is expressed under the *Pet1* promoter, resulted in restoration of 5-HT synapses in the vulnerable motor pools (~90% of WT levels), and restored the 5-HT neuromodulation effect on the L1 spinal reflex compared to their SMA counterparts. Behaviorally, the dysfunction of 5-HT synapses in SMA resulted in impairment of locomotor behavior as observed from EMG activity from TA muscles in freely moving mice at P10. In contrast, selective restoration of SMN in 5-HT neurons improved significantly left-right hindlimb muscle alternation during locomotor activity. Together, our study uncovers a severe serotonergic dysfunction in SMA mice and proposes the serotonergic pathway as a new therapeutic target.

Title: Ddx17 regulates fus-mediated neurodegeneration in an rgg-domain dependent manner

Authors: T. FORTUNA[1], S. KOUR[2], E. N. ANDERSON[2], C. WARD[2], D. RAJASUNDARAM[2], C. J. DONNELLY[3], H. WYNE[4], F. SHEWMAKER[5], ***U. PANDEY**[1]; [2]Pediatrics, [1]Univ. of Pittsburgh Med. Ctr., Pittsburgh, PA; [3]Dept. of Neurobio., Univ. of Pittsburgh, Pittsburgh, PA; [4]Biochem., Uniformed Services Univ., Bethesda,, MD; [5]Biochem., Uniformed Services Univ., Bethesda, MD

Abstract: Mutations in Fused in Sarcoma (FUS) have been linked with juvenile and aggressive form of amyotrophic lateral sclerosis (ALS). Cytoplasmic aggregation and defects in DNA repair pathway have been linked with ALS pathogenesis. However, the molecular mechanisms and genetic modifers of DNA damage repair pathway are yet not known. While doing RNA-sequencing analysis of the *Drosophila* brains expressing FUS, we identified significantly altered genes and pathways involved in FUS-mediated neurodegeneration *in vivo*. We found that the DEAD-Box Helicase 17 (DDX17) expression level was significantly downregulated in response to mutant FUS in *Drosophila* and human cell lines. Interestingly, mutant FUS recruits nuclear DDX17 into cytoplasmic stress granules and biochemically interacts with DDX17 through the RGG1 domain of FUS. Importantly, genetic upregulation of DDX17 reduces cytoplasmic mislocalization and sequestration of mutant FUS into cytoplasmic stress granules. We identified DDX17 as a novel regulator of the DNA damage response pathway whose upregulation repairs defective DNA damage repair machinery caused by mutant neuronal FUS ALS. In addition, we show DDX17 is a novel modifier of FUS-mediated neurodegeneration in vivo. Our findings indicate DDX17 is downregulated in response to mutant FUS, and restoration of DDX17 levels suppresses FUS-mediated neuropathogenesis and toxicity in vivo

Title: C-boutons and their Influence on Amyotrophic Lateral Sclerosis Disease Progression

Authors: *T. L. WELLS, J. R. MYLES, T. AKAY;
Med. Neurosci., Dalhousie Univ., Halifax, NS, Canada

Abstract: Amyotrophic Lateral Sclerosis (ALS) is an adult-onset neurodegenerative disease with progressive motor neuron death, where patients usually die within five years of diagnosis. Previously we showed that the C-boutons, which are large cholinergic synapses to motor neurons that modulate motor neuron activity, are necessary for behavioural compensation in mSOD1^{G93A} mice, a mouse model for ALS. Since the C-boutons likely increase the excitability of surviving motor neurons to compensate for motor neuron loss during ALS disease progression, we reasoned that amplitude modulation through the C-boutons likely increases motor neuron stress and worsens disease progression. By comparing male and female mSOD1^{G93A} mice to mSOD1^{G93A} mice with genetically silenced C-boutons (mSOD1^{G93A}; Dbx1::cre; ChAT$^{fl/fl}$) (mSOD1^{G93A}/C^{off}), we show that the C-boutons do not influence the humane endpoint of mSOD1^{G93A} mice (mSOD1^{G93A} = 156.4 ± 7.3 days, n = 17; mSOD1^{G93A}/C^{off} = 152.5 ± 7.9, n = 12); however, histological assessment of the neuromuscular junction shows that C-bouton silencing significantly improves fast-twitch leg muscle innervation over time (mSOD1^{G93A} n = 18; mSOD1^{G93A}/C^{off} n = 11). Using behavioural analysis, we also provide evidence that C-bouton silencing in combination with swimming (mSOD1^{G93A}/C^{off} swim) is beneficial for the behavioral capabilities of mSOD1^{G93A} mice (mSOD1^{G93A} rest n = 5; mSOD1^{G93A} swim n = 5; mSOD1^{G93A}/C^{off} swim n = 11). Lastly, we provide evidence that C-bouton silencing in combination with swimming in mSOD1^{G93A} mice significantly delays the humane endpoint relative to C-bouton silencing alone, but not relative to mSOD1^{G93A} mice with C-boutons intact (mSOD1^{G93A}/C^{off} swim = 162.6 ± 6.8 days, n = 5, ANOVA $p<0.05$). Our observations suggest that manipulating the C-boutons in combination with a modulatory-targeted training program may therefore be beneficial for ALS patients.

Title: Chronic pain and fatigue symptoms in a mouse model of Gulf War Illness

Authors: H. NGUYEN[1], P. SAHBAIE[2], L. GOBA[4], J. SUL[4], A. SUZAKI[4], D. J. CLARK[2], ***T.-T. HUANG**[3];

Abstract: More than twenty five years after the end of the Gulf War (1900-1991), a substantial contingent of veterans still suffer from a number of health problems affecting the neurological and musculoskeletal systems; the most common symptoms include chronic pain and fatigue. This constellation of symptoms is collectively termed Gulf War Illness (GWI). The etiology of GWI remains elusive, yet likely involves exposure to various chemicals as well as physical and psychological stresses unique to the GW theatre. Using a mouse model of GWI, by repeatedly exposing mice to a combination of Gulf War chemicals (pyridostigmine bromide, permethrin, N,N-Diethyl-m-toluamide, and chlorpyrifos) and mild immobilization stress, we assessed their pain susceptibilities and fatigue symptoms at various intervals following Gulf War agents exposure. The mouse model recapitulated several aspects of the human illness, including hyperalgesia, impaired descending inhibition of pain, and increased tonic pain. There is a close association between chronic pain and fatigue in GWI patients. Consistent with this clinical observation, the mouse model showed a significant reduction in physical endurance on the treadmill. Examination of skeletal muscles suggested that reduction in mitochondrial functions may be the source of the fatigue symptoms. Increased oxidative stress has been implicated in GW agent exposure. To assess whether enhanced antioxidant capacity can counter the effects of GW agents, transgenic mice overexpressing extracellular superoxide dismutase (SOD3OE) were examined in this study. The negative impacts of GW agents, particularly in pain susceptibilities, were largely diminished in SOD3OE mice, suggesting that increased oxidative stress was associated with the development of these Gulf War symptoms.

Title: Sex differences in the behavioral changes of brief-access alcohol consumption induced by trigeminal nerve injury in C67BL/6 mice

Authors: *R. ANDRADE GONZALEZ[1,2], E. PERRUSQUIA HERNANDEZ[1,2], M. HERNANDEZ CAMPOS[1], I. PEREZ MARTINEZ[2];
[1]Seccion de Estudios de Posgrado e Investigacion, Escuela Superior de Medicina, CDMX, Mexico; [2]Facultad de Estudios Superiores Iztacala, Univ. Nacional Autonoma de Mexico, Cuautitlan Izcalli, Mexico

Abstract: Chronic pain is a significant risk factor for developing alcohol use disorder in different rates between men and women. During regular alcohol consumption, a disruption of goal-directed control promotes the transition from casual to chronic alcohol consumption and increased ethanol consummatory behaviors; the former is predictive of alcohol use disorder development. Prior work has shown that chronic pain promotes alcohol consumption exclusively in male rodent models. However, the underlying processes that control this increased consummatory behavior haven't been elucidated. This work aimed to assess the behavioral changes in male and female C57BL/6 mice alcohol consumption patterns with trigeminal neuropathic nerve injury. Following mental nerve injury or sham surgery in male and female mice, behavioral tests were performed to evaluate sensory impairments and changes in the licking microstructure of alcohol consumption in a brief access test. Our results showed that mice with mental nerve injury developed allodynia, hyperalgesia, and spontaneous pain, more severely in male rodents, observed as hypersensibility to mechanical stimulation and excessive facial grooming. Female mice in both groups showed an increased alcohol consumption compared to males, related to more licks in a cluster. Mental nerve injury caused a more efficient licking behavior in male mice, as quantified by the Mean Primary ILI. Our data demonstrate that female mice consume alcohol and quinine in an aversion-resistant manner, regardless of the treatment. In contrast, male mice with mental nerve injury are susceptible to higher alcohol consumption in prolonged access periods due to greater automaticity in alcohol drinking.

Title: Thermal nociception in large Theraphosid spiders using the plantar Hargreaves test apparatus

Authors: A. UPTON[1], B. KENNEDY[2], *D. COHN[3], C. TAYLOR[3], S. BAKER[4], C. TRIM[1], **S. TRIM**[4];
[1]Canterbury Christ Church Univ., Canterbury, United Kingdom; [2]Vet. Invertebrate Society,

Sandwich, United Kingdom; [3]Transpharmation Ltd, Sandwich, United Kingdom; [4]Venomtech Ltd, Sandwich, United Kingdom

Abstract: Where model invertebrates have been used for nociception, they have typically been selected for their rapid generation time and potential for genetic manipulation. This has often left challenges with regards to behaviour assessment and pharmacological interventions. To date, arachnid pain research has been focused on true spiders (Aranaeomorphae) such as the wandering spider *Cupiennius* salei and jumping spiders *Servaea incana* with only a preliminary mention of theraphosidae. Theraphosid spiders, erroneously called tarantulas, are large (several over 25cm and 100g) hirsute arachnids commonly kept in zoological collections, as private pets and increasingly laboratories thus making them available for further study. In contrast to flies and nematodes, theraphosids are of similar size to small rodents and thus suitable for use in experimental equipment designed for rodents, with some caveats and extra considerations. Although spiders are not protected under ASPA all work plans had passed through ethical review. To understand if and how theraphosids respond to thermal laser stimulation 39 animals representing eight Genera were tested after a period of acclimatisation to the test chamber, similar to the rodent protocol. Thermal nociception testing using the standard rodent Plantar Hargreaves test apparatus (Ugo Basile, Gemonio, Italy) demonstrated that the instrument was sensitive enough to detect the theraphosid tarsus (aka foot) and its subsequent withdrawal, recording the time as expected. Each spider was tested three times with three different legs. One of the benefits of spiders is that they still have five more untested legs. This baseline study demonstrated that Theraphosid spiders respond to a thermal stimulation with a foot withdrawal in a similar way to rodents and many individuals exhibited foot rubbing after stimulation. Withdrawal latencies means were between 10 and 18 seconds and varied between Genera and with weight of animal. Spiders of the Genus of *Grammostola* were the least variable and therefore used for the follow-on studies of sensitisation. There was a slight trend ($R^2 = 0.38$) towards heavier spiders having longer latencies, but as it is normal practice to age and weight match study animals, so this was not unexpected. Using the *Grammostola* spp. Spiders further demonstrated a significant ($P = 0.007$) reduction in withdrawal latency to a repeated stimulation. A needle stick injury in the plantar surface of the tarsus generated a 35% reduction in withdrawal latency which took 52 days to return to normal levels. This is the first study to show utility of the Hargreaves equipment in invertebrates.

Title: Systematic Isoform-Selective Heat Shock Protein 90 Inhibitors Improve the Therapeutic Index of Morphine

Authors: *K. CHOU, C. S. CAMPBELL, P. BENJARANO, D. DURON, J. M. STREICHER; Univ. of Arizona, Tucson, AZ

Abstract: Opioids are the benchmark for severe acute pain; however, severe side effects including respiratory depression and addiction limit their viability. One approach to improve opioid therapy focuses on a dose-reduction strategy by amplifying opioid analgesia without boosting side effects. To this end, we've focused on Heat shock protein 90 (Hsp90), a central protein regulator in the cell; ongoing studies have shown that inhibition of Hsp90 in the spinal cord improves morphine antinociceptive potency by 2-4 fold in acute and chronic pain while reducing tolerance, rescuing established tolerance, and not changing reward and constipation, enabling a dose-reduction strategy. However, our results also showed that non-selective Hsp90 inhibitors given systemically (intravenous, IV) have the opposite effect, blocking opioid pain relief. To surmount this roadblock, we determined which Hsp90 isoforms regulate opioid pain relief in brain and spinal cord in mice using selective small molecule inhibitors and CRISPR/Cas9 gene editing. We found that Hsp90α alone regulated opioid signaling and pain relief in the brain. However, in the spinal cord, we found that the isoforms Hsp90α, Hsp90β, and Grp94 all regulates opioid signaling and pain relief. This led to our hypothesis that targeting spinal cord Hsp90 with isoform-selective inhibitors given IV could boost opioid pain relief without altering side effects, enabling a dose-reduction strategy. We tested this hypothesis with the novel Grp94-selective inhibitor KUNG65 and the novel Hsp90β-selective inhibitor KUNB106, given at a 1mg/kg dose IV in male and female CD-1 mice, followed by a 24hr treatment time, then analysis of opioid antinociception and side effects. We found that systemic (IV) KUNG65 treatment resulted in a 1.9 fold increase in morphine potency to relieve tail flick pain with similar findings for KUNB106, consistent with our earlier studies injecting inhibitors directly into the spinal cord. We also found that both KUNG65 and KUNB106 boosted morphine potency in paw incision pain. Additionally, we found that KUNG65 and KUNB106 injection could rescue established morphine tolerance in the tail flick assay, again as we found for direct spinal cord injection. These results support our hypothesis that isoform-selective Hsp90 inhibitors can engage Hsp90 in the spinal cord when given systemically, resulting in improved opioid antinociception and side effects; strongly suggesting that Hsp90 isoform-selective inhibitors could be a powerful new tool to improve opioid therapy through a dose-reduction strategy, and further show that this effect can be achieved through a translationally relevant dosing route.

Title: Dim light at night differentially alters mechanical sensitivity in female and male TALLYHO/JngJ mice

Authors: *R. C. WHITE, J. R. BUMGARNER, J. A. LIU, R. J. NELSON;
Neurosci., West Virginia Univ., Morgantown, WV

Abstract: Circadian rhythms are endogenous physiological and behavioral cycles that have a period of about 24-hours. These rhythms are synchronized to the environment by several entraining cues, the primary of which is light early during the day. Disrupted circadian rhythms are caused by irregular synchronizing cues, for example, exposure to dim light at night (dLAN). The induction of artificial LAN in society has become ubiquitous, affecting 80% of the global human population. LAN has adverse effects on several physiological functions, such as metabolism, locomotor activity, clock genes, peripheral and central inflammation, obesity, and weight gain. Importantly, dLAN exposure has been associated with exacerbated pain behavior in rodents, specifically cold hyperalgesia and mechanical hypersensitivity. Type ll diabetes mellitus (T2DM) is a metabolic disorder characterized by insulin resistance that affects millions of individuals every year. Diabetic peripheral neuropathy is a common side effect of T2DM, impacting more than 50% of patients. In this study, we sought to examine the effects of dLAN exposure (5 lux) on the progression of diabetic peripheral neuropathy in TALLYHO/JngJ (TH) mice that develop T2DM. We hypothesized that dLAN exposure exaggerates pain behaviors associated with the early stages of diabetic neuropathy. We observed that 4-weeks of dLAN exposure differentially altered mechanical withdrawal thresholds in male and female TH mice, leading to hypo- and hyperesthesia, respectively. These data suggest that dLAN exposure may play a role in the progression of hyper- or hypo-esthesia associated with T2DM.

Title: Sex differences in the long-term course of neuropathic pain behavior after spared nerve injury

Authors: M. MILLECAMPS[1], ***L. CHAUDHRY**[2], S. SOTOCINAL[2], L. S. STONE[3,2], J. S. MOGIL[2];
[1]McGill Pain Ctr., Montreal, QC, Canada; [2]McGill Univ., Montreal, QC, Canada; [3]Dept. of Anesthesiol., Univ. of Minnesota, Minneapolis, MN

Abstract: The vast majority of preclinical pain literature uses only young male rodents as subjects, and contains experiments lasting only several weeks after the painful injury. This *status quo* has a major disconnect with the clinical reality: chronic pain patients who tend to be older, female, and—by definition—with pain lasting more than 3 months. To study long-term trends in pain behavior and lifespan, we repeatedly tested male and female C57BL/6 mice over the course of 24+ months following a spared nerve injury (SNI). Early after surgery, both sexes display equivalent levels of mechanical hypersensitivity, measured via von Frey testing. As we have previously observed, hypersensitivity resolved by 6 months post-SNI in female mice, while remaining at high levels in male mice. Unexpectedly, starting at 12 months post-SNI, mechanical hypersensitivity reappears in female mice, at levels equaling or even exceeding that of males. This parabolic pattern in female mice is also observed for cold pain (acetone drop test) and guarding behavior (Attal scores). The impacts of chronic pain on lifespan are currently inconclusive, as most mice in both SNI and sham surgery groups remain alive. Ongoing experiments are investigating underlying mechanisms for these sex-specific patterns of behavior, with one possible explanation involving the development of pain-maintaining microglial senescence at different time points post-injury in male versus female mice. We believe that preclinical pain researchers who wish to study truly “chronic” pain must incorporate much longer time points after injury.

Title: Effects of Spinal Manipulation and Mobilization techniques on trunk compliance in chronic low back pain: A secondary analysis of the RELIEF Study

Authors: *A. STAMENKOVIC[1], R. SABO[1], S. M. VAN DER VEEN[1], B. C. CLARK[2], P. E. PIDCOE[1], J. S. THOMAS[1];
[1]Virginia Commonwealth Univ., Richmond, VA; [2]Ohio Musculoskeletal and Neurolog. Inst., Athens, OH

Abstract: Mechanisms of chronic pain are multifaceted and can be driven by biological, psychological and social factors. For low back pain, therapeutic interventions such as spinal manipulation and mobilization are sometimes considered first-line treatment options based on their potential to reduce internal mechanical stresses, and influence para-spinal primary afferent activity in the propagation of central sensitization. As these chronic pain mechanisms are associated with increases in low back stiffness (or decreases in trunk compliance), we examined whether such therapeutic interventions influenced a simple measure developed by the authors to quantify trunk compliance.

The RELIEF Study was a RCT comprised of a 3-week intervention, and 4-week follow-up to examine the effectiveness of thrust-based spinal manipulation, to non-thrust spinal mobilization, and a sham cold laser placebo. A sample of the cohort (n=58, 57% female) underwent seated trunk-based perturbations using a custom-designed multi-axial perturbation device, at baseline, immediately following the first intervention session, upon the completion of all intervention sessions, and after 4 weeks. A trunk compliance index (TCI, defined as the inverse of stiffness) for each perturbation direction (eliciting trunk flexion, extension, left and right lateral flexion, and left and right rotation) was calculated by dividing the magnitude of trunk displacement due to the perturbation, by the force of the applied perturbation load normalized to participant body weight. We fit a linear mixed effects model (fixed effects: Treatment, Time, Treatment*Time) for each direction accounting for differences of trunk compliance at baseline, and including sex, and baseline disability and pain scores as covariates. Regardless of perturbation direction, there were no significant interactions between treatment groups across any of the recorded time points (e.g., flexion: Treatment*Time, $F_{(6,147.7)} = 0.37$; $p = 0.895$). These findings are consistent with the clinical outcomes from the RELIEF Study, which found no effect of intervention on measures of pain or disability.

Of note, when compared to a matched healthy control cohort, the TCI is shown to be significantly reduced in 5 of 6 directions in back pain individuals and has strong distinguishing capacity (ROC area under curve = 0.898; sensitivity = 93.88; specificity = 73.47). Our novel measure for trunk compliance (i.e., TCI) should be examined in future work to determine its robustness as a biomarker of low back pain.

Title: Nerve constriction with a synthetic absorbable suture does not model centralized chronic pain in rats

Authors: *O. UDDIN[1], R. MASRI[2], A. KELLER[1];
[1]Univ. of Maryland Sch. of Med., Baltimore, MD; [2]Dept. of Advanced Oral Sci. and Therapeut., Univ. of Maryland Sch. of Dent., Baltimore, MD

Abstract: Chronic pain severely impacts quality of life. Understanding the mechanisms underlying chronic pain is a high priority due to the associated economic burden, inadequate treatment options, and clinical impact. Elucidating the transition from acute to chronic pain is especially vital; doing so requires the use of valid animal models. Chronic pain often persists in the absence of tissue damage. An informative animal model of chronic pain should replicate this finding. Many animal studies model neuropathic pain by constricting a peripheral nerve with an absorbable suture or removable cuff. These studies assume that pain persists after removing the constriction, modeling chronic pain in humans. Data from cuff constriction models suggest that, while reflexive signs of pain resolve when the cuff is removed, affective components of pain persist (PMID: 25209272). Here, we modeled trigeminal neuropathic pain using a vicryl ligature-based chronic constriction injury of the infraorbital nerve (CCI-ION) in 7 male and 12 female Wistar rats. We sought to determine whether reflexive and ongoing signs of pain (assessed by facial tactile sensitivity and facial grimace scoring, respectively) persist in the absence of nerve pathology. At 2 weeks and 4 weeks post CCI-ION, tactile thresholds were lower than baseline, suggesting tactile hypersensitivity (2 weeks: Wilcoxon matched pairs test, W= -143.0, p=0.0008, Cohen's d=0.94, large effect size. 4 weeks: Wilcoxon matched pairs test, W=-148.0, p=0.0017, Cohen's d=0.82, large effect size). Grimace scores at these time points were higher than baseline, indicating ongoing pain at 2-4 weeks post-CCI (2 weeks: paired t-test, t(18)=5.960, p<0.0001, Cohen's d=1.72, large effect size. 4 weeks: Wilcoxon matched pairs test, W=186.0, p<0.0001,

Cohen's d=1.58, large effect size). By 8 weeks post-CCI, tactile thresholds were indistinguishable from baseline values (Wilcoxon matched pairs test, W=-5.0, p=0.90), whereas grimace scores remained elevated ($t(14) = 3.749$, p=0.0022, Cohen's d=1.22, large effect size). By 11 weeks post-CCI, grimace scores returned to baseline values (paired t-test, $t(7)=0.92$, p=0.39). Despite resolution of pain behaviors to baseline levels, 7 out of 8 infraorbital nerves, harvested at 15 weeks post-CCI, had histology findings of ongoing inflammation or foreign body reaction in the injured nerve. Thus, the vicryl-based CCI-ION model does not represent the development of purely central chronic, neuropathic pain.

Title: The analgesic effects of cannabinoids and terpenoids on a Zebrafish model for nociception and pain

Authors: *A. KIM, W. ALLISON, D. ALI;
Univ. of Alberta, Edmonton, AB, Canada

Abstract: With many communities affected by the opioid crisis, it has become of paramount importance to explore methods of pain management outside of treatments with opioids. One alternative that has seen a recent surge in interest is the cannabis- and related phytochemical-based treatments. Some cannabinoids and terpenoids have been shown to have analgesic and anxiolytic effects in various model systems; however, the analgesic effects of the vast majority of terpenoids in cannabis plants remain unknown. In this study I used a zebrafish model of nociception and pain to test the analgesic effects of cannabinoids, terpenoids and a combination of these compounds. Zebrafish provides a robust and high-throughput model system for such inquiry and may serve as a more ethical alternative compared to other conventional models of pain. We used acute exposure to acetic acid as a noxious stimulus, which provides a means by which to assess nociception and analgesia. Using behavioural assays, we confirmed the ability of acetic acid to elicit a change in locomotion in larval zebrafish. Acetic acid at 0.1% resulted in a decrease in the mean activity of 5 day old (dpf) zebrafish compared to controls. Exposure to low concentrations of acetic acid (0.001% - 0.01%), on the other hand, led to a drastic increase in mean activity in the larvae – which was approximately four times the activity seen in the controls. An acute treatment with cannabidiol (CBD) at 2.5 µg/mL, 5 µg/mL and 10 µg/mL,

prevented the subsequent acetic acid-induced increase in movement. Interestingly, tetrahydrocannabinol (THC) and certain terpenoids also found in cannabis, failed to prevent the effects of acetic acid by themselves but showed some ability to enhance the preventative effects of CBD when administered in conjunction with it. Together, CBD at 2.5 µg/mL and THC at concentrations as low as 0.5 µg/mL showed activity levels that were not significantly different from that of the baseline control. Similar results were observed with terpenoids such as α-pinene at 50 µg/mL and linalool at 1 µg/mL. These findings lay the foundation for a more thorough investigation of the therapeutic effects of cannabinoids, terpenoids and combinations of the two, as well as a mechanistical understanding of how such effects arise at cellular and systemic levels.

Title: Effect of ceftriaxone on nociceptive behaviors induced by spinal nerve ligation

Authors: *C. G. GUZMAN PRIEGO[1], **I. I. RAMOS RODRIGUEZ**[1], E. RODRÍGUEZ PALMA[2], J. E. TORRES LOPEZ[1];
[1]Univ. Juárez Autónoma De Tabasco, Villahermosa, Mexico; [2]Ctr. de Investigacion y de estudios Avanzados del Politécnico Nacional, México, Mexico

Abstract: "Effect of ceftriaxone on nociceptive behaviors induced by spinal nerve ligation" Introduction: the International Association for the Study of Pain (IASP) defines pain as "an unpleasant sensory and emotional experience associated with actual or potential tissue damage or resembling such damage". According to its neurophysiological mechanism, pain can be classified as nociceptive, inflammatory, dysfunctional, and neuropathic. The lASP defines neuropathic pain (NP) as "pain caused by injury or disease of the somatosensory nervous system" and can be classified according to its anatomical location as central or peripheral. Studies suggested that beta-lactam drugs are involved in neuropathic pain, the administration of beta-lactam drugs, such as ceftriaxone, have shown antiallodynic, antihyperalgesic, and antinociceptive effects on inflammatory pain. Objective: the aim of this study was to evaluate the effect of ceftriaxone on nociceptive behaviors induced by spinal nerve ligation (SNL) in Wistar strain rats. Material and methods: experimental study, 36 female Wistar strain rats of 140-160 g were used and divided into the following groups: naive, sham, SNL rats treated with saline solution, SLN rats treated with pregabalin 30 mg/kg p.o., SNL rats treated with gabapentin 300 mg/kg p.o., SNL rats treated with ceftriaxone at doses of 10 and 100 mg/kg intraperitoneally (i.p.). Nociceptive behaviors were determined by the up and down method. This experiment was

performed according to international guidelines on ethical aspects for experimental pain research in animals. Results: in the establishment of the allodynic behavior induced by spinal nerve ligation, a reduction of the paw withdrawal threshold was observed in the time course, which occurred from day 1 and was maintained for 28 days post-ligation. With the administration of pregabalin and gabapentin, antiallodynic behavior was observed in the time course and the areas under the curve (AUC) of the time course of antiallodynic behavior, a significant difference was observed between the pregabalin, and gabapentin groups compared to vehicle with a value of p=0.0001. The administration of ceftriaxone at a dose of 100 mg/kg i.p., showed an antiallodynic response starting at 30 minutes and reached its maximum peak at two hours in the time course, and in the AUC a significantly different response was observed from the vehicle group with a value of p=0.0001. Conclusions: Ceftriaxone was shown to induce an antinociceptive effect in rats subjected to SNL, and a dose-dependent behavior of ceftriaxone (10-100 mg/kg i.p.) was observed.

Title: Mechanisms of sensory adaptation over behaviorally relevant time scales in mouse barrel cortex

Authors: *Z. DOBLER[1,2], C. PORTERA-CAILLIAU[2,3];
[1]Univ. of California, Los Angeles Interdepartmental Ph.D. Program In Neurosci., Los Angeles, CA; [2]Dept. of Neurol., [3]Dept. of Neurobio., David Geffen Sch. of Med. at UCLA, Los Angeles, CA

Abstract: Typical nervous system function depends on the ability of sensory circuits to adapt their activity to the statistics of the surrounding environment and filter out irrelevant stimuli (e.g., non-salient or non-threatening). Stimulus-specific sensory adaptation, characterized by a progressive decrease in neuronal activity with ongoing stimulation, is a universal phenomenon across species and sensory modalities. Most previous studies of adaptation focused on rapid timescales (less than 500 ms), but much less is known about adaptation to sensory stimuli occurring over tens of seconds, which is more relevant to an animal's behavior. Here, we assess

the role of adaptation in the barrel field of the mouse somatosensory cortex (S1BF), a crucial region for processing tactile stimuli transmitted through the whiskers. Whether such adaptation is stimulus-specific, and whether S1BF neurons exhibit the same adaptive firing patterns across a variety of stimuli has not been explored. We investigated adaptation within S1BF to an array of stimuli of various durations and intervals and asked if it can generalize across stimuli of different frequencies. We performed in vivo 2-photon calcium imaging (GCaMP6s) of layer 2/3 excitatory neurons in awake Slc17-Cre x Ai162 mice during repetitive whisker stimulation. To assess whether adaptation is comparable across different stimuli, we exposed mice to bouts of 10 repetitive whisker stimulations at various stimulus durations and interstimulus intervals. S1BF neurons exhibited dynamic and complex response profiles, with some cells exhibiting classic adaptive responses and a minority showing facilitating responses; still, most responsive neurons fired inconsistently to individual stimuli with fluctuating response magnitudes. To assess whether adaptation generalizes, we performed frequency switch experiments, exposing mice to a bout of 10 repetitive whisker stimulations followed by a second bout at an alternate frequency. Switching to a higher alternate frequency attenuated adaptation in strongly adapting neurons, while switching to a lower one did not. Future studies will explore the mechanisms of sensory adaptation over these prolonged time scales to better understand how the neuronal representation of sensory stimuli changes with repetitive exposure.

Title: Automated home-cage mouse training of a whisker-based tactile working memory task

Authors: *D. LEE[1,2], G. HOUSE[3], A. CAREY[3,2], D. LAMAY[3,4], J. L. CHEN[3,1,2];

Abstract: Understanding the neural correlates of task learning requires unbiased observation of learning behavior. Human-guided mouse training of complex goal-directed tasks is a time-consuming process. This method of training limits the number of animals which can be trained in a given period of time and introduces potential human error and biases in the training of subjects. To increase training throughput and assess variability in learning in an unbiased manner, we

have designed an automated training system which allows mice to learn a whisker-based tactile working memory task from their home cage. The system contains components to deliver whisker and auditory stimuli, deliver rewarding and aversive stimuli, and monitor animal entry and licking behavior. Multiple animal cages can be connected to a shared training system. Singly housed mice gain scheduled access to the training module in a manner that enables simultaneous training of multiple animals while controlling for social interactions and hierarchies. We have developed software that intelligently tracks mouse performance and adjusts training settings across multiple stages of training on a two-alternative forced choice delayed match to sample task. Mice can successfully be trained to expert performance within three to four weeks. The learning trajectory of individual animals can be analyzed using a dynamic model of sensory decision-making fit to behavioral data. Through this, variability in learning and behavior strategies are observed across both inbred and outbred mouse strains.

