Abstract: Valproic acid (VPA) is an effective and commonly prescribed drug for epilepsy and bipolar disorder. However, children born from mothers treated with VPA during pregnancy exhibit an increased incidence of autism spectrum disorder (ASD). Although VPA may impair brain development at cellular level, the mechanism of VPA-induced ASD has not completely addressed. The previous study has found that VPA treatment strongly reduces neuronal δ-catenin mRNA level. δ-catenin is important for the control of glutamatergic synapses and strongly associated with ASD. Interestingly, VPA inhibits dendritic morphogenesis in developing neurons, which is also found in neurons lacking δ-catenin expression. We thus hypothesize that prenatally exposure to VPA significantly reduces δ-catenin levels in the brain, which disrupts glutamatergic synapses, contributing to the development of ASD. Here, we found that VPA impaired the development of cultured mouse cortical neurons, which was reversed by elevating δ-catenin expression. Prenatally exposure to VPA significantly reduced synaptic δ-catenin levels and impaired ultrasonic vocalization (USV) in newly born pups. Importantly, we found that prenatal VPA treatment significantly decreased neuronal activation in the arcuate nucleus of the hypothalamus, which is important for the production of animals' USVs following isolation from the nest. Finally, VPA significantly reduced the levels of AMPA receptors and postsynaptic density 95 (PSD-95), a key scaffolding protein in excitatory synapses, in mouse newborns, which likely contributed to reduced neuronal activation. Therefore, these results suggest that VPA-induced ASD pathology can be mediated by loss of δ-catenin functions.

Title: The autism-associated loss of δ-catenin functions disrupts social behavior

Authors: *R. ROACH[1], H. MENDEZ-VAZQUEZ[1], K. NIP[1], S. CHANDA[1], M. SATHLER[1], T. GARVER[1], R. DANZMAN[1], M. MOSELEY[1], J. ROBERTS[1], O. KOCH[1], A. STEGER[2], R. LEE[1], J. ARIKKATH[3], S. ROH[1], S. KIM[1];

Abstract: δ-catenin is expressed in excitatory synapses and functions as an anchor for the glutamatergic AMPA receptor (AMPAR) GluA2 subunit in the postsynaptic density. The glycine 34 to serine (G34S) mutation in the δ-catenin gene has been found in autism spectrum disorder (ASD) patients and results in loss of δ-catenin functions at excitatory synapses, which is presumed to underlie ASD pathogenesis in humans. However, how the G34S mutation causes loss of δ-catenin functions to induce ASD remains unclear. Here, using neuroblastoma cells, we identify that the G34S mutation increases glycogen synthase kinase 3β (GSK3β)-dependent δ-catenin degradation to reduce δ-catenin levels, which likely contributes to the loss of δ-catenin functions. Synaptic δ-catenin and GluA2 levels in the cortex are significantly decreased in mice harboring the δ-catenin G34S mutation. The G34S mutation increases glutamatergic activity in cortical excitatory neurons while it is decreased in inhibitory interneurons, indicating changes in cellular excitation and inhibition. δ-catenin G34S mutant mice also exhibit social dysfunction, a common feature of ASD. Most importantly, pharmacological inhibition of GSK3β activity reverses the G34S-induced loss of δ-catenin function effects in cells and mice. Finally, using δ-catenin knockout mice, we confirm that δ-catenin is required for GSK3β inhibition-induced restoration of normal social behavior in δ-catenin G34S mutant animals. Taken together, we reveal that the loss of δ-catenin functions arising from the ASD-associated G34S mutation induces social dysfunction via alterations in glutamatergic activity and that GSK3β inhibition can reverse δ-catenin G34S-induced synaptic and behavioral deficits.

Title: Butyrate Protects Against Propionic Acid-Induced Toxicity in SH-SY5Y Cells: Implications for Autism Spectrum Disorder

Authors: *A. K. BHATTI[1], B. GETACHEW[2], R. L. COPELAND[2], Y. TIZABI[2];

Abstract: Autism Spectrum Disorder (ASD), a neurodevelopmental disorder, is characterized by persistent deficits in social interaction, social communication, and manifests in early childhood. It is followed by significant impairment in social and occupational functions in adolescence and adulthood. Although genetics have been implicated, the exact causes of ASD have yet to be fully elucidated. New evidence suggests that dysbiosis or perturbation in gut microbiota may play an important role in ASD etiology. Short chain fatty acids (SCFAs) such as butyrate, acetate, and propionate are metabolites produced by gut bacteria during the fermentation of dietary fibers. They play a crucial role in the bidirectional communication between the gut and the brain, commonly referred to as “gut-brain axis” (GBA). These compounds can modulate various functions including neurotransmitter synthesis, energy metabolism, and inflammation. However, high levels of PPA can have neurotoxic effects and is used to generate a rodent model of ASD. Indeed, elevated PPA levels have been detected in children suffering from ASD. Butyrate, on the other hand, has been shown to have protective effects against various toxicants. Butyrate acts through G protein-coupled receptors (Gi/o and Gq) and is a well-known histone deacetylase inhibitor. Its important role in maintaining homeostasis of GBA is well established. In this study, we sought to determine whether butyrate may also protect against PPA-induced toxicity in SH-SY5Y cells. These cells, derived from human neuroblastoma cells, are considered representative of dopaminergic neurons, a neurotransmitter that is also affected in ASD. Exposure of SH-SY5Y cells to 2mM PPA for 24h, resulted in a concentration-dependent toxicity and approximately 25% cell death was observed. This toxicity was completely blocked by pretreatment with 20μM butyrate applied one hour prior to PPA. These preliminary findings render further support to the protective properties of butyrate and provide a conceptual basis for deeper investigation of potential therapeutic use of this SCFA in ASD. Future directions should include further elucidation of mechanism(s) of action of butyrate and its involvement in GBA, as well as in-vivo evaluation of its effectiveness in animal models of ASD.

Abstract: Translational control is an important regulatory mechanism in neural plasticity, particularly during neurodevelopment. Dysregulation of this critical step is implicated in several pathologies, including Autism Spectrum Disorder (ASD). The IMPrinted and AnCienT gene (IMPACT) is a protein coding gene with a highly conserved RWD domain across eukaryotic species. IMPACT is a translational regulator via a negative regulation of General Control Nonderepressible 2 (GCN2) kinase activity. GCN2 phosphorylates the alpha subunit of Eukaryotic Initiation Factor 2 (eIF2α) as a cellular stress response. GCN2's phosphorylation of eIF2α serves as an inhibitor of eIF2 and its ternary complex, which causes a repression of general translation of mRNAs and decreased global protein synthesis. Paradoxically, a small subset of mRNAs are up-regulated. This translational regulatory mechanism also plays a critical role in the nervous system under physiological conditions, such as neural wiring, synaptic plasticity, long-term memory consolidation and learning. However, the impact of chronic phosphorylation of eIF2α throughout neurodevelopment has not been explored. In this *in vivo* study, we investigated the neurological effects due to loss of IMPACT, using a transgenic mouse model which removed the expression of IMPACT ($IMP^{-/-}$) and therefore its regulatory effect on GCN2. This in turn led to increased GCN2 expression and increased phosphorylation of eIF2α. We found that loss of the IMPACT protein causes deficits in social novelty preference, elicits repetitive behavior, and impairs long term memory. It also triggers anxiety and impairs memory extinction and spatial memory. Many of these phenotypes are present in patients with neurodevelopmental disorders, particularly ASD. We also identified specific mRNAs translationally regulated by IMPACT in the hippocampus and in the prefrontal cortex. Of particular note, Cytoplasmic FMR1 Interacting Protein 2 (CYFIP2) expression is increased in the hippocampus in $IMP^{-/-}$ compared to wild type mice. Taken together, our research supports the hypothesis that IMPACT is an important translational regulator in neurodevelopment, and mutations that impair its function may have implications in neurodevelopmental disorders such as Autism Spectrum Disorder.

Title: A targeted antisense oligonucleotide therapeutic approach for Timothy syndrome

Authors: *X. CHEN[1], F. BIREY[2], M.-Y. LI[1], O. REVAH[3], R. LEVY[1], M. THETE[1], N. REIS[1], N. SAKAI[1], K. KAGANOVSKY[1], S. NISHINO[1], J. HUGUENARD[1], S. PASCA[1];

Abstract: Timothy syndrome (TS) is a debilitating multi-system disorder characterized by cardiac long QT syndrome, autism, epilepsy, and other long-term neuropsychiatric conditions. TS is caused by pathogenic variants in the *CACNA1C* gene encoding the L-type calcium channel. TS type 1 (TS1) is associated with a heterozygous gain-of-function variant in the alternately spliced and developmentally enriched *CACNA1C* exon 8A, as opposed to its counterpart exon 8. We reported cellular defects in TS1 patient-derived neural cells, including extended expression of the mutant 8A in human neural cells likely due to splicing interference. Therefore, switching expression of *CACNA1C* from the exon 8A to the postnatally enriched exon 8 isoform emerges as a potential therapeutic strategy. Here, we developed a promising therapeutic strategy by effectively decreasing the exon 8A isoform of *CACNA1C* using antisense oligonucleotides (ASO) in human cells *in vitro* and, following transplantation, in rodents. The ASO-mediated switch from 8A to 8 isoforms of *CACNA1C* can robustly rescue the channel inactivation defect and depolarization-induced calcium rise in patient-derived cortical organoids, and can effectively rescue cortical interneuron migration in TS1 forebrain assembloids. By leveraging our transplantation platform in which human neurons mature and integrate into rat brain circuit, we

demonstrate that a single intrathecal ASO administration can genetically and functionally rescue defects in human patient-derived cortical neurons in vivo. These results suggest suppression of the mutation-carrying isoform of *CACNA1C* could be developed as a treatment for TS1 in humans. Moreover, these experiments highlight the potential of a multi-level, *in vivo* and *in vitro* stem cell model-based approach for identifying strategies to reverse disease-associated pathophysiology.

Title: Altered Chandelier Cell Within the Autism-Associated 16p11.2 Microdeletion Mouse Model

Authors: *A. A. BENN;
NBS, Penn State Col. of Med. Neurosci. Grad. Program, Hershey, PA

Abstract: Autism spectrum disorder (ASD) describes a family of neurodevelopmental disorders (NDDs) that comprise a broad range of conditions such as abnormal reaction to sensory stimuli, deficits in social interaction and communication, as well as restricted behaviors. The exact cause of ASD is unknown; however, numerous genes and environmental factors have been identified as contributing to the disorder. It is known that recurrent copy number variations in the human 16p11.2 locus have been linked to ASD phenotypes. A plausible model for autism proposes that alterations to cortical interneurons contribute to synaptic excitatory/inhibitory imbalance within the autistic cerebral cortex, whereas hyperexcitability, increased spiking, and cortical circuitry noise induce ASD symptoms. Gamma-aminobutyric acid (GABA) inhibitory neurotransmission is required for the regulation of brain rhythm and spontaneous neuronal activities during development. Strikingly, the number of GABAergic parvalbumin-expressing interneurons specifically chandelier cells (ChCs) is reduced in the pre-frontal cortex (PFC) of individuals with ASD. Furthermore, fMRI studies comparing humans with the 16p11.2 microdeletion and mice with similar genetic deficiency indicate that both species have diminished PFC neuronal connectivity. Altogether, the prior evidence suggests that the 16p11.2 microdeletion and a reduction in the number of ChCs are potential risk factors contributing to the development of ASD.Overall, the goal of the study was to test the link between the 16p11.2 microdeletion and its impact on ChCs in the cortex of a transgenic 16p11.2 $^{del/+}$ mouse model. Results demonstrate that there are cortical region-specific differences in the number and size of ChC boutons which

innervation pyramidal neurons within the 16p11.2 $^{del/+}$ mouse. Additionally, the number of ChCs across cortical regions and layers differ between the wild-type and the 16p11.2$^{del/+}$ mice.

Title: A reduction in the autism associated gene Lysine Demethylase 6B (KDM6B) alters cortical development in human pluripotent stem cell derived cell types and brain organoids

Authors: *J. E. BUTH, H. GULESSERIAN, S. RYAN, A. DURRANI, T. ISHIDA, F. TURCIOS, B. G. NOVITCH;
Neurobio., UCLA, Los Angeles, CA

Abstract: Autism spectrum disorder (ASD) is a heritable lifelong developmental disability that affects 1-2% of the population worldwide. Individuals experience challenges with social interaction, communication, and repetitive behaviors. Treatments include behavioral therapy, medications, and assistive technology focused on improving the patient's quality of life. Pathological studies of ASD brains point to changes in cortical cytoarchitecture, synapse formation/pruning, altered excitatory/inhibitory neuron balance, and microglial activation, but the mechanisms of how this occur remains unclear. 100s of ASD-risk genes have been identified, many of which modify histones/chromatin. KDM6B is a histone modifier that removes repressive tri-methyl marks on lysine 27 of histone 3 to promote gene expression; a heterozygous loss of function is associated with ASD. Previous studies have shown KDM6B is highly expressed during neurodevelopment in all cell types in the brain. In mice, overexpression results in upregulation of neuronal/astroglial genes and knockdown results in a microcephalic phenotype with fewer cortical neurons. In microglia, KDM6B knockdown exaggerates inflammation leading to neuronal death in vitro. As many clinical trials for neurological disorders based on mouse data fail, findings need to be validated with human models. To determine whether the reduction in cortical neurons was due to changes in neural progenitors (NPC) or microglia, we compared the effect of KDM6B inhibition or CRISPR knockdown using human pluripotent stem cell (hPSC)-derived NPCs, brain organoids, and microglia. Many KDM6B targets are neuronal, so we hypothesized a reduction in KDM6B would result in reduced production of neurons. We found KDM6B inhibition in NPCs maintained NPC identity and reduced neuron differentiation.

To better recapitulate human development, we then assessed changes in brain organoids and found the ratio cortical cell types was altered. As KDM6B also plays a role in inflammation, we hypothesized a reduction in KDM6B would lead to activation of microglia. We tested how KDM6B activity would affect microglia (1) gene expression, (2) migration, and (3) phagocytosis. We found a reduction in KDM6B altered microglial expression of activation markers, increased migration, and reduced phagocytosis. As microglia/neurons interact during development, future studies will incorporate microglia into the organoid model to assess how knockdown in the organoid, microglia, or both effects development and maturation. These results provide a better understanding of developmental changes leading to ASD and help narrow the focus of possible treatment targets.

Med., Osaka Univ., Osaka, Japan

Abstract: Autism spectrum disorders (ASDs) are neurodevelopmental conditions characterized by altered social communication, stereotyped behaviors, and restricted interests. Although molecular and cellular pathogenesis of ASD remains largely unclear, impaired neural development is likely to contribute to ASD. Recent genetic studies have suggested that de novo mutations occurring in children of patients, which are not present in their parents' genomes, may be involved in the risk of ASD and that 102 recurrently de novo mutated genes may be critically associated with ASD. Among these risk genes, the ANK2 gene is classified as a high-confidence ASD gene in the SFARI database. The ANK2 gene encodes Ankyrin-B, a scaffolding protein that regulates the intracellular localization of specific membrane proteins. Currently, the roles of ANK2 in early neural development in the embryonic stages, during which abnormalities have been suggested in patients with ASD, remain unclear. In this study, we analyzed the roles of ANK2 in early neural development. Firstly, we found that Ank2 was highly expressed at embryonic day 14 to 18, when neurons are extensively generated, suggesting that ANK2 may regulate early neural development. Then we analyzed the function of ANK2 in early neural development using in utero electroporation and found that ANK2 knocked down cells were remained in the intermediate zone and subventricular zone. These results argue that ANK2 knock down impairs early neural development in the cerebral cortex. We then examined the effect of ANK2 knockdown on neurite outgrowth using the neuroblastoma Neuro2A cell line, which is widely used as a model for evaluating neuronal development, and observed that ANK2 knockdown decreased total neurite length per cell. Finally, to analyze the molecular mechanisms underlying the developmental abnormalities caused by ANK2 knockdown, we performed RNA sequencing using total RNAs extracted from ANK2 knocked down Neuro2A cells. We performed Gene Ontology (GO) analysis using differentially expressed genes between ANK2 and mock knockdown cells and found a significant enrichment of GO terms related to neuronal development and differentiation. Taken together, these results suggest that ANK2 regulates early neural development during embryonic stages and that de novo mutations in the ANK2 gene impair the neural development, which may be associated with the onset of ASD. Our current results contribute not only to elucidate the molecular and cellular pathogenesis of ASD but also to identify intermediate phenotypes of ASD and eventually to stratify patients with ASD based on the molecular and cellular pathogenesis.

Title: Reduction of SYNGAP1 in Parvalbumin (PV)-positive GABAergic neurons impairs long-range cortico-cortical connectivity

Authors: *S. NASKAR[1], P. STEVENSON[2], J. QI[3], S. LEE[4];
[1]NIMH/NIH, Bethesda, MD; [2]NIH, Natl. Inst. of Mental Hlth., Washington, MD; [3]NATIONAL INSTITUTES OF HEALTH, Baltimore, MD; [4]NIH, NIH, Natl. Inst. of Mental Hlth. (NIMH), Bethesda, MD

Abstract: Impairment of long-range connectivity has been attributed to a wide range of neurodevelopmental disorders (NDDs). Previously, we reported that diverse long-range inputs from different brain areas recruit specific types of GABAergic INs in the primary somatosensory cortex (S1). This input-area-dependent recruitment of specific GABAergic INs plays an important role in active sensory processing. Abnormal sensory perception is common in NDDs, and the mechanisms that underlie impaired sensory processing associated with NDDs are not well studied. Haploinsufficiency of the *SYNGAP1* (Synaptic Ras GTPase Activating Protein1) gene has been shown to impair sensory processing and cognition in both humans and mice. Reduction of SynGAP1 in mice causes cognitive deficits by enhancing glutamatergic transmission and increasing excitatory connectivity. While the importance of SynGAP1 in excitatory neurons has been reported, the role of SynGAP1 in cortical GABAergic neurons is largely unknown. Here, we asked whether and how the disruptions of SynGAP1 in different GABAergic IN subtypes lead to the impairment of input-area-dependent corticocortical communication. Using optogenetics and *ex vivo* electrophysiology with specific deletion of *SYNGAP1* in Parvalbumin (PV)-positive GABAergic neurons, we found that the long-range cortical inputs to PV INs in S1 are altered. In PVCre: SynGAP1$^{flox/+}$ mice, PV neurons in S1 receive abnormally strong excitatory inputs from the whisker-related primary motor cortex (wM1). Since it is known that SynGAP1 regulates the level of AMPA receptors at the postsynaptic membrane of excitatory neurons, we asked whether the NMDA and AMPA conductance are altered for wM1 inputs to S1 in PVCre: SynGAP1$^{flox/+}$ mice. We found that the NMDA/AMPA ratio from PV INs was significantly higher in PVCre: SynGAP1$^{flox/+}$ mice compared to that of the control upon stimulation of wM1 inputs. Interestingly, high-frequency optical stimulation (HFS) of wM1 inputs led to a significant reduction of NMDA current amplitude in PVCre: SynGAP1$^{flox/+}$ mice, indicating a lack of NMDAR-mediated plasticity. Indeed, PVCre: SynGAP1$^{flox/+}$ mice failed to discriminate between a novel and familiar texture when subjected to a novel texture discrimination task, indicating a lack of learning. Together, our data suggest that *SYNGAP1* plays a critical role in regulating the excitatory synaptic strength from long-range inputs to cortical GABAergic neurons. Our results also suggest that PV-specific SynGAP1 haploinsufficiency impairs NMDAR-mediated plasticity, which may negatively impact learning.

Abstract: Fragile X syndrome (FXS) is the most prevalent heritable autism spectrum disorder (ASD), characterized by hypersensitivity and difficulty adapting to new sensory stimuli. Individuals with FXS often exhibit visual perception and learning impairments. Previous studies have described attenuation of 4-8 Hz oscillations, aberrant functional connectivity in Fmr1 KO mice, and impaired short-term (STP) in Fmr1 KO mice, the model of FXS. The reciprocal connections between the primary visual cortex (V1) and higher visual areas are crucial in cognitive processes. However, the impact of FXS on inter-areal connectivity remains poorly understood. To shed light on this phenomenon, we developed a new perceptual experience paradigm that induced familiarity-specific 4-8 Hz oscillations in V1 and the lateromedial area (LM), a part of the ventral pathway in mice. Using *in vivo* simultaneous silicon probes recordings and channelrhodopsin-2-assisted circuit mapping (CRACM) in acute brain slices, we investigated the strength and characteristics of long-range functional connections between V1 and LM in wildtype (WT) and Fmr1 KO mice before and after the visual experience. Simultaneous recordings of V1 and LM showed that the 4-8 Hz visual experience-dependent oscillations of both local field potentials and single-unit activity were lower in power and shorter in duration, and unit population firing rates were also lower in the V1 and LM of Fmr1 KO mice, which indicated deficits in communication between LM and V1. CRACM of feedforward projections revealed increased synaptic strength from V1 onto pyramidal cells (PCs) in all cortical layers of LM after visual experience in WT, while only a mild increase in the superficial layer II/III in Fmr1 KO mice. CRACM of feedback projections revealed decreased synaptic strength from LM onto PCs in layer II/III of V1 and increased strength in deep layer V after experience in WT, but no changes in Fmr1 KO mice. The visual experience also induced dendritic spine morphology plasticity we observed using super-resolution imaging and increased c-Fos expression in the visual cortex in WT but not in Fmr1 KO mice. Interestingly, some of the synaptic properties of the feedback projections in Fmr1 KO mice appeared to improve following visual experience, such as the paired-pulse ratios as a measurement of STP. Our findings provide the first measurements of the inter-areal synaptic connectivity before and after visual experience

in WT and Fmr1 KO mice, along with simultaneous *in vivo* recordings of neural activity, and indicate that visual training may serve as a promising therapeutic intervention for ASD.

Abstract: Contactin-associated protein-like 2, CNTNAP2 or Caspr2, is a cell adhesion molecule that belongs to the neurexin superfamily. Genetic variation in *CNTNAP2* is associated in neurodevelopmental conditions such as Autism spectrum disorders, schizophrenia, and cortical dysplasia focal epilepsy syndrome (CDFE). At the cellular level, CNTNAP2 plays a crucial role in modulating structural plasticity, including dendritic arborization and dendritic spines. Recent studies have revealed that CNTNAP2 undergoes ectodomain shedding, resulting in the release of a soluble ectodomain (sCNTNAP2), which regulates neuronal synchrony. However, it is still unknown if CNTNAP2 ectodomain shedding impacts dendritic architecture.
In this study, we show that ASD-associated CNTNAP2 mutations affect sCNTNAP2 levels, due to retention in the endoplasmic reticulum or altered processing by MMP9. We demonstrate that CNTNAP2 mutants display alterations in dendritic arborization, probably derived from modified levels of shed ectodomain. Our study sheds light on the mechanisms underlying the role of CNTNAP2 ectodomain shedding in neuronal connectivity. These findings may have significant implications for the development of targeted therapies aimed at modulating CNTNAP2 function and improving neuronal connectivity in individuals with neurodevelopmental disorders.

Abstract: *EXOC4* (exocyst complex component 4), which encodes the EXOC4 protein, is a mutated gene found in patients with autism spectrum disorder (ASD). EXOC4 is known to play an essential role in rapid membrane expansion, which occurs during the outgrowth of neurons and synaptogenesis. However, the mechanism by which mutations in the *EXOC4* gene lead to the ASD phenotype remains unclear. In the current study, cerebral organoids derived from induced pluripotent stem cells (iPSCs) with various *EXOC4* mutations generated by CRISPR-Cas9 gene editing were used. We found that *EXOC4* haploinsufficiency induces enlargement of cerebral organoids and delayed generation of cortical neurons, serving as an *in vitro* correlate of patients' macrocephaly and cognitive impairment. Remarkably, we also discovered defects in dendrite arborization and synapse development that recapitulate *EXOC4*-specific traits. Our results uncover that *EXOC4*-dependent molecular deficits provoke ASD characteristics and confirm the potential utility of CRISPR engineering in cerebral organoids for neurodevelopmental disease modeling.

Title: The variety and activity of neural precursors in a dorsal forebrain spheroid model of Down syndrome

Authors: *A. AYOUB[1,2], T. F. HAYDAR[1,2];
[1]Children's Natl. Hosp., Washington, DC; [2]George Washington Univ. Sch. of Med. and Hlth. Sci., Washington, DC

Abstract: Down syndrome (DS) is the most common genetic form of intellectual disability (ID). Early events in fetal corticogenesis are preferentially affected in DS and possibly contribute to the lifelong cognitive impairments associated with ID. The major determinant of neocortical size is the properly timed genesis of neurons and glia from neural precursor cell (NPC) populations. While several classes of NPCs have been identified, how they contribute to neocortical growth during normal development and their roles in DS remain to be elucidated. Here we investigate the diversity, proliferation potency and differentiation of NPCs during early cortical development in DS. We differentiated isogenic lines of induced pluripotent stem cells (iPSCs) derived from people with DS into human cortical spheroids with dorsal forebrain characteristics using small molecules and growth factors to mimic *in vivo* development and drive regional specificity. We perform high-resolution 3D imaging of entire cleared spheroids using 2-photon microscopy and a combination of immunohistochemical markers to characterize the architectonic features, size, and cellular composition of rosette structures to determine how these proliferative rosettes relate to overall spheroid size by genotype. EdU proliferative assays and co-immunofluorescent staining are performed to label dividing precursor cells and assess the relative degree to which proliferating cells undergo self-renewal or differentiation. Single-nuclei RNA sequencing will be performed to assay the heterogeneity and proportion of NPCs, and the different classes of neurons and glia contemporaneously generated. These experiments will temporally characterize the development of cortical progenitors and their progeny during the first month of development. We have demonstrated successful generation and 3D imaging of trisomic and euploid dorsal forebrain spheroids. We find that trisomic spheroids are consistently smaller in size and display altered gross morphology compared to isogenic euploid controls. We will investigate differences in the parameters and cellular composition of each rosette as well as the NPC proliferation kinetics between genotypes. Specifically, trisomic spheroids show altered precursor cell specification, proliferation, and distribution as well as reduced neurogenesis compared to euploid. By identifying specific changes in NPC dynamics in trisomic cells, we will elucidate some of the cellular changes underlying the neuroanatomical deficits occurring during very early development in DS.

Title: Normalization of DSCAM in the Ts65Dn mouse model of Down Syndrome ameliorates dendritic phenotypes in the dentate gyrus of the hippocampus

Authors: *R. NEFF[1,3], T. HERGENREDER[3,4], B. YE[2,3,4], G. G. MURPHY[1,3];

Abstract: Down Syndrome (DS) results from trisomy of human chromosome 21 (HSA21) and is characterized by physical and psychomotor impairments, and neurodevelopmental delays. Determining the genetic substrates that underlie the impairments observed in DS will not only lead to viable treatments for DS individuals, but also provide insight into the role of those genes in normal cognition. The Down Syndrome Cell Adhesion Molecule (DSCAM) is located on HSA21 and has been shown to be crucial for mediating neurodevelopmental processes such as presynaptic growth. It remains unknown as to whether DSCAM contributes to cognitive phenotypes and neurodevelopmental changes associated with the hippocampus, a region critical for learning and memory. The Ts65Dn mouse model of DS replicates many of the human phenotypes, including abnormalities in neuronal structure within the hippocampus. Through genetic correction of DSCAM (i.e., normalization) in the Ts65Dn, we aim to determine the relative contribution of DSCAM overexpression to the cognitive phenotypes in DS. In this study, we utilized Golgi-Cox staining in fixed brain tissue from 5-6-month-old mice to study the morphology of dendritic spines in the CA1 and dentate gyrus (DG) regions of the dorsal hippocampus. We observed regional differences in DS spine density, with an increase seen in CA1 pyramidal cells and a decrease in granule cells of the DG. Additionally, there was an enlargement of DS spines across all regions examined. We hypothesized that spine enlargement might be a compensatory effect in response to the enhanced inhibition and altered excitatory-inhibitory imbalance observed in the Ts65Dn mouse model of DS. Using immunostaining and confocal microscopy followed by unbiased analysis, we observed an increase in the number of inhibitory synapses on the pyramidal cell soma within the DS CA1 hippocampus. This phenotype was then ameliorated by DSCAM normalization. Furthermore, we saw that DSCAM normalization reduced spine length and area in CA1 and DG, correcting the spine enlargement seen in Ts65Dn. We also show that the deficit in DS granule cell spine density in the DG was restored with DSCAM normalization. As adult neurogenesis is deficient in DS, and the DG is one of the few brain regions where this process takes place, we are now quantifying newborn neurons in the DG using doublecortin (DCX) immunostaining to determine to what extent DSCAM normalization impacts adult neurogenesis in the Ts65Dn mouse model of DS. Overall, our findings provide evidence for DSCAM overexpression as a central contributor to the abnormalities in neuronal structure within the DS brain and suggest a promising therapeutic target for DS research.

Key words: GENUS, neurogenesis, embryo, Down syndrome, prenatal, Ts65Dn
Non-invasive sensory stimulation using light and sound at 40 Hz (Gamma ENtrainment Using Sensory stimuli, or GENUS) has been shown to reduce the pathological features of Alzheimer's disease. Unpublished work from our lab further showed that GENUS can be extended to treat other neurological disorder such as Down Syndrome (DS). We show here that GENUS promotes hippocampal neurogenesis and increased synaptic density in adult DS mouse model known as Ts65Dn. Since DS is a developmental disorder, we further tested whether prenatal GENUS treatment can rescue DS phenotypes that appear at the embryonic stage. We exposed the pregnant dam to GENUS and showed that it increased brain size and the thickness of cortical plate in the embryonic brain. Single nuclus RNA-seq experiments further demonstrated that prenatal GENUS treatment increased the expression levels of the genes that are downregulated in Ts65Dn embryonic brain. Many of these genes are involved in neurogenesis and cell migration. Overall, our data suggest that prenatal GENUS treatment could be a potential therapeutic tool for DS.

Title: Unraveling the role of somatostatin hilar interneurons in engram formation in Down syndrome.

Authors: *M. SABARIEGO NAVARRO, C.-L. SIERRA NOGUERA, A. ZAMORA MORATALLA, M. DIERSSEN;
Systems Biol., Ctr. for Genomic Regulation (CRG), Barcelona, Spain

Abstract: Down syndrome is the most prevalent genetic cause of intellectual disability but the mechanisms underlying cognitive impairment remain obscure. Our research has shown that engram formation is impaired in a mouse model of Down syndrome, the Ts65Dn, but the underlying causes of this deficit have not yet been fully understood. We here hypothesized that alterations in inhibitory microcircuits leading to overinhibition could contribute to the disrupted formation of hippocampal engrams in Down syndrome. Single-nuclei RNA sequencing revealed changes in cell composition with significant increases in specific subtypes of inhibitory interneurons in the Ts65Dn hippocampus, including somatostatin (SST+), vasoactive intestinal peptide-expressing (VIP+), and calretinin+ interneurons. Moreover, these interneurons exhibited an altered transcriptomic profile, particularly the SST+ cells, with alterations in genes which modulates the excitability of these cells as *Hcn1* and *Grik1*. To investigate the role of SST+ neurons in Down syndrome, we crossbred trisomic mice with transgenic mice expressing the Cre recombinase under the SST promoter. Through Contextual Fear Conditioning (CFC) experiments and using cFos as a measure of neuronal activity, we discovered that there was an increased number of cFos expressing SST+ cells upon CFC training. To establish a causal link between this phenotype and memory deficits in trisomic mice, we employed viral constructs containing chemogenetic tools to modulate the activity of SST neurons during engram formation. Remarkably, when we inhibited hilar SST+ cells during training, we observed a rescue in CFC performance, suggesting that the increase of cFos expressing (activated) SST+ interneurons impairs the formation of associative memories in the Down syndrome mouse model. Taken together our results suggest that in Down syndrome SST+ cells are more excitable and more prone to be activated upon learning, impairing engram formation and, ultimately, memory processes.

Title: Dissecting the cellular landscape of Down syndrome hippocampus

Authors: *M. PEREZ GONZALEZ[1], J. CONSTABLE[1], M. KUROSAWA[1], P. M. MUZA[1], S. J. WEST[2], V. TYBULEWICZ[3], E. M. FISHER[1];

Abstract: Down syndrome (DS) is caused by trisomy of human chromosome 21 (Hsa21). Defective cell proliferation and neurogenesis but increased number of glial cells, have been found in DS brains. These alterations are believed to disturb homeostasis and affect brain development contributing to intellectual disability (Lee et al., 2016). Here, we aim to study the cellular composition of the hippocampus of DS mouse models, ultimately to identify candidate genes and their contribution to cognitive impairment. For this, we work with mouse models with segmental duplications of Hsa21 orthologous genes on mouse chromosome 16 (Mmu16). Cell counts are assayed in Dp(16Lipi-Zbtb21)1Tyb (Dp1Tyb) mice at 3-4 months of age, which have cognitive deficits (Chang et al., 2020). If a difference from wildtype (WT) littermates is identified with counts of individual cell types, we also assayed those cells in 3-4 month Dp(16Mir802-Zbtb21)3TybEmcf (Dp3Tyb), Dp(16Lipi-Hunk)9TybEmcf (Dp9Tyb) and Dp(16Mis18a-Runx1)2TybEmcf (Dp2Tyb) - which form a genetic mapping panel of the duplicated region in Dp1Tyb mice. Cell counting is performed using thick coronal sections from the dorsal hippocampus, which are optically cleared and immunolabelled using the ABSOC protocol (Muza et al., 2023). Dp1Tyb mice have higher hippocampal density of neuropeptide Y (NPY)+ and calretinin+ cells compared to WT mice but no changes in parvalbumin+ cells, indicating that there is increased numbers of specific subtypes of interneurons in these mice, consistently with an hypothesis postulating that excessive GABAergic signaling in DS contributes to cognitive impairment (Contestabile et al., 2017). Dp1Tyb mouse hippocampus has higher levels of IBA1+ cells and augmented density of S100B+ but not GFAP+ cells, suggesting increased density of microglia and certain astrocyte subpopulations. As S100B is also expressed in oligodendrocyte precursor cells (OPCs), density of NG2+ cells was also assessed, and indeed Dp1Tyb mice present increased numbers of OPCs. Using a genetic mapping approach, we have determined that the increased NPY cell density observed in Dp1Tyb mice was present in Dp3Tyb mice but not in Dp9Tyb or Dp2Tyb so there must be at least one gene present between Mir802 - Zbtb21 on Mmu16 causing an increase in hippocampal NPY+ interneuron density. Alterations in cell populations are likely to contribute to cognitive impairment in DS. Identifying the genes causing these alterations is essential to develop effective treatments for cognitive dysfunction in DS. Here, we have mapped a dosage-sensitive gene(s) causing an increase in NPY interneurons to the Dp3Tyb region that is duplicated for just 39 coding-genes.

Title: Effects of a postnatal Dyrk1a functional copy number reduction in the Ts65Dn mouse model of Down syndrome on sensorimotor development

Authors: *L. E. HAWLEY[1], L. JOHNSON[1], K. HEAGY[1], C. R. GOODLETT[2], R. J. ROPER[1]; [1]Dept. of Biol., [2]Dept. of Psychology, Indiana University-Purdue Univ. Indianapolis, Indianapolis, IN

Abstract: Down syndrome (DS) is the triplication of human chromosome 21 (Hsa21) and causes abnormal brain and behavior development. Overexpression of *DYRK1A*, triplicated in DS, causes impairments in neuronal proliferation, differentiation, and cell cycle progression. Inhibition of DYRK1A is a candidate therapeutic for DS, but questions remain regarding when to start treatments. The Ts65Dn DS mouse model contains an extra segmental chromosome, adding a third copy of ~ half of Hsa21 orthologs. We found amplified DYRK1A expression in brain tissues of trisomic pups on postnatal day (P) 6, suggesting P6 may be a critical stage of altered brain development in this DS mouse model. We hypothesized that a functional reduction of *Dyrk1a* gene copy number before P6 in otherwise trisomic pups would rescue sensorimotor delays typical in Ts65Dn growth. A doxycycline-induced truncation of one *Dyrk1a* allele initiated on P0 resulted in euploid (Eu), trisomic (Ts,*Dyrk1a*$^{+/+/+}$), and trisomic mice with 2 functional copies of *Dyrk1a* (Ts,*Dyrk1a*$^{+/+/-}$). PCR confirmed excision with a novel primer probing the DNA bridge created by this deletion. Pups were tested daily from P3 to P21 with a battery of 14 neurobehavioral milestone assessments. Ts,*Dyrk1a*$^{+/+/+}$ pups consistently weighed less than Eu matched littermates, a disparity that widened with age through P21. Reducing *Dyrk1a* copy number in Ts,*Dyrk1a*$^{+/+/-}$ did not significantly improve these deficits. For cliff aversion and negative geotaxis, there were no significant differences among groups in mean age meeting criterion, but the Eu mice showed a wider range of ages (positively correlated with body weight) while the Ts,*Dyrk1a*$^{+/+/+}$ and Ts,*Dyrk1a*$^{+/+/-}$ pups had a smaller range at criterion uncorrelated with body weight. Locomotor activity was assessed in 10-minute sessions at P10, P13, P16, and P19. Total distance traveled increased in all groups across ages, but the magnitude of increase varied according to genotype. Eu pups opened their eyes significantly earlier ($\bar{x}$=13.4) than Ts,*Dyrk1a*$^{+/+/+}$ ($\bar{x}$=15.1) or Ts,*Dyrk1a*$^{+/+/-}$ ($\bar{x}$=15.4) pups; a noteworthy increase in P13 Eu pup activity level may be due to this earlier eye opening. Ts,*Dyrk1a*$^{+/+/-}$ pups had significantly lower activity levels at the three earlier ages compared to Euploid littermates. At P19, mean activity levels of female Ts,*Dyrk1a*$^{+/+/+}$ mice were significantly higher than female Eu and Ts,*Dyrk1a*$^{+/+/-}$littermates. In contrast, mean activity levels of P19 males did not differ among the three genotype groups. These findings to date suggest that certain sexually dimorphic trisomic phenotypes that are sensitive to *Dyrk1a* dosage in Ts65Dn mice may emerge during postnatal development.