Title: Cortical processing dynamics during sensory-guided behavior using a tactile virtual-reality task

Authors: A. ARMSTRONG[1], K. HU[2], *Y. VLASOV[1,2,3];
[1]Neurosci. Program, [2]Bioengineering, [3]Beckman Inst. of Advanced Sci. and Technol., Univ. of Illinois Urbana-Champaign, Urbana, IL

Abstract: Our goal is to determine how neuronal populations in the mice barrel cortex are organized in dynamic functional networks that guide behavioral choices downstream during a whisker-dependent task. To enrich the number of activity states that neuronal populations encounter during a task trial, we designed naturalistic tactile virtual reality [1] behavioral experiments that load cortical circuits with difficult yet manageable cognitive tasks and, at the same time, elicit an ethologically relevant behavior. The head-fixed animal runs freely on a suspended ball treadmill with movement tracked in a 2-dimensional VR plane. Moveable walls on either side of the animal snout are coupled to the animal run, thus producing an illusion that the animal is running in a winding virtual corridor with programmed left and right turns being guided only by the whiskers touching the walls. Of specific interest for our study is the choice period: the time interval when the animal first senses the approaching wall with whiskers until it makes a choice to change the direction of his run. To record from large neuronal populations

during active navigation in a tactile VR, 64channel multi-electrode arrays are acutely implanted into the principle whisker barrel thus recording massive single-unit spiking activity across all cortical layers. Using Scnn1a-TG3-Cre x Ai32 mice, with Cre expression limited to 85% excitatory neurons in layer 4 of the cortex, enables optical tagging of individual L4 stellate cells as well as to manipulate these populations using optogenetics. We observed distinct layer-dependent stratification of spiking activity of neuronal populations recorded simultaneously during naturalistic whisker-dependent behavior in our VR. To uncover latent temporal dynamics of cellular-level interactions in recorded neuronal populations during the choice period we focused on analysis of pair-wise temporal correlations of spike timing. Both classical jitter-corrected cross-correlograms (CCG) and novel machine learning based analytical approaches reveal distinct dynamics of organization of neuronal populations into functional networks across all layers. The extracted patterns of dynamic connectivity are changing rapidly during the choice period at specific times for stimulus presentation, motor action preparation and choice execution when the running direction is changed. Observed correlation of whisker-guided behavior with dynamics of laminar network connectivity can help to reveal specific dynamic organization of columnar microcircuits and shed light on tactile information flow during perceptual decision making. Title: Brain-wide networks for functionally-distinct principal neuron in the primary somatosensory cortex

Authors: *A. R. INACIO, K. LAM, F. PEREIRA, C. R. GERFEN, S. LEE;
NIMH, NIH, Bethesda, MD

Abstract: Principal neurons in the primary sensory cortices exhibit heterogeneous patterns of activity, not only in response to sensory stimuli but also, during spontaneous movements. Yet, how these heterogeneous, behavioral state-dependent patterns of activity arise is largely unknown. Longitudinal two-photon calcium imaging uncovered a remarkably stable correlation between the activity of principal neurons in layers II/III of the primary somatosensory cortex and spontaneous movements. This population activity could reliably predict spontaneous movements, but with a subset of neurons accounting for most of the prediction accuracy. The activity of

movement-encoding neurons could not be explained by direct sensory feedback, as paralysis of the contralateral whisker pad did not disrupt the correlation with ipsilateral whisker movements and locomotion. During pharmacological blockade of neuromodulators, the activity levels were altered, but the correlation of neuronal activity with spontaneous movements was largely maintained. By contrast, glutamatergic transmission blockers nearly abolished this correlation. Single cell-initiated monosynaptic retrograde tracing and whole-brain presynaptic network analysis revealed that movement-encoding neurons receive characteristic subcortical inputs. Finally, simultaneous imaging of layers II/III principal neurons and closed-loop optogenetic silencing of identified inputs during spontaneous movements altered spontaneous activity. Our study provides a connectivity rule that supports the representation of spontaneous movements in the primary somatosensory cortex.

Title: Stochastic resonance in the mouse barrel cortex by multisensory integration

Authors: *J. A. MARTINEZ CABRAL[1], P. E. TRUJILLO GARIBAY[1], L. P. OSUNA CARRASCO[1], C. TORO-CASTILLO[1], M. TREVINO VILLEGAS[2], B. *DE LA TORRE-VALDOVINOS[1];
[1]Electrónica, Univ. de Guadalajara - CUCEI, Guadalajara, Mexico; [2]Neurociencias, Univ. de Guadalajara - Inst. de Neurociencias, Guadalajara, Mexico

Abstract: Stochastic Resonance (SR) is a phenomenon that occurs in non-linear systems, where their response to a subthreshold signal is optimized by noise. Its presence has been demonstrated in different biological systems, ranging from simple models (i.e. mice) to more complex models (i.e. humans), also, a variety of techniques have been explored to test the scope of this phenomenon. Since SR has been applied mostly in integrative electrophysiology models, it is in our interest to implement an application of this phenomenon at a functional level in the nervous system, for which reason this study is intended to investigate whether the SR phenomenon occurs through multisensory integration in the mouse Barrel Cortex (BC).
Vibrissae were stimulated by mechanical protraction to 22 adult mice of the C57BL black strain (weight: 23 ± 5 grams) through two input signals, a pulse stimulus and a white noise signal modulated at 8 standard deviation levels applied in two different protocols: ipsilateral and contralateral route. An electrode in BC and a reference electrode were implanted to perform an

average of 4 Evoked Field Potential (EFP) recordings, in which the difference in amplitude and signal-to-noise ratio (SNR) was evaluated at each noise level applied.
When applying the ipsilateral noise protocol, there is an increase in the amplitude of the potential with an intermediate level of noise with respect to the basal level and after this level a decrease is observed ($P < 0.01$), the same for the SNR. In the case of the contralateral noise protocol, although less noticeable, a similar behavior is observed ($P < 0.05$). These results confirm the presence of SR since this behavior is characteristic of this phenomenon, which suggests that the properties of the signals that are introduced in different pathways are coupled in some structure previous to BC (e.g. thalamus or superior colliculi) through multisensory integration and it results in the appearance of this phenomenon in a subsequent structure, specifically, in this case, BC.

Title: Environmental enrichment restores the long-lasting sequelae of perinatal fentanyl exposure

Authors: *J. B. ALIPIO[1], L. M. RIGGS[2], C. HAGA[1], M. E. FOX[1], K. ARAKAWA[1], R. BALAJI[3], M. PLANK[1], N. P. CRAMER[1], M. LOBO[1], A. KELLER[1];
[1]Anat. & Neurobio., [2]Psychiatry, Univ. of Maryland Sch. of Med., Baltimore, MD; [3]Univ. of Maryland Col. Park, College Park, MD

Abstract: The use of synthetic opioids, like fentanyl, among pregnant women has increased substantially in the last decade, leading to an increase in the number of infants exposed to opioids perinatally. This exposure can result in neuropsychiatric abnormalities that persist to

adolescence and even adulthood. To better understand the molecular, behavioral, circuit, and network-level abnormalities that result from fentanyl use during pregnancy, we developed a preclinical model of perinatal fentanyl exposure. We found that adolescent male and female C57Bl/6 mice exposed to fentanyl during perinatal development have increased anxiety-like behavior and sensory maladaptation. Consistent with the role of the primary somatosensory cortex (S1) in sensory-related processing, fentanyl-exposed mice had a reduction in the probability of spontaneous and evoked glutamate release onto S1 layer V neurons, and an increase in these metrics in layers 2/3. Expression of long-term potentiation (LTP) in S1 layer 2/3 neurons was also impaired. *In vivo* electrocorticogram activity in awake behaving mice revealed suppressed ketamine-evoked cortical oscillations. Morphological analysis of S1 pyramidal neurons showed reduced dendritic complexity, length, and reduced soma size. Fentanyl-exposed mice had abnormal cortical mRNA expression of key receptors involved in synaptic transmission, plasticity, and neuronal growth and development, consistent with the electrophysiological and morphological findings. We asked if these long-lasting effects can be restored by a non-invasive intervention. We demonstrate that developmental exposure to environmental enrichment ameliorates many of fentanyl's deleterious behavioral effects, including hyperactivity, enhanced sensitivity to anxiogenic environments, and sensory maladaptation. The deficits in synaptic function and plasticity were also restored by environmental enrichment. Environmental enrichment also affected neurons in control mice, who showed reduced LTP and long-term depression (LTD), and higher frequency of miniature excitatory postsynaptic currents, compared to mice raised in standard caging. These results demonstrate that the lasting somatosensory-related effects of fentanyl can be reversed with a non-invasive intervention introduced during early development. These findings can inform ongoing efforts to develop actionable steps toward mitigating the consequences of opioid abuse among pregnant women.

Title: Learning enhances encoding of time and temporal surprise in primary sensory cortex

Authors: *R. RABINOVICH, D. KATO, R. BRUNO;
Columbia Univ., New York, NY

Abstract: Primary sensory cortex has long been believed to play a simple role in the initial processing of sensory information. However, cortical activity is influenced by other modalities, task context, reward, and behavioral state; conversely, the superficial layers of cortex tend to respond sparsely to sensory stimulation. We demonstrate that reinforcement learning dramatically alters representations in superficial layers of mouse primary somatosensory cortex. Using in vivo two-photon microscopy of calcium indicators, we longitudinally tracked layer 2/3 neurons as mice learned an object detection task. Learning recruited previously unresponsive neurons, enlarging the neuronal population sensitive to touch (n=10 mice). In contrast, cortical responses habituated upon repeated exposure to unrewarded stimuli (n=7 mice). The ability of a linear decoder (a support vector machine) to identify the stimulus (the presence or absence of the object) and predict the choice (whether or not the mouse displayed anticipatory licking) from population activity improved along with animals' performance. Moreover, training improved population encoding of the passage of time, and unexpected deviations in trial timing elicited even stronger responses than touch did. In conclusion, the superficial layers of sensory cortex exhibit a high degree of learning-dependent plasticity and are strongly modulated by non-sensory but behaviorally-relevant features, such as timing and surprise.

Title: Rapid re-organisation of layer 2/3 barrel cortex accompanies learning of a whisker detection task

Authors: *A. I. M. IUGA, G. P. FOUSTOUKOS, S. CROCHET, C. C. H. PETERSEN;
Brain Mind Institute, École Polytechnique Fédérale De Lausanne, Lausanne, Switzerland

Abstract: The precise neural circuit mechanisms underlying reward-based learning of a goal-directed sensorimotor transformation remain to be determined. In order to begin to directly investigate this question, we developed a novel single-session learning whisker detection task. This allows for continuous monitoring of behaviour and neuronal activity during the whisker learning process, which may be important for mechanistic insight. In this task, water-restricted

mice are initially trained to lick a reward spout in response to a brief auditory stimulus. Once expert in the auditory detection task, they are presented with interleaved auditory stimuli and single whisker deflections. Over the course of a single recording session, mice learn to associate the novel whisker stimulus with reward availability.Pharmacological and optogenetic inactivation demonstrated the causal contribution of the primary whisker-related somatosensory cortex (wS1) for the acquisition and execution of the task. Consequently, we performed two-photon calcium imaging in order to monitor neuronal activity in wS1 during whisker learning. Our results indicate that a subset of neurons in layer 2/3 of wS1 change their activity across learning. This re-organisation correlates with learning to lick in response to whisker deflection in a reward-dependent manner. Moreover, such re-organisation occurs on a fast time-scale and can be observed during the course of a single training session. High-speed orofacial videography was acquired during the imaging session. Ongoing movement analysis, using DeepLabCut and a generalised linear models, shows that motor movements do not account for the observed changes in neural activity.In summary, we have established a robust single-session reward-based learning paradigm, amenable to detailed investigation of the mechanisms underlying learning and execution of a simple goal-directed sensorimotor transformation.

Title: Neural representations of behavior in olfactory cortex

Authors: *M. SEPPO, A. AOUN, Z. LEVIN, A. PIERRÉ, A. FLEISCHMANN;
Dept. of Neurosci. and the Robert J. and Nancy D. Carney Inst. for Brain Science, Brown Univ., Providence, RI

Abstract: The cerebral cortex transforms sensory information into behavioral outputs. The site and nature of this transformation remains an area of active study. In the olfactory system, odorants activate unique ensembles of neurons in piriform cortex with high variability. We hypothesize that this variability can largely be explained by changes in behavioral state, and that piriform cortex is driven by behavior even under spontaneous conditions, as observed in neocortical brain areas. Here, we investigate this question by performing multiplane, two-photon calcium imaging in the piriform cortex of awake, head-fixed mice during spontaneous and odor-

evoked epochs, while monitoring behavior using videography and physical sensors. Multivariate linear modelling of the activity of individual neurons reveals that activity in piriform cortex is substantially behaviorally driven. Facial movements predict neural activity more than locomotion and sniffing. We find that odor representations occur in ensembles that partially overlap with behavioral ensembles. Future experiments will identify by gene expression and connectivity, neuron types that are preferentially driven by odors or behavior. This work will build towards understanding the functional impact of early sensory-motor integration.

Title: Statistical learning of odor sequences in primary olfactory cortex

Authors: A. P. FINK[1], R. AXEL[2], ***C. SCHOONOVER**[3];
[1]Neurosci., [2]ZMBBI, [3]Columbia Univ., New York, NY

Abstract: Classical results in experimental psychology (Blodgett/Tolman, Sokolov, Brogden, Groves/Thompson, Berlyne) have documented that animals continuously learn complex features in their sensory environment. This faculty does not depend on external reinforcement to drive learning, only the existence of structure in the world. How does an organism form a model of the world's statistics when the vast majority of the time it is neither rewarded nor punished for doing so? We have developed a behavioral paradigm for the head-fixed mouse that permits observation of exploration and statistical learning simultaneous with longitudinal recording of populations of single units. Mice presented a sequence of two neutral odorants A-B initially investigate the stimuli and then habituate following repeated experience over three days. Recordings in primary olfactory (piriform) cortex show that over this same time period the magnitude of the population response to the A-B sequence decreases markedly, with responses during the B epoch nearly abolished. However, presentation of B alone elicits strong activity; and if B is omitted from the A-B sequence, the piriform responds vigorously to its absence, producing a response that matches the expected timing of the omitted stimulus even though there is no odorant molecule in the nares. Taken together, these concordant behavioral and electrophysiological results show that response magnitude in both behavior and in piriform activity scales inversely with the degree to which an event is predictable. This suggests that activity in piriform does not strictly reflect

physical stimuli, but rather a model of the statistics of the olfactory environment, formed over the course of statistical learning. Familiar stimuli that contain little new information are filtered out, whereas the content of unanticipated events is transmitted to regions downstream.

Abstract: The anterior piriform cortex (APC) is thought to be a site of odor encoding. The trilaminar structure and proximity to odor sensory input make the APC highly tractable for dissecting the role of cortical circuitry in sensory processing.
We investigated excitatory-inhibitory (E:I) synaptic plasticity in APC following odor learning. Briefly, mice were trained to discriminate between two overlapping odor mixtures in a digging task. These mice were triple transgenic- expressing a conditional cre-recombinase for targeted recombination in active populations (TRAP); a non-conditional cre-recombinase in either parvalbumin (PV) or somatostatin (SST)-interneurons, and a reporter (tdTOM). These mice also express cre-dependent Channelrhodopsin (ChR2) via viral transfection. Thus, there was conditional expression of ChR2 and tdTom in an ensemble of excitatory neurons that were active during the task, as well as unconditional expression of ChR2 and tdTom in select inhibitory interneurons. Following behavioral training, we targeted these APC population neurons for recording and/or reactivation in vitro.
We performed voltage clamp recordings from ensemble (tdTom+) and non-ensemble (tdTom-) PNs while electrically stimulating the intracortical tract that recruits recurrent excitation and inhibition. PNs were held at -50 mV or >0 mV to isolate excitatory post-synaptic currents (EPSCs) and inhibitory pre-synaptic currents (IPSCs) respectively. After training, EPSCs and IPSCs both showed significantly increased amplitudes in tdTom(+) ensemble PNs compared to PNs outside the ensemble (tdTom-). The increase in excitation is balanced by the increase of

inhibition as the two positively scale together. Since inhibition is mediated by a diverse cell population, we further investigated how inhibition mediated by two classes of inhibitory neuron, PV and SST, scales with excitation. To answer this, we recorded EPSC and IPSC responses in tdTom(+/-) PNs in response to light activation of ChR2+ PNs and PV or SST interneurons. Preliminary findings suggest that inhibition mediated by both PV and SST interneurons scales with excitation. While increases in PV-mediated inhibition appear to be selective for active ensemble neurons (tdTom), changes in SST-mediated inhibition are more broadly distributed. Taken together, our findings suggest that both classes of interneuron may play a role in balancing changes in excitation following odor task learning.

Title: Information processing by distinct projection neuron types in the mouse olfactory cortex

Authors: *S. DASTE, A. FLEISCHMANN;
Dept. of Neurosci. and the Robert J. and Nancy D. Carney Inst. for Brain Sci., Brown Univ., Providence, RI

Abstract: Sensory cortexes contain a multitude of neuron types projecting to different target areas. Determining their distinct functional properties is essential to better understand how stimulus information is transmitted across brain areas. Piriform cortex (PCx), the main recipient of sensory input from the olfactory bulb, contains neurons that project to numerous areas, including the Olfactory Bulb (PCx_{OB}) and the medial Prefrontal Cortex (PCx_{mPFC}). Both PCx_{OB} and PCx_{mPFC} cells are deep-layer pyramidal cells, however, whether they selectively encode distinct stimulus information is unknown. Here, we record neuronal activity in the PCx of awake behaving male and female mice (4-6 months old) using GRIN lens technology and two-photon calcium imaging microscopy. We label PCx_{OB} and PCx_{mPFC} subpopulations using retrogradely transported Adeno-associated virus, and we determine their response properties under passive odor presentation. We show that PCx_{OB} and PCx_{mPFC} subpopulations (n=5 mice each) can accurately be identified based on their odor response profiles. Moreover, odor identity is more efficiently encoded in PCx_{mPFC} neurons compared to PCx_{OB} neurons. Our results suggest that

odor information coding differs between PCx neuron types, providing new insights into how olfactory information is routed across brain areas.

Title: Re-engineering development to test models of sensory coding

Authors: *M. AHMED, E. A. PEDERSEN, D. L. WILLIAMS, E. J. CLOWNEY;
Dept. of Molecular, Cell. and Developmental Biol., Univ. of Michigan, Ann Arbor, MI

Abstract: We experience countless sensory cues on a day-to-day basis. How is the brain wired to deal with this wide and unpredictable array of stimuli with only a limited set of neurons? To do this, principal neurons of sensory perception and associative learning regions receive information about cues in combinations. There is an expansion of inputs from a small set of neurons onto a much larger set of postsynaptic cells, and each postsynaptic cell only receives a few inputs (average of ~5). Such sparse, combinatorial innervation is seen in multiple perceptual and learning centers such as the cerebellum, the hippocampus, and the vertebrate and fly olfactory systems. Theoretically, the density and complexity of sensory inputs to principal neurons of these regions optimize the tradeoff between stimulus representation and discrimination. However, this has not been tested at the functional level. To test this relationship experimentally, we are using the *Drosophila* mushroom body (MB) as our model system, as it is the simplest and best studied of these associative learning regions. Within the MB, individual Kenyon cells (KCs) receive combinatorial inputs from a few olfactory projections neurons (PNs) to represent odors. To determine the relation between circuit form and function *in vivo*, we have developed a suite of chemical and genetic methods to manipulate MB cell repertoires during development. In our work to date, we find that: (1) sparseness of PN inputs to KCs is robust to changes in the size of PN and KC populations, (2) KCs orchestrate connectivity density: the number of dendrites they produce during development is relatively inflexible, while olfactory PNs adjust their production of presynaptic sites several fold to adjust to developmental perturbations, and (3) when sparseness is preserved, KC ability to represent odors is largely intact. Seeing that the KC dendrite number is largely unaltered across all the manipulations

supports the significance of the number of inputs received by KCs. Going forward, we are developing ways to “break” the sparse innervation of KCs by PNs by directly changing the number of dendrites produced by KCs. This will allow us to test *in vivo* the role for sparse innervation in sensory coding and associative learning. Ultimately, this work will not only contribute to our understanding of the connectivity architecture underlying sensory coding, but also allow us to manipulate development to shape object representation in the brain.

Title: Gabaergic innervation of the olfactory cortex by basal forebrain long-range projecting neurons

Authors: *R. C. ARANEDA[1], P. S. VILLAR[2];
[1]Univ. of Maryalnd, College Park, MD; [2]Biol., Univ. of Maryland, College Park, MD

Abstract: Sensory perception requires the coordination of sizable neuronal assemblies across multiple brain regions; yet, how such cooperation is achieved is not understood. Previous studies have shown that long-range projecting neurons influence the activity of interconnected regions by modulating specific circuit domains and are necessary for sensory binding and memory formation. Particularly, the processing of early sensory signals in the olfactory bulb (OB) is highly regulated by basal forebrain long-range GABAergic neurons (BF-LRGN). This GABAergic afference influences the OB output by acting on local GABAergic circuits. Activation of BF-LRGNs produces an overall desinhibitory effect on the output neurons, decreasing their firing precision, and reducing the intensity of local oscillatory activity. Furthermore, BF-LRGNs also innervate higher order targets in the olfactory pathway, including the olfactory cortex, however the physiological properties and function of these GABAergic projections remain unknown. Here, using conditional genetics and confocal microscopy we studied the distribution of BF-LRGN projections to the piriform cortex (PC). We found that the BF-LRGN innervation was highest in layer 1 of PC (norm. pixel intensity 0.72 ± 0.01, n= 7 slices, 2 mice) and layer 3 (norm. pixel intensity 0.46 ± 0.001, n= 7 slices, 2 mice), where abundant axonal boutons can be observed. In contrast, layer 2 of PC, which contains the highest number of pyramidal neurons, exhibited a lower degree of innervation (norm. pixel intensity 0.35

± 0.001, n= 7 slices, 2 mice), suggesting a differential influence of BF inhibition across the PC cellular layers. Moreover, using whole cell electrophysiology in brain slices and optogenetics we examined the postsynaptic targets of BF-LRGNs in the PC. Surprisingly, we found that light stimulation of LRGN expressing channelrhodopsin-2 consistently evoked short latency (~5 ms) responses in all cortical layers of the PC (layer 1: -3.2 ± 2.2 pC, n= 2; layer 2: -20 ± 5 pC, n= 3; layer 3: -4.5 ± 2 pC, n= 2). These results suggest that BF GABAergic projections are well poised to influence the activity of local GABAergic cells as well pyramidal cell function in the PC through fast inhibitory transmission.

Title: A general theory of olfactory learning and representation

Authors: *T. A. CLELAND[1], J. A. COOK[2], A. BORTHAKUR[3];
[1]Psychology, [2]Mathematics, [3]Computat. Biol., Cornell Univ., Ithaca, NY

Abstract: Theories of sensory representation must consider not only physiological response properties that are sensitive to changing stimuli, but also a broader set of factors such as robustness to natural interference and how the properties of individual circuit elements can be coordinated into a functional system. Broadly, we propose that odor representations are embedded in spike timing-dependent representations on the gamma/beta timescale, which govern dynamic neuronal interactions and plasticity within the deep olfactory bulb (OB) and between the OB and its follower cortices. We first describe how this architecture can be mapped to a generalized geometric framework for odor category learning, using the tools of smooth manifold theory. Beginning with the space of all possible physical inputs to the olfactory system (the irreducibly high-dimensional R-space), we incorporate a dynamic model for perceptual learning to transform this input space into a smooth, pliable perceptual space termed S-space. S-space embeds R-space, but also admits the capacity for experience-dependent category learning, progressively developing hierarchical, quasi-discrete categories (corresponding to learned odors) atop an intact physical similarity metric. This framework yields interpretable depictions of behavioral phenomena such as stimulus generalization and the speed-accuracy trade-off. Importantly, this odor learning depends on locally-governed synaptic plasticity within olfactory

bulb, indicating that geometries that fix curvature (whether spherical, hyperbolic, or otherwise) must be ruled out in favor of a flexible geometric framework that can be described using the theory of sheaves. In computational models based upon these principles, spike timing-dependent plasticity at the mitral-granule cell synapse generates highly configural feature detectors that iteratively modify the spike timing-dependent activity of olfactory bulb principal neurons. The resulting attractor dynamics are able to denoise raw chemosensory inputs in which known odors of interest are substantially occluded by background odorants that compete for the same receptors, thereby disrupting the cross-receptor pattern on which odor recognition ostensibly depends. This model also exhibits rapid online learning (in which subsequent learning does not disrupt existing representations), and suggests a necessary role for adult neurogenesis as an efficient mechanism to enable lifelong learning of meaningful odors.

Title: Top-down feedback gates flexible coding strategies in olfactory cortex

Authors: *Z. CHEN[1], K. PADMANABHAN[2];
[1]Brain and Cognitive Sci., [2]Neurosci., Univ. of Rochester, Rochester, NY

Abstract: In chemical sensation, multiple models have been proposed as to how odors are represented by patterns of neuronal activity in the olfactory cortex. One hypothesis is that the combinatorial patterns of activity restricted within specific sniff-related time windows are critical for encoding information about odors, while another proposes that the patterns of neural activity evolve across time, and it is this temporal structure that is essential for encoding odor information. Each model has experimental support and draws upon theoretical frameworks that make them appealing, but it remains unclear how these different models encode odor information, and the extent to which these are different instantiations of a single overarching strategy of computing. We hypothesize that different findings on how piriform cortex codes for odor information can be reconciled by examining the role of feedback from piriform cortex to the bulb. To test this hypothesis, we built a realistic spiking neuronal network model which

recapitulated the circuit architecture within and between the main olfactory bulb and piriform cortex and studied how centrifugal feedback influenced odor information encoded by the piriform cell population. We found that top-down feedback to the olfactory bulb shaped the information transmitted to the olfactory cortex by switching between these two models. Using a detailed model of the early olfactory system, we demonstrated that feedback control of inhibitory granule cell activity in the main olfactory bulb restructured the firing patterns of piriform cortical cells across time. This translated to performance gains in both the accuracy and reaction time of odor discrimination tasks. Taken together we propose a new framework for early olfactory computation, one in which top-down feedback to the bulb flexibly gates the temporal structure of neural activity in olfactory cortex, allowing the early olfactory system to dynamically switch between combinatorial codes and temporal codes.

Title: Neural representation of odor mixtures in the piriform cortex evolves to balance identity coding and learned categorization

Authors: *A. BERNERS-LEE[1], E. SHTRAHMAN[1], J. GRIMAUD[2], V. N. MURTHY[1]; [1]Dept. of Mol. and Cell. Biol. and Ctr. for Brain Sci., Harvard Univ., Cambridge, MA; [2]École de biotechnologies, Sup'Biotech, Villejuif, France

Abstract: Animals and the neural circuits that support their behavior have a natural trade-off between categorized and unique representations of stimuli. We investigated how learned odor mixtures are encoded and evolve in the posterior piriform cortex of mice while they learn to discriminate a unique target odor mixture against hundreds of nontarget mixtures. We find that a significant proportion of piriform neurons discriminate between target and nontarget odor mixtures, and that neurons that prefer the target odor tend to respond with brief increases in firing rate at odor onset compared to sustained and/or decreased firing. Mice also learn that new probe odors, which contain a mixture of target and nontarget components, are nontarget odors. Although a portion of neurons distinguish between probe and non-target odor mixtures and between different non-target mixtures, there are significantly fewer of these neurons than there are target-discriminating neurons. In addition, we analyze the population vector (PV)

correlations across trial types and find that the population representation for these mixtures change differently across sessions. Probe PVs tend to become more similar to nontarget PVs over sessions, while individual repeated nontarget mixtures tend to become more similar to themselves (the representation becoming more distinct or unique). Although probe and repeated nontarget trial types change their PV representations in different ways, they both allow for better population decoding of the category decision (target/non-target). These data show that populations of piriform neurons are able to change their representation of complex stimuli in different ways to balance categorical and identity encoding in a manner that may be useful for learning in a changing environment.

Title: Requirements for experience-dependent PKA activity in brain learning and memory circuitry

Authors: *J. C. SEARS[1], K. S. BROADIE[2];
[1]Biol. Sci., Vanderbilt Univ., Nashville, TN; [2]Vanderbilt Univ. Dept of Biol. Sci., Nashville, TN

Abstract: Protein Kinase A (PKA) activity drives learning and memory plasticity, but PKA circuit requirements and disruption in neurological disorders remain to be determined. Our goal is to test PKA mechanism in the *Drosophila* central brain Mushroom Body (MB) learning and memory circuitry, which projects via distinct lobes that have subdivided innervation patterns mapping to behaviorally-relevant output neurons. Our previous work demonstrates that both Fragile X Mental Retardation Protein (FMRP) and autism-associated PKA-anchor Rugose (Neurobeachin homolog; NBEA) promote PKA activity in MB Kenyon cells. Using a PKA activity biosensor that forms reversible GFP foci upon PKA phosphorylation (PKA-SPARK), we find young animals (0 days post-eclosion: 0 dpe) display almost no lobe PKA-SPARK foci, whereas 7 dpe animals display striking PKA-SPARK activity localized to two distinct circuit nodes. This increased signaling occurs more strongly in females relative to males, and loss of phosphodiesterase Dunce/PDE4 results in reduced PKA-SPARK activity. This acute onset of PKA activity suggests early experience-dependent signaling in specific MB circuits connections. Consistent with this hypothesis, rearing in reduced sensory stimuli environments results in much

less PKA activity. Moreover, removal of FMRP and Rugose/NBEA results in drastically reduced PKA activity, also suggesting disruption of experience-driven signaling. Taken together, these results define a new paradigm for testing the experience-dependent requirements for PKA activity in brain learning and memory circuitry. Ongoing work focuses on MB circuit mapping of this PKA signaling mechanism, testing early-life critical period requirements, and combining Fragile X syndrome and other ASD disease models with variable sensory environment manipulations.

Title: Identifying and redressing H-reflex contamination by the M response in the flexor carpi radialis muscle

Authors: *J. S. CARP[1,2], M. A. LASKY[1,4], R. A. MARINELLI[1,4], J. H. BARNES[1,5], J. A. BRANGACCIO[1], J. R. WOLPAW[1,2,3], J. J. S. NORTON[1,3];
[1]Natl. Ctr. For Adaptive Neurotechnologies, Stratton VA Med. Ctr., Albany, NY; [2]Sch. of Publ. Hlth., [3]Dept. of Electrical and Computer Engin., Univ. of Albany, State Univ. of New York, Albany, NY; [4]DPT Program, Mercy Col., Dobbs Ferry, NY; [5]Univ. of Delaware, Newark, DE

Abstract: The H-reflex (HR) is an important tool for experimental evaluation of spinal excitability, neurological diagnosis, and new rehabilitation strategies. Assessment of HR size is straightforward in distal muscles, e.g., soleus (SOL), where there is little or no temporal overlap of the direct muscle response (MR) and the HR, but can be problematic in more proximal muscles, e.g., flexor carpi radialis (FCR), where there can be substantial overlap between MR and HR.
To assess HR contamination by the MR (study approved by Stratton VA IRB), we recorded electromyographic responses evoked over a wide range of stimulation currents in the SOL (n=15) and FCR (n=11) muscles of 26 neurologically normal subjects. MR and HR sizes were calculated as mean rectified amplitudes within time windows starting at the onset of the earliest

large phase of each response and ending at the offset of the adjacent large phase of the opposite polarity. Visual inspection of the responses evoked over a wide stimulus range revealed contamination of the HR by the MR in all FCR, but not SOL. Recruitment curves constructed from the individual trials showed the failure of the HR to be fully suppressed at the stimulus current that elicited the maximum MR (Mmax) in FCR, but not in SOL (mean H at Mmax±SD (as % of Mmax)=21±8% and 8±4%, respectively). After limiting the HR window to the second (i.e., longer-latency) of the largest phases of the HR, the HR at Mmax of FCR and SOL were comparable to each other (mean±SD=10±6% and 6±5%, respectively) and to that of SOL using the full analysis window. To validate that limiting the HR window to the second large phase of the HR reduces contamination by the MR, we evaluated the correlation between the two largest oppositely signed phases of the HR. We hypothesized that contamination of the HR by the MR in the FCR would be manifested as a deviation from symmetric growth with increasing current. In fact, the largest positive and negative phases of the HR were highly correlated in SOL (mean r±SD=0.94±0.10; min/max=0.66/1.00), but were poorly correlated in FCR (mean r±SD=0.42±0.33; min/max=-0.09/0.87) (SOL≠FCR by t-test, $p<0.01$). In FCR, the phases were highly correlated up to 1.04±0.04 times the current that elicited the maximum HR, but this linear relationship deteriorated as current was further increased.
These results suggest that the FCR (but not SOL) HR is frequently contaminated by the MR at high stimulation levels. We propose that restricting the time window in which the HR size is evaluated to the second large phase of the HR can reduce this contamination. This should facilitate generation of more accurate data, which can benefit experimental and translational studies and clinical practice.

Title: Flexor carpi radialis H-reflex operant conditioning

Authors: *J. J. S. NORTON[1], S. DEVETZOGLOU-TOLIOU[1], J. A. BRANGACCIO[1], D. E. GEMOETS[2], D. HAHN[1], S. M. HECKMAN[1], T. M. VAUGHAN[1], J. S. CARP[3], J. R.