Title: Increased NMDA-receptor-mediated calcium influx in iPSC-derived neurons from individuals with Down syndrome

Authors: J. DA SILVA FAUSTO[1], T. GLASER[2], A. HENNING ULRICH[2], A. C. S. COSTA[3], ***B. L. ZAMPIERI**[1];
[1]Hosp. Israelita Albert Einstein, São Paulo, Brazil; [2]Dept. of Biochemistry, Chem. Inst., Univ. of São Paulo, São Paulo, Brazil; [3]Dept. of Psychiatry, Case Western Reserve Univ., Cleveland, OH

Abstract: Down syndrome (DS, or trisomy 21, T21), is the most common genetic cause of intellectual disability. Individuals show a spectrum of cognitive and neurobehavioral impairments with deficits in memory and learning. Calcium (Ca^{2+}) signaling is an essential mechanism for neuronal function, transducing electrical activity into intracellular molecular signals. N-Methyl-D-aspartate receptors (NMDARs) are glutamate-gated channels with high Ca^{2+} permeability, thus central for learning and information processing in the brain. Dysfunction and hyperactivity of NMDARs may lead to Ca^{2+} overload, synaptic noise, and neuronal death. We aim to investigate NMDAR-mediated Ca^{2+} influx in induced pluripotent stem cells (iPSCs)-derived neurons from individuals with DS. iPSCs were established from urine-derived cells isolated from 6 individuals with DS (T21-iPSCs) and 4 controls. Differentiation into cortical neurons was performed using the dual SMAD inhibition strategy and confirmed by immunoreactivity for neuron-specific markers and the obligate GluN1 subunit of the NMDAR. To investigate Ca^{2+} influx, iPSC-derived neurons (DIV 75+) were loaded with Fluo 4-AM (5 μM) for 40 min at 37°C. Imaging and washes were performed with artificial cerebrospinal fluid. Imaging was done using an ECLIPSE-TiS microscope with a 10X objective at 2 frame/s for 10 min. Baseline recordings were done for 30s after which 1 μM glycine was added and then 1 min later 500 μM NMDA. In a different set of neurons NMDAR blocker memantine (10 μM) was added 2 min before the addition of NMDA. Data were analyzed using NIS-Elements Advanced Research software. Fluorescence traces were normalized to the initial fluorescence intensity and mean peak amplitude values (DF/F0) were calculated from specified regions of interest manually selected. Area under the curve (AUC) was calculated with the integration function. Results show that the influx of Ca^{2+} and AUC were significantly higher in untreated T21-iPSC-derived neurons compared to untreated controls ($p=0.0003$ and $p<0.0001$, respectively). Blocking the NMDA receptors with 10 μM memantine had no detectable effect on the influx of Ca^{2+} in T21-neurons, but it significantly reduced the AUC in treated T21-neurons compared to untreated T21-neurons ($p=0.030$). The effect of memantine on the Ca^{2+} influx is being further investigated in our laboratory. T21-iPSCs-derived neurons revealed alteration in NMDA receptor-mediated

calcium influx, leading to increased Ca^{2+} activity. These findings provide supporting to the hypothesis of excessive NMDAR signaling based on previous observations in mouse models of DS and that NMDAR should be further investigated in DS.

Title: Altered adhesions and local translation in Down syndrome hiPSC-derived cortical neurons

Authors: *K. RYGEL[1], M. AGRAWAL[2], N. KIRKISE[1], S. BAILEY[2], G. GOTBERG[1], P. CASSIDY[2], S. KELEMEN[2], T. BUMBLEDARE[2], L. KERSHNER[2], A. MONTAZZOLI[2], C. NEIFERT[2], K. WELSHHANS[1];
[1]Biol. Sci., Univ. of South Carolina, Columbia, SC; [2]Biol. Sci., Kent State Univ., Kent, OH

Abstract: Down syndrome is a neurodevelopmental disorder resulting from the triplication of human chromosome 21. One ubiquitous phenotype of Down syndrome is intellectual disability, which results, in part, from altered neuronal connectivity. During development, neuronal growth cones sense and respond to guidance cues to reach their appropriate synaptic targets and form this neuronal connectivity. Two critical mechanisms that regulate this process are local translation and adhesion. Prior work suggests that local translation may occur at adhesion sites, thus connecting these two processes. To better understand how neuronal connectivity is altered in Down syndrome, here we used both human fibroblasts and human induced pluripotent stem cell (hiPSC)-derived cortical neurons from apparently healthy individuals and individuals with Down syndrome and examined changes in local translation and adhesion. Fibroblasts are a valuable model for discovering potential cellular and molecular processes underlying axon growth and guidance during neuronal development because these two cell types use similar migration mechanisms. We first used a transwell migration assay and found a decrease in cell migration in Down syndrome fibroblasts. Using a puromycin assay, we also found that local translation in the leading edge of Down syndrome fibroblasts is altered. Multiple proteins in the adhesion complex, including paxillin, vinculin, talin, and RACK1, are increased in Down syndrome fibroblasts. Using hiPSC-derived cortical neurons, we performed a Dunn chamber turning assay with the attractive guidance cue, netrin-1, and found that growth cone turning is lost in hiPSC-derived neurons from individuals with Down syndrome. Additionally, both talin

and RACK1 are significantly increased, and local translation is decreased in growth cones of Down syndrome hiPSC-derived neurons at basal conditions. We are currently examining whether adhesion proteins, local translation, and growth cone turning are altered following stimulation with the attractive guidance cue brain-derived neurotrophic factor (BDNF). Taken together, this work shows that dysregulation of local translation and adhesion-based mechanisms during development may contribute to the neuronal connectivity changes that occur in Down syndrome.

Title: Feeding ability and intrinsic tongue maturation at weaning in the Ts65Dn mouse model of Down syndrome

Authors: *T. J. GLASS[1], R. E. BRUTTO[2], B. A. CHATWIN[2];
[1]Univ. of Wisconsin, Madison, Madison, WI; [2]Univ. of Wisconsin Madison, Madison, WI

Abstract: Down syndrome (DS) is associated with developmental delays and difficulties related to feeding during infancy and childhood. Successful weaning, or transitioning from suckling to independent deglutition, requires dramatic developmental change in movements of the tongue. However, little is known about whether maturation of the intrinsic tongue is impacted in DS. This study tests the hypothesis that DS causes delays in maturation of the tongue muscle system at weaning. Methods: The Ts65Dn mouse model of DS and euploid sibling controls were evaluated at 21 days of age to quantify measures related to eating and drinking during a 24-hour period immediately after weaning. Mice were also evaluated at 35 days of age, which is a timepoint associated with mature mastication and drinking behaviors (n = 14-16 male mice and 8-14 female mice per group). After behavioral assays, intrinsic tongue muscles were sectioned and stained to permit quantification of myofiber size and percentages of myofibers expressing Myosin Heavy Chain isoform (MyHC) 2a and MyHC 2b. Separate data analysis was performed for anterior, middle, and posterior regions of intrinsic tongue muscles (n=5-6 male mice and 5-6 female mice per group). Data were analyzed by 2-way ANOVA and mixed effects analysis as appropriate. Results: At 21 days of age, Ts65Dn lost a significant amount of weight compared to euploid controls during the 24 hours immediately after weaning (p=.0004). Ts65Dn consumed significantly less food (p=.009) and significantly less water (p=.025) during this time period.

However, there were no genotype-specific differences in weight change or feeding measures over a 24-hour period at 35 days of age. Preliminary results of intrinsic tongue analysis at 21-22 days of age indicate significant differences as a function of anatomical region within the intrinsic tongue muscle system in myofiber size (p=.001) and MyHC isoforms (p=.005), but not as a function of sex or genotype. Conclusions: Ts65Dn show significant differences in feeding efficacy at weaning, but do not show these differences two weeks later. Weaning may be a process that is particularly susceptible to oromotor delays in DS, and the Ts65Dn mouse model is useful for studying these delays. At weaning, the intrinsic tongue muscle system has dramatic anterior-to-posterior specificity in the properties of myofibers. While Ts65Dn and controls broadly share major organizational principles of the tongue muscle system at weaning, work is ongoing to increase sample sizes in tongue muscle analysis to permit detection of genotype-specific and sex-specific differences with smaller effect sizes, if present.

Title: Neocortical development in the novel TcMAC21 Down syndrome mouse model

Authors: *Z. ATAK[1,3], S. GANDHI[4,2], K. A. PASION[1], J. WILLIAMS[1,5], T. F. HAYDAR[1,6,3]; [1]Ctr. For Neurosci. Res., [2]Ctr. for Neurosci. Res., Children's Natl. Med. Ctr., Washington, DC; [3]Neurosci. and Cognitive Sci., Univ. of Maryland, College Park, MD; [4]Sch. of Neurosci., Virginia Tech., Virginia, VA; [5]Biol., Howard Univ., Washington, DC; [6]Sch. of Med. and Hlth. Sci., George WashingtonUniversity, Washington, DC

Abstract: The cerebral cortex is a six-layered structure that develops from a simple epithelial sheet during early embryonic development. The neocortex subserves cognition, social behavior, speech, and motor skills, behaviors known to be detrimentally impacted by trisomy 21/Down's syndrome (DS). Prior research using mouse models of DS has revealed that cortical neuronal precursor proliferation and fate specification are faulty in DS and may underpin adult behavioral alterations. Here we utilized a novel mouse model of DS, TcMAC21, in which each cell contains an extra copy of the human long arm of chromosome 21 (HSA21q), harboring 93% of the protein-coding genes present on HSA21q. How triplication of HSA21q leads to the structural and behavioral manifestations of DS remains unclear. Our goal in this study is deeply characterize prenatal neurogenesis in the TcMAC21 brain. In particular, we will assess whether lineage-specific neurogenesis, a key mechanism of cortical neuron diversification, is altered in this novel DS mouse model. We utilized acute EdU labeling to capture cycling cortical neural precursor cells in the S phase of the cell cycle in TcMAC21 trisomic and control brains to determine precursor proliferative capacity and positioning in the embryonic neocortex. Furthermore, we

performed in utero electroporation (IUE) surgeries to fate-map neurons born through direct and indirect neurogenesis. To determine the contribution of different precursor lineages to cortical development in TcMAC21, brains were collected and analyzed 24 hours after IUE. Neural precursor cell marker and morphology data were obtained by immunohistochemical staining of electroporated tissue slices. Thus far, we have not detected significant differences in mediolateral and rostrocaudal cortical measurements between euploid and trisomic brains, either prenatally or postnatally. This finding is very different from previous DS mouse models. At the microstructural level, we found evidence of altered cortical plate thickness and lamination patterns in the trisomic brain. Our experiments so far revealed no overall differences in levels of proliferation between euploid and trisomic cortices. However, we detected altered positioning of proliferative precursors in trisomic cortices. Moreover, our preliminary lineage analysis in TcMAC21 mouse embryos has demonstrated a decrease in the number of intermediate progenitor cells and consequently in the neurons that they normally produce. Focused analysis of TcMAC21 brain development may improve our understanding of humans developing with trisomy 21.

Title: Microglia morphological and functional differences in the developing Down syndrome brain

Authors: *I. RIVERA[1,2,3], M. LIOUDYNO[2,3], B. HSU[4], T. XIAO[4], A. MISHRA[4], J. BUSCIGLIO[1,2,3,4];

Abstract: Lifespan studies investigating the development of Alzheimer's disease (AD) in individuals with Down syndrome (DS) has provided insight into various contributing factors,

including mitochondrial dysfunction, oxidative stress, neuroinflammation, microglial alteration, and accelerated amyloid beta accumulation. While microglia morphological changes and neuroinflammation have been observed in DS as early as during childhood, the precise timing of the emergence of chronic inflammation and microglial alterations in DS, which arises as a genetic disorder at conception, remains unclear. Here, we explore microglia morphology and function in the Dp(16)1Yey/+ (Dp16) mouse model of DS at early stages of development. Immunofluorescence analysis using the microglial marker IBA1 at postnatal day (P)9, corresponding to an infantile stage of development, showed increased surface area in cortical microglia, and increased cell body area, branch number and branch length in hippocampal microglia. Building upon our lab's previous findings demonstrating the therapeutic potential of mitochondrial catalase (mCAT) in reducing oxidative damage and reversing mitochondrial dysfunction in Dp16 cells in vitro; we investigated whether overexpression of mCAT could reverse the microglia alterations in infantile Dp16 mice by generating a mCAT:Dp16 transgenic mouse model. Preliminary results indicate that overexpression of mCAT in Dp16 mice reverses the above-described alterations in microglia morphology. Thus, the abnormal microglia phenotype observed in trisomic mice is associated with oxidative stress and mitochondrial dysfunction in infant trisomic mice. Analysis of both normal and Down syndrome human prenatal cortical tissue showed similar microglial alterations. Further we evaluated microglial function, by establishing microglia cultures from euploid and trisomic prenatal cortical tissue suspensions. Phagocytic function was tested using fluorescent bioparticles and IBA1 immunostaining. Preliminary results indicate that trisomic microglia exhibited an increase in particle engulfment per cell compared to euploid cultures. Ongoing analysis of cell-specific gene expression profiles and functional assays will further characterize the structural and functional differences in trisomic microglia. These results suggest that early interventions during development may be crucial to prevent and/or reduce chronic inflammation and microglial structural and functional abnormalities in DS.

Title: Anti-nkcc1 gene therapy rescues cognitive deficits and alleviates neuroinflammation in the ts65dn mouse model of down syndrome

Authors: *F. GHANDOUR, A. CONTESTABILE, L. CANCEDDA;
Brain Develop. and Dis., Italian Inst. of Technol., Genova, Italy

Abstract: A common feature of diverse brain disorders is the alteration of GABA-mediated inhibition due to aberrant intracellular chloride homeostasis induced by changes in the expression and/or function of chloride transporters. Notably, pharmacological inhibition of the chloride importer NKCC1 is able to rescue brain-related core deficits in animal models of these pathologies, and in some clinical studies in patients. In this study, we tested the potential therapeutic applications of NKCC1 gene knock-down by intraparenchymal injection of three different doses of adeno-associated virus type 9 (AAV9) expressing neuron-specific artificial microRNA (amiR) targeting NKCC1 in adult animals of the Ts65Dn mouse model of Down syndrome (DS). We found that NKCC1 silencing rescued cognitive impairment of Ts65Dn mice toward their WT littermate levels. Moreover, we showed that basal microglia over-activation, a characteristic feature of DS phenotype, was also rescued by reducing neuronal NKCC1 expression in Ts65Dn mice. Notably, AAV9 vector expressing neuron-specific NKCC1 amiR also prevented astrogliosis, microglial activation and NF-kB upregulation induced by control AAV9 injection in both wildtype and Ts65Dn mice. Our results provide compelling evidence that NKCC1 is implicated in cognitive dysfunctions in neuroinflammation in DS adult mice, thereby firmly supporting the potential breakthrough of NKCC1 knockdown gene therapy in DS.

Title: Augmented GIRK2 channel signaling in neonatal Ts65Dn mice: Implications for aberrant formation of developing neural circuits in Down syndrome

Authors: J. JIN, D. CHAN, B. LE, A. TAN, ***A. KLESCHEVNIKOV**;
Univ. of California San Diego, La Jolla, CA

Abstract: Down syndrome (DS) is a genetic disorder resulting from the triplication of chromosome 21 (HSA21) and is characterized by cognitive impairment. Neuronal and synaptic abnormalities most profoundly accumulate during the initial period of brain development. We hypothesized that triplication of *Kcnj6*, which encodes Girk2 subunits of G-protein-coupled potassium channels, contributes significantly to the development of faulty neural circuits in early brain development in DS. To assess the feasibility of this hypothesis, we compared neuronal and molecular properties of *Kcnj6*/Girk2 in neonatal Ts65Dn mice, a genetic model of DS. Consistent with previous observations in adult animals, Western blot analysis showed that Girk2 protein levels were approximately 50% higher in the hippocampus of Ts65Dn *vs*. 2N neonatal

(p5-p8) mice. The efficiency of Girk2 channel signaling was also considerably increased in the hippocampus of neonatal Ts65Dn mice. Thus, bath applications of the GABAB agonist baclofen (40 μM for 5 minutes) to acute hippocampal slices evoked greater whole-cell currents and produced a more substantial reduction in input resistance in granule cells of Ts65Dn compared to 2N pups. Furthermore, neuronal excitability, which depends on the functional activity of Girk2 channels, was significantly reduced in regular Ts65Dn mice, but not in Ts65Dn mice with only 2 copies of *Kcnj6* (Ts65Dn/*Kcnj6*++- mice). Indeed, the threshold currents required for neuronal excitation were in 2N 25.5±2.9 pA, in Ts65Dn 45.7 ± 6.2 pA ($p = 0.01$), and in Ts65Dn/*Kcnj6*++-: 21.0 ± 1.1 pA ($p = 0.3$, n.s.). Finally, the spontaneous activity of neurons, which depends on neuronal excitability, was lower in Ts65Dn *vs*. 2N cells. Thus, in support of our hypothesis, this data suggests that the triplication of *Kcnj6* and subsequent increased expression of Girk2 result in enhanced Girk2 channel signaling, leading to reduced neuronal excitability and spontaneous neuronal activity during the period of intensive synaptogenesis. These alterations may contribute to the formation of faulty neural circuits in the hippocampus of mouse models of Down syndrome.

Title: Defective engram allocation contributes to impaired fear memory performance in Down syndrome

Authors: *Á. FERNÁNDEZ BLANCO, A. ZAMORA-MORATALLA, M. SABARIEGO NAVARRO, C. SIERRA NOGUERA, M. DIERSSEN;
Systems Biol., Ctr. for Genomic Regulation, Barcelona, Spain

Abstract: Down syndrome (DS) is the most common genetic form of intellectual disability and is caused by the triplication of the human chromosome 21. Memory deficits are a hallmark feature of DS, but the underlying cellular mechanisms are not completely understood. Our laboratory and others demonstrated alterations in key mechanisms that are fundamental for engram formation and reactivation in DS mouse models. These previous results led us to propose that DS is a model of defective engrams. Thus, we investigated engram-specific alterations using

engram tagging techniques and chemogenetic intervention in Ts65Dn, a DS mouse model. We detected a sparser neuronal activation in Ts65Dn mice after both the acquisition and recall of a contextual fear conditioning memory in the dentate gyrus, compared to WT mice. Memory impairment was not recovered by artificially reactivating the trisomic engram cells using clozapine N-oxide (CNO) in Ts65Dn mice. While WT engram cells showed an enhanced number of dendritic spines compared to non-engram cells, trisomic engram cells did not, indicating a lack of structural plasticity that is required for a proper memory consolidation. Moreover, we also found that trisomic engram cells did not enhance their excitability immediately after memory recall, which has been reported to be important for context discrimination. Our results indicate that the trisomic engram is not properly formed, thus preventing memory to be completely recalled in the future. Hence, focusing on strategies capable of restoring the process of engram formation, such as manipulating neuronal excitability, might be promising to rescue memory deficits in trisomic mice.

Title: Spatiotemporal gene expression profiling in Down Syndrome reveals perturbed microglia-neural cell interactions in the subventricular niche

Authors: *A. FENG, B. KUKREJA, N. TAHMASIAN, B. RUSU, T. CAO, B. KALISH; Neurosci. and Mental Hlth., The Hosp. For Sick Children, Toronto, ON, Canada

Abstract: Down syndrome (DS) is the most common genetic cause of intellectual disability. However, our current understanding of the early-life molecular alterations contributing to DS pathogenesis remains limited. Here, we employed a multi-modal spatial and single-cell gene expression analysis of mouse and human fetal brain tissue to identify transcriptomic changes during both early life and aging in DS. Using Multiplex Error-Robust Fluorescent In-Situ Hybridization (MERFISH), we curated a panel of 500 genes and performed cross-sectional comparisons between euploid (n=3) and Ts65Dn mouse model of DS (n=3) brain samples at postnatal day 0 (P0) and 6 months (6mo). Simultaneously, we employed single-nucleus RNA sequencing (snRNA-seq) on human fetal euploid (n=5) and DS (n=5) brain tissues collected during gestational weeks 13-19. Over 1 million mouse cells were profiled by MERFISH, while over 107,000 human cells were profiled by snRNA-seq. Focusing on the subventricular zone (SVZ) in P0 mice, our spatially-resolved differential gene expression analyses revealed a

downregulation of the cell surface ligand CD47, responsible for the “don’t eat me” signal, in several neuronal lineages, including transit-amplifying progenitors, neuroblasts, and mature neurons. Concurrently, our snRNA-seq results demonstrated a similar downregulation of CD47 and CD24 across neuronal cells of the fetal DS brain. CD33, a cell surface ligand known to reduce microglia phagocytosis upon activation, was downregulated in P0 Ts65Dn SVZ microglia. These findings indicate the downregulation of receptors implicated in the "don't eat me" signaling pathway accompanied by a concomitant increase in phagocytic microglia expression in the DS brain. In addition, spatially-aware ligand-receptor analysis of the P0 SVZ revealed differentially expressed cell-cell interactions involving chemokine, interferon, and sonic hedgehog ligand and receptors between immune and cell types along the neuronal lineage. Moreover, pathway analyses revealed significant alterations in signaling pathways known to impact microglial activity, including the Wnt, JAK/Stat, Notch, cytokine, and interleukin pathways. Based on these collective findings, we propose that microglial dysregulation leads to negative reprogramming of NSCs within the neurogenic niche in DS, thus contributing to impaired neurogenesis, altered neuronal morphology, and cortical hypocellularity in DS.

Hosp., Boston, MA; [7]Martinos Ctr. for Biomed. Imaging, Charlestown, MA; [8]Columbia Univ., New York, NY

Abstract: Individuals with Down syndrome (DS) are at a high risk of developing Alzheimer’s disease (AD), which is thought to be due to the overexpression of the amyloid precursor protein on chromosome 21 and associated early age of onset of beta-amyloid plaque accumulation. AD

progression in the neurotypical population is associated with hippocampal volume loss and a decline in memory. Additionally, there is a relationship between decreases in hippocampal subfield volumes, particularly the cornu ammonis 1 (CA1) and subiculum, and cognitive decline. Here, we assess the relationship between CA1 and subiculum volumes and memory performance in older adults with DS who progressed clinically to mild cognitive impairment (MCI) and dementia compared to those who remained cognitively stable (CS). We used 1mm3 T1-weighted MRI scans from 74 cognitively stable individuals with DS (mean age 48 +/- 6.18, 45% female) enrolled in the Alzheimer's Disease in Down Syndrome (ADDS) study that included 3 sites. Hippocampal subfields were segmented using Deep Fusion Labeling for Automated Segmentations for the Hippocampus (DeepFLASH) software, and were normalized by total intracranial volume. Memory performance was assessed with the modified cued recall test (mCRT). Participants who converted to dementia or MCI in the follow-up visit, approximately 18 months later, were deemed as converters (n=11 or 15% of sample). We assessed the relationship between regions of interest and memory using linear regression analysis and evaluated the differences between sub-groups using linear regression analysis. Sex and site were used as covariates. Lower memory scores were associated with reduced subiculum volume across all participants (R2=.084, p=.032). No association between memory performance and volume was found in the CA1 (R2=.007, p=.329). Additionally, we found no differences in subiculum and CA1 volumes between the converter and non-converter groups. Our results suggest that decreased subiculum volume is associated with worse memory scores in older adults with DS who converted from CS to MCI or dementia. Future analysis will investigate the effect of structural changes in the hippocampus on longitudinal memory decline in this cohort and in younger adults with DS.

Abstract: Down syndrome (DS) is associated with a heightened risk of developing Alzheimer's disease (AD), with an estimated 70% of individuals manifesting AD by age 60. Neurofilament light chain (NfL) is a protein that is a marker for axonal injury and is elevated in cerebrospinal fluid and blood with neurodegeneration. Plasma NfL levels increase with age and with AD progression in individuals with DS. This study investigated the association between plasma NfL, hippocampal subfield volumes, and memory function in DS. The analyses included 109 participants with DS from 3 sites (age 49.3 ± 6.6 years, 47 female, 78 cognitively stable, 21 mild cognitive impairment, 10 possible dementia). We collected T1-weighted 1mm3 magnetic resonance imaging (MRI) scans to assess subfield volumes, modified Cued Recall Test (mCRT) scores to measure episodic memory performance, and plasma to measure NfL. MRI data were processed with DeepFLASH, a recently-developed deep learning-based tool for automatic segmentation of hippocampal subfields. We hypothesized a positive association between hippocampal subfield volumes and memory function and a negative association with plasma NfL.
After adjusting for covariates (age, sex, site) and intracranial volume, we found significant positive associations between volumes of hippocampal subfields (dentate gyrus/CA3, CA1, and subiculum) and mCRT scores. Our findings also revealed that higher plasma NfL levels, which indicate more neurodegeneration, were associated with decreased subfield volumes in the hippocampus and poorer memory performance on the mCRT.
While the memory-volume correlations showed no difference across clinical groups, the correlations between hippocampal subfield volumes and plasma NfL were present only in individuals with MCI and dementia.
These results highlight the vulnerability of all hippocampal subfields to neurodegeneration in individuals with DS. Increases in plasma NfL may reflect clinically-relevant hippocampal atrophy, demonstrating its potential use as a biomarker for neurodegeneration in this population.

Abstract: Blood brain barrier (BBB) alterations have detrimental consequences on brain development, resulting in cognitive and behavioral deficits. In a 22q11.2 deletion syndrome mouse model, also known as Di George syndrome, an impairment of the BBB has been recently described (Crocket et al., 2021). This BBB defect was confirmed in the LgDel/$^{+}$ mouse model of the syndrome, extensively characterized at the neurobiological and behavioral level (see Castellani G et al. abstract n. 2023-S-9935-SfN). In this animal model, a perinatal OXT treatment was found to rescue developmental trajectories and behavioral deficits in adolescent and adult mice. These effects were linked to an increase of the tight-junction protein claudin-5 and restoration of BBB integrity (see Castellani G et al. abstract n. 2023-S-9935-SfN) suggesting a new, direct effect of OXT on brain microvascular endothelial cells.
Here, we thus investigated at the cellular and molecular level the effects of OXT on brain microvascular endothelial cells, focusing on early postnatal developmental stages. To check the formation and integrity of the barrier, we prepared brain microvascular endothelial cells (BVEC) from wild type (WT) and LgDel/$^{+}$ mice at postnatal day 3-5 and we measured transepithelial electrical resistance (TEER), small solutes permeability and claudin-5 levels. Cells were treated for up to 14 days with OXT or vehicle. We observed that chronic OXT treatment in LgDel/+ BVEC i) significantly increased TEER; ii) restored permeability for the small tracer Lucifer yellow; iii) normalized claudin-5 levels. Similar effects on TEER, permeability and claudin-5 levels were also observed in WT BVEC cells and confirmed in two well established brain endothelial cell lines, BEND-3 and hCMEC/D3 cells, routinely used to study BBB properties *in vitro*. OXT effects on proliferation, migration and tube formation are in progress. As these results indicate a key role of OXT in regulating brain microvascular endothelial cells, we investigated the molecular targets of OXT. We found that BVEC, hCMEC/D3 and BEND-3 express OXT receptors (OXTR) and V1a vasopressin receptors (V1aR), both of which are pharmacological targets of the neuropeptide. We are currently testing a series of selective OXT and vasopressin agonists and antagonists to dissect the intracellular pathways that contribute to barrier properties of brain microvascular endothelial cells.

Title: Unveiling the molecular mechanisms of neurodevelopmental alteration in a SETD1A-deficient forebrain organoid model

Authors: *Z. SUN[1], H. ZHU[1], Y. SUN[1], J. FAN[1], B. XU[1], J. A. GOGOS[1,2,3,4];
[1]Psychiatry, Columbia Univ., new york, NY; [2]Mortimer B. Zuckerman Mind Brain and Behavior Inst., [3]Dept. of Physiol. and Cell. Biophysics, [4]Dept. of Neurosci., Columbia Univ., New york, NY

Abstract: Genetic disruption of *SETD1A*, a lysine methyltransferase best known for its role in mediating methylation of the lysine 4 on the histone H3 protein, is robustly associated with schizophrenia (SCZ) ($p = 1x10^{-12}$) and confers substantial risk for SCZ (odds ratio = 20). *SETD1A* mutations appear to increase neurodevelopmental vulnerability but the detailed mechanisms, including the genomic binding properties and targets of SETD1A in the developing human brain, as well as the cell type-specific alterations resulting from *SETD1A* mutations remain largely unknown. To address these questions, we generated forebrain organoid models of the developing human cerebral cortex derived from wild type and mutant isogenic human induced pluripotent stem cells (hiPSCs) carrying *SETD1A* SCZ risk mutations introduced by CRISPR/Cas9 genome editing. Chromatin profiling using CUT&Tag assays combined with RNA sequencing on sorted cortical neurons led to the identification of high-confident target genes, which are significantly enriched in neuropsychiatric genetic liability. Using single-cell RNA sequencing and follow-up experimental validation, we find that *SETD1A* disruption leads to the changes in the expression of lineage driver genes and altered development of cortical excitatory neurons. The aberrant transcription program underlying impaired development contains molecular signatures of key regulatory factors known to modulate neurogenesis. Our ongoing experiments are investigating the morphological and functional alterations caused by *SETD1A* deficiency. Our study advances our understanding of SETD1A genomic binding

properties, uncovers molecular and neurodevelopmental alterations due to *SETD1A* mutations and may facilitate efforts for therapeutic interventions.

Title: Unraveling the Pathological Mechanisms and Reversibility of Neurodevelopmental Defects in Linear Nevus Sebaceous Syndrome caused by dysregulation of KRAS

Authors: Y. KIM, *H.-E. LEE, S. BAEK;
POSTECH, Pohang-si, Korea, Republic of

Abstract: Linear nevus sebaceous syndrome (LNSS) is a neurocutaneous disorder arising from somatic gain-of-function mutations in *KRAS* or *HRAS*. LNSS brains exhibit neurodevelopmental defects, such as cerebral defects and epilepsy, yet the underlying pathological mechanisms and potential treatment strategies remain largely unclear. In this study, we demonstrate that the introduction of $KRAS^{G12V}$ during mouse cortex development induces subcortical nodular heterotopia and heightened excitability, effectively recapitulating major pathological manifestations observed in LNSS. Additionally, we uncover that the reduced firing frequency of inhibitory neurons, independent of $KRAS^{G12V}$ expression, disrupts the delicate balance between excitation and inhibition. Leveraging transcriptional profiling following destabilization domain-mediated clearance of $KRAS^{G12V}$ in human neural progenitors and differentiating neurons, we identify reversible functional networks that contribute to LNSS. Neurons expressing $KRAS^{G12V}$ exhibit molecular changes associated with delayed neuronal maturation, the majority of which can be restored upon $KRAS^{G12V}$ clearance. These findings provide valuable insights into the molecular networks involved in the reversibility of some neuropathologies observed in LNSS, arising from dysregulation of the RAS pathway.

Title: Transcription factor 4 coordinates striatal neuron specification, maturation, and dopamine transmission

Authors: *N. ROBINSON[1], J. HINDS[1], L. JAMES[3], S. THOMPSON[1], J. TUSCHER[1], L. IANOV[2], B. PHILPOT[3], J. DAY[1];
[1]Neurobio., [2]Civitan Intl. Res. Ctr., Univ. of Alabama at Birmingham, Birmingham, AL; [3]Cell Biol. and Physiol., Univ. of North Carolina, Chapel Hill, NC

Abstract: The striatum subserves myriad roles in motor learning, executive function, and motivated behaviors. At a molecular level, striatal development is governed by spatiotemporally precise gene expression programs that are orchestrated by master transcription factors (TFs) operating within progenitor populations of the ganglionic eminences (GEs). Notably, a host of neurodevelopmental disorders are caused by mutations in these TFs and are characterized by delayed motor development coupled with cognitive and behavioral dysfunction, thus implicating the striatum in the pathophysiology of these disorders. Pitt-Hopkins syndrome (PTHS), which is caused by loss-of-function mutations in the neuronal master TF, transcription factor 4 (TCF4), manifests as a constellation of motor and behavioral symptoms. However, the extent to which striatal neurodevelopment is impaired in PTHS remains poorly understood. Using gene expression profiling across diverse paradigms of rodent and human striatal neurodevelopment, we have uncovered a previously unknown function for TCF4 in regulating gene networks governing neurogenesis, cell type specification, and neuroplasticity in medium spiny neurons (MSNs) and their GE progenitors. Notably, these transcriptional networks are disrupted in the striatum of *Tcf4*$^{+/-}$ mice, which serve as a robust preclinical model of PTHS. Mechanistically, TCF4 choreographs the temporal dynamics of MSN fate specification, and TCF4 deficiency results in persistent progenitor marker expression in the mature striatum. Moreover, TCF4 controls the distribution of D1- *versus* D2-MSNs, which mediate the motor and behavioral outputs of the striatum through their coordinated responses to dopamine. In line with this, modulation of *Tcf4* expression using an innovative dual CRISPR activation/interference strategy alters the transcriptional and electrophysiological responses of MSNs to dopamine. Our results reveal TCF4 as an essential regulator of the molecular events that define MSN development and neuromodulation. These findings expand our fundamental understanding of neurodevelopment and provide a foundation for examining the contributions of TCF4-driven transcriptional programs in the striatum to neurodevelopmental disease.

Title: Maternal Environment Shapes Mouse Embryonic Hindbrain Vulnerability to Prenatal Alcohol Exposure: Insights from Allele-Specific Expression Analysis

Authors: N. ELAZZABI[1], J. RICHARD ALBERT[1], P. PAVLIDIS[2], *K. HAMRE[3], D. GOLDOWITZ[1];
[1]Med. Genet., [2]Psychiatry, Univ. of British Columbia, Vancouver, BC, Canada; [3]Univ. of Tennessee Hlth. Sci. Ctr., Memphis, TN

Abstract: Fetal alcohol spectrum disorders (FASD) pose a global challenge, encompassing lifelong neurocognitive and growth deficiencies resulting from prenatal alcohol exposure (PAE). Previous studies on monozygotic and dizygotic twins, as well as investigations using selectively bred and inbred rodents, have implicated the role of both maternal and fetal genetics as risk factors for FASD. Notably, certain mouse inbred lines (e.g, C57BL/6) exhibit susceptibility to PAE-induced morphological malformations, while others (eg, DBA/2J) demonstrate relative resistance. However, the primary determinants of FASD susceptibility, whether it is the maternal environment, the fetal genome, or both, remains poorly understood. In the present study, we employed a mouse model of PAE to generate inbred and hybrid F1 embryos using female and male C57BL/6J (B6) and DBA/2J (D2). We implemented four mating schemes: B6xB6, B6xDBA, DBAxB6, DBAxDBA (maternal strain X paternal strain). On embryonic day 9, around the time of neural tube closure, pregnant female mice were randomly assigned to a two-dose gavage of either an iso-caloric control (maltose dextrin) or an alcohol (a total dose of 5.8g/kg) treatment group. Seven hours following the administration of the first dose, we collected the E9.5 embryos, dissected the hindbrains, and performed RNA extraction. Employing a multi-pronged approach utilizing both allele-specific and allelic agnostic RNA-seq differential analysis, our findings demonstrate: (1) a lack of evidence supporting PAE-induced differential allelic expression, including genomic imprinting and strain-biased expression AND (2) embryos with identical genomic compositions but developing in mothers of different inbred lines exhibit contrasting responses to ethanol exposure. PAE significantly alters gene expression in hybrid embryos developing in B6 mothers, with a comparable significant increase and decrease in gene expression observed. In contrast, minimal changes in gene expression are seen in hybrid embryos developing in D2 mothers. Specifically, the genes with significant increases in expression are associated with immune effector processes such as leukocyte-mediated immunity. Conversely, the genes with significant decreases in expression are involved in histone modifications, particularly peptidyl-lysine acetylation. Based on our findings, we conclude that the maternal environment has a significant role in determining the vulnerability of the embryonic hindbrain to ethanol-induced transcriptome changes. These findings provide molecular insights into the mechanisms underlying FASD vulnerability.

Title: Effects of Oxidative Stress During Cortical Development

Authors: *A. ACHANTA[1], B. C. CAMPBELL[1], M. CAMPBELL[2];
[1]UCSD, La Jolla, CA; [2]UCSD Dept. of Neurosciences, La Jolla, CA

Abstract: The balance of oxidation and reduction (redox) reactions are critical for normal cellular function. An excess of reactive oxygen species (ROS) creates a redox imbalance, leading to oxidative stress. Oxidative stress can damage cellular components and disrupt normal cellular mechanisms, making it a critical cellular phenomenon to understand. To determine the natural redox state of developing cortical neurons, we electroporated mouse embryos with Grx1-roGFP2 at E13 and performed both live and modified fixed imaging of the embryo brains at E15. For the modified fixed imaging, brain slices were first alkylated by NEM treatment before fixation to lock the sensor's status. On the other hand, sequential detection of oxidized and reduced Grx-roGFP2 during live confocal imaging allowed the determination of neuronal redox states. After establishing the baseline redox states, we exposed the pregnant mice to different concentrations of known oxidants and reductants (diamide and DTT) to create a gradient of the redox state at those concentrations of the oxidants and reductants. We next sought to determine the developmental impact of the most commonly prescribed analgesic during pregnancy, acetaminophen. Acetaminophen, when metabolized, generates toxic byproducts which deplete glutathione, one of the most abundant and critical antioxidants in the brain, increasing neuronal susceptibility to oxidative stress. We exposed pregnant mice to acetaminophen and compared the neuronal redox state to that after exposure to known oxidants and reductants to assess the impact of the acetaminophen. Our data shows that assessing the susceptibility of developing neurons to changes in the redox system is critical for understanding environmental stressors and their impact on neurodevelopment. This knowledge can further elucidate the mechanisms of many neurodevelopmental disorders as well as the potential environmental causes.