WOLPAW[1];
[1]Natl. Ctr. for Adaptive Neurotechnologies, Albany, NY; [2]US Dept. of Veterans Affairs, Albany, NY; [3]Natl. Ctr. For Adaptive Neurotechnologies, Albany, NY

Abstract: H-reflex operant conditioning is a promising new method for improving motor control impaired by incomplete spinal cord injury (iSCI) or other neurological injury or disease (Thompson et al., J Neurosci, 2013). In this protocol, participants learn to increase (up-condition) or decrease (down-condition) H-reflex size. In people with spasticity due to iSCI, H-reflex down-conditioning can trigger widespread beneficial plasticity that improves movement. H-reflex operant conditioning is non-invasive, and has no known adverse side effects; it can complement existing therapies and enhance functional recovery (Norton and Wolpaw, COBS, 2018). Previous studies have operantly conditioned the H-reflex of the soleus muscle in the leg (Thompson et al., J Neurosci, 2009; Thompson et al., J Neurosci, 2013). We are now extending H-reflex operant conditioning to the arm, specifically to the forearm muscle flexor carpi radialis (FCR).
The protocol is based on the leg protocol described by Thompson et al. (J Neurosci; 2009). In this first arm study, participants without neurological impairment complete 6 baseline (i.e., control) and 24 conditioning sessions (1 hr/session; 3/wk X 10 wks). Participants maintain a predefined level of FCR EMG activity prior to H-reflex elicitation by a stimulus that is continually adjusted to maintain a predefined M-wave size. Concurrent EEG data are recorded every sixth session. In control trials, the participant receives no feedback on H-reflex size; in conditioning trials, s/he receives immediate reward if H-reflex size is below (down-conditioning) or above (up-conditioning) a criterion.
To date, 13 healthy participants (6 down- and 7 up-conditioned) have completed the protocol; and we have analyzed the data from 11 of these participants. A comparison of the ratio of the H-reflex size from the 6 baseline sessions to the average H-reflex size from the last 6 conditioning sessions shows that eight of the 11 participants successfully changed their reflex size in the instructed direction (t-test). In one of the other three participants, H-reflex size did not change; in two participants, the H-reflex size changed, but not in the desired direction. Data indicate that operant conditioning of the FCR H-reflex is possible. Following confirmation of these initial results and further development, we plan to investigate FCR H-reflex conditioning for motor recovery in Veterans who have had a stroke.

Title: A BCI-enhanced H-reflex Operant Conditioning System

Authors: *S. DEVETZOGLOU TOLIOU[1,3], J. P. MCLINDEN[5], M. ADAMEK[1,6], J. A. BRANGACCIO[1], J. S. CARP[1], J. HILL[1], J. J. S. NORTON[1,3], Y. SHAHRIARI[5], J. R. WOLPAW[2,4];

Engin., Univ. of Rhode Island, West Kingston, RI; [6]Neurosci., Washington Univ. Sch. of Med., St. Louis, MO

Abstract: H-reflex operant conditioning (OC) can improve motor function following spinal cord injury (SCI) and potentially stroke and other neuromuscular disorders (*Thompson et al., J Neurosci, 2013*). Thompson et al. (2018) showed that, following brain-computer interface (BCI) training to control the amplitude of EEG mu (8-13Hz) or beta (15-30Hz) sensorimotor rhythm (SMR) activity, H-reflex size correlated with this amplitude.
Encouraged by this work, we are developing a BCI-enhanced H-reflex OC system. This system simultaneously records EMG and EEG. In standard H-reflex OC, the H-reflex is elicited when the participant maintains a predefined level of EMG activity for at least two sec. In the BCI-enhanced system, the H-reflex is elicited when the participant satisfies pre-defined criteria for both EMG and SMR levels.
Our BCI-enhanced H-reflex OC system combines BCI2000 (*Schalk et al. IEEE TBME, 2004*) and the Evoked Potential Operant Conditioning System (EPOCS). BCI2000 records EEG data and extracts SMR features (i.e., mu and beta amplitudes). The SMR features are transmitted to EPOCS through the BCI2000 AppConnector. EPOCS records and processes the EMG activity and provides feedback to the participant on both EMG and SMR levels.
As an initial test of the functionality of the combined system, we studied two participants. The Stratton VAMC IRB approved the study. We first trained (~8 sessions over 6 weeks) each participant to modulate SMR amplitude to select targets on a computer screen (*Wolpaw et al., Clin Neurophysiol, 1991*) with >70% accuracy (chance: 50%). We also completed two H-reflex screening sessions to identify optimal sites to stimulate and record the H-reflex of the flexor carpi radialis muscle. The participant then completed two H-reflex OC sessions. Each session comprised 100 standard H-reflex conditioning trials and 100 BCI-enhanced H-reflex conditioning trials (i.e., SMR above a criterion value).
The initial results: (1) show that the combined BCI2000/EPOCs OC system works smoothly online; and (2) suggest that SMR activity in the 1 sec before H-reflex elicitation is higher with the BCI-enhanced system. If additional data confirm these results, we will begin to assess whether the BCI-enhanced OC system can increase the rate, magnitude, and/or reliability of H-reflex operant conditioning, and can thereby increase the ability of this new rehabilitation

method to complement other therapies and augment recovery of useful function after stroke, spinal cord injury, or other neuromuscular disorders.

Title: Separating overlapping M-wave and H-reflex components of spinal evoked potentials

Authors: *D. GUPTA[1,2], J. S. CARP[1,3], J. BARNES[1,4], J. S. NORTON[1,2], J. HILL[1,2];
[1]Natl. Ctr. for Adaptive Neurotechnologies, Stratton VA Med. Ctr., Albany, NY; [2]Dept. of Electrical and Computer Engin., [3]Sch. of Publ. Hlth., Univ. at Albany, State Univ. of NY, Albany, NY; [4]Dept. of Physical Therapy, Univ. of Delaware, Newark, DE

Abstract: The Hoffmann reflex (HR) is the electrically induced analog of the spinal stretch reflex. It is an important tool to assess the modulation of spinal reflex activity, and it is useful for motor rehabilitation research in people with spinal cord injury. At low-intensity stimulation, efferent action potentials travel from the alpha motor neuron to the muscle (recorded as HR), and at higher intensities, they also travel directly to the muscle (recorded as M-wave (M)) and antidromically to the motor neuron, colliding with the HR. At supramaximal intensity, as M reaches M_{max}, the HR is largely cancelled. In distal muscles, such as the soleus (SO), this is typically reflected in recruitment curve measurements where the HR gradually increases with increasing stimulation intensity, and, then, decreases to a small percentage of M_{max} at supramaximal intensity. In more proximal muscles, such as the flexor carpi radialis (FCR), the M-wave substantially overlaps the HR at higher intensities, increasing the H measurements and distorting the curve. We hypothesize that mathematically separating these waves with a blind source separation algorithm-constrained independent component analysis (cICA), could eliminate M contamination of the HR at higher stimulation levels.
We use single-channel EMG from FCR (n=9) and SO (n=15), eliciting HR and M from stimulation of the median and the posterior tibial nerve, respectively. Data was collected with

informed consent; Stratton IRB approved this study. Responses were captured over a wide range of stimulation intensities, 4 trials/intensity, 5-s interstimulus interval. Epochs (0-60ms) were created relative to stimulation onset. Area under the curve was calculated for predefined M and H response windows, per stimulation intensity. These time-windows were marked manually, based on trials where these responses were least contaminated; the same trials were also used to construct the reference signals for the cICA. Two statistically independent components that matched the reference signal morphologies. They were projected back to the EMG signal space to obtain the de-contaminated trials. Contamination at high intensities is evident in raw FCR data, where H at M_{max} (as % of M_{max}) was 28.7$\pm$6.9 (mean+SD), compared to 8.3$\pm$4.1 for the less contaminated SO. cICA reduced it significantly for FCR to 9.6$\pm$7.6, $p < 0.01$ (Mann-Whitney U test), bringing it to a more typical range like the soleus. As expected, it did not reduce soleus H at M_{max} significantly (5.4$\pm$4, $p > 0.01$). M_{max}, and H and M responses at lower intensities remained largely unchanged. This preliminary analysis demonstrates the cICA based improvement in HR evaluation for proximal muscles.

Title: Noninvasive, multielectrode array-based platform for operant conditioning of soleus H-reflex

Authors: *M. MCKINNON[1], N. HILL[2,3], A. PREYER[1], M. GOEBEL[1], D. HOCHMAN[1], J. NORTON[2,3], J. CARP[2,4], J. WOLPAW[2,3,4], A. K. THOMPSON[5], I. CLEMENTS[1]; [1]BioCircuit Technologies, Atlanta, GA; [2]Natl. Ctr. for Adaptive Neurotechnologies, Albany Stratton VA Med. Ctr., Albany, NY; [3]Dept. of Electrical and Computer Engin., [4]Sch. of Publ. Hlth., Univ. at Albany, State Univ. of New York, Albany, NY; [5]Dept. of Hlth. Sci. and Research, Col. of Hlth. Professions, Med. Univ. of South Carolina, Charleston, SC

Abstract: Spinal cord injury can produce spasticity and impair locomotion; operant conditioning of the soleus H-reflex can reduce spasticity and improve locomotion. At present, this conditioning is highly specialized and technically challenging, hindering widespread dissemination of this powerful therapy. We are developing a clinically practical system for semi-automated H-reflex operant conditioning by leveraging the capabilities of transcutaneous multielectrode arrays for both stimulation and recording. At present, inter- and intra-subject variability makes automation of this therapy difficult. Here we explore how array-based processing techniques can reduce sources of extrinsic variability and thereby improve the robustness of automation.
Flexible, adhesive arrays of hydrogel electrodes enabled both targeted stimulation of the tibial nerve and high-density surface EMG recording of the resulting M- and H-waves at the soleus. We obtained soleus H-reflex/M-wave recruitment data from healthy volunteers of either sex. EMG signals were amplified and digitized with a custom 32-channel recording device that provides high quality, low-noise electrophysiological data. Custom software was used to visualize the processed data.
Multielectrode recording arrays cover a larger area of the soleus with higher spatial resolution compared to standard bipolar electrodes, providing a more comprehensive picture of soleus recruitment. A novel optimization algorithm uses this information to automatically correct electrode misplacement for a given person on subsequent days. A wavelet-based approach to automatically detect the H-reflex and reliably determine its amplitude was developed and tested on manually curated clinical datasets. This approach was validated on novel datasets and showed similar performance to expertly curated data. A separate multielectrode array designed for stimulation allows selective targeting of the tibial nerve while minimizing discomfort. Algorithms for automatically selecting the optimal stimulation parameters are in development. These experimental results suggest that this combination of multichannel stimulation and multielectrode recording in a single platform will serve clinicians who wish to perform operant conditioning therapy. Furthermore, this platform may be useful for clinicians and clinical researchers interested in targeted muscle stimulation and high-resolution EMG recording for additional applications beyond the soleus H-reflex conditioning.

Title: The excitability of soleus H-reflex pathway during standing in the paretic and non-paretic legs of people with hemiparesis due to stroke: initial studies.

Authors: *J. A. BRANGACCIO[1], A. M. PHIPPS[2], J. R. WOLPAW[1,3], A. K. THOMPSON[2]; [1]Natl. Ctr. for Adaptive Neurotechnologies, Stratton VA Med. Ctr., Albany, NY; [2]Dept. of Hlth. Sci. and Research, Col. of Hlth. Professions, Med. Univ. of South Carolina, Charleston, SC; [3]Sch. Pub. Hlth., St Univ. NY, Albany, NY

Abstract: Spasticity and spastic hyperreflexia are common in people after stroke. The role of spasticity in post-stroke gait disorders is uncertain. Neurophysiological studies often exam only the paretic side. However, unilateral measures alone are probably not sufficient for evaluating post-stroke movement disorders and impaired motor control. Thus, in this study, we measured the soleus H-reflex during standing in paretic and non-paretic legs of individuals with hemiparesis due to stroke, and in both legs of individuals with no known neurological conditions. The MUSC IRB approved this study. In 11 individuals with hemiparesis due to stroke and 7 individuals without stroke, soleus H-reflex/M-wave recruitment curves were measured bilaterally during standing. Soleus and TA EMG levels were recorded bilaterally and a stable soleus background EMG level was maintained throughout measurement (typically 5-18 μV) in the test leg. Tibial nerve stimulus intensity increased from just below H-reflex threshold to an intensity just above that needed to elicit the maximum M-wave (Mmax). Two-to-four responses were obtained at each intensity. In people after stroke, peak-to-peak maximum H-reflex (Hmax) in the paretic leg was (3.39± 1.78mV, 53% $\pm$ 19 %Mmax), significantly larger (p=.03 by paired t-test) than that in non-paretic leg (2.11± .83mV, 33% ± 15%Mmax). During the paretic leg H-reflex measurement, the contralateral (non-paretic) TA was more active than the paretic TA (p=.01 by paired t-test); whereas during the non-paretic H-reflex measurement, TA was similarly active in both the non-paretic and paretic legs (p=.63 by paired t-test). Among individuals without stroke, the side-to-side difference in H-reflex size averaged (10% ±11%Mmax); and TA activity was minimal in both legs. The results indicate that the standing H-reflex after stroke is larger on the paretic side than the non-paretic side. While maintaining moderate soleus activity during standing, those with stroke showed increased TA activity in both the paretic and non-paretic leg. These results suggest: 1) stroke is not a unilateral event, EMG during standing is altered in both legs; 2) a paretic TA (producing foot drop) may be activated in standing. Further studies are underway to better understand the neurophysiological mechanisms and functional impact of side-to-side differences in spinal reflexes post-stroke.

Title: The Effect of Postural Task on Lower-Limb Reflex Excitability

Authors: *O. DARICI, H. HODGSON, S. AJAO, T. BUTT, A. D. KUO, R. M. PETERS; Fac. of Kinesiology, Univ. of Calgary, Calgary, AB, Canada

Abstract: Reflex excitability is traditionally assessed as the muscle response to transient electrical nerve stimuli (Hoffman, or H-reflex). An alternative is Noisy Tendon Vibration (NTV), where the tendon is vibrated with a noisy signal to induce electromyography (EMG) responses, quantified by its correlation with stimulus. Excitability can thus be assessed continuously throughout a movement without inducing discrete perturbations. We sought to test whether NTV yields different postural excitability than H-reflex, which does not mechanically activate muscle spindle afferents that may be critical to actual reflexes. We measured NTV in three different postural conditions: quiet standing, standing while holding a support bar (to reduce lower limb proprioceptive input), and sitting. Previous H-reflex results show that holding a support bar diminishes responses compared to quiet standing, whereas sitting enhances responses. We applied NTV with a custom-developed vibrator, using white noise stimulus (bandwidth 0-100 Hz) to the right Achilles tendon of 5 healthy adult subjects, recording vibration motor acceleration as the input stimulus. Output was recorded as EMG from soleus, medial gastrocnemius, and tibialis anterior. Frequency- and time-domain correlation analysis (coherence and cumulant density, respectively) was performed between EMG and acceleration data (3 min per trial). Center of pressure (COP) trajectory was used to quantify posture variability. We found significant input-output correlation at 40-100 Hz for all conditions (coherence, p;<0.05), indicating the main frequency range of reflexes. Correlation was 90% smaller for sitting compared to standing (coherence, p;<0.05), and 52% smaller with support bar compared to standing (p;<0.05). Time domain (cumulant density plots) responses exhibited peaks at around 40 ms, indicating relatively short latency reflexes, regardless of the task. The

support bar condition yielded decreased anterior-posterior COP compared to standing (p;<0.05), suggesting less reliance on the ankle for balance, and thus lower coherence. NTV indicates reduced reflex excitability for sitting and holding the support bar, compared to standing. This could be due to presynaptic reflex inhibition and/or other competing inputs to the motor neuron pool. The ankle may rely less on spindle afferents when not actively maintaining balance. NTV can quantify reflexes continuously and may yield information complementary to H reflexes, with respective advantages yet to be tested thoroughly.

Title: The rat tail musculature as a hyper-redundant model for evaluating the role of muscle synergies, especially the co-contraction synergy

Authors: *C. L. CLELAND[1], A. C. KAHLE[2], L. HARRIS[2], E. DICKSON[2], A. PEROE[2], T. TOLLEY[2], L. JAGANNATHAN[2], A. ADAWI[2];
[2]Biol., [1]James Madison Univ., Harrisonburg, VA

Abstract: A central question in motor control is how the CNS overcomes the computational challenges of movement planning. Synergies have been proposed as one solution, which are effectively studied in hyper-redundant systems such as the octopus arm. We propose the rat tail as an ideal mammalian system to explore synergies, since the combination of external muscles and muscle fascicles (in the pelvis with long tendons extending into the tail), and the intrinsic muscles (within the tail), approach 300 in number, creating extensive muscular redundancy. The specific aim of our research is to use four complementary approaches - tail EMG, tendon lesions, movement reconstruction, and computer biomechanical simulation - to determine the spatial-temporal pattern of tail muscle activity during the NWR, with the broader goal of identifying and characterizing muscles synergies, especially the co-contraction synergy. For the four approaches; EMG: eight extrinsic and/or intrinsic rat tail muscles were selectively recorded during the heat-evoked tail NWR. LESION: Extrinsic tendons were sectioned so that the NWR could be compared before and after the lesions. RECONSTRUCTION: The behavioral NWR was first characterized by high speed video. Next, under anesthesia, individual tail muscle tendons were manually pulled and the tail movement video recorded. Finally, tail movement primitives were computationally combined to identify the potential pattern of muscle activity underlying the NWR movement. SIMULATION: A biomechanical model of the tail was developed in Simulink

to identify the torques sufficient to create movement that matched heat-evoked tail NWR behavior. In the extrinsic muscles, agonist activity as expected, preceded antagonist activity, but only slightly (10 ms), with the agonist and antagonist muscles co-activated over most of the movement. Non-negative matrix factorization suggested that nearly half of the EMG could be accounted for by a co-contraction synergy. In further support, lesions of all lateral extrinsic tendons resulted in movement in the opposite direction, into the stimulus. In contrast, the intrinsic muscles showed nearly simultaneous activity, consistent with predominant co-activation. Reconstruction and simulation studies suggest that small tail movements are accomplished by only a few tendons acting near the site of stimulation, while large movements require more extensive bilateral muscle activation. Together, our results suggest that movement of the tail during the NWR is dominated by a co-contraction synergy.

Title: Postural movements accompany the heat-evoked tail and limb nociceptive withdrawal response in unrestrained rats

Authors: *M. PAVLICHENKO, S. MAVI, M. PEGELOW, C. L. CLELAND;
Biol., James Madison Univ., Harrisonburg, VA

Abstract: The nociceptive withdrawal response (NWR) is commonly used to elucidate movement strategies employed by the CNS. NWR studies typically use animal restraint, most commonly a tube to study tail movement, or a box to study limb movement. However, it is possible that restraints change behavior in comparison to rats that roam freely, potentially by obscuring whole body movements associated with the NWR of the tail and foot. Furthermore, restraint in a tube could also change the NWR tail movement itself, leading to different latencies, magnitudes, and directions of response. Thus, our goal was to quantify differences in the heat evoked NWR in the tail and limbs of rats that were either "restrained" or "free range". Rats (n=15) were restrained in clear tubes or boxes, or allowed to roam freely over a 3'x3' glass table. Foot and tail NWRs were elicited by noxious heat stimuli (980 nm laser diode) delivered to the lateral aspect of the tail at five rostral-caudal locations, or the plantar surface of each of the four feet. Low speed (60 fps) video was recorded from below the rat, or high-speed video (650 fps) was recorded from above. Low speed video data was collected to quantify whole body movements in free range trials, while high speed data was collected specifically to compare

restrained and free range tail movements. Heat stimulation of the tail and foot in free range rats evoked NWRs that were accompanied by short latency (133 ms) whole body movements. These movements were either a 180° rotation or movement in the forward direction, with individual rats evoking consistent responses across trials and days. Comparing high speed video of the tail NWR in restrained and free range rats indicated no significant difference in latency, magnitude, or direction of response. Together, our results indicate that whole body movement consistently accompanied free range tail and foot NWRs evoked by heat stimuli, either as a 180° rotation or as movement forward. Other known movements that consistently accompany NWRs are the crossed extension reflex, head turn and front paw stepping, which suggest that the function of the NWR should be understood in the context of a broader constellation of responses. Interestingly, rats that turn 180° do so consistently across trials and days, while rats that move forward are also similarly consistent. Finally, quantification of the tail NWR in restrained and free range rats showed no significant differences in latency, magnitude, or direction, which validates the use of restraint in tail NWR studies.

Title: Chemogenetic activation of the medial preoptic area ameliorates deficits in maternal behavior in a rat model of postpartum depression

Authors: *A. ANDERSON[1], K. PIZARRO-COLON[2], M. PEREIRA[3];
[1]Neurosci. and Behavior Program, Univ. of Massachusetts, Amherst, Amherst, MA; [2]UNIVERSITY OF MASSACHUSETTS, AMHERST, AMHERST, MA; [3]Dept. of Psychological and Brain Sci., Univ. of Massachusetts Amherst, Amherst, MA

Abstract: Maternal behavior that is sensitive to the needs of young is essential for the healthy development and wellbeing of all mammals. Mothers who experience postpartum depression often exhibit deficits in maternal behavior. Our prior research suggests that the medial preoptic area (mPOA), a brain region critical for maternal behavior, plays a significant role in coupling appropriate caregiving with the needs of the young. The goal of the present study is to examine whether hypofunction of the maternal mPOA underlies depression-related parenting disturbances in new mothers. To accomplish this goal, we used the Wistar-Kyoto (WKY) rat model of depression and excitatory Gq-DREADD (Gq-coupled designer receptors exclusively activated by

designer drugs) to activate the mPOA of WKY mothers during interaction with pups. WKY mother rats display a depression-like phenotype, including deficient maternal behavior, relative to control Sprague-Dawley (SD) rats, reminiscent of those in human mothers with postpartum depression. Elevating the activity of the mPOA ameliorated deficits in maternal behavior of WKY mothers compared to vehicle-treated WKYs, to levels characteristic of control SD mothers. Other behaviors, including general exploration, self-grooming, and eating or drinking, were not affected by chemogenetic activation of the mPOA. Together, our results suggest that the mPOA plays a key role in coupling sensitive caregiving behaviors to resolve the needs of the young.

Title: Alterations in corticotropin-releasing factor receptor type 1 in the preoptic area and hypothalamus in mice during the postpartum period

Authors: *D. G. ZULOAGA[1], R. M. DE GUZMAN[1], Z. J. ROSINGER[1], K. E. PARRA[1], N. J. JUSTICE[2], J. JACOBSKIND[1];
[1]Psychology, Univ. at Albany, Albany, NY; [2]Metabolic and Degenerative Dis., Univ. of Texas, Houston, Houston, TX

Abstract: Corticotropin-releasing factor (CRF) signaling through CRF receptor 1 (CRFR1) regulates autonomic, endocrine, and behavioral responses to stress, as well as behavioral changes during the maternal period. Previous work in our lab reported higher levels of CRFR1 in female compared to male mice within the rostral anteroventral periventricular nucleus (AVPV/PeN), a brain region involved in maternal behaviors. In this study, we used CRFR1-GFP reporter mice to investigate whether the reproductive status (postpartum vs. nulliparous) of acutely stressed females affects levels of CRFR1 in the AVPV/PeN and other regions involved in maternal functions. Compared to nulliparous, postpartum day 14 females showed increased AVPV/PeN CRFR1-GFP immunoreactivity and an elevated number of restraint stress-activated AVPV/PeN CRFR1 cells as assessed by immunohistochemical co-localization of CRFR1-GFP and phosphorylated CREB (pCREB). The medial preoptic area (MPOA) and paraventricular hypothalamus (PVN) of postpartum mice showed modest decreases in CRFR1-GFP

immunoreactivity, while increased CRFR1-GFP/pCREB co-expressing cells were found in the PVN following restraint stress relative to nulliparous mice. Tyrosine hydroxylase (TH) and CRFR1-GFP co-localization was also assessed in the AVPV/PeN and other regions and revealed a decrease in co-localized neurons in the AVPV/PeN and ventral tegmental area of postpartum mice. Corticosterone analysis of restrained mice revealed blunted peak, but elevated recovery, levels in postpartum compared to nulliparous mice. Finally, we investigated projection patterns of AVPV/PeN CRFR1 neurons using female CRFR1-Cre mice and revealed dense efferent projections to several preoptic, hypothalamic, and hindbrain regions known to control stress-associated and maternal functions. Together, these findings contribute to our understanding of the neurobiology that might underlie changes in stress-related functions during the postpartum period.

Abstract: The postpartum period is characterized in part by a hypoactive stress response. This persistent state of resilience that mothers experience is adaptive in helping to maintain maternal care in the face of stressors and can likely be accounted for by changes in the hypothalamic-pituitary-adrenal (HPA) axis after parturition. In particular, using two transgenic mouse lines (CRFR1-GFP and CRFR1-Cre-tdTom), we found that corticotropin-releasing factor receptor 1 (CRFR1) uniquely appears in oxytocin neurons in the PVN and SON in postpartum mice. Male mice and reproductively naïve female mice do not possess this co-localization of CRFR1 and oxytocin neurons, and CRFR1 itself is entirely absent from the SON of nulliparous females. Furthermore, no co-localization of CRFR1 with PVN vasopressin neurons were found in any

mice. CRFR1/OT co-localization increases gradually in the PVN and SON throughout the postpartum period and peaks around postpartum day (PD) 21, and persists until at least PD 28. Using c-Fos immunohistochemistry, we were able to determine that these CRFR1/OT neurons are activated by acute restraint stress, indicating that these neurons might be contributing to the difference in stress response observed in postpartum mice as measured through lower CORT concentrations in postpartum relative to nulliparous mice following the stressor. To further illustrate the functional implications of this co-expression of CRFR1 in oxytocin neurons, we used in vitro electrophysiology in magnocellular PVN neurons to detect an increase in firing rate in presumed oxytocin neurons in response to CRF bath application to the region. This research provides insights into a potentially adaptive mechanism that occurs in postpartum females which might serve to increase stress resilience and facilitate maternal behavior under conditions of stress. The functional role of this neuroadaptation will be tested in future experiments.

Title: Female reproduction affects CRF receptor expression in the midbrain dorsal raphe

Authors: *T. A. MEINHARDT[1], Z. A. GRIEB[2], J. S. LONSTEIN[1,2];
[1]Behavioral Neurosci. Program, Dept. of Psychology, [2]Neurosci. Program, Michigan State Univ., East Lansing, MI

Abstract: The transition to motherhood involves neurobiological changes that allow for the display of caregiving behaviors. In both women and laboratory rodents, two hallmarks of motherhood that facilitate caregiving are reduced anxiety and stress responsiveness. This is partially controlled by the neuropeptide, CRF, acting in many brain sites. In male rodents, CRF influences affective behaviors and stress responsiveness by influencing serotonin originating in the midbrain dorsal raphe (DR). Previous work from our lab has shown that DR serotonergic output is essential for female postpartum affective and caregiving behaviors. To uncover the neuromechanisms of the reduced anxiety and stress responsiveness seen in the postpartum period, the current study aimed to quantify CRF receptor (CRFR) expression within the female rat DR across reproduction. In Experiment 1, levels of CRFR1 and CRFR2 mRNA within the

DR of virgin, mid-pregnant, recently parturient, and postpartum day 7 females were assessed using qPCR. More CRFR2 mRNA was found in the recently parturient and postpartum day 7 females compared to virgins, while less CRFR1 mRNA was found in recently parturient females compared to virgins. Experiment 2 using dual-label fluorescent *in situ* hybridization (RNAscope, ACDBio) is determining if this CRFR2 increase and CRFR1 decrease occurs on serotonin and/or GABA neurons. Colocalization of CRFR1 and CRFR2 with GAD_{65} and TPH2 in all 5 subregions of the DR is being assessed within these same groups. Virgin males are included to identify possible sex differences. These results will further uncover the CRFR-related mechanisms driving the reduction in postpartum anxiety and stress responsiveness. They also have implications for when this change does not occur, such as in cases of postpartum depression and/or anxiety, which affects 15-20% of peripartum women worldwide. Further understanding of the neurochemical mechanisms driving postpartum affective behaviors will inform the generation of new treatments for these disorders, and improve the lives of millions of women and their children.

Title: Altered early postpartum period activity of estradiol, progesterone, and oxytocin is associated with the severity of depression-related maternal behavior deficits in Wistar-Kyoto rats

Authors: *S. B. WINOKUR, K. PIZARRO-COLON, P. MUDDASANI, K. TAKINAMI, O. YILDIRIM, V. LEE, N. SORIAL, M. PEREIRA;
Psychological and Brain Sci., Univ. of Massachusetts Amherst, Amherst, MA

Abstract: Maternal caregiving behaviors in the early postpartum period are at a deficit in mothers who experience depression during the postpartum period. The risk of developing maternal behavior dysfunction associated with postpartum depression (PPD) has previously been linked with altered gestational levels of estradiol and progesterone, as well as decreased medial preoptic area (mPOA) oxytocinergic activity in the early postpartum period. It is currently unclear whether estradiol and progesterone signaling actively contribute to ongoing depression-

related maternal behavior deficits. Estradiol, via the estradiol receptor alpha (ERα), stimulates the release of oxytocin from the hypothalamus. Thus, disrupted early postpartum estradiol activity could actively disrupt oxytocinergic synthesis and action, leading to depression-related maternal behavior deficits. Considering that PPD is a highly prevalent disorder that impacts maternal health and well-being as well as child socio-emotional development, determining the role of postpartum estradiol, progesterone, and oxytocin in ongoing maternal behavior is critical to bettering diagnostic measures and treatments for depression-related disturbances in parenting. The goal of the current study was to investigate the association between maternal behavior and estradiol, progesterone, and oxytocin signaling. To this aim, we used Wistar-Kyoto (WKY) rats, who display a depression-like phenotype and deficient maternal caregiving behaviors relative to control Sprague-Dawley (SD) rats, which recapitulates many features of depression in human mothers. Estradiol and progesterone serum concentrations were measured in early postpartum SD and WKY mothers via ELISAs, ERα and oxytocin receptor levels were evaluated via qPCR, and ERα, oxytocin, and cFOS expression was measured via immunohistochemistry (IHC) in the maternal mPOA. Together, our data suggest that increased estradiol and progesterone activity in the mPOA mediates the severity of depression-related maternal behavior deficits. Ongoing analyses aim to evaluate this process in other maternal mesocorticolimbic brain regions to begin piecing together a functional circuit that underlies depression-related maternal behavior deficits.

Title: The impact of chronic stress on perifornical urocortin-3 neurons in virgin and lactating female parenting

Authors: *B. ABDELMESIH, R. ANDERSON, A. AUTRY;
Albert Einstein Col. of Med., Bronx, NY

Abstract: Parenting is a set of behaviors aimed at providing protection and care for young during early development and in some species, including mammals, is necessary for survival. Infant directed behaviors are complex, sexually dimorphic behaviors governed by neural circuits that are still poorly understood. Although laboratory female mice are typically parental towards infants, stress can lead to adverse behaviors such as infant neglect or even attack. Chronic stress

has been shown to be a prominent risk factor in developing postpartum mood disorders but its impact on genetically defined neural populations relevant to parenting is not well understood. Recently, our lab uncovered a genetically defined population of neurons that lead to negative infant-directed behaviors, urocortin-3 neurons in the perifornical area of the hypothalamus ($PeFA^{ucn3}$). When these neurons are inhibited in virgin females using a pharmacogenetic method (designer receptors exclusively activated by designer drugs [DREADD]), females retrieved pups to the nest faster. We then sought to interrogate the effects of chronic stress on parenting behavior and the activation levels of $PeFA^{ucn3}$ in both virgin and lactating females. Using two different models of chronic stress, we observed differences in how chronic stress affects both parental behaviors and $PeFA^{ucn3}$ activation between virgin and lactating females. We then successfully used inhibitory DREADDs on $PeFA^{ucn3}$ to ameliorate stress-induced deficits in parenting. Our findings help elucidate how chronic stress impacts a key neural population involved in parenting and suggest that activation levels are altered to protect against the adverse effects of stress in motherhood.

Title: Effects of cannabis use during pregnancy on maternal care and anxiety-like behavior in rats

Authors: *A. M. BROWN[1], A. N. MALENA[1], H. V. WEIMAR[1], H. R. WRIGHT[1], D. E. GINDER[2], R. J. MCLAUGHLIN[1,2];
[1]Integrative Physiol. & Neurosci. Dept., [2]Psychology Dept., Washington State Univ., Pullman, WA

Abstract: The use of cannabis during pregnancy is a growing public health concern. Unfortunately, as the cannabis industry has been rapidly expanding, research on the effects of cannabis use during pregnancy remains limited and the effects of maternal cannabis use on both the mother and offspring are still largely unknown. Human studies indicate that women who use cannabis during pregnancy are more likely to experience post-partum symptoms of depression, but a causal relationship has not yet been systematically investigated. To address this gap in knowledge, we implemented a novel model of cannabis vapor self-administration in pregnant rat

dams to examine the extent to which maternal cannabis use affects maternal care and anxiety-like behavior during the post-partum period. Female Sprague Dawley rats were trained to self-administer either d^9 tetrahydrocannabinol (THC)-dominant cannabis vapor (69.9% THC; 150 mg/mL) or vehicle vapor on a fixed-ratio-1 schedule during one-hour sessions twice daily throughout mating and gestation. Maternal care behavior was video monitored during the first postnatal week and analyzed using pose estimation and machine learning approaches. After weaning, dams were subjected to a battery of behavioral assays designed to measure stress coping and anxiety-like behaviors, and plasma concentrations of circulating corticosterone were measured following acute swim stress to determine whether there are long-term changes in behavioral and neuroendocrine stress reactivity following maternal cannabis use. Results indicate that cannabis self-administering dams showed greater discrimination for the vapor-associated operandum and received significantly more vapor deliveries than VEH self-administering dams. Preliminary data indicate no significant difference in elevated plus maze behavior in cannabis-exposed dams relative to vehicle-exposed dams. Other endpoints are currently being analyzed, but we hypothesize that maternal cannabis use will decrease the frequency of maternal care events and the time spent engaging in pup-directed behavior. Additionally, we predict that maternal cannabis use will increase time spent immobile in the forced swim test and augment swim stress-induced corticosterone secretion compared to dams that had self-administered vehicle vapor. Ultimately, we hope that adopting this approach will generate more translationally relevant preclinical data that can be used to inform pregnant mothers of potential effects of consuming cannabis on their postpartum mental health, as well as the potential effects in their offspring.

Title: Comparing the impact of morphine and buprenorphine on maternal care and behavior in a translational rodent model of opioid exposure during pregnancy

Authors: C. M. WALLIN, S. R. NEOLE, L. M. RICHARDSON, N. KULAGLIC, A. M. MYERS, S. E. BOWEN, *S. BRUMMELTE;
Psychology, Wayne State Univ., Detroit, MI

Abstract: The opioid epidemic has resulted in many opioid-dependent pregnant women being pharmacologically treated with opioid maintenance therapies (e.g., buprenorphine or methadone) to combat the negative effects of misused opioids on the mother and developing offspring. Clinically, buprenorphine produces preferable outcomes for exposed infants compared to methadone or misused opioids. However, the behavioral and neurological effects of buprenorphine on the maternal brain and maternal caregiving behaviors are not well understood. Given differences in buprenorphine's mechanism of action (partial mu-agonist, kappa antagonist) and that of morphine (full mu-agonist), exposure to these drugs during pregnancy may have distinct effects on neurological networks critical in the transition to motherhood. We implemented a translational rodent model to mimic chronic opioid (mis)use (morphine exposure, 2-6mg/kg/day s.c.) or maintenance opioid drug use (buprenorphine exposure, 1mg/kg/day s.c.) to investigate the behavioral and neurochemical consequences of gestational opioid exposure on dams and their offspring. Female rats (N=50) were mated with drug naive males (N=10) in house. Opioid or saline administration to females began prior to pregnancy and was either continued until postpartum day 2 or discontinued shortly before parturition on gestational day 19. Dams were evaluated for maternal behaviors through meticulous observations of licking and grooming, nursing, avoidance, nesting behaviors and other pup directed or non-pup directed behaviors. Further, dams were challenged using several behavioral tests including a pup retrieval test (motivation assessment), a cricket hunting task (behavioral selection assessment), and a two-chamber preference test (assessment of preference for pup odor). Our preliminary findings indicate that both continued and discontinued buprenorphine exposure resulted in more maternal care deficits and pup avoidance, increased postpartum pup mortality, and maternal deficiencies in both the pup retrieval task and hunting task, as compared to dams in our saline-control group. On the other hand, both continued and discontinued morphine exposure seemed to result in fewer deficits in maternal behavior as compared to buprenorphine. Future analyses will evaluate the brains collected from opioid-exposed dams on postpartum day 2 for neurological changes. More research is essential to understand how buprenorphine interacts with the maternal brain network during the transition to motherhood to help avoid possible negative consequences on maternal care, the maternal brain and compounded effects on opioid-exposed offspring.

Title: A translational rodent model of gestational buprenorphine or morphine exposure: offspring outcomes

Authors: *A. M. MYERS, N. KULAGLIC, S. R. NEOLE, L. M. RICHARDSON, C. M. WALLIN, S. E. BOWEN, S. BRUMMELTE;
Dept. of Psychology, Wayne State Univ., Detroit, MI

Abstract: The recent opioid epidemic and escalation of opioid use during pregnancy have resulted in a drastic increase in gestational exposure to opioids. Opioid-dependent women are typically given opioid maintenance therapies (i.e., buprenorphine or methadone) to mitigate harmful effects on the fetus. However, the consequences of exposure to synthetic opioids such as buprenorphine during gestation on fetal outcome and brain development are poorly understood. Our translational rodent model aims to characterize neonatal mortality and morbidity after continued or discontinued gestational opioid exposure. Female rats received either morphine (2-6mg/kg twice daily, s.c.; to mimic opioid use disorder) or buprenorphine (1mg/kg s.c.; to mimic opioid maintenance therapy) from preconception until late gestation ('discontinued' on gestational day (GD) 19, mimicking withdrawal before parturition) or until postnatal day 2 ('continued'). Pups were either sacrificed on postnatal day 2 or fostered to a naïve foster dam and allowed to reach young adulthood for behavioral testing. Buprenorphine resulted in higher pup mortality, reduced body weight, and increased neonatal withdrawal symptoms compared to controls and morphine-exposed pups. Somewhat surprisingly, discontinuation of buprenorphine on GD 19 did not appear to rescue these effects. Preliminary behavioral data from young adult offspring suggest that gestational opioid exposure did not result in changes to anxiety-like behavior (elevated zero maze) or pain sensitivity (hot-plate test). This suggests that fostering opioid-exposed offspring may potentially rescue or protect them from negative effects of gestational opioid exposure or opioid-induced changes in maternal care. Offspring brains collected at postnatal day 2 will be analyzed to determine the effects of gestational opioid exposure on brain-derived neurotrophic factor (BDNF) concentration in the hippocampus and prefrontal cortex as a measure of neurodevelopment. More research is needed to understand how buprenorphine affects pregnancy outcomes and subsequent offspring well-being in order to avoid negative consequences in human mothers undergoing opioid maintenance treatment.

Title: Sex, aggression and parental care: The neural and transcriptomic underpinnings of context dependent behavior

Authors: *R. DEANGELIS[1], M. BALLARD[1], H. A. HOFMANN[2];
[2]Integrative Biol., [1]Univ. of Texas, Austin, TX

Abstract: Social behavior is inherently complex as individuals must integrate dynamic environmental cues within their current social context to display adaptive behavior. Pair bonding and parental care each comprise suites of behavioral displays with the motivational state of either promoting reproductive opportunities or increasing offspring survival. Here, we ask whether behaviors with shared motivational states (e.g., offspring care vs. offspring defense) share similar neural activity patterns and single-cell transcriptomes in dopaminergic reward regions of the brain. Conversely, neural substrates underlying behaviors similar in display (e.g., offspring defense vs. mate defense), but with distinct motivational states, may share cellular and transcriptomic similarity in brain areas sensitive to environmental information. The monogamous convict cichlid (*Amatitlania nigrofasciata*) is an ideal model system, as males and females readily form pair bonds, which they reinforce through affiliative displays, while also aggressively guarding mates against conspecific rivals. Additionally, both sexes jointly provision their offspring and vigorously defend them against predators. Hence, both pair bonding and parental care contain stereotypical elements of aggression and affiliation. Using immunohistochemical detection of the phospho-S6 ribosomal protein (pS6), we first identified patterns of neural activity throughout the vertebrate Social Decision-Making Network (SDMN) and the activity of dopaminergic, oxytocin, and vasopressin neurons in key nodes of the SDMN. We then used single nuclei RNA sequencing (snRNA-seq) of the preoptic area to identify (i) cell types (ii) the transcriptional response of behaviorally active cells and (iii) gene co-expression modules associated with either distinct motivational states and/or behavioral displays. The integration of both brain wide patterns of neural activity, the distribution and activation of oxytocin, vasopressin, and dopamine neurons, as well as the transcriptional response of POA cells will broaden our understanding of how context-dependent social behavior is coordinated within the brain.

Title: Fetal and neonatal iron deficiency disrupts inner retinal vasculature development

Authors: N. C. A. R. RIBEIRO[1], C. LEWIS[2], B. K. HANSON[3], C. A. SERFATY[1], *G. W. ANDERSON[3];
[1]Univ. Federal Fluminense, Niterói, Brazil; [2]Univ. of Minnesota Duluth, Duluth, MN; [3]Univ. of Minnesota, Duluth, MN

Abstract: The retina is the most metabolically active tissue in the body. To meet this high metabolic demand, this tissue has two vascular systems: one external (the choroidal vasculature) and one internal (the inner retina vasculature). Iron (Fe) is required for oxygen transport and is also involved in several enzymatic and metabolic reactions in the retina. Fe deficiency (FeD) is associated with delayed latencies on visual evoked potentials in children. In this work, we evaluated how FeD during the fetal and neonatal period affects retinal development. Sprague-Dawley pregnant rats were fed an Fe-deficient diet on embryonic day 2 (E2). Control (CT) dams were fed an Fe-sufficient diet and both groups drank deionized water. Tissues were harvested from rat pups on postnatal days (P) 7, 14 and 21. FeD significantly lowered blood hemoglobin levels in FeD compared to control pups at P7 (FeD 80.37 mg/ml ± 4.3 n:12; CT 131.3 mg/ml ± 6.0 n:14 $p< 0.05$) and at P14 (FeD 67.18 mg/ml ± 2.7 n:18; CT 119.1 mg/ml ±5.1 n:17 $p<0.05$). RNA sequencing (RNA-seq) was performed on harvested P14 retinal tissue (6 CT and 6 FeD) to investigate FeD impact on the transcriptome. We identified 26 differentially expressed genes including *Lgr1, CxCL12, Apln, Adgr6, Flt1, PFKB3, Adgrf5 and Lats2* (angiogenesis and vasculogenesis associated genes), *Vwf* and *Nrgn* (endothelial cell associated genes), and *C1qa,* a gene expressed in retinal microglial cells and involved in retinal angiogenesis and retinal degeneration. We further analyzed the impact of FeD on blood vessel formation in the developing retina through immunohistochemical approaches. We found increased arterial branch points/mm vessel length in the superficial layer of vessels in FeD at P7 (FeD 39 branch points ± 1.5 n:6; CT 30.4 branch points ± 2.5 n:5 $p<0.05$) and P14 (FeD 25.6 branch points ± 2.3 n: 7; CT 33.7 branch points ± 1.8 n:6 $p<0.05$) demonstrating increased retinal vascular density in FeD. The arteriole width also increased in FeD (FeD 39.7 micrometers ± 1.2 n:8; CT 30.3 micrometers ± 1.0 n:8 $p<0.05$) at P14. Confocal Z-stack images showed an increase in the number of microglia cells in the deep layer of blood vessels (FeD 15.6 cells/area ± 0.1 n:5; CT 11 cells/area ± 1.3 n:6 $p<0.05$) at P14. These results show that developmental FeD impacts retinal blood vessel formation. These impacts are likely driven through responses to tissue hypoxia and may contribute to perturbation in visual function.

Title: Notch3 directs differentiation of brain mural cells from human pluripotent stem cell-derived neural crest

Authors: *B. D. GASTFRIEND[1], M. E. SNYDER[1], R. DANEMAN[3], S. P. PALECEK[1], E. V. SHUSTA[2];
[1]Dept. of Chem. and Biol. Engin., [2]Dept. of Chem. and Biol. Engin. and Dept. of Neurolog. Surgery, Univ. of Wisconsin-Madison, Madison, WI; [3]Departments of Neurosciences and Pharmacol., UCSD, La Jolla, CA

Abstract: Objective and rationale: Brain pericytes and vascular smooth muscle cells, collectively termed mural cells, regulate development and function of the blood-brain barrier (BBB) and control brain blood flow. Unlike the mesoderm-derived mural cells of other organs, forebrain mural cells are derived from the neural crest. Molecular signals controlling this differentiation process are poorly understood, with loss of function experiments suggesting roles for TGF-β, PDGF, and Notch signaling. Furthermore, existing *in vitro* models of human brain mural cells derived both from primary cultures and human pluripotent stem cells (hPSCs) have markedly reduced expression of key mural cell genes, including *NOTCH3,* compared to *in vivo* samples, and require serum-supplemented culture media. Thus, we sought to determine whether activation of Notch3 in hPSC-derived neural crest could direct the differentiation of brain mural cells with an improved transcriptional profile. **Methods and results:** We generated a bicistronic lentiviral vector encoding the human Notch3 intracellular domain and green fluorescent protein (N3ICD-GFP). We transduced p75-NGFR$^+$ HNK-1$^+$ neural crest cells derived from hPSCs with N3ICD-GFP lentivirus or GFP-only lentivirus in serum-free E6 medium. Compared to GFP-transduced neural crest, N3ICD-GFP-transduced cells exhibited upregulated expression of the mural cell transcripts *PDGFRB, RGS5*, *FOXS1*, *TBX2*, and *HEYL*. In contrast, transduction of TBX2-GFP did not produce such an effect. In N3ICD-GFP-transduced cells, we observed increased protein-level expression of PDGFRβ and both full-length and cleaved Notch3. We additionally evaluated the ability of the resulting cells to self-assemble with endothelial cells (ECs) in a cord-formation assay and to induce BBB properties in ECs. **Conclusions:** Our data suggest that activation of Notch3 signaling is sufficient to direct differentiation of neural crest to brain mural cells, and that multiple brain mural cell-associated transcription factors are downstream of Notch3 signaling. We also establish a new, serum-free differentiation protocol for generation of hPSC-derived brain mural cells for downstream *in vitro* modeling applications.

Title: Anatomical organization of the rat subfornical organ

Authors: *A.-I. HICKS[1], S. KOBRINSKY[2], S. ZHOU[1], J. YANG[3], M. PRAGER-KHOUTORSKY[4];
[1]Physiol., [2]Pharmacol., McGill Univ., Montreal, QC, Canada; [3]Physiol., McGill Univ., McGill University, QC, Canada; [4]Ctr. for Res. in Neurosci., McGill Univ., Montreal, QC, Canada

Abstract: The subfornical organ (SFO) is a sensory circumventricular organ located along the anterodorsal wall of the third ventricle. SFO lacks a complete blood-brain barrier (BBB), and thus peripherally-circulating factors can penetrate the SFO parenchyma. These signals are detected by local neurons providing the brain with information from the periphery to mediate central responses to humoral signals and physiological stressors. Circumventricular organs are characterized by the presence of unique populations of non-neuronal cells, such as tanycytes and fenestrated endothelium. However, how these populations are organized within the SFO is not well understood. In this study, we used histological techniques to analyze the anatomical organization of the rat SFO and examined the distribution of neurons, fenestrated and non-fenestrated vasculature, tanycytes, ependymocytes, glia cells, and pericytes within its confines. Our data show that the shell of SFO contains non-fenestrated vasculature, while fenestrated capillaries are restricted to the medial-posterior core region of the SFO and associated with a higher BBB permeability. In contrast to non-fenestrated vessels, fenestrated capillaries are encased in a scaffold created by pericytes and embedded in a network of tanycytic processes. Analysis of c-Fos expression following systemic injections of angiotensin II or hypertonic NaCl reveals distinct neuronal populations responding to these stimuli. Hypertonic NaCl activates ~13% of SFO neurons located in the shell. Angiotensin II-sensitive neurons represent ~31% of SFO neurons and their location varies between sexes. Our study provides a comprehensive description of the organization of diverse cellular elements within the SFO, facilitating future investigations in this important brain area.

Title: Regional Heterogeneity and Vulnerability of Pericyte Populations in the Mouse Brain During Normal and Pathological Aging

Authors: *H. BENNETT[1], Y.-T. WU[2], Y. KIM[3];
[1]Penn State Col. of Med., Middletown, PA; [2]Penn State Collage of Med., Harrisburg, PA; [3]Col. of Medicine, Penn State Univ., Hershey, PA

Abstract: Aging is often complicated and accelerated by vascular and neurodegenerative diseases, such as Alzheimer's disease (AD). Increasing evidence indicates that vascular pathology, such as pericyte loss, precedes neuronal degeneration, and contributes to the aging progression and severity of AD. Specifically, recent studies have implicated pericyte dysfunction in both normal aging and neurodegenerative diseases. Pericytes are a mural cell type that primarily encapsulate the microvasculature, playing a critical role to maintain the integrity of the blood brain barrier. Despite this significance, questions remain as to whether there is loss of pericytes in normal aging and how this relates to the role of pericytes in AD. Here, we sought to study how pericyte populations across the whole mouse brain are impacted by aging as well as β-amyloid (Aβ) accumulation, since this is implicated in AD. We used transgenic reporter mice (PDGFRβ-Cre crossed with Ai14 mice) to label vascular mural cells, including pericytes, and compared 2-month-old adult mice with aged 18-month-old mice. We further crossed PDGFRβ-Ai14 mice with the 5xFAD model of Familial AD, as a model of aggressive and accelerated Aβ accumulation, to study how this insult may affect pericyte populations in the brain. These mice were studied at the symptomatic stage for this mouse model, which is at 8 months of age. We used serial two-photon tomography to image the entire mouse brain at cellular resolution and developed computational pipelines to selectively detect and map the distribution of capillary pericytes in a reference brain. Interestingly, we found that normal aging is associated with reduced pericyte density in regions of the basal forebrain at 18 months, particularly the magnocellular nucleus, which is often implicated in AD, as well as layer 6 across regions of the isocortex. Moreover, we identified that accumulation of Aβ in the 5xFAD model reduced pericyte density in several sensory regions of the thalamus and brainstem, as well as the retrosplenial cortex. Our data suggests that normal aging and aging in the setting of Aβ accumulation confer differing vulnerabilities of pericyte populations in multiple regions of the mouse brain.

Title: Dim light at night exposure alters hippocampal vascular structure

Authors: J. R. BUMGARNER[1], W. H. WALKER II[1], O. H. MELÉNDEZ-FERNÁNDEZ[1], J. A. LIU[1], J. C. WALTON[1], A. C. DEVRIES[2], ***R. J. NELSON**[1];

Abstract: Artificial light at night (LAN) is a pervasive facet of modern life. Because circadian rhythms rely on consistently timed environmental cues to maintain internal and external synchrony, the ubiquity of LAN poses a serious challenge to health. LAN exposure leads to numerous negative physiological consequences, including impaired metabolic, endocrine, and immune function. LAN also increases the risk for diseases such as obesity, cancer, and cardiovascular disorders. Previous research has demonstrated that as few as 3-4 nights of LAN exposure can induce depressive-like responses, as well as alter cytokine and neurotrophic transcript expression in the hippocampus of rodents. Acute exposure to LAN also alters hippocampal expression of angiogenic signaling transcripts. Given the circadian regulation of the cardiovascular system, the consequences of LAN exposure on the structure of hippocampal vasculature were examined by exposing female and male CFW mice to 4-nights of LAN. We hypothesized that LAN exposure impairs the structural organization of the cerebrovasculature. Using corrosion casting and μCT imaging, whole mouse brain 3D vasculature datasets were generated, and the CA1, CA3, and dentate gyrus of the hippocampi were segmented. LAN was observed to reduce hippocampal vascular volume and alter the distribution of small-diameter vessels in both the CA1 and CA3. These results indicate that circadian rhythm disruption can impair the structural organization of cerebrovasculature, highlighting the need to reduce LAN in clinical and other contexts.

Title: Modulation of iron release by endothelial cells by transferrin at the blood-brain barrier

Authors: *S. BARINGER, E. NEELY, K. PALSA, I. A. SIMPSON, J. R. CONNOR;
Penn State Col. of Med., Hershey, PA

Abstract: While iron plays an important role in many bodily functions, it is especially crucial to the highly metabolically active brain, acting as both an electron donor and acceptor in cellular metabolism. As such, maintaining a proper balance of brain iron levels is vital to cellular function. Excessive amounts of brain iron can lead to neurodegenerative diseases and inadequate amounts can lead to cognitive impairment and Restless Legs Syndrome. Regulation of iron uptake into the brain is required, however the mechanism of such regulation is largely unknown. Our lab has previously shown that brain iron uptake is mediated at the level of the endothelial cells (ECs) of the blood-brain barrier (BBB) and regulation is modulated by apo (iron poor) and holo (iron rich) transferrin (Tf) in the cerebrospinal fluid (CSF). **Here we aimed to address the mechanism by which apo- and holo-Tf control iron release from ECs.** Mini osmotic pumps were implanted into mice with a catheter inserted into the lateral ventricle. A steady-state infusion of sham (nothing), artificial CSF, 1 mg/ml of apo-Tf, or 1 mg/ml of holo-Tf occurred for 48 hours at which time the mice were injected intraperitoneally with radioactive ^{55}Fe-Tf or ^{55}Fe-H-ferritin (Fth1). After 24 hours, brains were collected and fractionated into microvessels and rest of whole brain. We found 1) infusion of apo-Tf increased ^{55}Fe-Tf uptake by 42% ($p<0.05$) and release into the brain by 40% ($p<0.05$) while holo-Tf did not, 2) there was a sex difference in the regulation of ^{55}Fe-Tf uptake, and 3) infusions did not have an effect of ^{55}Fe-Fth1 uptake. To investigate the mechanism of Tf's regulation on iron release from ECs, we employed human induced pluripotent stem (hiPSC)-derived ECs. ECs were loaded with ^{55}Fe on Transwell bi-chamber plates, and concentrations of apo- or holo-Tf ranging from 0.01 to 100 uM were placed in the basal chamber. By determining iron release from ECs at hourly intervals, the Km of apo-Tf iron release and Ki of holo-Tf iron release were calculated. In separate experiments, $FeCl_3$ loaded ECs were incubated with apo- or holo-Tf concentrations in the basal chamber. After 8 and 24 hours of incubation, the cells were collected and lysates were used in western blotting to probe for key iron regulatory protein expressions. We found that 0.1 uM holo-Tf decreased ferroportin (Fpn) expression by 50% ($p<0.05$). Collectively, these results demonstrate that apo- and holo-Tf modulate iron release from ECs through interactions with Fpn. These data establish the mechanism for regulation of iron uptake into the brain, demonstrate a sex-specific regulatory mechanism, and suggest the mechanism for regional regulation of brain iron uptake.

Title: Cadasil pathology in a pericyte-specific inducible cre mouse

Authors: *A. M. NIKOLAKOPOULOU, Z. ZHAO, A. CHAKHOYAN, X. HE, B. V. ZLOKOVIC;
Physiol. and Neurosci., USC, Los Angeles, CA

Abstract: Cerebral autosomal dominant arteriopathy with subcortical infarcts and leukoencephalopathy (CADASIL) is a rare genetic disorder affecting the small blood vessels in the brain. CADASIL is associated with vascular accumulation of mutant Notch3 protein, dysregulation of cerebral vessels, and dementia. Pericytes, the vascular mural cells located within the basement membrane of blood microvessels that control BBB permeability, regulate cerebral blood flow (CBF) and participate in the clearance of brain toxic byproducts, express Notch3. Dysfunction of pericytes has been implicated in BBB breakdown, hypoperfusion and CBF reduction, inflammation, neuronal degeneration and cognitive impairment. Here, we report developing an inducible CADASIL (*ROSA26-LSL-Notch3$^{+/R169C}$*) pericyte-specific Cre (*Atp13a5-Cre$^{ERT2+/+}$)* mouse model (*Atp13a5-Cre$^{ERT2\ +/-}$; ROSA26-LSL-Notch3$^{+/R169C}$)*, where mutant Notch3 specifically accumulates in pericytes. This model will give us the advantage to specifically study the effects of aggregation of mutant Notch3 in brain pericytes and subsequent deficits of the blood brain barrier at any stage during lifespan and can be a useful tool in the study of neurodegeneration and development of therapeutics.

Title: Transient Blood Brain Barrier Opening During Cortical Spreading Depression Results from Dynamic Reorganization of the Tight Junction Protein Claudin-5

Authors: *J. R. WAHL[1], A. VIVEK[1], S. PALOMINO[1], M. ALMUSLIM[1], K. E. COTTIER[2], E. LIKTOR-BUSA[1], J. M. STREICHER[1], T. P. DAVIS[1], T. W. VANDERAH[1], T. M. LARGENT-MILNES[1];
[1]Med. Pharmacol., Univ. of Arizona Col. of Med., Tucson, AZ; [2]Mol. Microbiology and Immunol., Johns Hopkins Univ., Baltimore, MD

Abstract: Cortical spreading depression (CSD) has long been suggested as a potential cause for pain experienced during migraine. CSD events trigger intracranial neurogenic inflammation and activation by releasing several substances into the extracellular space, including glutamate, K+, H+, and ATP. The resulting increase of K+ and glutamate in the extracellular space induces propagation of the CSD event by depolarizing surrounding neurons. CSD events are closely tied to potential pathophysiologic states of the blood brain barrier (BBB) and neurovascular unit (NVU). The BBB is composed of cerebral endothelial capillary cells tightly bound together by tight junction (TJ) proteins on the luminal side of vessel, and adherens junctions (AJ) proteins on abluminal side of vessel, creating a highly selective and permeable physical and biochemical barrier between peripheral circulation and the central nervous system (CNS). Dynamic alterations of the aforementioned tight junction proteins allow for a potentially pathologic alteration to the discrete regulation of substance influx and efflux to the brain present during normal homeostatic physiologic conditions at the BBB. One consequence of CSD is transient change in permeability of BBB of sufficient magnitude to allow small molecules (<400 g/mol) to pass from blood into the brain. Prior research has demonstrated total TJ protein expression remains unchanged during CSD, leading to the investigation of the underlying mechanisms occurring in these proteins responsible for the functional alterations leading to the observed openings in the BBB. My current studies therefore aim to elucidate these underlying mechanisms by investigating the hypothesis that reorganization of TJ proteins, not changes in overall expression, underscore the observed transient opening in the BBB during CSD events. Utilizing *in vitro* models of the BBB in addition to comparative studies utilizing animal, preclinical, and proteomic techniques, I aim to find a elucidate a physiologic link connecting CSD events in the cortex to the pathologic condition of migraine with aura.

Title: Alpha melanocyte stimulating hormone (α-MSH) alters brain endothelial function in ABCD1-deficient human brain endothelial cells via NUR77-dependant regulation of tight junction proteins.

Authors: *C. G. BERGEN[1], S. K. MCCARTHY[1], C. A. LUSK[1], P. L. MUSOLINO[2]; [1]Neurol., [2]Massachusetts Gen. Hosp., Boston, MA

Abstract: X-linked adrenoleukodystrophy (ALD) is a neurologic disorder caused by mutations in ABCD1, a gene that encodes for the peroxisomal half-transporter adenosine triphosphate-binding cassette domain 1. This mutation causes an accumulation of very long chain fatty acids (VLCFAs) in body fluids and tissues. Most patients with ALD suffer from adrenal gland insufficiency and hyperpigmentation due to elevated levels of Adrenocorticotropic hormone (ACTH) and α-MSH. Using MetaCore genomic analysis, we determined ACTH and α-MSH melanocortin receptors (MCRs) pathway involved in regulation of endothelial tight junction (TJ) proteins. To assess whether loss of ABCD1 and adrenal insufficiency could contribute to the disruption and increased permeability of the blood brain barrier (BBB) seen in the cerebral demyelinating form of ALD we used siRNA to silence the gene in HBMECs and test molecular and functional changes after α-MSH stimulation via qPCR, Western Blot and transmigration. We found that α-MSH supplementation lead to decreased expression of NUR77 and Claudin-5, the predominant TJ in brain white matter endothelium. In turn, increased permeability to leukocytes was observed after α-MSH supplementation in ABCD1-deficient HBMECs compared to controls. This work presents for the first time a potential new therapeutic target that could restore endothelial TJ function and decrease BBB permeability to leukocytes to prevent cerebral demyelination in ALD. Further research of these pathways may uncover new links between melanocortin regulation, hormonal dysregulation and cerebral degeneration in ALD.

Title: Exosomes are involved in iron transport from Human blood brain barrier endothelial cells and are modified by iron status.

Authors: *K. PALSA, S. L. BARINGER, I. A. SIMPSON, J. R. CONNOR;
Penn State Col. of Med., Hershey, PA

Abstract: Iron is essential for normal brain development, and its deficiency is associated with reduced cognitive performance. To enter the brain, transferrin (Tf) bound iron is taken up by endothelial cells (ECs) via transferrin receptor (TfR) at the luminal side. Iron is released within the ECs and can be egressed via Ferroportin (FPN)/Hephaestin (HEPH) dependent mechanism to the albuminal side. We previously demonstrated that ferritin heavy chain (HFT) also transport iron to the brain via endothelial cells, implying alternate iron transport mechanisms. Here-in we investigated role of exosomes in mediating the HFT or Tf mediated iron transport across the blood brain barrier (BBB) ECs. The study used ECs derived from human induced pluripotent stem cells (hiPSC) that are grown in bicameral chambers. hECs were labeled with ^{55}Fe from the apical side for a period of 24h. The cells were then treated with Desferroxamine (DFO, an iron chelator, 100µmol/L) or Ferric ammonium citrate (FAC, an iron source; 100µmol/L) or PBS or 1 mg/mL of human apo-Tf or 100 µg/mL HFT for 24 hours. Exosomes from the basal media were isolated by ultracentrifugation (120,000 *x g*), Exosomal content was confirmed by immunoblotting for CD81, an exosomal marker. We also measured the relative ^{55}Fe radioactivity, Tf, and HFT levels in the exosomal fraction as compared to the basal media supernatant. When cells were exposed to Tf or Hft, the ^{55}Fe activity in the exosomal fraction was 292% and 103% higher, respectively compared to the supernatant fraction. Tf and HFT were also released from the ECs in exosomes but only when the cells were exposed to apo-Tf and HFT treated cells not under control conditions. Moreover, the exosomal-associated Tf levels were higher when ECs were pre-treated with FAC and subsequently treated with apo-Tf versus pre-treatment with DFO. The number of exosomes were higher when cells were treated with FAC compared to DFO, as evidenced by higher CD81 density. These results indicate that iron transport across the BBB is mediated via the exosomal pathway and is modified by iron status of the hECs providing evidence for novel alternate mechanisms of iron transport into the brain.

Title: Transferrin receptor expression (TfR) across species and age informs potential safety and efficacy of TfR-targeted therapies

Authors: *M. PIZZO, Y. CHENG, M. CALVERT, A. ARGUELLO, D. CHAN, K. CHEW, J.-H. CHOW, S. DEVOS, J. DUGAS, C. HA, K. HENNE, D. JOY, M. KARIOLIS, K. LECHTENBERG, S. LIANOGLOU, C. MAHON, T. SANDMANN, M. SIMON, E. THOMSEN, R. TONG, R. WELLS, M. DENNIS, A. ESTRADA, K. GADKAR, J. W. LEWCOCK, P. SANCHEZ, Y. J. Y. ZUCHERO, R. MEISNER, R. G. THORNE;
Denali Therapeut., South San Francisco, CA

Abstract: Understanding transferrin receptor (TfR) expression and distribution across species and different ages is critical for the translation of TfR-targeting therapeutics. However, few studies have carefully compared these aspects across the major species of importance in drug development of these biotherapeutics: mouse, macaque, and human. Here, we have utilized multiple methods to cross-validate TfR expression and distribution in normal tissues and with age in wild-type mice, chimeric TfRmu/hu knockin mice, cynomolgus monkeys, and humans. We compared TfR expression in the brain and peripheral organs using in situ hybridization, immunohistochemistry, and ultra-high multiplexed imaging to visualize expression and localization. RNA-seq and western blot was further used to understand overall level of expression across species. We observed a generally high level of agreement between species, with brain, bone marrow, placenta, and gastrointestinal tissues having among the highest levels of expression within certain cell types. Interestingly, TfR expression was high in Schwann cells of peripheral nerves from mouse and cynomolgus monkey samples, but TfR was mostly absent in human samples.

It is currently unclear whether TfR expression is altered with age and whether such changes, if present, may significantly impact the transport of TfR-targeting therapeutics into the brain. We therefore investigated the uptake of a monovalent mouse TfR-binding antibody in young and aged wild type mice. Immunohistochemistry of brain sections revealed high endothelial TfR protein expression in mice aged 3, 15, and 24 months. Importantly, brain concentrations of the TfR-binding antibody were unchanged with age. Cellular localization and level of expression in human brain was also evaluated between pediatric, adult, and aged samples.

Our characterization of TfR expression with age and across species will help inform the interpretation and translatability of studies evaluating the biodistribution, brain targeting, and efficacy of TfR-targeted therapeutics for neurodegenerative diseases, including antibody transport vehicles (Kariolis et al. Sci Transl Med 2020), enzyme transport vehicles (Ullman et al. Sci Transl Med 2020), and other TfR-binding architectures (Arguello et al. bioRxiv 2021).