Title: Confirming a gain of function (GoF) pathogenic mechanism related to PASC1 Syndrome through treatment with antisense oligonucleotides (ASOs)

Authors: *M. FAIRBANKS SANTANA[1], A. D. GUEMEZ-GAMBOA[2];
[1]Dept. of Neurosci., [2]Physiol., Northwestern Univ., Chicago, IL

Abstract: Confirming a gain of function (GoF) pathogenic mechanism related to PACS1 Syndrome through treatment with antisense oligonucleotides (ASOs).Authors *M. Fairbanks Santana, A. D. Guemez-Gamboa; Neuroscience, Northwestern University, Chicago, IL.**DisclosuresM. Fairbanks Santana:** None**. A. D. Guemez-Gamboa:** None.**Abstract**PACS1 Syndrome is a neurodevelopmental disorder (NDD) caused by a single missense R203W substitution in the Phosphofurin Acidic Cluster Sorting 1 (PACS1) protein. PACS1 is known for its roles in the endosomal pathway and, more recently, it is being studied for its functions in the cell nucleus. Over 200 patients have been identified with PACS1 Syndrome, all presenting the same variant, and all display convergent phenotypes of Autism Spectrum Disorder (ASD) and intellectual disability (ID). Analysis conducted in our lab has shown that mature neurons are strongly enriched for risk genes of NDDs with overlapping phenotypes of PACS1. Moving forward, I am investigating whether ASO-mediated changes in gene expression from PACS1 R203W derived neuronal cell models are consistent with a GoF mechanism, additionally researching the potential of ASOs as a treatment. First, I tested the effect of four different non-allele specific PACS1 ASO candidates, provided by IONIS Pharmaceuticals, in induced pluripotent stem-cell (iPSC) derived neurons (iNeurons). Differentiation was induced by overexpression of transcription factor neurogenin-2 (NGN2). iNeurons were then matured for 3 weeks prior to a 72-hour treatment. Control ASOs were used at a concentration of 20 µM, whilst the PACS1 candidates were studied at concentrations of 1, 10 and 20 µM. The knock-out effect was then evaluated through Western blotting and candidate PACS1 ASO 0001 was identified as the most effective option to move forward. I obtained neurons for three different isogenic pairs: two patient lines and their respective CRISPR/Cas9 corrected cell lines, as well as wildtype line and its corresponding R203W edited variant. I treated two separate differentiations for all cells with both positive and negative control ASOs as well as PACS1 ASO 0001. Running this experiment in parallel with three different CRISPR edited PACS1 full knock-out lines, my objective is to discern ASO efficiency. Extracted RNA after treatment was then submitted for Bulk RNA Sequencing. I expect to assess whether changes in the transcriptomic profile due to a lack of PACS1 as caused by ASO treatment are a result of a GoF mechanism, as well as examining if genotype specific DEGs are restored and confirm therapeutical viability.

Title: Understanding mechanisms underlying white matter regeneration after rodent and piglet perinatal hypoxia

Authors: *L. ROSKO, K. BRANCH, V. GALLO;
Neurosci., Children's Natl. Hosp., Washington, DC

Abstract: Diffuse white matter injury (DWMI) is a highly prevalent neonatal brain injury leading to life-long neurological and motor impairments such as those seen in cerebral palsy. Perinatal hypoxia (HX) is a major contributor to DWMI with rodent HX models recapitulating many hallmarks of neurological damage occurring in DWMI patients. Since DWMI is a modifiable risk for adverse neurodevelopmental outcomes, understanding the cellular and molecular mechanisms underlying HX could lead to new therapies that harness endogenous regenerative mechanisms. Previous work from our lab shows that endothelin-1, an important signaling molecule present in radial glial cells of the subventricular zone (SVZ), is essential for maintaining rodent progenitor proliferation in development and after white matter demyelination. In addition to rodents, in this study, we utilized a piglet model which is gyrencephalic and highly translational to humans. We hypothesized that endothelin-1 signaling may regulate progenitor proliferation in SVZ after HX in both rodents and piglets. To investigate this hypothesis, we utilized a rodent HX model where male and female mice were exposed to 10.5% oxygen from postnatal (P) day P3 to P11 and then sacrificed at varying timepoints to investigate cellular expression of endothelin-1 and its receptors A (EndrA) and B (EndrB). We show that about one week post HX, endothelin-1 (p=0.009, n=4) and EndrB mRNA (p=0.03, n=3) are upregulated in the SVZ with little change in expression of EndrA mRNA (p=0.4, ns, n=4). The rodent SVZ displays increased proliferation of $Olig2^{+}$ oligodendrocyte lineage cells (OLC) one week following HX (p=0.048, n=3), but this proliferative response is ablated when endothelin-1 is removed from radial glial cells using a *nestin-cre^{ER}* model (p=0.025, n=3). Furthermore, the removal of endothelin-1 from radial glia led to fewer OLC in the white matter 3 weeks following HX (p=0.019, n=3). This suggests that endothelin-1 is essential for the proliferation of OLC in the rodent SVZ following HX. We also investigated endothelin-1 signaling in the piglet brain after HX using a model where male and female neonatal piglets were exposed to 10.5% oxygen from P3 to P14. In normoxic piglets, endothelin-1 is highly expressed in $sox2^{+}$ radial glia (100%, n=2) and expressed in about ten percent of oligodendrocyte precursor cells (10% +/- 1.2, n=2). Preliminary data suggest that endothelin-1 expression increases in the piglet SVZ following HX. These data suggest that endothelin-1 signaling could play a role in progenitor regeneration after hypoxia with a potential therapeutic avenue for developing therapeutics for infants with DWMI.

Title: Cerebellar Spatial Transcriptomic Landscape of Neonates with Sudden Infant Death Syndrome (SIDS)

Authors: J. GHAEMMAGHAMI, A. VALENZUELA, T. DEAN, V. GALLO, *P. KRATIMENOS;
Children's Natl. Hospital, George Washington Univ. Sch. of Med. and Hlth. Sci., Washington, DC

Abstract: Approximately 3500 infants die annually in the United States from sudden infant death syndrome (SIDS). The cerebellum makes direct connections with vital centers of brainstem nuclei, indicating a potential neurological link between abnormal cerebellar development and SIDS.We hypothesized that cerebellar cytoarchitectural and molecular abnormalities in the human neonate result in neural circuitry disruption, leading to cardiorespiratory suppression and SIDS.We analyzed postmortem human cerebellum from term infants with SIDS and compared them with matched non-SIDS subjects to delineate mechanisms of SIDS pathogenesis. We performed neuropathological analysis combined with bulk, single-cell, and spatial transcriptomics. We compared postmortem human cerebellum of infants with SIDS with matched controls, and we found disrupted cytoarchitecture, including 1) Purkinje cell (PC) and Granule cell (GC) heterotopias. Furthermore, significant changes in the morphology of PCs were also observed, together with a thicker external GC layer (EGL), indicating arrested migration of the GCs from the EGL to the Internal granule cell layer (IGL). To investigate the molecular mechanisms underlying cerebellar abnormalities in SIDS pathogenesis, we defined the transcriptome of early postnatal human cerebellum using RNA-seq. We found a significant number (904) of differentially expressed genes (DEGs) between SIDS and matched controls, indicating complex changes in specific gene networks that regulate cerebellar functions in infants with SIDS. Using spatial and single-cell transcriptomics, we identified maturational signature differences in infants with SIDS compared to matched non-SIDS subjects.The current studies provide a comprehensive analysis of cerebellar abnormalities that contribute to dysfunctional cerebellar-brainstem circuitry in infants with SIDS. Our study may contribute to developing novel biomarkers for primary or secondary preventative strategies of SIDS.

Title: *MED13L* and its pathogenic variants influence the dendritic development of cerebral cortical neurons in mouse brain

Authors: *K.-I. NAGATA, N. HAMADA;
Inst. Dev. Res., Aichi Dev. Disability Ctr., Kasugai, Japan

Abstract: The Mediator complex comprises multiple subcellular subunits that collectively function as a molecular interface between RNA polymerase II and gene-specific transcription factors. Recently, genetic variants to one subunit of the complex, known as MED13L, has been implicated in syndromic intellectual disability and distinct facial features, frequently accompanied by heart defects. We investigated the impact of 5 disease-associated MED13L variants on the subcellular localization and biochemical stability of MED13L protein in vitro as well as in vivo. In overexpression assays using cortical neurons from embryonic mouse cerebral cortices transduced by in utero electroporation-mediated gene transfer, we found that mouse orthologues of human MED13L-P866L and -T2162M missense variants accumulated in the nucleus, while the S2163L and S2177Y variants were diffusely distributed in the cytoplasm. In contrast, we found that the Q1922-term truncation variant barely detectable in transduced cells, a phenotype reminiscent of this variant that results in MED13L haploinsufficiency in humans. Next we analyzed these variants for their effects on neuronal migration, dendritic growth, spine morphology, and axon elongation of cortical neurons in vivo. There, we found that overexpression of P866L variant resulted in reduced number and length of dendrites of cortical layer II/III pyramidal neurons. Furthermore, we show that mMED13L-knockdown abrogated dendritic growth in vivo, and this effect was significantly rescued by co-expression of an RNAi-resistant mMED13L, but weakly by the T2162M variant, and not at all by the S2163L variant. However, overexpression of the S2163L variant inhibited mature dendritic spine formation in vivo. Expression of each of the 5 variants did not affect neuronal cell migration and callosal axon elongation in vivo. Taken together, our results demonstrate that MED13L expression is relevant to corticogenesis and influences the dendritic branching characteristics of cortical excitatory neurons. Our study also suggests that disease-associated MED13L variants may directly cause morphological and functional defects in cortical neurons in different ways.

Abstract: Epigenetic regulation plays a critical role in gene expression dynamics during brain development, and its dysregulation has been implicated in neurodevelopmental disorders. KDM6B (also known as JMJD3), an H3K27me3 specific demethylase, is a high-risk autism spectrum disorder (ASD) gene; mutations at the *Kdm6b* locus have also been found in schizophrenia (SCZ) and intellectual disability (ID) patients. However, it remains largely unknown whether deletion of *Kdm6b* during development results in phenotypes associated with neurodevelopmental disorders. We therefore generated *Kdm6b* conditional knockout (cKO) mice using a *Nex*-Cre line, in which Cre recombinase was expressed in postmitotic excitatory neurons in the developing neocortex and hippocampus. Results showed that adult *Kdm6b* cKO mice exhibited hyperactivity in open field tests and reduced sociability in three-chamber tests. In addition, *Kdm6b* cKO pups at postnatal day 7 emitted less calls than control pups after being separated from their dams in an ultrasonic vocalization test. These results indicate that dysfunction of *Kdm6b* in cortical and hippocampal excitatory neurons leads to behavioral abnormalities associated with neurodevelopmental disorders. Remarkably, we also found that *Kdm6b* cKO results in abnormal neocortical layer structures such as a significant reduction of cortical expression of the layer 4 marker RORb (also a high-risk gene for ASD) and mislocalization of SATB2-positive callosal neurons to layer 1. Furthermore, a reduction in the size of rostral areas containing the prefrontal cortex (PFC) was observed in the early postnatal stages. In addition to these morphological abnormalities, a physiological excitation/inhibition (E/I) imbalance within the medial PFC was observed, which may underlie behavioral deficits associated with neurodevelopmental disorders. RNA-seq analysis revealed dynamic molecular changes in *Kdm6b* cKO mice, and the differentially expressed genes were highly enriched in psychiatric disease-related genes. Taken together, our data indicate that KDM6B in postmitotic excitatory neurons plays a pivotal role in cortical layer and neural circuit formation, which may be necessary for suppressing neurodevelopmental disorders, through the regulation of gene expression dynamics during development.

Abstract: During development, the blood brain barrier is vulnerable to the lipophilic properties of Deltamethrin (DM) a type of commonly used pesticide. With the popularity of DM and other related pesticides in both agricultural and general public use, there is growing concern of links between developmental pyrethroid exposure and the incidence of neurodevelopmental disorders. Brain derived extracellular vesicles (BDEVs) are phospholipid nanovesicles involved in communication between cells that have been linked to the pathophysiology of neurological diseases. Here, we hypothesized DM exposure during development alters the role of the biogenesis of BDEVs, which may lead to dysfunctional synaptic plasticity in the hippocampus. Using a developmental exposure model, pregnant dams were exposed to 3 mg/kg/72 hours, equivalent to 1mg/kg/day, DM or vehicle through pregnancy and lactation. At post-natal day 30 BDEVs were extracted from both control and DM-exposed males and analyzed by transmission electron microscopy (TEM) to determine size and validated by western blot analysis. BDEVs were marked with a green-fluorescent membrane marker to locate them in the brain after ICV injections. Male WT mice received either control or DM-exposed exosomes and processed for hippocampal slice electrophysiological field recordings. BDEV presence in the hippocampus was confirmed in all slices used for recording fEPSP in the CA1 region. To study the effects of BDEVs (control vs. DM) on synaptic plasticity at Schaffer collateral - CA1 pyramidal cell synapses, a high-frequency stimulation was used to induce long-term potentiation (LTP) paradigm. We found that WT mice treated with BDEVs from DM-exposed animals showed significantly impaired LTP, with no changes in basal synaptic transmission (input-output curves and pair-pulse ratio). These results indicate that BDEVs play a key role in DM-induced neurotoxicity in the brain.

Title: Uncovering the cellular mechanism of Schizophrenia associated gene SETD1A heterozygous mutation in a human neural model

Authors: *X. SU[1,2], Y. HONG[3], H. ZHANG[4], L. WANG[2], S. ZHANG[4], Q. YANG[3], H. SONG[3], J. DUAN[4], G.-L. MING[3], Z. P. PANG[2];

Sch., New Brunswick, NJ; [3]Dept. of Neuroscience, Perelman Sch. of Med., Univ. of Pennsylvania, Philadelphia, PA; [4]Dept. of Psychiatry, Northshore Univ. Healthsystem, Evanston, IL

Abstract: Rare mutations in SETD1A are strongly associated with schizophrenia (SZ), a debilitating mental disorder affecting 1% of the population, and other severe neurodevelopmental disorders. SETD1A encodes a component of the histone methyltransferase complex producing mono-, di, and trimethylated histone H3 at Lysine 4 (H3K4). H3K4 trimethylation (H3K4me3) and H3K4me1 are epigenomic marks of active gene transcriptional promoters and enhancers, respectively. Interestingly, histone methylation has also been suggested as one of the most enriched gene pathways in common variant-based genome-wide associations studies (GWAS) of major psychiatric disorders. However, the detailed molecular mechanism by which it causes neuronal dysfunction is still unclear. Recent advances in stem cell biology have allowed the efficient conversion of human stem cells into defined neuron subtypes allows to address this question. Using CRISPR/Cas9 gene editing, we have generated isogenic hiPSC lines carrying heterozygous mutations of SETD1A on different genetic backgrounds. We are able to generate neuronal subtypes including excitatory, inhibitory and dopaminergic neurons to study cell-type specific impact of SETD1A heterozygous mutations. Preliminary morphological and electrophysiological analyses of induced excitatory neurons carrying SETD1A heterozygous mutations showed defective synaptic transmission. The transcriptomic result reveals dysregulated synaptic gene expressions in induced excitatory neurons carrying SETD1A heterozygous mutations, which suggests SETD1A heterozygous mutations may lead to synaptic dysfunction in excitatory neurons. Ongoing experiments are evaluating SETD1A heterozygous mutations with functional, morphological, biochemical and genomic parameters in other neuronal subtypes to understand the cellular mechanisms that how SETD1A heterozygous mutations contributes to the pathogenesis of SZ. The study enables us to perform a well-controlled assessment of the impact of SETD1A heterozygous mutations on the molecular and cellular mechanisms underlying deficits in early neurodevelopment and synaptic properties.

Abstract: Mutations in the X-linked RNA helicase DDX3X cause DDX3X syndrome, a neurodevelopmental condition frequently associated with autism spectrum disorder. DDX3X escapes X chromosome inactivation in human and mice, resulting in higher expression in female brains when compared with male brains. Further, mutations in the *DDX3X* gene affect primarily females. DDX3X regulates mRNA translation, but the mechanisms of action in neurons, the impact of clinical mutations, and the influence of sex have not been studied yet.Using a *Ddx3x*^{flox} mouse line generated at the Seaver Autism Center, we developed a cellular model to examine the impact of *Ddx3x* mutations in both male and female neurons. Primary cortical neurons were cultured from male embryos (*Ddx3x*$^{+/y}$ or *Ddx3x*$^{flox/y}$) or female embryos (*Ddx3x*$^{+/+}$, or *Ddx3x*$^{flox/+}$, or *Ddx3x*$^{flox/flox}$). Transfections with constructs carrying Cre and mCherry allowed us to model male control (*Ddx3x*$^{+/y}$) or null (*Ddx3x*$^{-/y}$) neurons, as well as female control (*Ddx3x*$^{+/+}$), haploinsufficient (*Ddx3x*$^{+/-}$) or null (*Ddx3x*$^{-/-}$) neurons. We also introduced *DDX3X* pathogenic mutations identified in male and female patients. We then examined dendritic arborizations and synapse number and morphology and compared sexes and genotypes. Additionally, we conducted immunoprecipitations and unbiased quantitative proteomics to gain insight into the molecular mechanisms underlying the effects of DDX3X mutations.Our findings demonstrate the critical involvement of Ddx3x in dendritogenesis and synaptogenesis, with its effects being influenced by both sex and gene dosage. Changes in neuronal morphogenesis were accompanied by alterations in the neuronal proteome, affecting the expression of proteins crucial for neuronal migration, neurite outgrowth, and those encoded by risk genes for neurodevelopmental disorders.

We also found that mutations identified in female patients are more deleterious than mutations identified in male patients.Our findings support a sex-specific role of *Ddx3x* in neuronal development and lay the bases to understand the sex biases in the prevalence and severity of DDX3X syndrome. These findings also contribute to a better understanding of the molecular mechanisms underlying DDX3X syndrome and may inform future research and therapeutic approaches.