Abstract: Immunoglobulin G (IgG)-based therapeutics are emerging as a promising treatment for central nervous system (CNS) disorders and characterizing distribution and efficacy of IgG in the central nervous system (CNS) will be critical for their successful translation. These characteristics are governed, in part, by the interaction between IgG and endogenous Fc receptors that bind to the crystallizable fragment (Fc region) of IgG immunoglobulins throughout the body. Suprisingly, the role of these interactions remains poorly understood at specialized fluidic interfaces in the CNS. Here, we investigated the expression and localization of two Fc receptors - (i) the neonatal Fc receptor (FcRn) that binds to IgG with high affinity at pH ~ 6.5, and (ii) the low affinity-binding ($K_d \sim 10^{-6}$ M) inhibitory Fc gamma receptor (FcγRIIb), at these interfaces in female Sprague-Dawley rats ($n = 4$). A similar immunohistochemical study was performed in rat and mouse brain-derived capillary endothelial cell cultures ($n = 4$) and glial cell cultures ($n = 4$). Cells from these primary cultures were also tested for mRNA expression of these receptors. We observed high FcRn and FcγRIIb immunoreactivity at the olfactory nerve layer, leptomeninges, glia limitans, perivascular spaces, ventricles, and choroid plexus in the rat brain. Cell immunoreactive for both FcRn and FcγRIIb predominantly included lymphatic endothelial cells in the meninges, perivascular macrophages, choroid plexus epithelial cells, and astrocytes. Diffuse immunoreactivity was also observed in neocortical neurons and astrocytes in the white matter tracts. In contrast, brain endothelial cells were immunoreactive for neither FcRn nor FcγRIIb in our study. In vitro immunofluorescence analysis in primary cell cultures of rat and mouse brain capillary endothelial cells further confirmed minimal FcRn and FcγRIIb immunoreactivity. Gene expression analysis further revealed high Fcgrt expression in isolated brain capillary endothelial cells for mice but not for rats. We hypothesize that high FcRn and FcγRIIb immunoreactivity in non-endothelial cells at these interfaces directly impacts IgG uptake and transport in the CNS by limiting IgG availability through weak/reversible binding at the perivascular and subarachnoid surfaces. Overall, our findings may potentially inform the engineering of antibody therapeutics for more efficient distribution within the CNS as well as provide new insights into the physiological factors influencing the distribution of endogenous IgG.

Title: Identifying Circuits That Underly Social Recognition Behavior

Authors: *M. RASHID;
Emory Univ. Neurosci. and Behavioral Biol., Atlanta, GA

Abstract: The ability to recognize familiar conspecifics from strangers is crucial for the survival of most mammalian species. In humans, an inability to recognize kin is associated with several types of dementia, including Alzheimer's disease. Despite the debilitating nature of social recognition deficits and the key role, social recognition plays in shaping animal behavior, the neural circuits underlying social recognition remain poorly understood. Recent evidence has determined the ventral hippocampus (vHPC) as necessary for social recognition. Of particular interest is the lateral septum since it is a major output of the vHPC and is a region that has been implicated in kin recognition. The exact contribution of vHPC projections to the lateral septum in allowing an animal to discriminate between familiar and novel conspecifics remains unknown. In this study, we used a combination of imaging and optogenetic methods to determine the role of the vHPC-LS projections in mediating social recognition. To test if vHPC-LS projections played a causal role in allowing mice to discriminate novel from familiar animals, we inhibited vHPC-LS neurons in a spatially specific manner in the proximity of either a novel or a familar mouse in a social discrimination assay. We found that inhibition of vHPC-LS neurons disrupted a mouse's ability to discriminate between a familiar and novel mouse. In contrast, control mice demonstrate an increased preference for the novel mouse. (ChR2 n=12 ;GFP n=7 , p=0 .037). To test if activating vHPC-LS neurons had an effect on social recognition, we first injected ChR2 bilaterally into vHPC and stimulated LS afferents while animals were engaged in a social discrimination task. Surprisingly, we found that activation of the anatomical subpopulation increased investigation around both a novel and familiar conspecific (ChR2 n=11 ; GFP n=8 , p=0 .032). In contrast, activating vHPC projections to the medial prefrontal cortex (mPFC) had no effect on social recognition behavior (ChR2 n=11 ; GFP n=8 , p=0 .041). These findings suggest that vHPC projections to the LS but not the PFC play a crucial role in social recognition. To further characterize the differences in neural dynamics of this population during social interactions with a novel versus a familiar mouse, we monitored the activity of the vHPC-LS using cellular-resolution imaging in freely moving mice in the same social discrimination task. Preliminary data shows that vHPC-LS neurons are active in the proximity of novel and familiar animals (n=2). By combining optogenetics and cellular resolution calcium imaging, this study provides the first insight into the role of vHPC-LS circuit in social recognition.

Title: Fos expression in the basomedial amygdala after habituation to novel food and novel context

Authors: *Z. IRVING, E. GREINER, G. PETROVICH;
Boston Col., Boston, MA

Abstract: Responses to novel stimuli are both adaptive and variable. Environmental and physiological differences impact how individuals respond to novel food and novel feeding environments. Our prior work established that novel food and novel context inhibit food intake in food deprived male and female rats, and that there were sex differences during habituation, with females habituating slower to eating in a novel context. Furthermore, we recently found that the anterior basomedial nucleus of the amygdala (BMAa) is robustly recruited during the first exposure to novelty. To establish the neuronal substrates underlying habituation to novelty, here we examined recruitment of the BMAa after repeated exposure. Adult male and female Long Evans rats (n=8/group) were food deprived for 20h prior to consumption tests in a novel or familiar (their home cage) context. Rats were given novel Test Diet pellets across 4 habituation sessions and 1 final testing session. Rats were perfused 90 minutes after the start of the final testing session and brain tissue was immunohistochemically processed for Fos detection in the BMAa. Consumption patterns analyzed by grams eaten as percent of body weight showed that during the first habituation session, consumption differed by sex ($F(1,28)=6.978$, $p=0.013$) and context ($F(1,28)=12.84$, $p<0.01$), with females and those in the novel context consuming less. All groups increased their consumption across the 5 habituation and testing sessions, and the rate at which consumption increased significantly differed across groups ($F(1,28)=227.398$, $p<0.01$), with rats tested in the novel context habituating slower to the novel food ($F(1,28)=11.396$, $p=0.002$). Across habituation sessions, rats in the novel context consumed significantly less than those tested in their home cage ($F(1,28)=11.451$, $p=0.002$), while sex approached significance during the final test ($F(1,28)=3.259$, $p=0.082$), with females consuming less. The Fos induction analysis within the BMAa found that the females tested in the novel context had the highest number of Fos positive neurons. Preliminary analyses of the BMAa (n=3-4/group) confirmed that females had a significantly higher number of Fos positive neurons than males ($F(1,9)=8.837$, $p=0.026$), and, while not significant, rats tested in the novel context had more Fos induction than those tested in their home cage ($F(1.9)=4.312$, $p=0.068$). Collectively, these results suggest that the BMAa is a part of the network that controls consumption during habituation to a novel food in a novel environment, and that increased activity in the BMAa may be correlated with suppression of feeding and sex differences.

Title: Activation of the amygdala & paraventricular thalamus after novelty exposure during consumption in male and female rats

Authors: *E. GREINER[1], G. D. PETROVICH[2];
[2]Psychology, [1]Boston Col., Chestnut Hill, MA

Abstract: Adaptive reactions to novel stimuli are essential for survival. One of the most important interactions with novel stimuli is with novel foods. Previously we found that novel food and novel context inhibited food intake in hungry male and female rats and induced Fos in the central amygdala (CEA). We also determined that in a novel context, males habituated to novel food faster than females, who maintained suppressed consumption through multiple exposures. Still, very little is known about the neural substrates that mediate the impact of novelty on consumption and underlie the behavioral sex differences. To fill this gap in knowledge, we analyzed Fos induction in key brain areas connected to the CEA in male and female rats that were exposed to either a novel or familiar food in a novel or familiar environment. Following 20h acute food deprivation, male and female Long Evans rats (n=8/group) were tested for consumption in either their home cage or in a novel context and were given either a familiar (rat chow) or novel (Test Diet pellets; TD) food. Rats were perfused 90 minutes after the start of testing and their brains were immunohistochemically processed for c-fos expression.Our analysis focused on the cell groups in the basolateral complex (basolateral, basomedial (BMA), and lateral nuclei of the amygdala) and the paraventricular nucleus of the thalamus (PVT). Within the basolateral complex, there was greater Fos induction in all cell groups for rats tested in a novel context with additional greater Fos induction within the anterior BMA for rats given a novel food. Analysis of the anterior PVT revealed greater Fos induction for rats tested in a novel context and for rats given a novel food. The effect of novel food was driven entirely by females who had greater Fos induction to a novel food than a familiar food, regardless of context, while males did not. Preliminary analysis of the posterior PVT indicates a similar pattern of activation to the anterior PVT. These results indicate that the basolateral complex and PVT are parts of the network that controls consumption when rats are exposed to novel foods or are fed in novel environments, providing important contextual information and

sex-specific activation to downstream targets, like the CEA. This work is the first step to establish the neural circuitry that mediates the impact of novelty on consumption.

Title: Behavioral examination of sex differences in food motivation and consumption under physiological satiety and hunger

Authors: *R. SHTEYN, D. S. LAFFERTY, G. D. PETROVICH;
Psychology, Boston Col., Chestnut Hill, MA

Abstract: Hunger and palatability could impact food consumption in concert or independently through homeostatic and hedonic mechanisms. A recent study from our group found sex differences in consumption of high-sugar pellets (Test Diet; TD) that suggested that females are particularly prone to consume palatable food regardless of hunger state. Males consumed TD consistent with their hunger state—fasted consumed more than sated, while sated females ate as much as fasted females. These sex differences were not observed in the consumption of standard rat chow, suggesting that food motivation for palatable food may be differently impacted by hunger and satiety in males and females. In addition to consumption, food motivation influences food-seeking behaviors and learning about food cues. Here we compared how both sexes learn about and consume palatable food under sated and hungry conditions during Pavlovian conditioning, extinction, and context-mediated renewal of responding. Male and female adult Sprague Dawley rats were either food restricted to 85% of their *ad libitum* body weight (BW) or fed chow *ad libitum* throughout the experiment (n=8 per group, 4 groups). Rats learned cue-food associations across 8 training sessions, each with eight tone (conditioned stimulus; CS) presentations immediately followed by two TD pellets (unconditioned stimulus; US). Following 4 days of extinction (CS-only presentations), rats were tested for renewal of conditioned responding (defined as time spent in the food cup during CS presentation) over two days, with one session taking place in the acquisition context and one in the extinction context, counterbalanced. Prior to and following all learning and testing sessions, rats were tested for consumption of TD and chow. Each test was conducted over two days with one-hour access to TD or chow in the home cage, with food type order counterbalanced. Preliminary consumption test analyses (grams eaten expressed as percent of BW) found that hungry rats ate significantly

more TD and chow than sated rats regardless of sex ($p<.001$). There were no significant differences in TD consumption between chronically hungry females and males during either the test that occurred before ($p=.082$) or after ($p=.121$) training. Importantly, sated females ate more TD than sated males during each test ($p=.003$, $p=.006$). These results suggest that females are more sensitive to palatable food when sated, but when chronically hungry, the drive to consume palatable and neutral-tasting food is similar for both sexes. Pending analyses will assess conditioned responding during cue-food acquisition, extinction, and renewal, and if they correlate with consumption in each sex.

Title: Dopamine correlates of habit versus goal-directed behavior in ventral tegmental area

Authors: *R. MAGNARD[1], P. H. JANAK[1,2], Y. VANDAELE[1];
[1]Psychological and Brain Sci., Johns Hopkins Univ., Baltimore, MD; [2]Solomon H. Snyder Dept. of Neurosci., Johns Hopkins Sch. of Med., Baltimore, MD

Abstract: Habitual performance is proposed to be mediated by a shift in reward seeking control from mesolimbic to nigrostriatal dopaminergic pathways. However, how midbrain dopamine (DA) neuron activity differentially signals habitual versus goal-directed performance remains largely unknown. To address this question, we tested male and female WT rats in two instrumental procedures, a lever insertion fixed-ratio 5 (LI5) task (n=7 males; 8 females) and a lever retraction fixed-ratio 5 (LR5) task (n=7 males; 8 females). In these tasks, the timing of lever insertion and retraction is varied so that insertion or retraction is a relevant cue signaling reward (sucrose 20%) availability while the other cue is made irrelevant. Rats were trained for 30 or 45 min daily sessions in the LR5 and LI5 respectively, to allow similar lever availability time. We then tested the goal directed or habitual behavior in satiety induced devaluation test. Finally, we compared activity of DA neurons via *in vivo* fiber photometry after VTA infusion of Cre-dependent GCaMP6f virus in adult TH-Cre rats, performing either LR5 (n=4 males; 2 females) or LI5 (n=1 male; 4 females) task, while DA neuron activity was monitored. We found for both male and female rats, behavior quickly becomes automatic and habitual in the LR5 task in which the LR cue predicts immediate reward delivery, as indicated by tests of satiety induced reward devaluation. We further observed a rapid shift in the activation of DA VTA neurons from reward

retrieval to the earlier LR cue, followed by a decrease in cue-related DA signals across repeated trials as rats develop habitual behavior. In contrast, behavior in the LI5 task, was goal-directed, and cue-induced DA activation remained relatively constant across trials and sessions, when reward availability was signaled by the LI cue, more distal from reward delivery. These results show manifest task differences in DA signaling that appear consistent with the difference in habitual versus goal-directed control of behavior.

Title: Asynchronous modulation of striatal PKA activity by dopamine during learning

Authors: *S. LEE[1], B. LODDER[1], Y. CHEN[1], T. PATRIARCHI[2], L. TIAN[2], B. SABATINI[1]; [1]Howard Hughes Med. Inst. - Harvard Med., Boston, MA; [2]Biochem. and Mol. Med., Univ. of California, Davis, Davis, CA

Abstract: Reinforcement learning models involving dopamine and basal ganglia postulate that midbrain dopamine neurons encode information about action and action outcome and provide a teaching signal to striatal spiny projection neurons in the form of dopamine release. Dopamine, in turn, is thought to guide learning via differential modulation of downstream protein kinase A (PKA) in each class of spiny projection neurons (SPNs). However, the real-time relationship between dopamine and SPN PKA activity during learning has not been directly tested due to the difficulty of measuring intracellular kinase activity in behaving animals. To address this limitation, we have developed a fluorescence lifetime photometry system to measure SPN PKA activity in freely behaving animals. Combining this technique with behavior, pharmacology, fiber photometry, and optogenetics, we have successfully measured the level of dopamine and the net PKA activity in each class of SPNs in the nucleus accumbens and found that positive and negative modulation of dopamine that evolves across training is both necessary and sufficient to

explain concurrent fluctuation in the PKA activity. More specifically, modulations of PKA in SPNs that express type-1 and type-2 dopamine receptors were dichotomous and asynchronous such that PKA activity was sensitive to increase and decrease in dopamine, respectively, that occurs at different phases of learning. Furthermore, employing cell-type specific viral overexpression of peptide inhibitor of PKA, we show that PKA activity in each class of SPNs contributes to reward based learning.

Title: An operant memory is encoded as a shift in neuronal population dynamics

Authors: *R. M. COSTA[1], D. A. BAXTER[2], J. H. BYRNE[1];
[1]Dept. of Neurobio. and Anat., The Univ. of Texas Hlth. Sci. Ctr. at Houston, Houston, TX;
[2]Engin. and Med., Texas A&M Hlth. Sci. Ctr. at Houston, Houston, TX

Abstract: Learning engages multiple brain regions and multiple neurons within each region, creating a high-dimensional neuronal population space. Yet, it remains unclear how learning reconfigures this high-dimensional space and whether it is possible to identify a lower-dimensional "*learning signature*". Here, we investigated this issue using an *in vitro* analogue of operant conditioning of *Aplysia* feeding behavior and single-neuron resolution voltage-sensitive dye imaging. Contingent training consisted of stimulating a dopamine-rich nerve following occurrences of ingestion buccal motor patterns (iBMPs) in isolated buccal ganglia. Training in the contingent group resulted in a significant increase in the rate of iBMPs relative to the yoked control group (N = 7, Wilcoxon signed-rank, P = 0.03), which received identical stimulation irrespective of iBMP occurrence. We recorded the activity of ~100 neurons per preparation during BMPs before and after contingent and yoked training. Although no significant difference was observed between groups in the overall firing rate (P = 0.81), the overall correlation among pairs of neurons was higher in the contingent group compared to the yoked group (P = 0.03). This result suggested that contingent training modified the relationship among the activities of multiple cells. To gain additional insights, we used a dimensionality reduction approach (non-

negative matrix factorization) to identify ensembles of coactive neurons. Two ensembles were identified that were highly consistent across preparations: a protraction module, which underlies the phase of BMPs responsible for forward movement of the animal's feeding apparatus; and a retraction module, which underlies the phase responsible for the backward movement. Next, we examined how recruitment of these modules over time was modified by training. We found that recruitment of the retraction module ($P = 0.02$), but not the protraction module ($P = 0.94$), was significantly advanced in time in the contingent group relative to the yoked group. We did not observe a difference between groups in the level of recruitment of either module (retraction, $P = 0.30$; protraction $P = 0.81$). In addition, each module displayed characteristic spatial distribution of neuronal somata across preparations, which was consistent with previously described protraction and retraction neurons. These results suggest that the primary signature of operant learning can be identified as a shift in recruitment of a lower-dimensional module, and points to the location of neurons contributing to that module.

Title: The role of superior colliculus inputs to midbrain dopamine centers in appetitive Pavlovian conditioning

Authors: *C. L. POISSON[1], C. R. HERUBIN[1], B. T. SAUNDERS[2];
[2]Dept. of Neurosci., [1]Univ. of Minnesota Twin Cities, Minneapolis, MN

Abstract: Appetitive Pavlovian conditioning relies on associations made between sensory stimuli ("cues") and rewarding outcomes. In our previous studies, we have shown that optogenetic activation of dopamine (DA) neurons in the ventral midbrain in the presence of a neutral visual cue is sufficient to create a Pavlovian association that promotes conditioned behavior in response to that cue (Saunders et al., 2018). Critically, the circuit mechanisms underlying the integration of cue-related sensory input into DA centers to form Pavlovian associations remain unclear. One candidate structure that could provide visual information about cues is the superior colliculus (SC), which receives direct retinal input, and sends projections to DA neurons in the ventral tegmental area (VTA) and substantia nigra pars compacts (SNc). The SC is known to be necessary for cue-evoked neural activity in DA neurons, but the behavioral

function of SC-VTA/SNc neurons is unclear. Here, we characterize the SC-VTA/SNc circuit and use optogenetics to modulate this pathway's activity during Pavlovian conditioning in rats. First, we used a dual-virus approach to determine which SC neurons innervate the ventral midbrain. This revealed projections from deep-layer SC that largely innervate the dorsal and lateral VTA and SNc. To manipulate activity of the pathway, we injected viruses expressing excitatory (ChR2) or inhibitory (eNpHR) opsins into deep layer SC and implanted an optic fiber in either VTA or SNc. We next trained rats in a Pavlovian conditioning procedure wherein visual cues were paired with optogenetic manipulation of terminals. Behavioral analysis revealed that excitation of these neurons failed to drive conditioned (i.e., learned) behavior towards the cue, in contrast to our previous studies targeting DA neurons directly. Notably, a subset of ChR2 rats demonstrated turning behavior. Turning was contralateral to stimulation hemisphere, and time-locked to laser duration. This suggests that the SC-VTA/SNc neurons can drive movement invigoration, presumably via their activation of DA neurons, but do not directly cause Pavlovian learning. In ongoing experiments, we are testing the working hypothesis that subsets of SC inputs to different DA populations may invigorate actions, and/or alter attention to relevant sensory information during learning.

Title: Brain-wide neural encoding of value and salience across need states

Authors: *A. J. BOWEN, D. J. OTTENHEIMER, N. A. STEINMETZ;
Biol. Structure, Univ. of Washington, Seattle, WA

Abstract: Value and salience are interrelated components of cognition that are thought to arise from distinct systems. As such, they are frequently studied independently in distinct brain regions. Here, we sought to evaluate the extent to which regions classically studied in relation to these cognitive variables exhibit specialized encoding. We designed a behavioral task that features integration of these components, in which thirsty mice were presented with stochastically rewarded (CS+) and unrewarded (CS-) Pavlovian cues. The probability that

sucrose delivery followed the CS+ varied across the session. On some trials, reward was replaced with highly salient white noise. Mice adapted their anticipatory licking for the CS+ to the reward history: when recent trials were frequently rewarded, mice licked more robustly. They also demonstrated distinct licking patterns to reward, reward omission, and white noise, and licking decreased dramatically across the session as mice became sated. Thus, this task permits the disambiguation of value and salience. Once mice were trained, we recorded from many thousands of neurons in a variety of cortical and subcortical regions using Neuropixels 2.0 probes. Targeted regions included ones associated with value, salience, and/or satiety (OFC, mPFC, NAc, LHA, NTS, PBN, CeA). The activity of a majority of neurons in all recorded regions was modulated following reward delivery. Preliminary analysis revealed neurons with a variety of coding properties. Some were tuned to satiety-gated salience, with decreasing activity following rewards but maintained white noise-driven activity across the session. Others were especially tuned to value, with reward responses modulated by reward history. These results begin to distinguish the unique coding properties of a variety of regions often associated with value, salience, and satiety.

Title: C-fos activation mapping of hierarchical vs. binary associative structures in reward prediction

Authors: *S. PETERSON, A. MAHERAS, J. I. CHAVIRA, B. WU, R. KEIFLIN;
Dept. of Psychological and Brain Sci., UC Santa Barbara, Santa Barbara, CA

Abstract: Research into the neural basis of reward prediction has often focused on predictions resulting from a binary association between some environmental stimuli and an ensuing rewarding outcome. Importantly, reward predictions and reward-seeking behaviors are also controlled by hierarchical associative processes. This refers to the acquired property of certain stimuli (often contextual stimuli) to inform subjects about the validity of ambiguous reward-paired cues (e.g., animals can learn that a reward cue is valid —i.e. results in reward— only if encountered in a certain context). Empirical behavioral studies and neural network simulations indicate that hierarchical and simple binary associations rely on different associative structures, suggesting partially dissociable neural substrates for these forms of reward predictions. Here we aimed to generate and compare the brain-wide activation maps corresponding to these two forms of reward prediction (binary vs. hierarchical associations). Three groups of rats were trained in

three different forms of Pavlovian discriminations. A first group of rats was trained in a context-dependent Pavlovian discrimination task, in which the validity of two brief auditory tones (A and B) to signal reward depended on contextual visual background (Cx1 and Cx2, alternating every 2 mins). Specifically, cue A was rewarded only in the Cx1 but not in the Cx2, while the opposite was true for cue B (Cx1: A^+ / B^- ; Cx2: A^- / B^+). A second group was trained in a simple Pavlovian discrimination task in which one cue reliably signaled reward in both contexts while the other cue was never paired with reward (Cx1: A^+ / B^- ; Cx2: A^+ / B^-). Finally, for a third group both auditory cues were ambiguous predictors of reward, regardless of the context (Cx1: $A^{+/-}$ / $B^{+/-}$; Cx2: $A^{+/-}$ / $B^{+/-}$). Therefore, all rats were exposed to the same cues, contexts, and rewards but relied on different associative structures to predict and seek reward. Following acquisition and maintenance of stable performance in these tasks, we collected the brains of all rats 120 min after the start of their last behavioral session and performed immunofluorescence mapping of c-fos expressing neurons in a selected set of structures. We observed that performance in these different tasks resulted in partially dissociable neural activation maps, presumably reflecting the different associative or cognitive processes engaged in these tasks. Of critical importance was the claustrum, which showed a strongly reduced activation in context-depended discrimination. This suggests that the claustrum could constitute a critical hub in the hierarchical control of reward seeking.

Title: The ventral tegmental area nociceptin system is engaged during stress and regulates motivated behaviors

Authors: *C. STINE, D. J. MARCUS, J. HANSEN, M. R. BRUCHAS;
Dept. of Anesthesiol. and Pain Med., Univ. of Washington, Seattle, WA

Abstract: Major depressive disorder (MDD) is a significant global health concern affecting over 160 million people worldwide. A central feature of MDD is anhedonia, which presents as abnormal approach-avoidance and loss of motivation. It is critical to understand the neural circuitry regulating expression of anhedonia in order to identify new, more effective therapeutic

targets. Our laboratory previously showed that nociceptin neurons in the paranigral ventral tegmental area (pnVTA^{Pnoc} neurons) act locally on nociceptin receptor (NOPR) expressed on dopamine neurons to limit motivation for reward, and upon activation can induce aversion (Parker et al., 2019, Cell). Because nociceptin has been implicated in the regulation of stress-related behavior, we hypothesize that stress engages the pnVTA nociceptin/NOPR system to regulate the expression of motivational deficits. To test this, we injected a Cre dependent genetically encoded calcium indicator (GCaMP6s) into the pnVTA of Pnoc-Cre mice and recorded prepronociceptin neuron activity during exposure to a range of stressful stimuli including open field test, elevated zero maze, aversive odor, tail lift, simulation of a looming predator, and foot shock. Fiber photometry recordings showed that exposure to each of these stressors induces nociceptin neuron activation, supporting our hypothesis that stress engages the pnVTA nociceptin system. To further test this nociceptin population's effect on motivation, we injected a Cre virus into the pnVTA of our Pnoc conditional knockout mice to induce loss of nociceptin. We then placed these mice through the progressive ratio test to determine how well they perform a task in order to receive a reward which exponentially increases in required effort with each trial, ultimately reaching a "breakpoint". The progressive ratio test showed that mice without pnVTA nociceptin were more motivated for reward than their control counterparts, obtaining more rewards and reaching a higher motivational breakpoint. Lastly, we completed retrograde tracing to identify GABAergic and glutamatergic inputs onto pnVTA neurons which labeled multiple afferent regions including the lateral hypothalamus (LH). Further electrophysiology studies confirmed that the LH has both GABA and glutamatergic connectivity onto pnVTA nociceptin neurons. Ultimately, these findings provide evidence that pnVTA nociceptin release constrains motivation for reward, identify potential afferent inputs that regulate pnVTA nociceptin activity, and offer new insight into stress-related behavioral states that engage this population. Abstract: Elegant work spanning decades has implicated the dorsomedial striatum (DMS) in how animals learn, perform and update goal-directed actions. Yet, the circuit- and molecular-level substrates involved in these behaviors remain largely unknown. Given the amygdala's role in encoding value, neural projections from specifically the basolateral amygdala (BLA) to the DMS are uniquely poised to sculpt action-outcome behaviors. Roughly 50% of the neurons in the DMS express dynorphin; although how dynorphin (dyn) itself coordinates these strategies is yet to be elucidated. Interestingly, ours and prior studies have shown that BLA neurons project exclusively to dynorphin neurons in the DMS and that DMS-projecting BLA neurons express kappa-opioid receptors (KOR). ***Hence, we hypothesize that BLA projections to the DMS coordinate outcome-based action learning and maintenance, under the control of dyn-KOR signaling.*** Here, we show that retrograde dyn transmission at BLA terminals in the DMS inhibits BLA-DMS activity during outcome delivery, refines increased activity during action, and promotes action-outcome behaviors for natural reward. Using fiber photometry in BLA terminals expressing GCaMP6s in the DMS, we show that BLA terminals are active during action and inhibited during outcome. We also observe that BLA-DMS activity changes dynamically and reversibly to manipulations in outcome-probability or outcome-value. Notably, we find that this engagement is sensitive to disruptions in dyn signaling via naloxone or through local deletion of dyn in the DMS, or KOR in the BLA. Using a novel dyn sensor (KLight1.3), we observe that DMS dyn is released during reward retrieval, suggesting that dyn release and subsequent KOR signaling inhibits BLA-DMS activity during outcome, following pellet retrieval. In parallel, using channelrhodopsin (ChR2) or a light-activatable Gi/o-coupled GPCR, parapinopsin (PPO) for time-locked optogenetic manipulations of BLA-DMS terminals, we find that photoactivation during outcome disrupts action and conversely, photoinhibition using enhances actions, suggesting that BLA-DMS activity during action is informed by outcome. ***Collectively, our data suggest that BLA-DMS activity informs outcome-dependent action and is regulated by dyn-KOR signaling at these terminals during outcome.*** Current work is focused on delineating how BLA-DMS axons differentially engender action or outcome using *in-vivo* 2-photon calcium imaging of DMS-projecting BLA neurons or BLA axon clusters in the DMS, and how their activity is differentially controlled by local dynorphin signaling in the DMS, during a novel, head-fixed operant task.

Title: The dual orexin receptor antagonist suvorexant reduces cocaine behaviors at non-sedating doses

Authors: *S. L. O'CONNOR[1], M. M. BILOTTI[1,2], M. H. JAMES[1,3];
[1]Brain Hlth. Institute, Rutgers, The State Univ. of New Jersey, Piscataway, NJ, [2]Joint Grad. Program in Toxicology, Rutgers, The State Univ. of New Jersey, Piscataway, NJ, [3]Dept. of Psychiatry, Robert Wood Johnson Med. Sch., Rutgers, The State Univ. of New Jersey, Piscataway, NJ

Abstract: Introduction: Blocking orexin (hypocretin) signaling is a promising novel strategy for the treatment of cocaine use disorder. Suvorexant is a dual orexin receptor antagonist that is FDA-approved for the treatment for insomnia and thus could be readily repurposed. Although there is some evidence in rat to indicate that suvorexant can reduce cocaine-related behaviors, this has not been tested in a model of cocaine self-administration that promotes an addiction-like phenotype. Moreover, the dose-response profile of suvorexant when administered via a clinically relevant route (p.o.) has not been examined, nor is it known if there are sedative effects at doses required to reduce cocaine behaviors. Thus, here we tested the efficacy of suvorexant (delivered p.o.) on the expression of two hallmark addition phenotypes and general activity in rats exhibiting a paradigmatic-induced addiction-like state. **Methods:** Male Long Evans rats (n=16) were assessed for baseline economic demand for cocaine using a within-session threshold procedure. Rats were then given daily intermittent access to cocaine (5min access every 30min for 6h) for 2 weeks before being reassessed for economic demand and compulsive (punished) responding for cocaine. The effect of suvorexant (0, 3, 10, 30mg/kg; oral gavage) on demand and compulsive responding was assessed. Potential sedative effects of suvorexant were assessed using a locomotor reactivity task. **Results:** Intermittent access to cocaine was associated with a significant decrease in demand elasticity for cocaine (increased motivation) which was reversed by suvorexant (10, 30mg/kg). Suvorexant was also effective at reducing compulsive (punished) responding for cocaine. At the minimum effective dose of suvorexant (10mg/kg), no sedative effects were observed on the locomotor activity test. **Discussion:** In rats that transitioned to an addiction-like state, suvorexant was effective at reducing key addiction endophenotypes at doses that are non-sedating, supporting the potential repurposing of this compound for the management of cocaine use disorder. Ongoing studies are testing for any effects of the minimum effective dose on cognitive/psychomotor outcomes, as well as the efficacy of suvorexant in reducing addiction behaviors in females.