Title: Toward understanding the molecular and cellular basis of RNA exosome-linked pontocerebellar hypoplasia type 1b: a cerebellar organoid model

Authors: *N. A. BARR, J. L. BURFORD, R. E. KANG, J. GADA, L. A. HIGGINSON, A. SETH, D. J. MORTON;
Mol. and Computat. Biol., USC, Los Angeles, CA

Abstract: Pontocerebellar Hypoplasia Type 1b (PCH1b) is a devastating autosomal recessive neurodevelopmental disorder characterized by significant atrophy of the cerebellum and pons. The cerebellum and pons integrate information from sensory systems, the spinal cord, and other parts of the brain to regulate breathing, motor movements, and learning motor behavior. Currently, there is no cure for PCH1b and treatment is purely palliative. Mutations that cause PCH1b occur in the *EXOSC3* gene, encoding a structural cap subunit of an essential RNA processing complex, the RNA exosome. The RNA exosome complex is an evolutionary conserved and ubiquitously expressed ribonuclease composed of structural and catalytic subunits that play a critical role in the post-transcriptional regulation of RNA. Although the RNA exosome is expressed in all cells and tissues, alterations in RNA exosome function disproportionately result in significant neurological impairments, thus underscoring the enhanced reliance of the nervous system on post-transcriptional regulation of gene expression. Cerebellar pathology in RNA exosome-linked PCH1b is challenging to understand based on current models of PCH1b. The goal of this study is to begin to define requirements for RNA exosome subunit EXOSC3 during cerebellar development through the study of *EXOSC3*-linked PCH1b mutations. To determine requirements for the RNA exosome during cerebellar development, we developed a 3D human induced pluripotent stem cell (hiPSC)-derived cerebellar organoid system to recapitulate neuronal dysfunction and degeneration known to characterize PCH1b. We have

engineered an allelic series of missense mutations encoding PCH1b-linked amino acid changes (EXOSC3-G31A and EXOSC3-G191C) of differing severity in hiPSCs via CRISPR/Cas9 technology to generate a cerebellar organoid model of PCH1b. We are combining single-cell transcriptomics and novel molecular tools to investigate the transcriptomic dynamics of generated cells during cerebellar differentiation as well as defining key post-transcriptional regulatory events mediated by the RNA exosome. My preliminary data show reduced organoid size as well as molecular and cellular defects that alter the differentiation of cerebellar cell lineages in organoids modeling EXOSC3-G31A, a severe genotype in individuals with PCH1b. Results from this work will provide a framework to study how the RNA exosome functions in early cerebellar development and has the potential to transform our understanding of PCH1b pathogenesis.

Title: The role of the Vsx2 super-enhancer during human retinal organoid development

Authors: *V. HONNELL, S. SWEENEY, M. DYER;
Developmental Neurobio., St. Jude Children's Res. Hosp., Memphis, TN

Abstract: Prior studies have identified thousands of enhancers with developmental stage-specific and cell-type specific activity in retinal neurons. However, the major challenge in the field is determining which enhancer(s) regulates each gene in a cell-type and developmental stage-specific manner. We recently identified a super-enhancer upstream of the *Vsx2* gene that is necessary and sufficient for the complex pattern of *Vsx2* expression during development. *Vsx2* is expressed in retinal progenitor cells and maintained in differentiated bipolar neurons and Müller glia. We found that this developmental stage-specific and cell-type specific expression pattern is achieved by distinct modules within the mouse super-enhancer. One module (Region 0) is responsible for retinal progenitor cell proliferation. Deletion of this module leads to microphthalmia. A separate module (Region 3) regulates bipolar cell genesis. Deletion of this module leads to a complete loss of a single cell type, the bipolar cells. Bipolar neurons are present in the Region 0 deletion retina and the eye is normal size in the Region 3 deletion retina demonstrating that the *Vsx2* super-enhancer is modular. We hypothesize that this pattern of expression will be recapitulated in a model of human retinal development. To test this hypothesis, we generated retinal organoids from human embryonic stem cells (hESCs)

containing the region deletions previously examined in mice. We examined cell type presence and retinal progenitor cell proliferation using RNA-sequencing, immunofluorescence, EdU labeling, and scRNA-seq across multiple stages of retinal organoid development. We found that Region 0 deletion organoids are small compared to wildtype controls, and that they recapitulate the phenotype observed in microphthalmic Region 0 deletion mice. These datasets will offer insights into the enhancer regions regulating *Vsx2* gene expression in humans and could identify previously unknown enhancer candidates contributing to microphthalmia.

Sci., Univ. of South Carolina, South Carolina Col. of Pharm., Columbia, SC

Abstract: Autism spectrum disorder (ASD) encompasses a spectrum of neurodevelopmental conditions characterized by impairments in social interaction, communication, and repetitive behaviors. Emerging evidence suggests that maternal immune inflammation during pregnancy, triggered by severe viral infections, may contribute to the development of some forms of ASD. Our study aims to elucidate the role of maternal immune activation (MIA) and the cytokine IL-17A in ASD pathogenesis. Animal studies have demonstrated that MIA leads to elevated levels of IL-17A in the developing offspring, resulting in ASD-like phenotypes. IL-17A, primarily produced by Th17 lymphocytes, has been detected in immune cells and plasma of children with ASD. However, the precise mechanisms through which IL-17A exposure impacts the development of early human neuronal circuitry and contributes to ASD pathogenesis remain poorly understood. To address this knowledge gap, we have developed human cellular models of neuronal development by leveraging the use of human embryonic stem cells (ESCs). Our preliminary findings indicate that exposure to IL-17A induces alterations in the expression of known ASD-associated genes and cytokine genes. Notably, these changes in gene expression are accompanied by a decrease in synaptic activity in IL-17A-exposed ESC-derived neurons. We

propose that IL-17A serves as a crucial mediator in ASD pathogenesis by modulating the regulation of both ASD-related and cytokine genes, as well as synaptic activity. Understanding the interplay between maternal immune inflammation, IL-17A, and ASD pathobiology holds promise for the development of targeted therapeutic strategies for individuals with ASD.

Title: Molecular mechanisms of translational control during human neuronal development in Fragile X Syndrome

Authors: *V. G. SHANKAR[1], I. TISNOVSKY[2], J. ZHANG[1], N. RAJ[4], O. KATSARA[5], M. KALINOWSKA[1], R. SCHNEIDER[5], G. J. BASSELL[4], E. KLANN[1,3];

Abstract: Dysregulation of translation forms the basis of the molecular pathogenesis of Fragile X Syndrome (FXS), one of the most characterized, X-inherited neurodevelopmental disorders, with individuals presenting intellectual disabilities and autistic spectrum disorder (ASD). FXS is caused by loss of the protein product of the *FMR1* (Fragile X Messenger Ribonucleoprotein 1) gene, which results in alterations in synaptic plasticity, neuronal development and growth, and an overall increase in global *de novo* translation and proteostasis. An RNA binding protein, FMRP (Fragile X Messenger Ribonucleoprotein) has a wide array of roles and appears to regulate the localization and the translation status of specific mRNAs, and it is required for proper differentiation and development of neurons. Although FMRP is known to regulate translation by affecting elongation, perhaps binding to and stalling ribosomes, the precise molecular mechanisms that are responsible for phenotypes in FXS have been elusive. Here, we explore the role of FMRP in regulating translation, particularly translation initiation, using excitatory neurons differentiated from patient-derived induced pluripotent stem cells (iPSCs). We observed changes in levels of various translation initiation factors (IFs) over the course of neuronal development in both FXS patients and normal individuals. Studies have shown that human neuronal development requires various stages of translational programming, with differentiation leading to progressively less actively translating cells. This reduced translational load appears to be via a switch to alternate, non-canonical translation initiation machinery, evident in changes in

levels of various translation IFs over the course of neuronal development. In FXS however, levels of certain non-cannonical IFs, such as eIF4G2, eIF4G1 and eIF3d continue to remain elevated through development, as do S6K and 4E-BP, effectors of the mTORC1 pathway. FXS patient-derived neurons are more sensitive to knock down of eIF4G2 (DAP5), but less sensitive to 4EGI-1 based inhibition of cap-dependent translation, hinting at a compensatory mechanism in place that necessitates eIF4G2 upon loss of FMRP. Regardless, proper translation control is lost in FXS over neuronal development, and growth of neurons is slower. We predict that neuronal development requires utilizing cap-dependent but eIF4E-independent methods of translation instead of the canonical eIF4-based translation initiation, a shift that is mediated directly or indirectly by FMRP.

Title: The regulation of mRNA stability during cortical development

Authors: *L. D. SERDAR[1], J. EGOL[1], G. HU[2], D. L. SILVER[3];
[1]Duke Univ., Durham, NC; [2]NIEHS, Durham, NC; [3]Duke Univ. Med. Ctr., Duke Univ. Med. Ctr., Durham, NC

Abstract: The cerebral cortex is a region of the brain responsible for higher cognitive function. Defects in cortical development are associated with neurodevelopmental disorders including autism and intellectual disability. Mechanisms controlling the dynamic regulation of gene expression in the developing brain are incompletely understood. While transcription has long been recognized as an important regulator of gene expression during corticogenesis, the contribution of mRNA decay is understudied. Here, we employ mouse models to investigate the mRNA stability landscape of the developing brain and reveal the consequences of misregulating mRNA stability in the cortex. We use SLAM-seq to measure mRNA decay rates transcriptome-wide across multiple stages of development. mRNA stability profiles are compared across each stage, and between mRNAs enriched in individual cortical cell types to generate an expansive

view of mRNA stability in the developing brain. We further examined the cis-acting factors underlying stability regulation and identified codon content as a major predictor of mRNA half-lives. To demonstrate the impact of mRNA decay on cortical development, we conditionally knocked out *Cnot3*, an essential component of the CCR4-NOT deadenylase complex, in neural progenitors. We find that loss of *Cnot3* leads to severe microcephaly and widespread p53-dependent apoptosis. These defects are accompanied by a reduction in progenitor density, prolonged cell cycle duration, and disorganization of cortical neurons. To assess the contribution of apoptosis to these phenotypes we generated *Cnot3;Trp53* double cKO mice, and discovered that defects in corticogenesis arise from both p53-dependent and independent mechanisms. Overall, our data reveal critical new insights into the mRNA stability landscape of the developing brain and underscore the important role of mRNA turnover during development.

Title: Identifying the molecular mechanism of PACS1 Syndrome pathogenesis

Authors: *A. L. SCHRODER, A. D. GUEMEZ-GAMBOA;
Neurosci., Northwestern Univ., Chicago, IL

Abstract: PACS1 Syndrome is a NDD hallmarked by craniofacial abnormalities and intellectual disability.Patients with PACS1 Syndrome have a single *de novo* missense mutation at c.607C>T of the Phosphofurin Acidic Cluster Sorting 1 (PACS1) protein, which causes an Arginine to Tryptophan substitution (R203W). PACS1 is a multifunctional sorting protein, with key roles in regulating trafficking of target proteins to and from the trans-Golgi Network (tGN). We have previously shown that PACS1 (+/R203W) forebrain organoids develop mature glutamatergic neurons with impaired expression of synaptic signaling genes when compared to isogenic controls.Additionally, PACS1 (+/R203W) neurons have prolonged network bursts, which has implications for circuit formation. While these results highlight the impact that the R203W variant of PACS1may play in the broader context of neuronal development, it remains unknown how the R203W variant alters the function of PACS1 in the cell. Using a combination of biochemistry and live cell imaging, we are now identifying how the R203W variant impacts the function of PACS1. TheR203W variant is in the Furin Binding Region (FBR) of PACS1, which is the region responsible for cargo protein interactions dependent upon acidic-cluster motifs. We hypothesize that theR203W variant will impact the trafficking dynamics of PACS1-associated cargo in between the tGN and plasma membrane through its interactions with membrane specific

adaptor proteins for localization. Our data indicates there is no difference between the localization of PACS1 WT and R203W. This, however, does not provide any information regarding the dynamics ofPACS1-associated trafficking, thus we are currently performing live imaging of PACS1 and its associated cargo. Given the localization of the R203W variant to the FBR, we are also performing BioID to identify how the R203W variant impacts PACS1 interactome, with the hypothesis that multiple binding interactions will be disrupted and/or gained as a consequence of this R203W substitution.

Title: The role of medial pulvinar in the maturation of Parvalbumin interneurons; implications in cognitive neurodevelopmental disorders

Authors: *N. SEYED HOSSEINI FIN[1], J. SCOTT[2], L. TEO[1], J. HOMMAN-LUDIYE[1], J. A. BOURNE[2];
[1]Monash Univ., Clayton, Australia; [2]Natl. Inst. of Mental Hlth., Washington DC, DC

Abstract: Background Cognitive neurodevelopmental disorders (CNDs) are associated with abnormal maturation of parvalbumin (PV+) interneurons in the prefrontal cortex (PFC). However, the mechanisms underlying this impairment remain unclear. The medial pulvinar (PM), a primate-specific thalamic subdivision, establishes widespread connectivity with the PFC. PV+ cells are particularly a major recipient of thalamic inputs. Mounting evidence indicates consistent PM disruption accompanied by decreased PV expression in CNDs. Thus, we investigated the time course of PV+ cell maturation in the PFC and examined the consequence of PM-PFC dysconnectivity during early postnatal life on PV+ cell maturation in adulthood.**Experimental design** Non-human primates (NHPs) recapitulate PFC subdivisions (i.e. dorsolateral PFC) as well as PM entity, similar to humans. Hence, an NHP model, the marmoset monkey, was selected for this research. We mapped the maturation trajectory of PV+ cells in the PFC in ages ranging from neonatal (postnatal day 7), infancy (postnatal month(pm)1), juvenile (pm3), and adolescence (pm9 and pm12) to adulthood (>pm19) (n=2). In the second experiment, we investigated the role of PM in the PV+ cell maturation by PM ablation through magnetic resonance imaging-mediated N-methyl-D-aspartate (NMDA) injection in the PM of neonates. NMDA injection leads to the excitotoxicity of PM neurones. The effects of early-life PM ablation on PV+ cell maturation were characterised in adulthood

(n=3).**Results** The density of PV+ interneurons (PV+ NeuN+ cells) peaked from neonatal to juvenile (0.01 vs. 0.09, p=0.005), while accumulation of perineuronal nets (PNNs) around PV+ cells (WFA+ PV+ cells) occurred between infancy and mid-adolescence (0.12 vs. 0.69, p<0.0001). PNN accumulation stabilises PV+ cell connectivity associated with the last stage of PV+ cell maturation. Notably, early-life PM lesion reduced PV+ cell density (0.13 vs. 0.06, p<0.0001), impaired PV+ inputs onto pyramidal neurones through quantifying perisomatic PV+VGAT+ puncta (0.24 vs. 0.09, p=0.002) and diminished the accumulation of PNNs around the PV+ cells (0.73 vs. 0.52, p=0.001) in the PM lesion compared to the control group. For statistics, the non-parametric Kruskal-Wallis test was accompanied by Dunn's multiple comparisons.**Conclusions** Our study underscores that PV+ cell maturation is protracted until mid-adolescence, and PM-PFC dysconnectivity alters this process leading to alterations of local neuronal networks, suggesting this subtype is a key determinant of normal PFC function. Further, the data support the PM hypo/dysconnectivity as a potential early indicator for CNDs diagnosis.

Title: Automated Processing of Neuronal Axon Initial Segment Morphology

Authors: *E. A. AQUINO, A. CONTRERAS, D. J. HINES, R. M. HINES;
Interdisciplinary Neurosci., Univ. of Nevada, Las Vegas, Las Vegas, NV

Abstract: The axon initial segment (AIS) is a highly specialized compartment of neuronal cells that controls cell firing. The AIS is an elaborate subcellular compartment of neurons with intracellular and extracellular components that concentrate and arrange voltage-gated ion channels and associated proteins critical for generating the action potential. A variety of homeostatically regulated factors can influence the probability of action potential generation at the AIS, including distance from the soma, AIS length, and changes in AIS diameter. Our understanding of the details of AIS morphology throughout development and pathology is somewhat limited due to the time-intensive analysis required to assess thousands of neuronal AIS at multiple time points. More autonomous, unbiased methods for analyzing large datasets are needed to expand our knowledge of AIS morphology throughout development and in nervous system pathology. In this project, we developed a new Python program to quickly and efficiently analyze immunohistochemically stained AISs in confocal images from different developmental

stages and animal models of human neurodevelopmental syndromes. It can individually label AISs, and provide morphology, proximity, and protein periodicity readouts for each AIS. This program will prove to be a powerful tool for experimenters interested in AIS analysis by improving the efficiency and fidelity of AIS analysis. Additionally, the program can be quickly altered to analyze the characteristics of other subcellular compartments. This research will aid in our understanding of AIS development, its progression, and how it is modified in neurodevelopmental disorders.

Title: Conditional ablation of Miro1 from cortical excitatory neurons causes agitative- and anxiety-like behavior in mice

Authors: N. KERN[1], M. SAKHEIM[1], M. CASE[1], L. JARRAHY[1], L. BASEL[1], C. CHAPMAN[1], R. SHIN[1], *A. K. MYERS[1], J. A. GOLDEN[2];
[1]Hamilton Col., Clinton, NY; [2]Cedars-Sinai Med. Ctr., Los Angeles, CA

Abstract: Cognitive disorders are a diverse group of diseases with complex etiologies, many posited to arise during development. Autism spectrum disorder, schizophrenia, and bipolar disorder are a cluster of cognitive disorders with associated behavioral features that manifest early in life and have a wide range of symptoms including repetitive behavior, agitation, and anxiety. While the etiology of these disorders is not completely understood, recent studies have implicated mitochondrial dysfunction playing a role. Mitochondria are double membraned organelles that produce ATP and buffer intracellular calcium. To perform their cellular functions, mitochondria use intracellular transport. Failure to move to metabolically active regions of the cell results in vital energy deficits and reduced buffering capacity. Mitochondrial Rho-GTPase 1 (Miro1) is a mitochondrial outer membrane protein known to participate in microtubule-based mitochondrial motility and homeostasis in neurons. Previous research suggests that abrogation of MIRO1 can contribute to the onset of neurodegenerative diseases including Amyotrophic Lateral Sclerosis, Alzheimer's Disease, and Parkinson's Disease. In this study, we ablated *Miro1* from excitatory neurons using an *Emx1-cre* and examined the behavior of the young mice. *Miro1* conditional mutant animals exhibited agitative-like behaviors including decreased nesting behavior, repetitive behaviors, and decreased interactions with littermates. They also spent less time in the center of an open space and showed increased freezing behavior during the open field test, both considered anxiety-like behaviors. Daily cage activity, social behavior, and brain cFos

levels were atypical in the *Miro1* conditional mutant mice. Our data associate MIRO1 with the pathogenesis of some developmental neurocognitive disorders and implicate mitochondrial localization in anxiety-like behaviors.

Title: Exploring the Roles of Reticular Thalamic Nucleus in Brain Function and Dysfunction

Authors: *D. KIM;
Biomedicine, Aarhus Univ., Aarhus, Denmark

Abstract: Autism spectrum disorder (ASD) is a highly heritable (70-90%) neurodevelopmental disorder. Individuals with ASD show sleep dysregulation and defects in sensory gating, which is one of the key hypotheses put forward to explain ASD-associated sleep disruptions. Both preclinical and clinical studies highlight that the zona incerta (ZI) and reticular thalamic nucleus (TRN) are key brain regions that gate both sensory inputs and regulate sleep. Thus, some aspects of ASD features could be contributed to these two brain regions. In addition, ASD-associated genes identified in large human genetic studies are highly enriched in the ZI and TRN. Despite the importance of the ZI and TRN in ASD, however, relatively little is known about the development of these regions, as well as the potential roles of ASD-associated genes in the process.ASD and other neuropsychiatric disorders are linked to the aberrant development of cortical GABAergic neurons. ASD-like features are shown with disruptions in the specification of cortical GABAergic neurons in animal models. Developing ZI and TRN GABAergic neurons express many transcription factors that control the development of cortical GABAergic neurons, some of which are linked to ASD. Using molecular and genetic approaches, we 1) characterize the molecular mechanisms controlling the development of the ZI and TRN, and 2) identify the roles of ASD-associated genes on the ZI and TRN development.Our data find that loss-of-function of these ASD-associated genes leads to a loss of GABAergic neurons and alters the E/I balance in the ZI and TRN. The dysfunction in ZI/TRN GABAergic neuronal development could potentially contribute to ASD features, and I am to improve our understanding of two brain regions that are closely linked with ASD pathology.

Title: Sleep and temperature deficits in a Dravet syndrome mouse model

Authors: *S. FADILA[1], B. BREUCHER[2], I. GONZÁLEZ DOPESO-REYES[3], E. KREMER[3], M. RUBINSTEIN[4];
[1]Human molecular genetics and biochemistry, Tel Aviv Univ., Tel Aviv, Israel; [2]PVM, BioCampus, CNRS, INSERM, Univ. of Montpellier, Montpellier, France; [3]IGMM CNRS, IGMM CNRS, Montpellier, France; [4]Sagol school for neuroscience, Tel aviv Univ., Tel aviv, Israel

Abstract: Rationale:Dravet syndrome (Dravet) is a developmental and epileptic encephalopathy (DEE) caused in most cases by de novo loss of function mutations in *SCN1A*. Sleep disturbances are very common in Dravet, and include problems initiating and maintaining sleep and daytime drowsiness. Problems in thermoregulation are also prominent in Dravet patients with reports of a tendency to overheat and decreased sweating. Thermoregulation is highly associated with mechanisms of sleep and sleep quality. Thus, we set to test if problems in temperature regulation and sleep deficits are connected in Dravet. **Methods**: To explore the neural link between thermoregulation and sleep, we performed body temperature, electrocorticography (ECoG), and depth recordings in the ventrolateral preoptic area (vLPO), with focus on the changes in body temperature in epochs of wake and NREM sleep. **Results**: Dravet mice exhibited lower baseline temperature, with reduced ability to maintain and control their body temperature in changing temperatures. Moreover, ECoG-temperature recordings revealed a failure to reduce their body temperature during wake-NREM transition. The vLPO is a sleep-promoting region involved in regulating body temperature. Recordings of the vLPO showed that an increase in the ambient temperature (from 25°C to 36°C) was associated with an increase in delta frequency (0.5-4Hz) in WT but not in Dravet mice. Delivery of *SCN1A* coding sequence using canine adenovirus 2 (CAV2-SCN1A) lead to an improved delta modulation in Dravet mice. Furthermore, chemogenetic-mediated increased activation of the vLPO also restored the temperature-dependent increase in delta activity. **Conclusions**: Together, our data indicate a connection between sleep and temperature deficits in Dravet and demonstrate an involvement of the vLPO and related regions.

Title: Developmental hearing loss-induced perceptual deficits are rescued by genetic restoration of pre- and postsynaptic cortical inhibitory mechanisms

Authors: *S. MASRI[1], R. FAIR[3], T. MOWERY[4], D. SANES[2];
[1]Ctr. for Neural Sci., New York Univ., Brooklyn, NY; [2]New York Univ., New York, NY; [3]NYU, New York, NY; [4]Rutgers Univ., Piscataway, NJ

Abstract: Even a transient period of developmental hearing loss during the developmental critical period can induce long-lasting deficits in temporal and spectral perception, which correlate with speech perception in humans. In gerbils, these hearing loss-induced perceptual deficits are correlated with a reduction of both ionotropic GABAA and metabotropic GABAB receptor-mediated synaptic inhibition. Therefore, we developed viral vectors to express proteins that would upregulate gerbil postsynaptic inhibitory receptor subunits (GABAA , Gabra1; GABAB, Gabrb1b) in pyramidal neurons, and an enzyme that mediates GABA synthesis (GAD65) presynaptically in parvalbumin-expressing interneurons. A transient period of developmental hearing loss from P11 to P23 during the auditory cortex critical period significantly impaired perceptual performance of the mongolian gerbil (Meriones unguiculatus, 52 normal hearing and 47 transient hearing loss animals of both sexes) on two auditory tasks: amplitude modulation depth detection and spectral modulation depth detection. We then tested the capacity of bilateral auditory cortex injections of each vector to restore perceptual performance on each task, relative to controls injected with GFP and to normal hearing animals. While both GABA receptor vectors increased the amplitude of cortical inhibitory postsynaptic potentials, only viral expression of postsynaptic GABAB receptors improved perceptual thresholds to those observed in normal hearing animals. Furthermore, presynaptic GAD65 expression in parvalbumin-expressing interneurons alone improved perceptual performance on spectral modulation detection. These findings suggest that recovering performance on auditory perceptual tasks depends on GABAB receptor-dependent transmission at the auditory cortex, especially at parvalbumin interneuron to pyramidal neuron synapses, and point to potential therapeutic targets for developmental sensory disorders.

Title: Developmental expression of P2X3 receptor in the mouse trigeminal ganglion

Authors: *M. ISHIKAWA[1], T. SATO[2], T. YAJIMA[2], K. MIZUTA[1], H. ICHIKAWA[2,3]; [1]Div. of Dento-oral Anesthesiol., [2]Div. of Oral and Craniofacial Anatomy,, Tohoku Univ., Sendai, Japan; [3]Sch. Organization Shokuryo Gakuin, Tokyo Shokuryo Dietitian Acad., Tokyo, Japan

Abstract: P2X3 receptor is activated by extracellular ATP. The purinergic receptor channel is associated with nociceptive transmission in the sensory ganglion. In this study, expression of P2X3 receptor was examined in trigeminal ganglion (TG) and facial tissues during development by immunohistochemistry. An avidin-biotin complex method was performed on the mouse TG and vibrrisal pad at postnatal day 0-21. At postnatal day 0 (P0), virtually all TG neurons were immunoreactive for P2X3 receptor. At P3-14, the proportion of P2X3-positive TG neurons gradually decreased (80-90%). And, approximately 60% of TG neurons in P21 mice contained P2X3 receptor-immunoreactivity. Only 40% of sensory neurons in the adult TG were immunoreactive for P2X3 receptor. In P21 and adult TGs, P2X3-containing neurons had mainly small to medium-sized cell bodies. At P0-7, numerous nerve fibers contained P2X3 receptor-immunoreactivity in the vibrissal pad. These nerve fibers showed intense immunoreaction and formed nerve bundles beneath vibrissae. They ascended their thick and thin branches toward vibrissae. Many P2X3 receptor-containing nerve fibers surrounded and entered vibrissal follicles. Within vibrissal follicles, P2X3 receptor-containing nerve fibers ramified repeatedly and made nerve terminals close to hair shafts. In the epithelium of the vibrissal pad, numerous free nerve endings also showed P2X3 receptor-immunoreactivity. At 14 and 21, P2X3 receptor-containing nerve fibers dramatically decreased in the vibrissal pad. As a result, some nerve terminal showed weak immunoreaction within hair follicles. However, many P2X3 receptor-containing nerve fibers within the epithelium appeared to remain unchanged. In the adult vibrissal pad, P2X3 receptor-containing nerve fibers were very infrequent. The present study suggests that P2X3 receptor and ATP play an important role in TG neurons during postnatal development.

Title: Development of a biomimetic spiking neural network model for multidimensional tactile perception

Authors: *J. KIM, S.-P. KIM;
Ulsan Natl. Inst. of Sci. & Technol., Eonyang-eup, Ulju-gun, Korea, Republic of

Abstract: Implementing an artificial tactile system that approaches the human perception level has proven to be a formidable challenge. This work proposes a biomimetic tactile perception model based on a Spiking Neural Network (SNN) to addresses this challenge. Designed to mimic the tactile pathway from cutaneous mechanoreceptors to S1 cortex, the proposed model utilizes a multi-layered SNN architecture, with each layer representing a distinct component in the tactile pathway. The first layer comprises Slowly Adapting-1 (SA-1) and Rapidly Adapting-1 (RA-1) afferent neurons, which receive tactile stimuli from mechanoreceptors stochastically. The second layer processes the information derived from SA-1 and RA-1 afferents in separate streams, simulating the functions of the cuneate nucleus. This layer follows the neuronal circuit mechanisms intrinsic to the cuneate nucleus, particularly the dynamic interaction between excitatory and inhibitory neurons that facilitates lateral inhibition for minimizing noise accumulation and maintaining the fidelity of spatial information. The final layer, wherein inputs from SA-1 and RA-1 afferents converge, is constructed to emulate the S1 cortex. This layer utilizes a diverse combination of excitatory and inhibitory fields for the encoding of various stimulus properties. The layered organization of the proposed SNN is capable of the processing of multidimensional tactile features, thereby enhancing the efficiency of information processing. In the static perceptual dimension, the proposed SNN could distinguish two separate points of pressure stimulation at 3mm or greater, which is on par with human performance. It also accurately identified a tactile stimulus orientation, ranging from 0 - 170 degrees in 5 degrees increments. This was achieved using only four types of final layer neurons oriented to 0, 45, 90, and 180 degrees by decoding their activity into the stimulus orientation with 90.1% classification accuracy. In the dynamic perceptual dimension, the proposed SNN demonstrated the ability to rapidly detect the slip of an object within 5 ms. Furthermore, it could estimate the speed of the object with a resolution of 1 mm/s and discriminate vibration frequency of a stimulus in the range from 1 to 100 Hz. These results not only reinforce the proposed model's competency in mimicking biological tactile systems but also provide substantial implications for enhancements in the architecture and functions of tactile intelligence systems.

Title: Neurophysiological consequences of developmental serotonin transporter disruption

Authors: *G. OCANA-SANTERO, H. WARMING, V. MUNDAY, C. GIBEILY, C. HEMINGWAY, H. A. MACKAY, A. SAHA, G. PARAMESWARAN, A. M. PACKER, T. SHARP, S. J. B. BUTT;
Univ. of Oxford, Oxford, United Kingdom

Abstract: The impact of serotonin on developing neural activity and consequences for emergent higher order cognition are poorly understood. Altered function of the serotonin transporter (SERT), arising from polymorphisms in the SERT promoter or embryonic exposure to selective serotonin re-uptake inhibitors (commonly prescribed antidepressants), is thought to be a risk factor in a range of neurodevelopmental psychiatric disorders but the mechanism is unknown. To examine this further, we performed longitudinal multiphoton imaging of transgenic mice to better understand how variation in SERT might affect serotonin dynamics and subsequently lead to pathological phenotypes during early postnatal life. Specifically, we imaged either neuronal activity using the GCaMP6s calcium indicator or serotonin dynamics using the fluorescent GRAB(5-HT3.0) biosensor in the somatosensory cortex of postnatal transgenic mice with specific neuron populations conditionally labelled with tdTomato. To perturb serotonin, we used either a SERT knock-out line or we dosed wildtype pups with the SERT inhibitor fluoxetine. The behaviour of head-fixed mice was simultaneously recorded with an infrared camera allowing us to assign neural activity and serotonin fluctuations to sleep-wake state. Experiments revealed that developmental serotonin dynamics in postnatal supragranular layers of S1 are defined by sensory stimuli and sleep-wake behavioural state. Reciprocally, SERT disruptions altered sleep architecture. We followed this up by assessing the impact of altered SERT on *in vivo* activity of both pyramidal projection neurons and GABAergic interneurons during a critical phase in development - the transition from synchronous to desynchronised activity mid-way through the second postnatal week. Finally, we investigated the long-term consequences of altered serotonin - both acute (SSRIs) and chronic (SERT KO) on sensory representation in the adult cortex of the same animals. Our data suggest that early postnatal life is a critical juncture in emergent cognition when SERT activity acts to sculpt and constrain emergent circuits. Thus, altered serotonin signalling likely leads to an imbalance in early sensory representation that manifests in a life-long manner.

Title: Gabaergic circuits reflect different requirements for emergent perception in postnatal mouse neocortex

Authors: F. GHEZZI[1], L. J. BARUCHIN[2], ***I. LAZARTE**[1], L. GEYER[3], N. HA[1], M. SHAH-OSTROWSKI[1], A. G. CIANCONE CHAMA[4], J. STACEY[1], J. HJERLING LEFFLER[3], S. J. B. BUTT[1];
[1]Univ. of Oxford, Oxford, United Kingdom; [2]Univ. of Sussex, Brighton, United Kingdom; [3]Karolinska Institutet, Stockholm, Sweden; [4]Univ. de Montréal, Montreal, QC, Canada

Abstract: Information transfer in the mammalian cerebral cortex is dependent on locally-projecting GABAergic interneuron circuits that are widely assumed to be uniform across neocortical areas. We demonstrate that this does not hold true during the highly dynamic period of postnatal life prior to the onset of active sensory exploration at the end of the second postnatal week. We developed an optotagging approach in neonates to determine the contribution of GABAergic interneuron to neonatal activity, including formative beta-frequency spindle burst oscillations, on the millisecond time scale. During the neonatal period, we find that a subset of interneuron defined by expression of the neuropeptide somatostatin (SST) differentially contribute to sensory-evoked activity in primary somatosensory (S1BF) and visual (V1) cortices. This functional divergence between the two areas is explained by differences in the transient circuits formed by these cells. In S1BF, layer (L)5 SST interneurons form transient, translaminar feed-forward circuits to directly regulate early sensory activity. Whereas in V1, SST interneurons do not receive direct thalamic input but are rather engaged in local feedback networks. We further performed Patch-seq analysis to distinguish if this divergence in function at the circuit and systems level arises due to either different SST subtypes across both areas or the same subtype fulfilling different roles in neonatal cortex in an area-dependent manner. The sum of these data suggests that SST interneurons in neonatal S1BF are specialized to regulate neonatal touch information in a manner not required in V1. Such area-dependent differences point to additional complexity in early GABAergic circuits, variations that further complicating our endeavors to understand the etiology of developmental psychiatric disorders.

Title: Nmda receptors maintain network diversity by suppressing parasitic correlations during development

Authors: *R. A. TIKIDJI-HAMBURYAN[1], M. T. COLONNESE[2,3];
[1]Sch. of Med. and Hlth. Sciences, George Washington Univ., Washington, DC; [2]Inst. For Biomed. Sci., [3]Sch. of Med. and Hlth. Sci., The George Washington Univ., Washington, DC

Abstract: In early development, cortical and subcortical networks exhibit several hallmark features, such as slow neuron dynamics, the dominance of NMDA synaptic receptors, and broad and imprecise connections. The developing visual system uses these features to respond appropriately to spontaneous retinal activity and refine thalamocortical connections (Colonnese and Phillips, 2018).
Recently we used large-scale network modeling to suggest that the level of NMDA receptor current regulates the precision of spike correlations in the developing dorsal lateral geniculate nucleus during the retinal waves (Tikidji-Hamburyan et al. 2023). We showed that NMDARs actively prevent the correlation of thalamic relay neurons on the millisecond timescale. Such temporally precise correlations dramatically reduce spatial information in the firing of thalamocortical neurons and are therefore expected to be detrimental to network refinement. We called such correlations parasitic, because they mask information essential for network formation. However, how parasitic correlations affect intracortical network formation is unclear. Here we use a theoretical approach (Gjorgjieva et al., 2009) and show that, if learning rules and dynamics of the adult cortical network are similar, parasitic correlations are expected to favor the formation of a single dominant group of excitatory neurons in the cortex (a clique) rather than the diverse connectivity required for vision. A phenomenological model of the visual cortex (Wu et al., 2020) confirmed these predictions, and indicated that a quarter of the excitatory neurons completely lose connections to postsynaptic pairs when the network is driven by input with parasitic correlations. Furthermore, inhibitory synaptic conductances are profoundly strengthened in models driven by parasitic correlations compared to normal activity. Such an increase in inhibitory drive would be expected to maintain the dominance of the excitatory clique.
Overall, our results suggest that visual thalamic networks developing in the absence of NMDA receptors are expected to produce parasitic correlations that reduce neural response diversity in the cortex, likely degrading visual responses and perception. This work suggests a novel role for NMDA receptors beyond their regulation of synaptic plasticity and coincidence detection.

Title: Corticothalamic excitatory feedback generates spindle-burst oscillations and amplifies the transmission of retinal waves during development

Authors: *M. T. COLONNESE[1], R. HERRERA-MOLINA[2];
[1]Pharmacol. and Physiol., The George Washington Univ., Washington, DC; [2]Leibniz Inst. for Neurobio., Magdeburg, Germany

Abstract: During the developmental period of thalamic axon ingrowth and circuit formation within the neocortex, the thalamocortical network produces powerful oscillations that synchronize activity throughout the cortex and associated thalamus. In the visual system, spontaneous retinal waves critical for receptive field development, drive ‘spindle-burst’ oscillations that arise in the lateral geniculate nucleus (dLGN) and synchronize activity in the visual cortex (VC). Here we use cre-dependent viral expression of excitatory channelrhodopsins and inhibitory DREADDs to determine the role cortiothalamic thalamic (CT) feedback during retinal waves. Using multielectrode recordings in headfixed unanesthetized neonatal mice, we show direct drive of the dLGN at P5 and P10 by NTSR1-cre neurons when retinal waves are present . NeuroPixel recordings show that CT feedback neurons oscillate in phase with spindle-burst oscillations in P5-6 mice. High-density multishank (NeuroNexus) recordings from dLGN reveal that relay neurons make eye-specific correlations that drop off with distance as expected if the dLGN is primarily driven by retinal waves. This nearest-neighbor synchronization depends on activity in VC as inhibition of cortical activity using DREADD expression in Emx1-cre mice eliminates eye-specific correlations and reduces total correlation among dLGN neurons. Reducing CT neuron activity also degrades the coherence of spindle-burst oscillations. Together our results show that corticothalamic feedback is critical for the normal transmission of retinal waves. CT feedback generates spindle-burst oscillations through a feedback excitatory loop that synchronizes and amplifies local retinal inputs during the period of retinal waves.