Title: Connectional Architecture of Sex-Different Vasopressin Neurons in the Bed Nucleus of the Stria Terminalis

Authors: *N. RIGNEY[1], G. J. DE VRIES[2], A. PETRULIS[2];
[2]Neurosci. Inst., [1]Georgia State Univ., Atlanta, GA

Abstract: The neuropeptide arginine-vasopressin (AVP) has long been implicated in the regulation of social behavior and communication. Ablations of the sex-different AVP-expressing cells within the bed nucleus of the stria terminalis (BNST) result in sex-different effects on these behaviors. Despite the substantial body of work implicating AVP in social behavior, evidence for inputs and outputs of BNST AVP cells is largely circumstantial. Here, we use a Cre-dependent, modified rabies virus (RV; for retrograde tracing) and a synaptophysin-tagged virus (for anterograde tracing) in combination with AVP-iCre (or iCre negative control) mice to map out monosynaptic inputs and outputs of BNST AVP cells. Adult male and female mice received unilateral injections of adeno-associated viruses (AAVs) expressing either Cre-dependent, TVA-eGFP (for driving cell infection by RV) and glycoprotein (for transsynaptic retrograde infection), or GFP-2A-Synaptophysin-mRuby into the BNST. For RV tracing, mice also received an injection of RV following a 10-day incubation period. Preliminary results indicate that BNST AVP cells in male mice show strong reciprocal connections with the lateral septum, ventral pallidum, medial amygdala, lateral and medial preoptic area, and premammillary nucleus, all regions known to be innervated by male-biased, sex-different AVP fibers. Whereas BNST AVP cells receive inputs from nucleus accumbens and the paraventricular nucleus of the hypothalamus, they do not project to these regions. In addition, BNST AVP cells also receive strong inputs from, but project moderately to, the lateral, anterior, and ventromedial hypothalamic areas. Conversely, BNST AVP cells receive few inputs from, but strongly project to, the lateral habenula, periaqueductal gray, dorsal raphe, piriform cortex, and anterior olfactory nucleus. Lastly, BNST AVP cells send moderate outputs to, but do not receive inputs from, the horizontal diagonal band and entorhinal cortex. Collectively, we establish that brain regions previously shown to contain sex-different AVP innervation receive projections from BNST AVP cells, while these areas (i.e., lateral septum, ventral pallidum) also provide input to drive these cells. The BNST and medial amygdala also display profound reciprocal connections, and therefore may function as a system for the regulation of sexually different social behavior. This information will be foundational for understanding sexually different function of AVP circuitry and future studies will differentiate inputs/outputs of AVP cells in the BNST and medial amygdala in both sexes.

Title: Sex differences in the neural circuits underlying voluntary exercise behavior

Authors: *N. JAMIL[1], M. K. TANNER[2], K. ABRAMS[2], A. HOHORST[3], E. C. LOETZ[2], B. N. GREENWOOD[1];
[1]Psychology, [3]Biol., [2]Univ. of Colorado Denver, Denver, CO

Abstract: Despite the beneficial effects of exercise on physical and psychological health, most people fail to achieve recommended levels of physical activity. Identifying the circuits that drive exercise behavior could lead to novel strategies to increase exercise participation and maximize the benefits of exercise, but the neural mechanisms governing voluntary exercise are unknown. Rats maintain high levels of voluntary wheel running (VWR) that consists of two distinct phases: acquisition and maintenance. During the acquisition phase, rats escalate their nightly running before reaching a plateau in the maintenance phase. This pattern of VWR closely resembles that of other appetitive operant behaviors, such as lever pressing for sucrose, suggesting that similar mechanisms may underlie both behaviors. Dopamine (DA) in the dorsomedial striatum (DMS) is known to support the initial acquisition of operant behavior, while DA in the dorsolateral striatum (DLS) governs its long-term maintenance. Interestingly, the acquisition phase of VWR is shorter in female rats than it is in males, suggesting that DLS-control over voluntary exercise might be facilitated in females compared to males. The goal of these experiments was to identify the circuits governing the acquisition and maintenance of VWR and determine if sex differences exist. We inactivated the DMS or DLS of adult, Long-Evans rats by injecting a GABAA/GABAB agonist into the DMS or DLS before a VWR bout during both the acquisition phase (4 d) and maintenance phase (4 wk) of wheel running. In males, inactivation of the DMS reduced VWR during the acquisition phase, but not the maintenance phase. In contrast, inactivation of the DLS reduced VWR during the maintenance phase but had no effect during the acquisition phase in males. In females, inactivation of the DMS had no effect on VWR in either phase, but DLS inactivation reduced VWR during both phases. Moreover, double fluorescent in situ hybridization revealed that VWR recruits D1-expressing neurons in the DLS more rapidly in females (days) than it does in males (weeks). These data suggest that the neural circuits that support voluntary exercise behavior depend on both the phase of exercise and sex. Results

illustrate there are sex differences in the recruitment of the DLS, which have the potential to reveal mechanisms implicated in exercise motivation and maintaining exercise behavior.

Title: Trans-synaptic Investigation of Upstream Regulators of the Mesolimbic Pathway

Authors: *K. OGUNSEYE[1], H. SUN[2], J. KASPER[2], J. HOMMEL[2];
[1], Ctr. for Addiction Research, Human Pathophysiology and Translational Med., [2]Ctr. for Addiction Research, Pharmacol. and Toxicology, Univ. of Texas Med. Br. at Galveston, Galveston, TX

Abstract: The mesolimbic pathway is well-characterized as an important mediator of motivated behavior for substances of abuse, highly palatable food, and other reinforcers. However, it remains unclear which specific neurons project onto the mesolimbic pathway. Typically, mono-synaptic (i.e., region A → region B) viral tracing techniques have been utilized to investigate mesolimbic neurocircuitry. Utilizing novel trans-synaptic viral techniques, in which at least three brains regions can be mapped concurrently (i.e., region A → region B → region C), we aim to trace upstream brain regions acting as regulators of the ventral tegmental area (VTA) → nucleus accumbens (NAc) mesolimbic pathway. We used stereotaxic surgical methods to microinject a retrograde adeno-associated virus (AAV) 6 expressing the avian derived receptor TVA (CMV AAV6 TVA mcherry) into the nucleus accumbens of 11-19 week-old C57BL/6 male mice. After adequate expression of AAV6, we injected a G-protein deleted rabies virus enveloped by the avian sarcoma leukosis virus receptor (EnvA G deleted GFP Rabies) into the VTA. Utilizing immunohistochemical studies, we observed appropriate mcherry AAV6 expression at the primary site of infection, the NAc, and expression of GFP rabies in the VTA. Rabies expression was also identified in the lateral hypothalamus, periventricular region of the hypothalamus, sub paraventricular region of the hypothalamus, throughout the nucleus accumbens, and prelimbic and infralimbic cortex indicating that these brain regions project directly onto the VTA → NAc pathway. These results demonstrate successful neuro-tracing of inputs into the mesolimbic pathway. This study highlights neuroanatomical evidence of upstream regions that may have modulatory effects specific for directing mesolimbic activity and function. This viral-tracing

strategy supports the elucidation of inputs more broadly into neural pathways instead of individual brain regions.

Title: The effects of selective inhibition of orexinergic projections from the lateral hypothalamus to the paraventricular nucleus of the thalamus on cue- and food-motivated behavior

Authors: *A. G. IGLESIAS[1], B. DE LA REA[2], S. WESTBROOK[1], S. B. FLAGEL[1]; [1]Michigan Neurosci. Inst., Univ. of Michigan, Ann Arbor, MI; [2]Ctr. for Neural Sci., New York Univ., New York, NY

Abstract: The survival of an organism is dependent on their ability to properly respond to cues in the environment. In rodents, individual differences in cue-motivated behaviors appear in a Pavlovian conditioned approach (PavCa) paradigm, wherein a discrete cue is followed by delivery of a food reward. Some rats, sign-trackers (STs), attribute excessive incentive motivational value to reward cues, which thereby transforms the cues into attractive and desirable stimuli that can gain inordinate control and lead to maladaptive behavior. Other rats, goal-trackers (GTs), primarily attribute predictive value to reward cues. Prior work using the ST/GT model has implicated the paraventricular nucleus of the thalamus (PVT) as a neural hub responsible for mediating differences in Pavlovian incentive learning, and orexinergic projections from the lateral hypothalamus (LH) to the PVT seem to be important in this regard. Lesions of the LH decrease the propensity to attribute incentive motivational value to reward cues, and administration of orexin (OX) antagonists into the PVT reduces the incentive value of reward cues. Thus, we postulate that orexinergic projections from the LH relay the incentive value of reward cues to the PVT. To address this hypothesis, we utilized transgenic OX-Cre Long Evans rats, which express Cre-recombinase in OX neurons. We selectively inhibited OX neurons projecting from the LH to the anterior PVT (aPVT) by infusing a retrograde Cre-dependent inhibitory (Gi) DREADD (Designer Receptors Exclusively Activated by Designer

Drugs) into the aPVT and administering systemic (i.p.) clozapine-N-oxide (CNO, 5 mg/kg). Adult male and female OX-Cre rats were characterized as STs or GTs following 5 PavCA sessions. To determine if inhibition of OX neurons in the LH-PVT pathway affects the incentive value of a reward cue, CNO or vehicle (VEH) was administered prior to a conditioned reinforcement task, where rats had to elicit an instrumental response for the lever-cue previously paired with reward. CNO-treated rats showed less responding for the lever-cue. To determine whether inhibition of OX neurons in the LH-PVT pathway had a general effect on motivated behavior and instrumental responding, CNO or VEH was administered prior to a fixed-ratio (FR) 1 task for food reward. Gi-DREADD activation did not appear to affect FR1 responding for small or large amounts of food reward. Thus, inhibition of OX neurons in the LH-PVT pathway diminishes the incentive motivational value of reward-cues, without affecting the valence of the reward itself. This orexinergic LH-aPVT pathway may therefore play a critical role in encoding the incentive value of reward-cues.

Title: High resolution MRI guided neuroanatomical tracing in Rhesus macaque

Authors: *A. ALIKAYA, D. SCHAEFFER, A. C. SILVA, W. R. STAUFFER;
Neurobio., Univ. of Pittsburgh, Pittsburgh, PA

Abstract: Dopamine projections to the striatum and cerebral cortex are heavily involved in learning, reward processing, movement, and decision making. However, the relative organization of striatal- and cortical-projecting dopamine neurons in the midbrain remains to be resolved. Neuroanatomical tracing can provide a wealth of information about the organization of neural circuits, but is highly dependent on the accuracy of tracer injection sites. Achieving millimeter-level precision and replicability of injection sites is particularly challenging when targeting small subcortical structures in large brains. High-resolution MRI scans are imperative in making such precise tracer injections. Here, we developed an approach using gadolinium (Gd) guided high-resolution MRI to inject retro-AAV into functionally related regions of the caudate nucleus and frontal cortex, and optimized scanning sequences to improve the visualization of the injection needle. We designed and built an MRI-compatible stereotaxic frame that enabled us to image Rhesus macaques in the supine position, using standard, clinical human MRI coils. We first used a high-field clinical (7T) MRI scanner to provide high-resolution images of baseline scans. We

used subsequent scans to monitor the stepwise advancement of a Gd filled injection needle into the brain through a chronically implanted chamber. The injection needle consisted of two pieces of silica tubing sealed together with cyanoacrylate to create a reflux-resistant cannula. We optimized MP2RAGE and susceptibility-weighted imaging (SWI) sequences to observe the advancement of the injection needle into intermediate regions of the associative caudate and to best resolve the coordinates of the Gd doped cannula at the injection site. Once we confirmed the location of the needle in the intermediate caudate, we used convection enhanced delivery to inject 10µl of virus doped with Gd (250:1), and used MP2RAGE MRI pulse sequences to verify the location. The contrast agent allowed for clear visualization of the spread of virus in real time. The methods described here will be applicable for precise targeting of other deep brain structures, and overall help improve accuracy and replicability in neuroanatomical tracing of circuits in large nonhuman primate brains.

Title: More than a gut feeling: cholecystokinin afferents to the nucleus accumbens encode aversion and modulate dopamine transmission

Authors: O. P. CULVER[1], J. PARRILLA-CARRERO[2], *T. JHOU[2];
[1]Neurosciences, [2]Med. Univ. of South Carolina, Charleston, SC

Abstract: Originally recognized for its role in regulating gastrointestinal physiology, cholecystokinin (CCK) is also one of the most abundant neuro-modulatory peptides in the brain, and is highly expressed in brain regions that regulate emotional processing and motivational behavior. These regions include the medial prefrontal cortex (mPFC), basolateral amygdala (BLA), and ventral tegmental area (VTA). Using CCK-Cre mice crossed to reporter mice, we found that inescapable footshock produces robust c-Fos expression preferentially in CCK+ neurons of the BLA, and VTA. Furthermore, using Cre-dependent viral expression of mCherry in CCK-Cre mice, we demonstrated that CCK+ BLA pyramidal neurons and CCK+ VTA dopamine neurons project to the nucleus accumbens (NAcc). Finally, bath application of CCK-8 (the most common form of CCK in brain) onto nucleus accumbens slice preparations increases extracellular dopamine, as measured by the genetically encoded dopamine sensor dLight1.2.

Overall, these data suggests that multiple distinct CCK+ projection neurons to the nucleus accumbens may play distinct roles in maladaptive behaviors associated with aversive processing and traumatic experience.

Title: Intrinsic Functional Connectivity in Childhood Predicts Somatic Symptom Change in Adolescence: A Four-Year Longitudinal Study

Authors: *C. SHAFFER[1], L. CUTTING[2], K. QUIGLEY[1], L. FELDMAN BARRETT[1], S. WHITFIELD-GABRIELI[1];
[1]Northeastern Univ., Boston, MA; [2]Vanderbilt Univ., Nashville, TN

Abstract: Identifying neural markers of prodromal mood disorder symptoms is crucial for understanding pathophysiological development and may inform intervention opportunities prior to disorder onset. Evidence suggests that the functional connectivity (FC) of brain regions implicated in visceromotor regulation and mood, such as the subgenual anterior cingulate cortex (sgACC), may be a viable marker of vulnerability in children, as it shows large-scale functional changes throughout development. Psychiatric research has linked aberrant connectivity patterns of the sgACC to the development of psychological and physical symptoms in children, adolescents, and adults. The present study hypothesized that FC patterns of the sgACC would predict changes in somatic complaints in a cohort of children at two time points. Ninety-three 7-year-old participants (39 female) who provided written informed consent and assent completed a baseline visit (T1) that included a resting-state MRI scan and a behavioral visit four years later (T2). Behavioral changes at T1 and T2 were assessed with the Somatic Complaints subscale of the Child Behavioral Checklist (CBCL-SOM). CBCL-SOM scores were not significantly different across age or gender and were not correlated with scan head motion. FC analysis was performed using a seed-driven approach; the sgACC seed was defined using prior exploration of sgACC connectivity in the developmental literature. A post-hoc analysis of covariance regressed CBCL-SOM change scores (T2 - T1) onto brain responses after controlling for initial severity at T1. The cluster-level threshold was set at $p < .05$ using false discovery rate correction for multiple comparisons, with voxel-wise t-value threshold of 3.40 (df = 89; $p < .001$). sgACC seed-to-voxel analysis revealed a cluster of voxels comprising the anterior and posterior inferior

temporal gyrus (ITG) and left middle temporal gyrus (MTG), which significantly predicted the four-year change from baseline on CBCL-SOM ($t_{92} = 4.72$, $p < 0.001$, β;=0.003). Specifically, greater connectivity between sgACC, ITG and MTG was associated with an increase in CBCL-SOM scores from T1 to T2. Results suggest FC patterns among regions implicated in visceromotor control and multimodal sensory integration may be a viable biomarker of change in somatic complaints across development. Somatic complaints are a key feature of adolescent mood disorder symptomatology. Our findings suggest that connectivity between the reported regions may contribute to the subjective sensory experience of the body for children. Thus, it may serve as a valuable biomarker of mood features that are unique to this developmental stage.

Title: High frequency feedback processing as it relates to suicidal ideation and behavior

Authors: *A. PAVULURI[1], J. S. ELLIS[2], M. ARENSON[1], T. E. JOINER[3], N. B. SCHMIDT[3], E. M. BERNAT[1];
[1]Univ. of Maryland, College Park, MD; [2]Tech. Resources International, LLC, Bethesda, MD; [3]Florida State Univ., Tallahassee, FL

Abstract: ***Background.*** Suicidal ideation and behavior may have different etiological pathways, specifically related to feedback processing, that could be better understood by identifying relevant ERP components. Our previous findings in delta (0-3Hz) and theta (4-7Hz) bands indicated that individuals with suicidal behavior, but not ideation, showed heightened neurophysiological response across multiple ERP components to gambling feedback, particularly to loss stimuli, suggesting increased salience and evaluative processing for those with suicidal behavior. This study aimed to assess emerging loss and gain sensitive higher frequency effects in alpha (8-12Hz), beta 1 (12-20Hz), beta 2 (20-30Hz), and gamma (30-60Hz) in the same data, to assess a more comprehensive model of gain and loss sensitive systems in relation to suicidal ideation and behavior. ***Methods.*** 271 subjects (55.7% female; mean age=35.75, SD=16.07; 30.6% veterans) completed a questionnaire battery and a multi-task protocol, including a gambling feedback task (Gehring and Willoughby, 2002), while data was collected from a 96-channel EEG system. Exploratory factor analysis was conducted across 20 self-report suicide

items from relevant questionnaires and produced 2 factors, corresponding to suicidal ideation and suicidal behavior and explaining 60.05% of the variance. Time frequency principal component analysis identified a late slow-wave (1000-2000ms; LSW) parieto-occipital (POZ) measure in alpha, and a LSW bilateral fronto-temporal (F7-FT7-F8-FT8) measure in beta 1, beta 2, and gamma. ***Results.*** All measured frequencies, including previously measured delta and theta bands, were significantly related to suicidal behavior, and not to ideation, except alpha, which showed a relationship to ideation, and not to behavior. Beta 1-LSW, beta 2-LSW, and gamma-LSW were positively correlated with loss ($r=.24$, $p<.001$; $r=.22$, $p<.001$; $r=.21$, $p<.002$, respectively) and gain ($r=.24$, $p<.001$; $r=.21$, $p<.001$; $r=.19$, $p<.002$, respectively), but not with loss-gain differences. Alpha-LSW was positively correlated with loss ($r=.14$, $p<.02$) and gain ($r=.14$, $p<.03$), but not with loss-gain differences. Fisher's z values confirmed that the correlations were stronger for behavior than for ideation for all measured frequencies, except alpha. ***Discussion.*** Broadly, the higher frequency results indicate increased activity for behavior relative to ideation, which was not differentiated between gain and loss conditions, with the notable deviation of alpha relating to ideation, but not to behavior. Findings provide new information about differentiating neurophysiological characteristics relevant to suicide.

Title: Exploring the interaction between emotion regulation and inflammation on changes in episodic memory in older adults

Authors: *E. E. DICKER, S. L. LEAL, C. P. FAGUNDES, B. T. DENNY;
Psychological Sci., Rice Univ., Houston, TX

Abstract: Older adults commonly experience chronic, low grade inflammation as a result of age-related dysregulation. Thus, older adults typically have higher concentrations of circulating proinflammatory cytokines such as Interleukin (IL)-6 and (IL)-8. This predicts the development of physical decline, cognitive decline and Alzheimer's Disease and related dementias (ADRD). In contrast, older adults demonstrate relative emotional strengths compared to younger adults by engaging in more adaptive emotion regulation strategies such as cognitive reappraisal. Emotion regulation is associated with altered immune functioning, and such a link may be an important biological pathway by which interventions targeting affect may improve immune system-related cognitive outcomes. To investigate whether emotion regulation strategies differentially moderate

the effect of inflammatory cytokine levels on cognitive decline, this study used data from the Survey of Mid-life Development in the U.S. (MIDUS), which included measures of emotion regulation (cognitive reappraisal and suppression) and immune function (levels of IL-6 and IL-8). There were 189 adults (mean age = 53 years) who participated in both the MIDUS II and MIDUS III data collections (10 years apart). Regression models measured whether MIDUS II self-report of cognitive reappraisal moderated the effect of MIDUS II serum MSD IL-6, and IL-8 (pg/mL) levels on a composite z-score of episodic memory (immediate and delayed word recall task) at the MIDUS II timepoint and the MIDUS III timepoint 10 years later. Another set of regressions was conducted using the same predictors and criterion, except for MIDUS II self-report suppression, another emotion regulation strategy. All four models controlled for age, sex, BMI, smoking status, alcohol use status, race, years of education, and self-rated health. Only age and sex were significant predictors of MIDUS II episodic memory composite scores. Neither emotion regulation strategy nor either pro-inflammatory cytokine levels predicted memory. However, MIDUS II levels of IL-8 was a significant positive predictor of episodic memory scores 10 years later. Self-reported cognitive reappraisal predicted higher episodic memory scores at the MIDUS III timepoint. MIDUS II level of education, smoking status, and alcohol status also became significant predictors of episodic memory scores 10 years later in expected directions. These findings indicate that inflammation and emotion regulation strategies may be linked to age-related memory decline and could potentially provide a therapeutic target for interventions to improve immune system-related cognitive outcomes.

Title: The effect of emotion regulation on negative affect and emotional mnemonic discrimination

Authors: *B. HAYES, A. HARIKUMAR, L. FERGUSON, S. LEAL;
Rice Univ., Houston, TX

Abstract: Throughout life, stressful and negative experiences are often encountered. Emotion regulation strategies can be used to mitigate the negative effects of these events. These strategies can range from altering our view of the current situation to actively trying to suppress the negative emotions they convey. Depression is associated with general episodic memory deficits as well as a negativity bias, where negative experiences are better remembered compared to neutral or positive experiences. Recent findings have shown that the negativity bias may be

driven by enhanced detailed memory, which is supported by hippocampal pattern separation. Mnemonic discrimination tasks have been developed to examine the behavioral correlate of hippocampal pattern separation and have been shown to be sensitive in detecting memory alterations in depression. The current study aimed to investigate how emotion regulation strategies may be able to modulate negative affect and mnemonic discrimination in individuals with depressive symptoms. Participants completed an emotional mnemonic discrimination task that taxes hippocampal pattern separation that included negative and neutral images, in which they rated their negative feelings towards each image during encoding and retrieval. During the first half of encoding, participants simply viewed the images and rated their negative affect towards the images. During the second half of encoding, participants were either trained to apply an emotion regulation strategy (distancing) and rate their negative affect or were simply asked to rate their negative affect as they did in the first half, applying no emotion regulation strategy (controls). Participants completed a battery of questionnaires including the Beck Depression Inventory-II to measure depressive symptoms. During retrieval, participants were shown the same images (targets), brand new images (foils), or similar but not identical images to those shown during encoding (lures). These lure stimuli are critical for taxing hippocampal pattern separation. We found that the use of an emotion regulation strategy (distancing) was successful in decreasing negative feelings towards negative stimuli (both during encoding and retrieval) in healthy and depressed individuals. Further, we found that applying distancing during encoding impacted memory, resulting in a decrease in the negativity bias in depressed individuals and an increase in neutral memory. This suggests that applying emotion regulation strategies may be an effective way to alter mood and memory in depression.

Title: Development of a face-name mnemonic discrimination task

Authors: *R. MANNION, A. PENA, A. HARIKUMAR, S. LEAL;
Rice Univ., Houston, TX

Abstract: Face-name associative memory encodes information about the relationship between faces and names, allowing us to put faces to names. Difficulty remembering faces is a common struggle for many people, especially as one ages. For example, if you meet someone with a beard one day and a week later see them again but they shaved their beard, it may be difficult to recognize them due to subtle differences in their facial features. Further, it can also be

challenging to remember people's names, especially when they sound phonetically similar to other names (e.g. Lauren and Laurel). Subtle changes in appearance, common facial characteristics across individuals, and similarity between names contribute to the struggle of remembering face-name associations. Computational models suggest the hippocampus performs two key computations: first, reducing interference among similar experiences by using non-overlapping representations (pattern separation); second, filling-in incomplete or degraded representations based on those previously stored (pattern completion). While prior work has examined face-name associative memory, it has not investigated memory for face-name stimuli that have a high degree of similarity in an ecologically valid context. To this end, we developed a face-name associative memory task where facial similarity (same or similar person) and name similarity (same or similar name) were varied. In addition, the race, gender, and emotional valence of the stimuli were evenly distributed among targets (i.e., repeated items), lures (i.e., similar but not identical items), and foils (i.e., new items). Participants were shown a series of faces paired with names during encoding. During retrieval, participants were first shown just the faces (repeated faces, lure faces, and foil faces) followed by a second memory test of faces paired with names (repeat names, lure names, and foil names). We found that memory for face-name associations was reduced for lures compared to targets. This suggests that the inclusion of faces and names that share overlapping features in a memory task may provide a more sensitive measure of face-name associative memory functioning as well as establish the underlying neural mechanisms that support face-name associative computations.

Title: The effect of antidepressants on emotional mnemonic discrimination

Authors: *T. PHILLIPS, R. VAS, A. HARIKUMAR, L. FERGUSON, S. LEAL;
Rice Univ., Houston, TX

Abstract: Depression is associated with general memory impairment as well as a negativity bias, where negative experiences are better remembered compared to neutral or positive experiences. One potential mechanism underlying this negativity bias may be pattern separation, a hippocampal computation that processes similar experiences using non-overlapping representations. Individuals with depression show reduced hippocampal volume and enhancement of negative mnemonic discrimination, the behavioral correlate of hippocampal pattern separation. Rodent studies have shown that antidepressants can reverse hippocampal

volume reduction and restore normal memory functioning, but these effects have not yet been tested in humans. One caveat to consider from human studies of antidepressants is that more than half of all depressed patients do not respond to antidepressants and must try different types until they find one that works for them. The current study investigated the effect of antidepressant use and their perceived effectiveness on an emotional mnemonic discrimination task. Depressed young adults who were taking antidepressants performed a computerized emotional mnemonic discrimination task that taxes hippocampal pattern separation. During encoding, participants were shown positive, negative, or neutral images. After a short delay, participants were then tested on their memory for the images they saw during encoding with the same images they saw during encoding (targets), brand new images (foils), or similar but not identical images to ones they saw during encoding (lures). Participants reported their depressive symptoms prior to taking antidepressants as well as their current depressive symptoms, where we calculated a change score to determine how effective participants felt the antidepressants were in reducing their symptoms. We found that individuals taking antidepressants who reported a greater improvement in their symptoms showed a reduction in negative lure discrimination and enhanced neutral lure discrimination compared to those who were taking antidepressants with no improvement in symptoms. This suggests that antidepressants may be beneficial in alleviating mood symptoms as well as reducing the negativity bias and improving memory.

Title: The effect of current perceived stress on emotional mnemonic discrimination

Authors: *R. VAS, T. PHILLIPS, A. HARIKUMAR, L. FERGUSON, S. LEAL;
Rice Univ., Houston, TX

Abstract: Stress can have profound impacts on memory. The hippocampus, a brain region involved in memory, can perform a key computation called pattern separation that allows for the orthogonalization between similar events. Previous research has examined the impact of stress on hippocampal pattern separation by inducing stress in the laboratory or by examining chronic stress (e.g. depression); however, little is known about how natural variation in current perceived stress in healthy young adults may impact memory. Here, we examined the impact of current perceived stress on an emotional mnemonic discrimination task that taxes hippocampal pattern separation. Participants (ages 18-35) reported their current level of perceived stress on a

modified version of the Perceived Stress Scale (PSS) that asked participants about their current level of stress as well as stress over the past month. We used this measure to split participants into low and high current perceived stress groups. After administration of the PSS, participants performed an emotional mnemonic discrimination task. During encoding, participants viewed scene stimuli, which they rated as positive, negative, or neutral. After a short delay, their memory was tested for the same exact images they saw during encoding (targets), brand new scenes (foils), and similar but not identical scenes to ones they saw during encoding (lures). We found impaired lure discrimination in young adults with higher current perceived stress compared to those with lower current stress levels, especially for positive stimuli. These results suggest current perceived stress greatly impacts emotional memory, especially for positive experiences.

Title: Examining the effect of retirement and cognitive activity on mnemonic discrimination

Authors: *L. A. FERGUSON, A. HARIKUMAR, S. L. LEAL;
Rice Univ., Houston, TX

Abstract: Aging is associated with memory decline, especially for experiences that have many overlapping features. The hippocampus, a brain region involved in memory, can perform a key computation called pattern separation to reduce interference across similar experiences. Older adults are susceptible to interference and show hippocampal pattern separation impairment. However, other factors may influence the degree to which memory becomes impaired with age. Retirement may result in a significant change in one's life such that a transition from life in the workforce to leisure time at home may negatively impact memory. The reduction in cognitive activity that accompanies retirement could potentially reduce cognitive reserve in aging. In the current study, we examined how retirement status and cognitive activity impacted performance on a mnemonic discrimination task that taxes hippocampal pattern separation. We examined general memory performance (target recognition) as well as detailed memory performance (mnemonic discrimination). Preliminary evidence suggests that retired older adults have worse mnemonic discrimination performance compared to working older adults. There were no group differences for target recognition, suggesting mnemonic discrimination may be a more sensitive measure of decline associated with retirement. Further, age and level of cognitive activity

significantly predicted mnemonic discrimination performance. This suggests that retirement status may impact memory performance and could contribute to age-related memory decline. Further, older adults may be able to maintain their cognitive reserve through educational and cognitively stimulating activities.

Abstract: Heart rate variability (HRV) is the fluctuation in the interval between heart beats reflecting heart-brain interactions, which help in the adaptation to environmental and psychological challenges. Following the recent push to establish neurobiological markers of psychiatric illness for improved nosology, HRV has been used as a transdiagnostic marker. Despite its promising utility in the field of psychopathology, efforts to improve research reproducibility, and generalizability have only recently emerged in this field. Regardless of efforts to increase generalizability there is a dearth of HRV research in Latin American samples. Moreover, there is limited research determining the test re-test reliability of various HRV measures and methods. Using HRV data (5 minutes during rest) from 3 visits during an academic year we calculated test-retest reliability in undergraduate and graduate students from various public and private universities in a city in northwest Mexico (n = 236). Participants also completed self-report personality and mood and anxiety questionnaires. We found that HRV measures demonstrated time consistency reliability and were associated with weight and BMI. However, we did not find any consistent associations with mood and anxiety disorder symptoms. Our results suggest that HRV is reliable over time and is associated with biometric data. However, we did not find links to psychiatric symptoms. Future studies should include larger community samples to test the generalizability and reproducibility of our results.

Title: Dorsal anterior cingulate cortex, anteromedial thalamus, and anterior insula effective connectivity during threat anticipation in individual with internalizing psychopathology

Authors: *M. RADOMAN[1], S. M. GORKA[2], K. L. PHAN[2], O. A. AJILORE[1];
[1]Univ. of Illinois at Chicago, Chicago, IL; [2]Ohio State Univ., Columbus, OH

Abstract: Converging lines of evidence suggest that heightened responses to unpredictable threat may be an important neurobiological marker of internalizing psychopathology. Prior data also indicate that aversive responding to uncertainty may be mediated by hyperactivation of several brain regions within the frontolimbic circuitry, namely the anterior insula (AIC), anteromedial thalamus, and dorsal anterior cingulate cortex (dACC). The present study aimed to understand how these three regions function as a network during U-threat and predictable threat (P-threat) anticipation in adults with internalizing psychopathologies. Towards this goal, functional magnetic resonance imaging (fMRI) and dynamic causal modeling (DCM) were used to examine effective connectivity among these three nodes in 22 healthy controls and 49 patients with various comorbid mood (depression and anxiety) disorders. During fMRI, participants completed a version of the well-validated No-Predictable-Unpredictable (NPU) paradigm. Six connectivity models, based on anatomic connections, were entered into Parametric Empirical Bayes (PEB) analysis to examine group-level differences in effective connectivity parameters between controls and patients. We further applied leave-one-out-cross-validation to evaluate the hypotheses about whether the effect size of connections identified in the PEB analysis was large enough to predict a participant's group (patient vs. control) from their neural response. The study yielded two main findings: (1) dACC to AIC connectivities during both P-threat and U-threat emerged as important group-difference parameters, but (2) only the effect size of dACC to AIC connectivity during U-threat was large enough to predict a participant's group. This study is the first to demonstrate in humans the key role of dACC projections to AIC in support of "top-down" threat processing. Further research efforts are needed to corroborate and expand the present findings.

Title: Genetic targeting of RGS14 to the nuclei of neurons induces sex-specific behavioral effects of cocaine in mice

Authors: *S. BRAMLETT[1], S. FOSTER[3], D. LUSTBERG[2], N. HARBIN[1], D. WEINSHENKER[4], J. HEPLER[5];
[2]Mol. & Systems Pharmacol., [1]Emory Univ., Atlanta, GA; [3]Dept. of Human Genet., Emory Univ. Sch. of Med., Atlanta, GA; [4]Dept Human Genet., Emory Univ. Sch. Med., Atlanta, GA; [5]Emory Universitty Sch. of Med., Atlanta, GA

Abstract: Psychostimulant addiction is a major public health problem that currently lacks any U.S. Food and Drug Administration-approved medications for treatment. Psychostimulants such as cocaine (COC) induce hyperdopaminergic signaling within the mesolimbic reward pathway to usurp the neural mechanisms of motivational drive. Regulator of G protein Signaling 14 (RGS14) is a multifunctional scaffolding protein in brain that is best understood for its role in suppressing synaptic plasticity and learning and memory in hippocampal area CA2. We have proposed that RGS14 regulates signaling in the nucleus accumbens in a similar manner to oppose the maladaptive engagement of learning and memory that forms the basis of addiction. Herein we examine the relationship of RGS14 to molecular and behavioral correlates of COC addiction, as well as the role that RGS14 subcellular localization plays in mediating the effects of COC. Two genetically manipulated mouse lines are used to accomplish these goals: one strain in which RGS14 is functionally deleted (RGS14-KO) and another in which RGS14 is confined to the nucleus by CRISPR/Cas9 introduction of a naturally occurring variant found in humans (RGS14-L504R). Behavioral tasks include acute locomotor response and locomotor sensitization to COC. Immunofluorescence co-staining of RGS14 and addiction-linked signaling proteins in striatal sections of mice treated with COC acutely and chronically are used to reveal intracellular mechanisms. Our analysis revealed extensive colocalization of RGS14 with D1 and D2 dopamine receptors in nucleus accumbens core and shell, supporting RGS14 regulation of reward pathway neurons. Furthermore, we found that subjects in which RGS14 is restricted to the nucleus (RGS14-L504R) show enhanced sensitivity to the locomotor activating effects of COC. This effect is demonstrated by a leftward shift in the dose-response curve and is driven by RGS14-L504R males. A different relationship is observed in the RGS14-KO group, which show

an augmented maximal response of COC-induced locomotor activation in a sex-independent manner. These results reveal exciting new information regarding the diverse roles that RGS14 can fill in respect to COC action depending on where it is localized in the cell, which may provide an avenue to much-needed therapeutics for psychostimulant addiction.

Title: Sex differences in the role of GILZ underlying formation and maintenance of drug-associated memory

Authors: *J. ROUNDS, E. KRAMÁR, M. WOOD;
Univ. of California, Irvine, Irvine, CA

Abstract: It is well established that stress can modulate interactions between drugs of abuse and memory processes in the brain. The conditions of a stressful experience can differentially impair or facilitate memory, and in certain situations may reinstate drug-seeking behaviors. However, the mechanisms by which stress leads to stable changes in neuronal function underlying long-term behavioral adaptations remain poorly understood. Here, we examined the role of a candidate X-linked gene (glucocorticoid-induced leucine zipper, GILZ) in regulating long-term drug-associated memory processes within the mouse nucleus accumbens (NAc) and ventral tegmental area (VTA). We found sex-specific patterns of baseline GILZ expression in both the NAc and VTA, where mRNA splice variants coding for the various GILZ protein isoforms were differentially expressed between adult male and female mice. The differential expression of these GILZ isoforms (known to regulate transcriptional activation as well as the integration of key signaling cascades involved in memory) thus suggests sex differences in the role of GILZ in reward-related regions. To determine whether GILZ expression is necessary for the formation of drug-associated memory, males and females were infused with a site-specific siRNA (targeted to either the NAc or VTA) to knockdown all splice variants of GILZ prior to training in a cocaine-conditioned place preference (CPP) protocol. We found that VTA-GILZ knockdown significantly blunted cocaine-CPP acquisition in males but not females in a dose-dependent manner. In addition, we found that intra-NAc knockdown of GILZ attenuates long-term potentiation (LTP, a key measure of synaptic involvement in memory formation) in males.

Together, these data suggest a sex-specific role of GILZ in contributing to stable changes in neuronal function underlying reward-related memory processes.

Title: Corticotropin-releasing factor receptor 1 in the basolateral amygdala regulates cocaine-memory reconsolidation in male and female rats

Authors: *J. L. RITCHIE, J. L. WALTERS, J. M. C. GALLIOU, R. J. CHRISTIAN, S. QI, M. I. SAVENKOVA, C. K. IBARRA, S. R. GROGAN, R. A. FUCHS;
Integrative Physiol. and Neurosci., Washington State Univ., Pullman, WA

Abstract: Exposure to drug-associated environmental stimuli can lead to the retrieval of powerful drug memories and elicit drug craving and relapse in individuals with substance use disorders. Drug memories can become destabilized upon retrieval, requiring memory reconsolidation to maintain their strength over time. The basolateral amygdala (BLA), a critical site of memory reconsolidation, robustly expresses corticotropin releasing factor receptor 1 (CRFR1). Thus, we evaluated whether BLA CRFR1 signaling is sufficient or necessary for cocaine-memory reconsolidation in Exp 1. Male and female Sprague Dawley rats self-administered cocaine in a distinct context for 10 days then received extinction training in a different context for 7 days. Next, the rats were exposed to the cocaine-paired context to reactivate cocaine memories and received bilateral intra-BLA vehicle, CRFR1 antagonist (antalarmin 500 ng/hemisphere), or exogenous CRF (0.2, 30, or 500 ng/hemisphere) infusions immediately, or 6 h (control), after memory reactivation. Drug-seeking behavior was assessed in the cocaine-paired context 3 d later to evaluate cocaine-memory strength. Intra-BLA CRFR1 antagonism immediately, but not 6 h, after memory reactivation attenuated drug-seeking behavior at test independent of sex. Conversely, intra-BLA CRF dose-dependently enhanced drug-seeking behavior selectively in females. In Exp 2, we aimed to identify the source of CRF in the BLA during cocaine-memory reconsolidation. Rats received intra-BLA infusions of Retrobeads^{TM} prior to behavioral training. Brain tissue was collected 2 h after memory reactivation (i.e., during reconsolidation) or home cage stay. Retrobeads^{TM}, CRF

immunoreactivity (IR), and c-Fos-IR (marker of neuronal activation) were visualized. BLA-projecting CRF-IR neurons in the anterior cingulate cortex, prelimbic cortex, and dorsal raphe, but not in the infralimbic cortex or anterior insular cortex, exhibited greater c-Fos expression after cocaine-memory reactivation relative to home cage stay. These findings indicate that CRF signaling in the BLA is necessary for cocaine-memory reconsolidation, and distinct extra-hypothalamic CRF circuits may be recruited to maintain cocaine-memory strength during reconsolidation.

Title: Corticotrophin Releasing Factor Receptor 2 in the basolateral amygdala enables Nonmuscle Myosin II-mediated disruption of methamphetamine-associated memory

Authors: *M. HAFENBREIDEL, S. B. BRIGGS, M. ARZA, A. TILLER, A. B. HALL, L. LIN, S. KHAN, S. E. SILLIVAN, S. PANDEY, M. D. CAMERON, G. RUMBAUGH, C. A. MILLER;
The Scripps Res. Inst., Jupiter, FL

Abstract: Substance use disorders (SUD) are perpetuated by associative memories that induce motivation to seek drug. We previously reported that inhibition of the actin motor ATPase nonmuscle myosin II (NMII) with the small molecule inhibitor blebbistatin (blebb), results in actin depolymerization and dendritic spine loss in the basolateral amygdala (BLA) and a retrieval-independent disruption of methamphetamine (METH)-associated memories and METH seeking. The effect is unique to BLA and specific to METH, as it does not interfere with other associative memories for foot shock, food reward or many other commonly abused drugs, including cocaine (COC). To investigate the source(s) of this selectivity, we used RNA-seq following conditioned place preference (CPP) conditioning to determine transcriptional differences between METH- and COC-associated memories. One gene selectively upregulated in METH-treated mice in BLA, but not hippocampus or nucleus accumbens, was *crhr2*, which encodes Corticotrophin Releasing Factor receptor 2 (CRF2). Besides its role in the stress

response, its ligand, CRF, is released in BLA following COC or METH administration, and CRF receptor 1, but not CRF2, is involved in COC-associated memory. Interestingly, CRF2 has been linked to NMII regulation outside the CNS, but its role and potential interaction with NMII in METH-associated memories was unknown. To test for this interaction, we first established the impact of CRF2 inhibition after METH CPP conditioning. Mice received intra-BLA infusions of vehicle or the CRF2 antagonist Astressin-2B (AS2B) after the final METH conditioning session. CRF2 inhibition was not sufficient to disrupt the memory, as both groups expressed a METH CPP when tested 48hr later. A second experiment established that, unlike AS2B, NMII inhibition with blebb (IP) shortly after the last METH conditioning session disrupted METH CPP expression. Taken together, these results enabled examination of the interaction between CRF2 and NMII. For this, mice received intra-BLA infusions of vehicle or AS2B after the last conditioning session, followed by blebb (IP) shortly after. METH CPP was disrupted in mice treated with vehicle and blebb, replicating our previous results. However, METH-associated memory was protected in mice that received AS2B and blebb. These results suggest that CRF2 is required in combination with NMII activity in BLA to render METH-associated memories and seeking-like behavior selectively vulnerable to NMII inhibition in the absence of retrieval. Indeed, CRF2 may represent a general target for destabilizing memory via (yet to be identified) downstream effects on NMII.

Title: Role of dopamine receptors in conditioned memory modulation

Authors: *T. LAPOINTE[1], F. LERI[2];
[1]Univ. of Guelph, Guelph, ON, Canada; [2]Psychology, Univ. Guelph, Guelph, ON, Canada

Abstract: Exposure to conditioned stimuli (CS) predictive of foot-shock enhance memory consolidation, a process of memory stabilization that is central to learning. There is evidence that dopamine D2 and D3 receptors modulate several responses to CSs, including freezing and step-through passive avoidance. Therefore, we employed a signalled active avoidance procedure (8 days; 30 trials/day; 0.8 mA) and spontaneous object recognition (SOR) task to examine whether

these DA receptors are involved in the memory enhancing action of a CS predictive of foot-shock. As such, male Sprague-Dawley rats were exposed to the avoidance CS immediately following the sample phase of the SOR task. Immediate post-sample exposure to the avoidance CS in the absence of shock enhanced object memory, and this effect was dose-dependently blocked by the beta-adrenergic receptor antagonist propranolol (10 and 20 mg/kg), thus confirming that this conditioned effect on object recognition is indeed facilitated by a modulation of consolidation. We then tested the D2 receptor antagonist pimozide (0.2 and 0.6 mg/kg) and D3 receptor antagonist NGB-2904 (0.1 and 5 mg/kg), both of which dose-dependently blocked the effect of post-sample CS exposure on object memory, while having no effect on avoidance behaviour. Overall, these results indicate an important role for DA D2 and D3 receptors in conditioned enhancement of memory consolidation.

Title: Role of perirhinal cortical nicotinic receptors in memory modulation by nicotine, cocaine, and their conditioned stimuli

Authors: *M. WOLTER[1], N. BAIDOO[1], K. A. MITCHNICK[2], C. WIDEMAN[1], B. D. WINTERS[1], F. LERI[3];
[2]Psychology, [1]Univ. of Guelph, Guelph, ON, Canada; [3]Psychology, Univ. Guelph, Guelph, ON, Canada

Abstract: It has been recently suggested that drug conditioned stimuli (CS) activate neurochemical systems of memory modulation that are directly activated by the drugs themselves. To test this hypothesis using two psychomotor stimulant drugs, nicotine and cocaine, male Sprague-Dailey rats received infusions of the nicotinic receptor antagonist mecamylamine (MEC) within the perirhinal cortex (PRh); a cortical region well known to be involved in consolidation object memory. To establish drug CSs, rats were confined for 2 h in a chamber (the CS+) after injections of 0.4 mg/kg nicotine or 20 mg/kg cocaine, and in another chamber (the CS−) after injections of vehicle. This was repeated over 10 days (5 drug/CS+ and 5 vehicle/CS− pairings in total). It was found that the memory enhancing action of post-sample 0.4 mg/kg nicotine was blocked by intra-PRh infusions of 10 and 30 μg/side MEC, and 30 μg/side MEC also blocked the memory enhancing effects of the nicotine CS. Interestingly, MEC did not block

the effects of cocaine, or the cocaine CS on object memory consolidation. These data indicate that a nicotine CS promotes memory consolidation by stimulating nicotine receptors in the PRh, an effect that is typically produced by nicotine itself. This cholinergic pathway, however, does not appear involved in memory modulation by CSs paired with other drugs.

Title: Neuronal ensembles in the prelimbic cortex mediate initial cocaine-seeking behavior in rats.

Authors: *B. SORTMAN, S. RAKELA, K. SIBSON, B. CERCI, C. GOBIN, B. WARREN; Univ. of Florida, Gainesville, FL

Abstract: Neuronal ensembles in the medial prefrontal cortex (mPFC) mediate well-trained self-administration for both drugs and natural reinforcers. We have previously shown that mPFC ensembles drive food self-administration behavior after as few as one training session. Here, we test the hypothesis that neuronal ensembles within the prelimbic cortex (PrL) rapidly form to drive cocaine-seeking behavior after initiating cocaine self-administration. To test this hypothesis, we used the Daun02 inactivation procedure in Fos-lacZ transgenic rats to selectively ablate neuronal ensembles formed during initial cocaine-seeking behavior. We trained adult male and female Fos-LacZ rats to self-administer cocaine intravenously (0.75 mg/kg/infusion) for between 1 to 12 days, until rats met acquisition criteria (e.g., ≥30 active lever presses and ≥70% of all lever presses on the active lever). The day after each rat met behavioral acquisition we bilaterally microinfused either Daun02 or vehicle into the PrL (2µg/0.5µl/side) of rats 60 minutes after a 30-minute non-reinforcing cocaine seeking test (i.e., induction day). Forty-eight hours later we measured cocaine-seeking behavior in a 30-minute test under non-reinforced conditions. Rats that received Daun02 pressed the active lever significantly less than rats that received vehicle ($p<0.05$). We then extracted the brains to assess total β-galactosidase activity and found that β-galactosidase expression was significantly lower in Daun02-treated rats compared to vehicle-treated controls ($p<0.05$). These data suggest that neuronal ensembles in the PrL rapidly form to mediate cocaine self-administration after initial behavioral acquisition.

Title: Self-administration acquisition rate predicts locomotor, but not reward sensitivity to cocaine in rats

Authors: *S. RAKELA, B. SORTMAN, M. REEVES, C. GOBIN, B. WARREN;
Dept. of Pharmacodynamics, Univ. of Florida, Gainesville, FL

Abstract: Most people who initiate cocaine use do not develop Cocaine Use Disorder. Differences in susceptibility begin to emerge after first exposure to cocaine: some users discontinue cocaine self-administration after a single exposure, some use intermittently over a long-period of time, and others promptly develop a compulsive binge pattern. In rodents, individual differences in cocaine self-administration also emerge rapidly. Some rats rapidly acquire cocaine self-administration behaviors, while others require multiple training sessions. Whether these differences reflect differences in cocaine sensitivity, motivation, or capacity to acquire the behavior remain unclear. Here, we attempt to determine whether rate of cocaine acquisition predicts subsequent cocaine self-administration behavior, locomotor sensitivity to cocaine, or seeking following two weeks of abstinence. We first evaluated 14 male Sprague-Dawley rats in an open field test to gauge initial locomotion and anxiety-like behavior. Next, we subjected rats to daily 3h cocaine (0.75mg/kg/infusion) self-administration sessions until rats met acquisition criteria (≥30 active lever presses, and ≥75% responding on the active lever). Upon meeting acquisition criteria, we trained rats for 10 additional sessions to ensure all had equal opportunity to self-administer cocaine. Following self-administration training, we measured performance in a progressive ratio test, locomotor sensitivity to cocaine, and lever pressing in a non-reinforced cocaine seeking test after 2w of forced abstinence. Early Learners exhibited significantly less locomotion following an intraperitoneal injection of cocaine than Late Learners, but did not differ in any other behavioral parameter examined. These results suggest that time taken to acquire cocaine self-administration behavior is not dependent on factors such as motivation for or exposure to cocaine, but rather may be linked to physiological factors that predispose rats to learn an operant task, such as cocaine sensitivity.

Title: Paternal Cocaine Self-Administration Enhances Fear-Related Phenotypes and Suppresses Synaptic Activity only in Male Offspring

Authors: *M. T. RICH, S. E. SWINFORD-JACKSON, S. T. MANKAME, S. J. WOROBEY, R. C. PIERCE;
Dept. of Psychiatry, Rutgers Univ., Piscataway, NJ

Abstract: Paternal exposure to cocaine induces epigenetic modifications that directly influence synaptic plasticity as well as memory- and reward-related behaviors. Given the high degree of comorbidity between substance use disorders and mental health illnesses, such as post-traumatic stress disorder (PTSD), we examined whether cocaine self-administration in male rats would produce fear-associated behavioral effects in drug-naïve progeny. Adult offspring were subjected to cue-dependent fear conditioning, followed by cue extinction. We observed no differences in fear-related freezing behavior during conditioning. However, cocaine-sired male offspring exhibited deficits in extinction as well as increased freezing upon retrieval of the extinction memory, indicative of enhanced and persistent fear-associated memory relative to saline-sired controls. Consistent with our previous results with other behavioral models, we found no differences in fear-related behaviors in female offspring. To determine a physiological correlate for these behavioral results, we next performed patch clamp recordings in the amygdala, a brain region that is highly involved in the encoding of emotionally salient memories. Despite no differences in baseline physiological measures, we found deficits in long-term potentiation (LTP) at cortico-amygdala synapses in male, but not female, offspring of cocaine-exposed sires. Prior research heavily implicates this circuit's involvement in fear extinction, suggesting that the resilience to fear memory extinction observed in cocaine-sired male progeny may be due to inherited deficiencies in genes that govern LTP induction. Ongoing studies are therefore investigating whether paternal cocaine exposure affects the expression of several known candidate genes that play a role in synaptic plasticity.

Title: The role of histone acetyltransferase activity in alcohol-induced neuroadaptations

Authors: *A. MONTES, C. DASTA-CRUZ, L. RAMOS-RODRIGUEZ, C. DEL VALLE-COLON, M. KUCHIBHOTLA, J. L. AGOSTO, A. GHEZZI;
Dept. of Biol., Univ. of Puerto Rico, Rio Piedras, San Juan, PR

Abstract: Excessive alcohol consumption is one of the most prevalent disorders among individuals in our society that affects adults, teens, and children that are born from alcoholic parents. Alcohol consumption leads to an homeostatic imbalance in the organism, followed by the development of adaptations in the brain leading to alcohol tolerance and physiological dependence. Recently, epigenetic mechanisms that alter gene expression and chromatin states have shown to be involved behind these alcohol-induced adaptations. However, much of the epigenetic mechanisms that lead to alcohol addiction are still unknown. In this study, we aim to determine the mechanism of histone modification upon alcohol exposure. To determine the effects of Tip60, a histone acetyltransferase, in alcohol tolerance, we used the model organism Drosophila melanogaster and the UAS-Gal4 system, to knock-down gene expression through RNAi of Tip60 in neurons (ELAV-GAL4/UAS-Tip60-RNAi). Using an activity monitor, we measured the difference in the rate of sedation upon alcohol vapor exposure of aged-matched, female ELAV-GAL4/UAS-Tip60-RNAi and control (ELAV-GAL4/UAS-GFP) adult flies. We found that Tip60 knock-down flies did not show a significant increase in sedation time between exposure to alcohol compared to control flies. These results suggest that Tip60 is involved in the development of alcohol tolerance. We also performed an RNA-sequencing of the whole brain of the aforementioned transgenic Drosophila to examine the transcriptional changes of alcohol sedated flies compared to mock-sedated flies after one day of exposure. This study reveals

differential expression of genes in neurons from ELAV-GAL4/UAS-Tip60-RNAi flies exposed to alcohol compared to mock-sedated flies, and for sedated and mock-sedated ELAV-GAL4/UAS-GFP flies, respectively. This suggests that alcohol exposure triggers significant transcription of ethanol-responsive genes, suggesting that complex gene networks might be involved in the development of alcohol tolerance. Collectively, our data can provide us new insights on how neurons adapt to alcohol through histone acetylation mechanisms.

Abstract: Alcohol consumption is known to induce cognitive impairments mainly affecting executive functions, episodic memory, and other capacities related to brain function. Nevertheless, the cellular and molecular mechanisms underlying such interactions are still unknown. Recent evidence has uncovered a similar interaction between ethanol exposure and cognitive function in the fruit fly, Drosophila melanogaster, which opens the way for molecular studies in a genetically tractable model system. Using olfactory conditioning assays where an odorant is used as a conditioned stimulus (CS) and is paired with a heat shock used as an unconditioned stimulus (US), it was shown that Drosophila larvae can learn to avoid the odor in future exposures. However,when the animals are exposed to a short acute dose of alcohol, they are no longer able to learn this association. Interestingly, larvae that have undergone prolonged chronic ethanol exposure seem to successfully avoid the odorant paired with the heat shock just as well as control ethanol-naive larvae, which is suggestive of ethanol-induced neuroadaptations. Our aim is to understand the genetic and cellular components responsible for this adaptation. For this, we employ RNA Sequencing technology to evaluate differences in gene expression in the brain of larvae chronically exposed to ethanol and in control larvae. With the knowledge

obtained from this study we could be able to understand ethanol's effect on learning and memory and gain an insight into how addiction may be contributing to damages in this behavior.

Title: Cortical and Thalamic Inputs to D2-MSNs Distinctly Mediate Alcohol Seeking and Extinction

Authors: *T. TAN[1], A. BINETTE[1,2], W. WANG[1], Y. HUANG[1], Y. CHENG[1], W. PURVINES[3], X. XIE[1], B. HENDERSON[1], H. GANGAL[3], X. WANG[1], J. WANG[1,2];

Abstract: The dorsal medial striatum (DMS), which plays an important role in alcohol use disorder (AUD), contains mainly dopamine D1 receptor (D1R)- and D2R-expressing medium spiny neurons (MSNs). While the contribution of D1-MSNs to AUD is relatively clear, little is known about the role of D2-MSNs. Here, we explore the distinct roles of D2-MSNs in seeking and extinction of operant alcohol self-administration. A novel D2-Cre transgenic rat was crossed with a tdTomato reporter line. Histology study revealed the tdTomato-expressing striatal MSNs projected to the external globus pallidus (GPe), but not the substantia nigra pars reticularta (SNr). Slice electrophysiological studies found the firing activity of these fluorescent neurons was inhibited selectively by a D2R agonist but not D1R agonist, demonstrating the selective Cre expression in D2-MSNs. Interestingly, optogenetic excitation of DMS D2-MSNs during operant alcohol self-administration (SA) transiently reduced alcohol-seeking behavior, whereas optogenetic induction of cortico-striatal long-term potentiation (LTP) in these neurons produced significant and long-lasting suppression of alcohol-seeking behavior. Next, we examined the role of D2-MSNs in the extinction and discovered glutamatergic potentiation D2-MSNs after extinction training. Consistently, optogenetic inhibition of D2-MSN projections in the GPe prevented alcohol extinction and facilitated reinstatement to alcohol seeking. Retrograde (with rabies) and antegrade (with AAV1-Cre) tracing studies showed mono-synaptic afferent from the centromedian thalamic nucleus (CM) to D2-MSNs. Optogenetic inhibition of CM neurons or optogenetic induction of long-term depression (LTD) of CM inputs to DMS D2-MSNs,

prevented alcohol extinction. Taken together, our results suggest DMS D2-MSNs and cortical inputs to this neuronal type negatively regulate operant alcohol-seeking behavior, and thalamic inputs to DMS D2-MSNs positively regulate the extinction of alcohol SA. These results establish circuit and synaptic mechanisms of D2-MSNs in regulating alcohol-seeking and extinction, which may provide a therapeutic strategy in using these mechanisms to treat AUD.

Title: Neurophysiological correlates of alcohol tolerance in the Mushroom Body of Drosophila melanogaster

Authors: N. L. FUENZALIDA-URIBE, C. IRIZARRY-HERNANDEZ, I. A. DIAZ-NIEVES, *A. GHEZZI;
Biol., Univ. of Puerto Rico, Rio Piedras, San Juan, PR

Abstract: Alcohol exposure can generate a series of behavioral adaptations that lead to the development of alcohol tolerance and dependence. These adaptations are critical components in the development of alcohol addiction. However, the neural mechanisms by which these adaptations occur remain unresolved. Here, we use a Drosophila model to explore the neurophysiological correlates of alcohol tolerance in the Mushroom Body of the fly—a key neuropil in the brain. Flies develop tolerance to alcohol after a single exposure, and this phenotype is accompanied by a series of behavioral adaptations that remain for days. Since the Mushroom Body (MB) is an integration center of several sensory stimuli, we assessed its role in underlying ethanol tolerance. Using a functional imaging approach, we studied the neurophysiology of the MB calyx in response to ethanol. Flies expressing the calcium sensor protein GCamp6s in MB neurons were treated with ethanol vapor (~95%) until anesthetized (~40 minutes). Twenty-four hours later, we record the intracellular calcium dynamics in the MB calyx. Tolerant flies showed a decreased response to a short ethanol exposure (3 seconds) compared to control flies, suggesting this brain area is involved in the neurophysiological processing of ethanol tolerance. This reduction in neural signaling correlates with the changes

observed in Drosophila behaviors related to ethanol exposure, suggesting a possible neural substrate for the behavioral adaptation to alcohol during tolerance.

Title: Pumilio -a translational regulator- as a modulator of alcohol tolerance via macrophages

Authors: *M. KUCHIBHOTLA, A. MONTES, E. W. O. ELIAS, J. A. RODRIGUEZ, J. AGOSTO, A. GHEZZI;
Biol., Univ. of Puerto Rico, Rio Piedras, San Juan, PR

Abstract: Alcoholism is the third leading cause of deaths. One of the key components in the development of alcoholism is the gradual increase in resistance to alcohol over repeated exposures. This adaptation is also known as tolerance, which is thought to involve many neural adaptations and plasticity within the brain leading to alcohol addiction. Alcoholism being a multifaceted disorder coupled with relapse, makes it harder for treatment. The Neuroimmune system is paving a new path in understanding the vital role of the innate immune system in the development of alcohol addiction and behaviors. Alcohol induced neuroinflammation and neurodegeneration at CNS is linked to both spiked systemic proinflammatory factors and mutations in these innate immune genes. Supporting the role of immunity and neuroimmune signaling in alcohol addiction. Therefore, there is a need for novel strategies and varied perspectives in treating alcoholism effectively. *Drosophila* studies have identified the RNA binding protein pumilio (pum) as a regulator of ethanol tolerance. Pum has also been linked to innate immunity and alcohol tolerance. Thus, the goal of this study is to investigate the role of pumilio in alcohol responses via macrophages, one of the key immune cells in the fly. To Determine how pum modifications within macrophages affect alcohol sensitivity and tolerance, we employed UAS/Gal4 binary system for targeted expression of pumilio RNAi transgene

precisely in hemocyte-specific driver line (hml-GAL4). We exposed age matched adult female progeny (hml-RNAipum and hml-GFP) to 50% ethanol and recorded sedation scores. We found that pum knockdown in hemocytes decreases ethanol tolerance without changing sensitivity. These findings suggest that hemocyte/brain communication contributes to alcohol responses and pum regulates crosstalk between hemocytes and brain by possibly altering these signaling. However, neuronal adaptations underlying this reduction in tolerance remain unknown. To understand those adaptations, transcriptome analysis of *Drosophila* whole brains was performed to survey genome wide expression profiles of hml-RNAi vs GFP flies after one exposure. Analysis of data is in the process. Our data indicate that Pumilio rather affects signaling between peripheral macrophages and the brain leading to neuronal plasticity. Mechanisms underlying these neuroimmune signaling pathways regulated by pumilio are worth exploring and can deepen our knowledge about the role of the immune system in alcoholism. Together these findings can spot macrophages as a possible potential novel therapeutic target in treating alcoholism.

Title: Regulated expression of the $GABA_A$receptor alpha2 subunit modulates the development of Alcohol Use Disorder

Authors: *J. BARKER, R. HINES, D. HINES;
Univ. of Nevada, Las Vegas Neurosci. Grad. Program, Las Vegas, NV

Abstract: The development of Alcohol Use Disorder (AUD) involves a combination of environmental and biological factors that lead to changes in both gene expression and function, dysregulation of proteins translated from mRNA, and synaptic plasticity. Both the timing and specific mechanisms that contribute to developing AUD remain unclear. Multiple studies have indicated an increase in expression of mRNA encoding the α2 subunit of the $GABA_A$ receptor following exposure to alcohol and other substances of abuse. In addition, genome-wide association studies of families with multiple alcoholics have shown single nucleotide polymorphisms in the GABRA2 gene, which codes for the α2 subunit. We find that the α2 subunit is highly expressed in the nucleus accumbens (NAc) on dopamine receptor D1 expressing cells. We also find that NAc expression of α2 subunit protein is increased upon voluntary access to alcohol. Mice with saturated α2 expression do not develop place preference for alcohol, and also do not increase voluntary consumption of alcohol in an intermittent access

paradigm. Our research suggests that regulated expression of the α2 subunit of the $GABA_A$ receptor is critical for the development of AUD. We are currently investigating the mechanisms that regulate α2 expression in the NAc during exposure to alcohol, including looking at proteins that control translation of α2 mRNA. These studies are expected to increase our understanding of the mechanisms underlying AUD, as well as promote the development of more specific therapies for treatment. These studies may also provide a potential target for early detection of those at-risk for AUD.

Title: Striatal dopamine dynamics in freely moving postnatal $Shank3^{-/-}$ mice

Authors: *M. JANECEK[1,2], R. T. PEIXOTO[1,2];
[1]Dept. of Psychiatry, [2]Ctr. for Neurosci., Univ. of Pittsburgh, Pittsburgh, PA

Abstract: Dysregulation of dopamine (DA) signaling in striatal circuits has emerged as a potential convergent mechanism in autism spectrum disorders (ASD). However, whereas striatal DA signaling has been well characterized during adulthood, little is known about its regulation during postnatal development. This knowledge gap persists due to technical limitations associated with early postnatal in vivo optical and electrophysiological measurements that are complicated by the rapid growth of connective and neural tissue. Of particular interest is the dorsomedial striatum (DMS), critical for learning and execution of motor actions, which may undergo a dopamine-sensitive maturation period in the first three postnatal weeks. Previously, we observed that mice with mutations in the SHANK3 gene (Shank3-/-), a highly penetrant risk factor for ASD, exhibit hyperactivity and increased corticostriatal connectivity of DMS during postnatal days (P) 10-20. Within this timeframe, Shank3-/- mice begin to present compulsive-like overgrooming and motor deficits, coinciding with pronounced psychomotor deficits in infants with ASD. These structural and behavioral phenotypes might underlie or arise from abnormal DA signaling. To address this question, we developed a fiber photometry protocol to measure striatal DA dynamics in freely moving ~P15 pups using the genetically encoded dopamine sensor dLight. We find that 14 days of expression suffice to induce robust dLight

expression in the striatum and demonstrate that the ~P14 skull can support a chronic fiber optic implant and a cement headcap for at least 2 days post implantation, permitting the pup to feed and to interact with the dam. We test both flat-tipped and minimally invasive custom tapered fibers to collect calcium and dLight fluorescence traces from the DMS in response to naturalistic stimuli in acute and chronic paradigms. Our protocol highlights the need for accessing neural substrates during early development and establishes an approach to probe dopamine dynamics in early postnatal mice.

Title: Early life antibiotic exposure alters postnatal neurogenesis in 16p11.2 neurodevelopmental disorder mice

Authors: *C. R. MCDERMOTT[1], A. MIRMAJLESI[2], X. ZHANG[3], X. ZHOU[1], J. H. MILLONIG[3], M. J. BLASER[3], E. M. DICICCO-BLOOM[1];
[1]Neurosci. and Cell Biol., Rutgers Univ. Robert Wood Johnson Med. Sch., Piscataway, NJ; [3]Ctr. for Advanced Biotech. and Med., [2]Rutgers Univ., Piscataway, NJ

Abstract: Neurodevelopmental disorders (NDDs) affect the lives of >17% of children and caregivers in the United States and result from the combination of genetic risk variants and exposure to environmental factors. The clinical heterogeneity of NDDs, even among those bearing the same genetic risk, suggests that environmental factors may act on certain genetic susceptibilities, making a Gene x Environment model warranted. A recently identified environmental factor that appears to be linked to increased NDD risk is exposure to cephalosporin antibiotics during the first 2 years of life. Extensive evidence indicates that antibiotic exposure decreases the diversity of gut bacteria (antibiotic-induced dysbiosis) which may consequently alter adult brain structure and behavior. However, little is known about its effects on developmental neurogenesis, which has been implicated in human genetic and animal model studies as a point of convergence in NDD pathogenesis. Our studies use a novel Gene x Environment model to determine how cephalosporin exposure alters postnatal neurogenesis in the genetically vulnerable 16p11.2 microdeletion (16pDel) mouse. This mouse models one of the

most frequently observed CNVs that accounts for ~1% of ASD and also results in other NDD phenotypes. To model early human life antibiotic exposure, wildtype (WT) and 16pDel littermates were exposed to water (control) or the cephalosporin, cefdinir, from postnatal (P) days 5-9 and sacrificed on P13 for analyses. Our preliminary studies examined the cerebellum and hippocampus, two regions that undergo postnatal neurogenesis throughout the first year of human life and are implicated in NDDs. Using immunoblot analysis, we found sex- and genotype-dependent effects of cefdinir exposure on cerebellar neuronal differentiation and hippocampal neurogenesis. Cefdinir-exposed WT mice had a 50% reduction in levels of hippocampal intermediate precursor marker, Tbr2, compared to controls. In genetically vulnerable 16pDel mice, cefdinir-exposed males had decreased hippocampal Cyclin E (mitosis marker) and increased doublecortin (differentiation marker) compared to controls, while cefdinir-exposed females had reduced levels of cerebellar doublecortin compared to controls. Thus, cefdinir effects were dependent on sex and genotype. These results collectively suggest that early life exposure to cephalosporin antibiotics alters postnatal neurogenesis in the genetically vulnerable 16pDel mouse. Ongoing work will assess effects on microbial community composition and function, neurodevelopmental gene expression, and behavioral outcomes related to NDDs.

Title: Early-life sleep disruption and genetic vulnerability interact to drive life-long behavioral deficits in a Shank3 autism model

Authors: *J. S. LORD, S. M. GAY, K. M. SMITH, K. M. HARPER, V. D. NIKOLOVA, S. S. MOY, G. H. DIERING;
UNC Chapel Hill, Chapel Hill, NC

Abstract: Sleep is a life-long essential behavior that supports brain development and maturation in early life. Comorbid sleep pathologies occur in over 80% of individuals diagnosed with Autism Spectrum Disorders (ASD), including young children; the lasting consequences of that sleep loss are unknown. Shank3 is a high-confidence ASD risk gene, and heterozygous mutation

of Shank3 is known to cause Phelan McDermid Syndrome, a severe developmental disorder characterized by intellectual disability, autism, and disrupted sleep. In our study, a clinical model mouse bearing C-terminal truncation (ΔC) of Shank3 (Shank3$^{+/\Delta C}$) differed minimally from wild type littermates in amount and quality of sleep. We suspected that normal baseline sleep might mask an underlying vulnerability to the effects of developmental sleep loss in Shank3$^{+/\Delta C}$ mice. Therefore, we tested the lasting effects of early-life sleep disruption (ELSD) on Shank3$^{+/\Delta C}$ mice and wild type littermates through mild mechanical perturbation from postnatal days 14 - 21. We also subjected a group of post-adolescent mice to sleep disruption at 8 weeks old (PASD). Compared to undisturbed controls, adult male Shank3$^{+/\Delta C}$ exposed to ELSD but not PASD demonstrated a marked deficit in sociability in the 3-chambered social test, reduced open field activity, and impaired pre-pulse inhibition. Adult female Shank3$^{+/\Delta C}$ exposed to ELSD or PASD showed a reduction in anxiety-like behavior in the elevated plus maze. These results establish a novel gene x sex x environment interaction model of ASD susceptibility and support early life sleep disruption as a significant vulnerability in the development of ASD.

Title: Sex-biased impacts of 16p11.2 hemideletion on the striatal proteome in mice

Authors: *M. J. MERFELD[1], K. SCHROEDER[2], E. WOOD[2], G. R. ROJAS[2], L. S. CURRY-POCHY[2], L. PARKER[3], N. M. GRISSOM[2];
[1]Univ. of Minnesota Grad. Program In Neurosci., Minneapolis, MN; [2]Dept. of Psychology, [3]Dept. of Biochemistry, Mol. Biol. and Biophysics, Univ. of Minnesota, Minneapolis, MN

Abstract: Many neurodevelopmental disorders, including autism spectrum disorder (ASD), intellectual and developmental disability (IDD), and attention deficit hyperactivity disorder (ADHD) are highly male-biased in their diagnosis. The 16p11.2 hemideletion is a copy number variation (CNV) that increases risk of diagnosis of these neurodevelopmental disorders. The risk of neuropsychiatric diagnoses is elevated in males relative to females with this CNV in human studies. To understand the molecular pathophysiology and sex-biased impacts of this genetic deletion, we used mice carrying a hemideletion of chromosome 7qF3 that corresponds to the 16p11.2 CNV region observed in humans. Previous work identifies sex-biased impacts in striatal

function in this mouse model, in particular, protein expression of the mapk3/ERK1 gene located in the CNV region. To explore global protein expression in the striatum, which may be altered by 16p11.2 hemideletion, we examined the striatal proteomes of male and female 16p11.2 hemideletion (n=3 per sex) and wild-type (n=2 per sex) mice. Scaffold Q+ was used to quantitate isobaric tagging for relative and absolute quantification (iTRAQ) peptide and protein identification. There were 5969 discernible proteins found in the striatum, only 9 of which are known to be affected by 16p11.2 hemideletion. Fitting with previous results from our lab (Grissom et al 2018), we found a downregulation of mapk3 protein in both sexes with the hemideletion, compared to wild-type controls. Preliminary analysis indicates that more proteins were found to be significantly different between male wild-type mice versus male 16p11.2 hemideletion mice compared to females across genotypes, supporting the hypothesis that males are differentially impacted by this genetic deletion. In addition, the vast majority of the proteins found to be differentially expressed have genetic loci outside of the 16p11.2 region. Analysis is ongoing at this time, with parallel reaction monitoring-mass spectrometry (PRM-MS) planned for targeted confirmation of these results.

Title: Social ranking is disrupted in Rett syndrome mice: exploring mPFC neuronal ensembles reflecting social hierarchy

Authors: *C. ACEVEDO-TRIANA, L. POZZO-MILLER;
Univ. of Alabama at Birmingham, Birmingham, AL

Abstract: Alterations in social behaviors are considered a key feature in several developmental neuropsychiatric disorders, such as autism and schizophrenia. The medial prefrontal cortex (mPFC) is involved in cognitive functions, behavioral regulation and flexibility, as well as social behaviors, and is dysfunctional in neurodevelopmental disorders due to its protracted postnatal development. Recent work in our lab showed that direct ventral hippocampal (vHIP) inputs to the mPFC regulate social memory, and are dysfunctional in *Mecp2* knockout (KO) mice, an experimental model for the syndromic autism Rett syndrome. However, how alterations in this vHIP-mPFC pathway affect the formation of social ranks, which require intact social memory, is

unknown. Here, we first confirmed that *Mecp2* KO mice don't have deficits in odor habituation/dishabituation, showing the expected preference for social stimuli observed in WT mice that is necessary to perform social tasks. Next, we used the social dominance "tube" test to identify the social ranking of 3-4 previously isolated mice. The hierarchy of social ranking of either WT or *Mecp2* KO mice housed together was established through 6 daily pairwise competitions using a round-robin format; winners were those mice that either pushed the opponent or waited for its retreat and exit the tube through the opponent's side; the mice with more wins were considered to be in the highest social rank. WT mice showed a stable hierarchy over 6 consecutive days, while *Mecp2* KO mice failed to show a stable ranking of winners. Behavioral ethograms built semi-automatically revealed that WT and *Mecp2* KO mice showed similar behaviors of dominance when they won the test (pushing forward, resistance), but the *Mecp2* KO winners showed submissive behaviors (slow retreat or remaining still inside the tube) more frequently than WT mice. Finally, WT mice with GCaMP8 expression in neurons of the prelimbic (PL) subregion of the mPFC were unilaterally implanted with a GRIN lens over the mPFC to image Ca2+ signals (as surrogates of neuronal spiking) with head-mounted miniscopes during the "warm-spot" test, an unrestricted social dominance test that allows the use of wired head-mount miniscopes. Different mPFC neuronal ensembles were specifically activated during the "warm spot" test as opposed to during unrestricted interactions with a WT mouse, indicating that this approach could be useful to compare and contrast with mPFC social ensembles in *Mecp2* mutant mice. We expect that identifying mPFC neuronal ensembles encoding social hierarchy will allow a deeper understanding of their contribution to altered sociability in Rett and other MeCP2 associated disorders.

Title: The role of the E3 ubiquitin ligase UBE3B in autism spectrum disorder

Authors: *S. VASHISTH, I. TUNCAY, K. KAUR, M. CHAHROUR;
UT Southwestern Med. Ctr., Dallas, TX

Abstract: Autism spectrum disorder (ASD) is a neurodevelopmental disorder characterized by impaired communication, abnormal social behaviors, and restricted and repetitive behaviors. Pathogenic mutations in *UBE3B* result in neurodevelopmental disease including intellectual

disability, complete lack of speech, and ASD. *UBE3B* encodes an E3 ubiquitin ligase, which functions in the ubiquitin-proteasome system (UPS) to tag substrate proteins with ubiquitin for degradation by the proteasome. The UPS is known to regulate several signaling pathways critical in neurodevelopment, including neurogenesis and synapse formation and function, and mutations in various UPS genes have been identified in ASD. To investigate the function of UBE3B and its contribution to ASD, we generated a brain-specific nestin-Cre conditional knockout (cKO) mouse model and evaluated ASD-like behaviors in neonatal and juvenile cKO mice. We found that cKO pups emit significantly fewer, shorter, and quieter ultrasonic vocalizations (USVs) when separated from their mothers compared to control pups, indicating a neurodevelopmental abnormality. In a direct social interaction task, cKO juveniles spent less time interacting with unfamiliar, age- and sex-matched conspecifics. In addition, we found that cKO mice had a slower mean latency to the target location than control mice in the Morris Water Maze task, suggesting that loss of UBE3B leads to deficits in learning and memory. To identify potential neuronal UBE3B substrates, we used stable isotope labeling by amino acids in cell culture (SILAC) of neural stem cells from wild type (WT) and constitutive *Ube3b* knockout (KO) mice. Selected candidates exhibited increased protein level and decreased ubiquitination in KO compared to WT cells. Gene ontology analysis indicated that the majority of identified candidate substrates are involved in synaptic function. Our findings suggest that brain-specific *Ube3b* deletion leads to ASD-like behaviors and that UBE3B may be involved in the synaptic function underlying these behaviors. Ongoing and future studies will further investigate the neuronal substrates of UBE3B and how loss of UBE3B alters synaptic transmission.

Title: Effects of TSC1 haploinsufficiency in the developing murine cerebellum

Authors: *I. SERRA[1], A. STRAVS[2], C. OSORIO[1], C. TUDORACHE[2], A. BADURA[1];
[1]Erasmus Med. Ctr., Rotterdam, Netherlands; [2]Leiden Univ., Leiden, Netherlands

Abstract: Autism spectrum disorder (ASD) is an early-onset neurodevelopmental disorder of heterogenous phenotypes, characterized by the presence of social deficits, and inflexible and repetitive behaviours. Despite its unknown etiology, several genetic variants have been

associated with increased ASD risk. Mutations in tuberous sclerosis complex 1 (*Tsc1*), a tumour suppressor gene that inhibits the mechanistic target of rapamycin (mTOR) pathway, leads to a disorder of the same name in which up to half of patients present with ASD. Amongst the different brain areas proposed to play a role in the development of ASD, the cerebellum is commonly reported to be altered, with atypical cell morphology, structure and altered cerebello-cortical connectivity found in people with this disorder. Furthermore, cerebellar-specific deletion of *Tsc1* in mice is sufficient to induce an ASD-like phenotype. Given, that the mTOR pathway is crucial for proper cell replication and migration, this suggests that dysregulation of this pathway, particularly during critical phases of cerebellar development, could contribute to the establishment of ASD. Here, we used a mouse model of Tsc1 to investigate gene and protein expression during embryonic and early postnatal periods of cerebellar development. We found that, at E18, mRNA levels of cerebellar interneuron and glial markers were decreased. This was accompanied by a downregulation of mTOR-related genes. Further, while at postnatal day 1, mRNA levels were comparable between mutants and controls, at P7, interneuron markers were increased in Tsc1 mutants. Additionally, differential gene correlation analysis revealed dynamic changes in gene pairs across development, with an overall loss of correlation between mTOR- and cerebellar-related genes in Tsc1 mutants compared to controls. These dynamic changes were also found across behavioural tasks, where animals were repeatedly tested both at juvenile and adult timepoints. Our findings indicate that E18 is a crucial timepoint in cerebellar development particularly susceptible to mTOR pathway dysregulation. This leads to changes in the regulation of genes contributing to the excitatory/inhibitory balance, a mechanism proposed to be involved in the etiology of ASD, which later likely impacts the behavioural presentation of juvenile and adult mice.

Title: Restoration of disease risk gene expression to treat neurodevelopmental disorders

Authors: *X. TANG;
Boston Children's Hosp., Boston, MA

Abstract: Neurodevelopmental disorders (NDD) affect one in six children in the US. Upwards of 90% of risk for NDD is genetically conferred by a large number of disease risk gene variants. Contrary to the common view that the NDD-related abnormalities caused by genetic mutations are cemented after brain development, it was demonstrated that replacing mutant genes experimentally in adult mice can largely rescue disease-related phenotypes, providing the basis for the ongoing effort to develop a gene therapy approach to treat NDD in patients. However, an intrinsic challenge to this approach is the limited applicability of expensive, personalized precision gene therapies for the majority of NDD patients presenting a broad range of mutations in one or multiple NDD risk genes. Therefore, it is critical to determine the common NDD disease mechanisms for developing broadly applicable therapeutic strategies.
We present recent work aiming to identify common molecular-level abnormalities induced by various NDD risk gene mutations (such as a reduction in KCC2 expression), and to develop pharmacological approaches (such as inhibition of the FLT3 kinase pathway) that rectify the perturbations in the expression level of disease risk genes to relieve NDD symptoms regardless of the complexity or uncertainty of the causes.

Title: Ectopic expression of germline genes with loss of histone demethylase KDM5C in X-linked intellectual disability

Authors: *K. M. BONEFAS[1,2], S. IWASE[1];
[1]Human Genet., [2]Neurosci. Grad. Program, Univ. of Michigan, Ann Arbor, MI

Abstract: Chromatin regulators are an important component of the epigenetic environment that can influence transcription to ultimately shape cellular identity. Currently, it is unclear why mutations in numerous chromatin regulators cause neurodevelopmental disorders (NDDs). For example, lysine demethylase 5c (KDM5C) erases the histone 3 lysine 4 trimethylation (H3K4me3) and loss-of-function mutations in *KDM5C* result in intellectual disability,

heightened aggression, and comorbidity with Autism Spectrum Disorder. Surprisingly, we found the *Kdm5c*-KO mouse amygdala and hippocampus — two brain regions important for these behaviors — aberrantly express many germline genes that have no known function in the brain. We found this apparent soma-to-germline transition occurs during early *Kdm5c*-KO embryogenesis and parallels germ cell development. This failure of *Kdm5c*-KO embryos to demarcate somatic and germline identity results in aberrant expression of germline genes across multiple tissues. Ectopic transcription of germline genes in the brain suggests *Kdm5c*-KO neuronal function may be impaired due to a failure to faithfully establish neuronal identity. Our work provides mechanistic insight into how KDM5C helps delineate the somatic and germline transcriptomes. This work also offers early insight into a novel mechanism by which chromatin regulators are essential for neurodevelopment and behavior.

Title: Sodium-dependent citrate transporter (SLC13A5) mutant mice suggest that dysfunction is not limited to citrate transport deficiency

Authors: *L.-J. CHEW[1,2], K. A. DE LEON[3], J. F. CARR[1], S. L. HELFAND[1], J. S. LIU[1,4,2]; [1]Dept of Mol Biol, Cell Biol and Biochem., [2]Ctr. for Translational Neurosci., [3]Dept of Neurosci., Brown Univ., Providence, RI; [4]Dept of Neurol., Rhode Island Hosp. and Warren Alpert Med. Sch. of Brown Univ., Providence, RI

Abstract: Mutations in the SLC13A5 gene, which encodes a plasma membrane citrate transporter, result in early infantile epileptic encephalopathy, a neonatal neurological disorder characterized by multi-focal seizures. Human genetics has identified commonly occurring missense and deletion mutations that abolish citrate transport, but it is not known how distinct mutations affect disease severity. We have chosen to address this by characterizing an array of SLC13A5 mutant mice: i) ablation of endogenous Slc13a5 gene (knockout), ii) the most common patient mutation, the G222R point mutation (equivalent to the human mutation G219R), and iii) the second most common patient mutation, the T230M (equivalent to the human mutation T227M). Our preliminary data indicates that at 3 months of age, the homozygous Slc13a5 knockout mouse, which shows abnormal neurotransmitter levels, and heterozygous T230M/+ mutant, both demonstrate mild epileptiform electroencephalogram (EEG) profiles.

Heterozygous and homozygous G222R point mutation mice have more severe epileptiform activity, but severe status epilepticus is observed only in heterozygous G222R/+ mice, suggesting a toxicity distinct from citrate transport deficiency. These changes in EEG spike activity are accompanied by corresponding tissue damage that is most severe in heterozygous G222R/+ brains, including reduced parvalbumin+ interneurons, MAP2, and increased astroglial hypertrophy in cerebral cortex and hippocampus. There is a loss of oligodendrocytes and increased astroglial reactivity in subcortical white matter, indicating widespread pathology. In HEK293T cells which lack endogenous SLC13A5, recombinant human SLC13a5 and T227M are localized at the plasma membrane. G219R mutant protein impairs cell growth, fails to colocalize in the plasma membrane, and appears perinuclear, colocalizing with mitochondrial markers Mitotracker Red, cytochrome C and Tomm20. Co-expression of the G219R mutant together with its wild-type counterpart prevents membrane localization of the wild-type protein, an event reversed by increasing concentrations of wild-type construct. Metabolic studies in HEK293T cells transfected with G219R revealed an increased rate of oxygen consumption and basal respiration, which suggests mitochondrial dysfunction. These results indicate that neuronal hyperactivity is differentially regulated by distinct SLC13A5 mutations. Loss of citrate transport function underlies epileptiform activity, likely due to altered neurotransmitter levels. However, specific missense mutations may acquire dominant gain-of-function effects which exacerbate neuronal hyperexcitability.

Title: Lead exposure risk correlates with anxiety symptoms in urban youth

Authors: *J. LOSIOWSKI, B. BORG, J. EVANSKI, H. MARUSAK;
Wayne State Univ., Detroit, MI

Abstract: Lead is a known neurotoxic metal, and lead-exposed children experience disrupted cognitive and behavioral development (i.e., lower IQ, poorer academic achievement, hyperactivity, antisocial behavior). While lead affects both urban and non-urban settings, children growing up in urban environments are at particularly high risk of lead exposure due to a

high concentration of automobile and industrial emissions, older homes, and water systems, where lead is commonly found. Though the detrimental effects of lead exposure on cognitive and behavioral health have been well documented, less is known about the impacts on *mental health*. The present study examined the effects of lead exposure risk on anxiety in youth living in urban vs. non-urban settings. Sixty-five adolescents (37 female) aged 10-17 years (mean age=13.05 $\pm$ 2.20) completed an online survey about mental health and environmental exposures. We split the sample into two groups: urban (n=19), defined as living in the city of Detroit, and non-urban (n=46), defined as living >50 miles of Detroit. Youth self-reported on their anxiety symptoms using the Screen for Child Anxiety Related Emotional Disorders questionnaire. Lead exposure risk was estimated using the zip code of the youth's current residential address. In particular, we used data from Data Driven Detroit to estimate the percent of children who tested positive for elevated blood lead levels in each participant's zip code from 2017-2019. Linear regression was used to test the impact of lead exposure risk on anxiety across the entire sample and in urban and non-urban subgroups, separately. Self-reported gender was used as a covariate in all analyses. Overall, lead exposure risk did not significantly predict anxiety across the entire sample. However, when considering urban and non-urban environments separately, lead exposure risk was a significant positive predictor of anxiety symptoms in urban (but not non-urban) youth. Our results revealed that a higher risk for lead exposure is associated with higher anxiety symptoms in youth living in urban (but not non-urban) settings. These data fit with a small but growing number of studies documenting detrimental effects of childhood lead exposure on lifelong mental health. Taken together, these data indicate that environmental exposures, such as lead exposure, can operate as unseen drivers of poor mental health, particularly in urban settings. These data also highlight the role of public policies to prevent lead exposure in vulnerable populations, including children and adolescents.

Title: Beyond age in adolescence cognition: a latent factor of puberty predicts development of executive functions ability in early adolescence.

Authors: S. POMPEIA, ***I. A. SEGURA**;
Univ. Federal de Sao Paulo, São Paulo, Brazil

Abstract: Executive Functions (EFs) develop during adolescence, an age when it is possible to observe the differentiation of EFs into three correlated but separable domains according to the Unity and Diversity Model of EFs. The improvement in EFs is believed to be due to profound structural and functional brain changes which can be partly due to experiences gained as adolescents age and/or to pubertal factors, which vary greatly among individuals in terms of onset and progression. However, pubertal effects on the development of EFs are often overlooked or, when they are controlled for, this is usually done using a single pubertal milestone or scores in a single scale. This is not ideal because puberty involves many physiological changes that are not captured by any single marker. The aim of the present study was to investigate the association of a latent variable of puberty with EFs factors from the EF Unity and Diversity Model in early adolescence, when puberty occurs. A total of 332 adolescents (188 girls) were tested cross-sectionally. The pubertal latent factor was built using a unifactorial Confirmatory Factor Analysis (CFA) solution with five indicators of pubertal status: 1) the Pubertal Developmental Scale (filled in by both parents and adolescents); 2) self-assessed Tanner staging (one measure of gonadal and one of adrenal development); and 3) salivary level of the dehydroepiandrosterone sulfate (testosterone did not load well on the model). Next, Structural Equation Modeling (SEM) was used to regress the puberty factor, controlled for age (in months), onto the three correlated factors of EFs, each composed by scores in two tasks: Updating (2-Back and Number Memory tests), Inhibition (Stroop Victoria and Stroop Happy-Sad) and Switching (Color Shape and Category Switch). Measurement CFA models were stablish for both EFs and puberty. The intercorrelated three-factor EF model was replicated and both CFA solutions presented good fit to the data with moderate to high factor loadings. The subsequent SEM model also retrieved adequate fit indices and all paths were statistically significant. In accordance with what is found with age, a higher pubertal latent trait predicted better EF in all the three domains, even after controlling for age. We conclude that puberty can be used as a construct to understand cognitive development because the puberty latent factor significantly predicted EFs abilities (controlled for age), reinforcing the importance of considering multiple pubertal measures when assessing cognition during adolescence.

Title: The potential for GENUS as an early intervention to prevent negative impact of early life adversity on later-life prosocial behavior.

Authors: *T. BEHRING[1], O. AGU[1], E. SHER[1], G. HASSAN[2], A. MANGANARO[1], R. LUDWIG[1], M. M. MYERS[1], M. G. WELCH[1], D. DUMITRIU[1];
[2]Developmental Neurosci., [1]Columbia Univ. Irving Med. Ctr., New York, NY

Abstract: Prosocial behavior is imperative to functioning in society. A lack of prosocial behavior is hallmark of many psychopathologies, including autism spectrum disorders (ASD), schizophrenia, and antisocial personality disorder. The prevalence of antisocial personality disorder is 1-4% of the population and has strong associations to early life stress (ELS). The mother-infant relationship is theorized to be the evolutionary antecedent to prosocial behavior and disruption of this relationship is a form of ELS associated with antisocial personality disorder and decreased prosocial behavior. In rats, the limited bedding and nesting (LBN) model, a form of ELS, is an effective disruptor of normal dam-pup interactions with long-lasting biobehavioral consequences. However, rodent models of ELS have not been used to study long-lasting prosocial behavioral deficits. The trapped-rat paradigm is a reliable and ethologically valid tool for testing prosocial behavior in rats. In prior work, we found cortical gamma power (~40 Hz), which is important for developing circuit plasticity and emotion regulation, to be decreased by ELS in rat pup frontal cortex. Gamma ENtrainment Using Sensory Stimuli (GENUS) has potential for rescuing deficits in cortical gamma power and has been used to treat cognitive and emotional deficits in other psychopathologies, such as Alzheimer's disease. Here, we present data on later-life prosocial behavioral deficits in LBN rats. From the ages of P2 to P9 LBN rats were reared in limited bedding conditions (100 mL corncob) and were tested on the trapped-rat paradigm during adulthood. LBN rats showed a decrease in prosocial behavior compared to their control counterparts. We further present preliminary findings that early life GENUS, using a flickering light, can entrain cortical gamma power during early development (P17-23). Our future studies will focus on replicating these results and testing the hypothesis that GENUS during early life will rescue later life prosocial behavioral deficits seen in our ELS rat model.

Title: Brain development during adolescence and the impact on psychiatric disorders and drug abuse: a scoping review

Authors: *S. CHIAVEGATTO[1,2], L. R. POIAN[1], L. D. LAMARCA[3];
[1]Pharmacol., Biomed. Sci. Inst. - Univ. of Sao Paulo, Sao Paulo, Brazil; [2]Psychiatry, Med. Sch. Univ. Sao Paulo, Sao Paulo, Brazil; [3]Sch. Pharmaceut. Sci. - Univ. of Sao Paulo, Sao Paulo, SP, Brazil

Abstract: Adolescence is a period of transformations in which new experiences are fundamental for the transition between childhood and adulthood. During this period, there is a drastic change in behavior, characterized by lack of impulse control and increased emotional response. Although this behavioral change can be essential for human development, it is also related to problems such as alcohol and drug abuse, as well as psychiatric disorders. Our objective is: a. to review scientific articles on human brain development that permeate the reckless behavior of adolescents; b. to understand the motivations underlying those behaviors; c. to disseminate the information found, to assist in preventive actions to the problems faced by adolescents.
Methods: A scoping review was carried out through the synthesis of articles published on the theme "Adolescent brain development", in the Medline database (PubMed) for the last 15 years. The filters "reviews" and "study in humans" were selected. Finally, a characterization was made in relation to the year of publication, country of origin and impact factor of the published journal.
Results: The analysis and synthesis of the 46 selected articles (out of 1,913) demonstrated that the period of adolescence is marked by a process of expressive changes in brain maturation. These occur asynchronously on different regions: primarily in areas of lower complexity (e.g. limbic subcortical systems) and later in more complex areas (e.g. cortical systems). Thus, in the adolescent brain, the limbic reward systems are already fully developed, while the cortical regulatory systems, still immature, are insufficient to perform adequate control, impairing the ability of adolescents to exert control over emotions, modify impulses and postpone gratification. Consequently, adolescence is characterized by an increase in risk behaviors and search for immediate rewards (e.g., drug abuse). Also, during this period, there is an increase in the incidence of psychiatric disorders, since the subcortical regions, which are less regulated during the maturation process (e.g., nucleus accumbens, amygdala), are the same described as altered in the pathology of the most common mental disorders (e.g., anxiety and depression). **Conclusion:** During adolescence, the active process of cerebral maturation characterizes a late plasticity, but the disparity between reward and control systems makes them more likely to suffer from various risks. Therefore, understanding the motivations behind the actions of this group is fundamental to ensure that environmental influences reach adolescents in a positive way, when developing strategies in public policies.

Title: Disruption of prefrontal GABAergic maturation during adolescence by early life adversity

Authors: *E. ARTUR DE LA VILLARMOIS, E. FLORES-BARRERA, K. Y. TSENG; Dept. of Anat. & Cell Biology, Univ. of Illinois at Chicago, CHICAGO, IL

Abstract: Early life experiences have been known to impact the development and maturation of corticolimbic connectivity and its regulation of cognitive and affective behaviors. For instance, individuals with a history of early life trauma are often at higher risk for anxiety-like disorders in adolescence, which are thought to result from a dysregulation of affective and cognitive processes, and the maturation of the prefrontal cortex (PFC) and associated neural circuits. It is therefore conceivable that early life events contribute to shape the developmental trajectory of PFC maturation during adolescence. To test this idea, we implemented an early life adversity paradigm (i.e., maternal separation, MS) and assessed to what extent PFC maturation of synaptic activity from postnatal day (P) 30 to adulthood becomes disrupted in both male and female rats. Data revealed that the normal developmental gain of PFC GABAergic synaptic activity was not observed in animals exposed to MS, while AMPA-mediated transmission was not affected. As a result of the selective GABAergic disruption in MS animals, the excitatory-inhibitory (E-I) ratio that normally becomes balanced by P50 remains unbalanced in adulthood (e.g., >1.0), resembling the level of E-I synaptic activity typically found in the immature PFC of P30-40 rats. Furthermore, transient chemogenetic inhibition of PFC GABA interneurons during this early adolescent period was sufficient to elicit a similar E-I imbalance that endures through adulthood. Collectively, our findings indicate that PFC inhibitory synapses are preferentially susceptible to early life adversity, likely through disruption of an activity dependent mechanism that is needed to enable the GABAergic maturation during adolescence. In turn, a disinhibited PFC state could increase the risk for psychiatric disorders during adolescence with abnormal affective and cognitive responses.

Title: The effect of adolescent isotretinoin exposure on the hippocampus, depressive-like behavior, and recognition memory

Abstract: 13-cis-retinoic acid (Isotretinoin) is a commonly prescribed medication for the treatment of persistent cystic acne but has also been shown to cause depressive behaviors and suicidal thoughts in patients. The hippocampus is a brain area involved in regulation of the stress response as well as cognitive functions such as novel memory formation, and alterations to this area may be important to the development of symptoms following adolescent isotretinoin exposure. In the present study, we assessed the effects of adolescent isotretinoin exposure on stress-coping behavior and novel object recognition, followed by measurement of hippocampal dopamine D2 receptor expression and dendritic spine density. From approximately postnatal day (P)35 through P49, C57BL/6J mice were injected with 1 mg/kg of isotretinoin intraperitoneally for 10 total injection days. From approximately P50 through P52, mice underwent novel object recognition testing, followed by a 6-minute forced swim test on approximately P53. Brains were extracted for western blotting of dopamine D2 receptor density in the hippocampus and striatum, and Golgi-Cox tissue staining for analysis of dendritic spine density. To date, our results indicate an increase in immobility in the forced swim test, but no effect on novel object recognition, in isotretinoin exposed mice compared to controls. These results suggest that adolescent isotretinoin exposure is associated with depressive-like behavior in mice but does not influence hippocampal dependent memory formation. Ongoing research aims to correlate hippocampal dopamine D2 receptor expression and dendritic spine density with our behavioral results.

Title: The effect of adolescent social isolation on nicotine conditioned place preference and stress-coping behavior.

Authors: A. C. KIRCKOF, *D. G. EHLINGER;
Psychological Sci., Univ. of Wisconsin-River Falls, River Falls, WI

Abstract: Adolescence is a sensitive period in brain development that is marked by increased susceptibility to chronic stress and the reinforcing effects of drugs of abuse, which may enhance vulnerability to neuropsychiatric conditions such as depression and substance use disorders. In the present study, we used an animal model to examine the effect of adolescent social isolation stress on coping behavior and nicotine reward. During the adolescent period from postnatal day (P)35-P49, male and female C57BL/6J mice were exposed to either social isolation (SI) stress or standard rearing (SR) conditions, as well as nicotine exposure (0.35mg/kg) four times between P35-P49 during a nicotine conditioned place preference (CPP) procedure. On approximately P50, stress-coping behavior was examined following a 6-minute forced-swim test (FST). Our behavioral results show that both male and female SI mice more rapidly develop nicotine CPP compared to SR mice, and that female SI mice exhibit increased levels of immobility in the FST. These results suggest that adolescent social isolation stress enhances the rewarding effects of nicotine and negatively impacts stress-coping behavior. Ongoing research efforts are examining structural (dendrite remodeling and spine density) and functional (c-fos expression) differences in the brains of SI versus SR mice using Golgi-Cox tissue staining of the dopaminergic reward pathway and immunohistochemistry of the ascending serotonergic system. Collectively, these analyses will help determine neurological correlates of adolescent susceptibility to the negative effects of chronic social isolation stress and inform our understanding of adolescent brain development and vulnerability.

Title: Rescuing anterior insula cortex neuronal hypoexcitability attenuates compulsive behavior in juvenile rats

Abstract: Development of self-regulatory competences during adolescence is partially dependent on normative brain maturation. Here we report that juvenile rats as compared to adult rats exhibit impulsive and compulsive-like behavioral traits, the latter being associated with lower expression of zif268 mRNA levels in the anterior insula cortex but not in the prelimbic cortex, possibly reflecting immature integration of interoceptive cues in rational decision-making. This is further substantiated with hypoexcitability of layer-V pyramidal neurons of the anterior insula cortex using slice electrophysiology, concomitant with lower excitatory glutamatergic inputs and ultimately lower functional recruitment of the anterior insula in juvenile rats as compared to adult rats. Importantly these electrophysiological differences between adolescent and adult rats were not observed in the layer-V pyramidal neurons of the prelimbic cortex. Chemogenetic rescue of the anterior insula cortex pyramidal neurons attenuated the compulsive trait suggesting that immaturity of the anterior insula cortex to integrate sensory and cognitive information in youngsters may contribute to inflexible behaviors in specific conditions of reward availability.