Title: Regional heterogeneity in the developmental maturation of thalamic reticular nucleus neurons

Authors: *P. PANG[1], M. T. COLONNESE[2];
[1]George Washington Univ., Washington, DC; [2]The George Washington Univ. Sch. of Med., The George Washington Univ. Inst. For Biomed. Sci., Washington, DC

Abstract: The thalamic reticular nucleus (TRN) provides the bulk of the inhibition to thalamocortical relay neurons in thalamus through closed recurrent loops with each thalamic nucleus. The TRN plays a critical role in the generation of sleep spindles and other oscillatory brain activity as well as the regulation of sensory attention, and cognition. Adult TRN neurons all express parvalbumin (PV)-a calcium binding protein that contributes to the bursting properties of TRN cells-and perineuronal nets (PNNs)-an extracellular matrix associated with the opening and closing of critical periods. How this expression is regulated during development and how it relates to function in thalamocortex is poorly understood. We examined the expression of PV and PNNs in visual and somatosensory TRN, two systems known to differ in the timing of their development. We quantified the number of neurons expressing PV and the normalized intensity of this staining on post-natal day (P)4, 9, and 15 using combined immunohistochemistry for PV and NeuroTrace in both visual (v)TRN and somatosensory (s)TRN. We find that at every age more neurons expressed PV in sTRN than vTRN, that in both regions the proportion of PV expressing neurons increased between P4 and P9 but was stable thereafter (sTRN: 56.9% ± 7.6%, n=4 for P4; 98.8% ± 0.4%, n=6 for P9; 94.4% ± 1.2%, n=6 for P15; vTRN: 12.3% ± 4.6%, n=4 for P4; 85.1% ± 8.9%, n=6 for P9; 87.6% ± 1.9%, n=6 for P15). The mean intensity of PV staining was more dynamic, increasing dramatically between P4 and P9 and again by P15 in vTRN but was relatively stable in sTRN (sTRN: 0.30 ± 0.04, n=4 for P4; 0.43 ± 0.01, n=6 for P9; 0.46 ± 0.02, n=6 for P15; vTRN: 0.10 ± 0.01, n=4 for P4; 0.16 ± 0.01, n=6 for P9; 0.25 ± 0.02, n=6 for P15). Qualitative evaluation of the developmental expression of PNNs suggest they follow PV maturation in both regions, with the sTRN first showing expression at P11 which increased at P14, and the vTRN first showing expression at P14 which increased at P21. Viral mediated tract tracing using conditional expression of EGFP in PV neurons reveals that dense axonal projections of the vTRN to the lateral geniculate nucleus and sTRN to the ventral posteromedial nucleus are robust even before full expression of PV. In summary, we find that while GABAergic TRN neurons, unlike cortical interneurons, express PV early in development, developmental upregulation of PV and accumulation of PNNs likely reflects and may influence maturation of activity in thalamus and cortex.

Title: A corticoreticular inhibitory feedback loop generates spindle-burst oscillations and synchronizes dLGN during retinal waves

Authors: *R. HERRERA-MOLINA[1,2], P. PANG[3], R. A. TIKIDJI-HAMBURYAN[3], M. T. COLONNESE[3];
[1]Leibniz Inst. for Neurobio., Magdeburg, Germany; [2]Cibqa, Univ. Bernardo O'Higgins, Santaigo, Chile; [3]Pharmacol. and Physiol., The George Washington Univ., Washington, DC

Abstract: During brain circuit formation, the developing thalamocortical network produces powerful oscillations that synchronize activity throughout the cortex and thalamus. In the visual system, spontaneous retinal waves, critical for receptive field development, drive 'spindle-burst' oscillations (～10Hz) that arise in the lateral geniculate nucleus (dLGN) and synchronize activity in the visual cortex (VC). Here we use cre-dependent viral expressions of excitatory channelrhodopsins and inhibitory DREADDs to determine functional connectivity and the role of inhibition from the thalamic reticular nucleus (vTRN) to dLGN during retinal waves. Using multi-shank high-density probes (NeuroNexus) to perform simultaneous recordings of dLGN and vTRN in head-fixed, unanesthetized P5 and P10 mice, we show that vTRN fires during retinal waves and participates in spindle-burst oscillations with zero phase offset to dLGN. Optogenetic stimulation of VC drives vTRN and dLGN with similar latency. Tract tracing with conditional expression of EGFP shows dense axonal arbors of both parvalbumin and somatostatin expressing TRN neurons to dLGN. Optogenetic stimulation of parvalbumin-expressing TRN neurons inhibits dLGN and 10 Hz stimulation of vTRN synchronizes activity in dLGN and VC at this frequency. These results, together with data showing that corticothalamic feedback neurons are required for spindle-bursts, and computational modeling of thalamo-cortico-reticular synaptic delays using modified spike-rate modeling approaches, suggest that spindle-bursts are generated by intact thalamo-cortico-reticular loop that results in recurrent excitation and long-latency inhibition in the relay thalamus.

Title: Refinement and maintenance of receptive field size in V1 neurons of mice occurs despite the absence of visual experience.

Authors: *P. FERNANDEZ, K. SUDANA, S. L. PALLAS;
Univ. of Massachusetts, Amherst, Amherst, MA

Abstract: The role of visual experience in the refinement of visual receptive fields has been studied for years using models with well-developed vision (e.g., carnivores, primates) but more recently in rodents exhibiting less elaborate visual processing circuitry. In nocturnal rodents, such as hamsters and mice, receptive fields refine completely before adulthood. However, hamsters dark reared from birth exhibit a reversion to large receptive fields by adulthood if kept in the dark. We demonstrated previously that in normally reared hamsters, the progressive decrease in receptive field (RF) size of visual neurons in the primary visual cortex (V1) and superior colliculus is achieved before adulthood. Dark reared hamsters also refine their RFs to adult size by adulthood (~60 postnatal days (pnd)), but then exhibit a gradual increase in RF size if kept in the dark after 60 pnd, suggesting a role of visual experience in the maintenance but not in the refinement of the RF sizes. We have now examined whether this difference from carnivores and primates is common to other nocturnal rodents. Abnormally large V1 RF sizes have been reported in dark reared mice around puberty, however, a more detailed study reporting the progression of RF size across different ages is still lacking. We investigated the changes in RF size of single unit V1 neurons (layer 2/3) in anesthetized mice at 30, 60 and 90 pnd. Our preliminary data show progressive refinement of V1 RF sizes between 30 and 60 pnd in normally reared mice (Normal RF areas at 30 pnd: 145 ± 16.8 deg^2, n=35; Normal RF areas at 60 pnd= 116± 16.8 deg^2, *n*= 37). Dark-reared mice exhibit a similar trend, showing increasingly refined RFs from P30 to P60 (DR RF areas at 30 pnd: 147± 24.1 deg^2, *n*=31; DR RF areas at 60 pnd: 121± 7.6 deg^2, *n*=73). Unlike hamsters, however, dark and normally reared mice retain refined RFs long into adulthood (Normal RF areas at 90 pnd: 96 ± 18.3 deg^2, *n*= 15; DR RF areas at 90 pnd: 83 ± 7.8 deg^2, *n*=70). Within each age group, no significant differences were observed between dark and normally reared individuals. These results suggest that in mice, both refinement and maintenance of RFs in V1 neurons are independent of visual experience. Our study is an important step in developing a better understanding of the role of visual experience in the development of visual processing circuitry in a commonly studied species.

Title: Microglia are Dispensable for Experience-Dependent Plasticity and the Maturation of Visual Circuitry

Authors: *T. BROWN, A. MCGEE;
Univ. of Louisville, Louisville, KY

Abstract: Microglia are proposed to be critical for the refinement of developing neural circuitry. However, evidence identifying specific roles for microglia is limited and often indirect. Here we examined whether microglia are required for the experience-dependent refinement of visual circuitry and visual function during development. We ablated microglia by chronically administering an inhibitor colony-stimulating factor 1 receptor and then examined the consequences for receptive field tuning of neurons in primary visual cortex (V1) and experience-dependent visual plasticity. Mice raised on chow containing PLX5662 from P14, the age of natural eye opening, lacked microglia by P18, prior to the opening of the critical period for experience-dependent visual plasticity. Despite the loss of microglia, the receptive field tuning properties of neurons in V1 were normal at P32, as was ocular dominance plasticity in response to brief monocular deprivation. Thus, none of these principal measurements of visual function differed in the absence of microglia. These findings contradict with the proposed critical role of microglia in refining neural circuitry. We conclude microglia are dispensable for experience-dependent plasticity and maturation of visual circuitry and function.

Title: The role of Robo1/Slit2 signaling in the formation of the mammalian direction-selective circuit

Authors: *J. KIRALY, A. L. KOLODKIN;
Johns Hopkins Med. Institutions, Baltimore, MD

Abstract: A major goal of modern neuroscience is to understand how complex neural circuits develop, function, and elicit behavioral responses. The direction-selective (DS) circuit in the vertebrate visual system is an excellent model for studying circuit assembly mechanisms since

DS circuits rely on proper execution of neural development programs to produce robust behavioral responses. Within the Accessory Optic System (AOS), DS circuits mediate the stabilization of slow object motion across the retina. This stabilization is primarily driven by a select set of retinal ganglion cells known as On direction-selective ganglion cells (oDSGCs). Individual oDSGCs responses to directional object motion are in part mediated by asymmetric inhibitory connections between starburst amacrine cells (SACs) and oDSGCs. In the AOS, oDSGCs preferentially respond to slow object motion in a single direction, leading to four major subtypes of oDSGCs tuned to respond to forward, backward, upward, and downward motion. Although direction-selectivity depends critically upon SAC-DSGC connections, the cellular mechanisms that establish such precise directional tuning remain unknown. Through single cell transcriptomics, we have identified a candidate gene that regulates vertical tuning in the mouse: *roundabout-1* (*Robo1*). Disruption of *Robo1* loss-of-function leads to a striking enhancement of vertical slow motion tracking, particularly in the downward response. Additionally, *Robo1* mutants exhibit significant and specific axonal projection defects to the medial terminal nucleus (MTN), a key AOS brainstem target that regulates this vertical tracking. Preliminary data from a SAC-specific conditional knockout of *Slit2*, a canonical *Robo1* ligand, reveal a similar behavioral phenotype, with increased downward tracking. These data suggest that *Robo1*/*Slit2* interactions within the retina are essential for the establishment of SAC-DSGC synaptic interactions and proper visual tracking of slow object motion. Furthermore, *Robo1* may play additional targeting roles for the refinement of downstream oDSGC axon targeting. Ongoing investigation of *Robo1/Slit2* signaling events will provide insight into how DS circuits are established and function.

Title: Investigating the role of R2B Receptor Protein Tyrosine Phosphatases (RPTPs) in mammalian direction-selective circuit assembly

Authors: *T.-H. LIN[1], T. AL-KHINDI[1], S. HARRIS[2], A. BALRAJ[4], F. A. DUNN[3], A. L. KOLODKIN[1];
[1]Johns Hopkins Univ., Baltimore, MD; [2]Ophthalmology, UCSF, San Francisco, CA; [3]UCSF, San Fransisco, CA; [4]Univ. of California San Francisco, San Francisco, CA

Abstract: The vertebrate retina harbors a complex array of neural circuits dedicated to detecting visual features. Among these circuits, the direction-selective (DS) circuit within the accessory

optic system (AOS) plays a crucial role in detecting slow motion and orchestrating the optokinetic reflex (OKR), a behavioral response that coordinates eye movements and allows image stabilization. There are four distinct types of direction-selective ganglion cells (DSGCs)—upward (up-oDSGCs), downward (down-oDSGCs), nasal-to-temporal and temporal-to-nasal (hoizontal-oDSGCs)—within the DS circuit of the AOS. However, the mechanisms underlying the acquisition of distinct directional tuning properties in these DSGCs remain unclear. To shed light on the development of the DS circuit, we have undertaken a comprehensive investigation using high-depth single-cell RNA sequencing and have successfully identified three R2B receptor protein tyrosine phosphatases (RPTPs) with selective expression patterns: Ptprk and Ptprm preferentially expressed in vertically tuned oDSGCs and Ptprt potentially expressed in horizontally tuned oDSGCs. Our preliminary findings indicate that the loss of Ptprk disrupts the upward OKR, alters upward oDSGC dendritic morphology, and impairs electrophysiological properties. Moreover, Ptprm mutants exhibit defects in vertical directional tuning, suggesting a potential interaction between Ptprm and Ptprk in AOS circuit functionality. Our ongoing research aims to unravel the mechanisms by which Ptprk tunes up-oDSGCs to detect upward motion and whether Ptprm and Ptprt function similarly to modulate the tuning of vertical and horizontal oDSGCs, respectively. This work may not only unveil a novel molecular code governing neural circuit assembly but also has the potential to provide valuable insights into the attainment of asymmetric computations within other neural circuits.

Title: Visual experience through a single, prematurely opened eye drives aberrant development of receptive field properties in visual cortex

Authors: *S. GRISWOLD[1], S. VAN HOOSER[2];
[1]Brandeis Univ., Boston, MA; [2]Brandeis Univ., Waltham, MA

Abstract: Cortical/cerebral visual impairment, or CVI, visual impairment occurring in the presence of a normal eye exam, or out of proportion with observed ocular pathology, is the most common cause of visual impairment in children in the developed world. This disorder of vision is more common in very preterm infants than their full term counterparts. Due to advances in neonatal medicine, very preterm infants are surviving with increasing frequency, causing a concomitant increase in CVI

Given that preterm infants may have up to 8 weeks of premature visual experience, and that premature vision is capable of aberrantly driving receptive field development in visual cortex, we propose that early exposure to visual stimuli may increase the susceptibility of preterm infants to CVI. Here we hypothesize that prematurely opening the eyes of ferrets will aberrantly impact the development of visual acuity in visual cortex (VC). We have tested this hypothesis by prematurely opening one or both eyes of ferrets at 25 days post parturition and subsequently examining the impact of premature eye opening on contrast sensitivity, direction tuning, orientation tuning, and temporal frequency tuning between P55-65. These receptive field properties were examined by recording from ipsilateral and contralateral monocular cortex while showing anesthetized animals drifting grating stimuli in which direction, spatial frequency, and contrast were covaried. We find that in ferrets that had one eye prematurely opened, cells in monocular cortex corresponding to the prematurely opened eye demonstrate reduced direction tuning and temporal frequency preferences in comparison with monocular cortex corresponding to the developmentally normal eye. Additionally, these cells had substantially altered temporal frequency preferences and a reduction in orientation angle preference for cardinal angles. These findings suggest that different amounts of visually evoked activity between the eyes can drive aberrant development, and that experience-dependent interactions between the inputs from the two eyes shape cortical circuitry before the canonical critical period for ocular dominance plasticity, and even prior to eye opening.

Title: Lrrn2 and Lrrn3a cell adhesion molecules specify precise retino-tectal connections in the zebrafish visual system

Authors: ***E. PUTTI**, F. EGGELER, G. FAINI, S. ALBADRI, F. DEL BENE, Seniot;
Inst. de la Vision, Paris, France

Abstract: Leucine-rich repeat proteins (LRR) play critical roles in various aspects of neuronal circuit development, from synapse formation to axon guidance. Within the LRR protein family, the leucine-rich repeat neuronal (LRRN) subfamily comprises distinct adhesion molecules, including Lrrn2 and Lrrn3a. Remarkably, their expression patterns are conserved across species, ranging from Drosophila to humans. However, the functional significance of Lrrn2 and Lrrn3a in the context of visual system formation and axonal targeting remains elusive. In Drosophila, the

orthologous protein Capricious governs the synaptic targeting of specific photoreceptors to precise laminae in the fly brain. To determine if similar mechanisms are at play in vertebrates, we examined the expression patterns of *lrrn2* and *lrrn3a* in the retina of zebrafish larvae. Our findings reveal sparse expression of these adhesion molecules in the developing retinal ganglion cells (RGCs). The absence of Lrrn2 and Lrrn3a lead to mistargeting defects in a specific subset of RGCs. These RGCs fail to reach their designated laminae in the retino-recipient optic tectum, impairing the formation of precise synaptic connections. Moreover, behavioral analyses reveal compromised hunting abilities in *lrrn2* and *lrrn3a* mutants. Together, our findings highlight a crucial role for Lrrn2/3a in the specification and function of precise retino-tectal circuits in the vertebrate visual system.

Abstract: Visual cortex undergoes considerable physical and morphological growth, especially during the first year of life. However, the development of the neural and glial cytoarchitecture across different visual areas remains unknown. Here, we used immunohistochemistry (IHC) in 7 ex vivo human brain samples, aged 34 gestational weeks (gw) to 9 years old (yo), to determine cytoarchitectural development in primary visual cortex (V1, calcarine) and higher-level place- (collateral sulcus) and face-selective (lateral fusiform gyrus) regions. IHC markers – neuronal nuclear protein (NeuN), aldehyde dehydrogenase 1 family member L1 (ALDH1L1), oligodendrocyte transcription factor 2 (Olig2) – and a 4′,6-diamidino-2-phenylindole (DAPI) counterstain identify neurons, astrocytes, oligodendrocyte lineage cells, and all cell nuclei, respectively. We developed a semi-automated pipeline to subsample confocal tilescan images over a total of 6,724 fields of view (FOVs; mean ± SD nuclei per FOV: 10.2 ± 5.9) across

cortical depths, brain regions and samples. For each FOV, automated nuclear segmentations, generated with a Statistical Region Merging algorithm (Nock & Nielsen, 2004), are manually corrected, and the overlapping IHC marker expression is confirmed to quantify the density and proportion of cells of each cell type. We observe that the total cell (DAPI) and neuron (NeuN) densities decrease significantly only from 34 gw to 3 months old (mo). In contrast, there is no significant age-related change in the density of astrocytes or oligodendrocytes. Furthermore, the development of the overall cell and neuron densities is similar across primary and higher-level visual areas. While the overall astrocyte density does not vary between cortical areas, the density of the oligodendrocyte lineage population is lowest in V1 regardless of age. We observe complementary changes in the relative cellular composition of visual cortex: the proportion of cells that are neurons decreases from 34gw to 3mo in all 3 visual areas, while the proportion that are oligodendrocytes only increases in the lateral fusiform gyrus. Together, these data suggest that there are changes to the neuron cytoarchitecture across all visual areas. Furthermore, the development of V1 versus higher-level visual cortex differs primarily in the oligodendrocyte lineage population. Characterizing cytoarchitectural changes in visual cortex provides insight into shared and unique developmental features across the human visual system and has important implications for functional development.

Title: Distinct developmental programs displayed by the Xenopus tadpole retinotectal and retinotegmental projections

Authors: *U. UDOH[1], K. ZHENG[2], K. G. PRATT[2];
[2]Zoology and Physiol., [1]Univ. of Wyoming, Laramie, WY

Abstract: The Xenopus tadpole retinotectal projection – the synapse between the retinal ganglion cells (RGCs) in the eye and the midbrain optic tectum – has served as a popular model to study how neurons self-assemble into circuits. But the retinotectal projection is only one of several components of the tadpole visual system. Using anatomical and electrophysiological approaches, we previously identified a functional retinotegmental projection, a direct projection from the RGCs to the ventral midbrain tegmental neurons. To compare these ventral and dorsal visual projections, we activated RGC axons by placing a bipolar stimulation electrode on the

optic chiasm and recorded RGC-evoked responses using an isolated brain preparation that allows access to both tectal and tegmental neurons. Recordings were carried out at three key stages of retinotectal development: stage 42 (approximately 5 days post-fertilization; dpf), 44-46 (7-9 dpf), and stage 48/49 (12-21 dpf). We found that the maximum strength of RGC input to tectal neurons peaked during stage 44-46, then steeply declined by stage 48/49. The addition of the N-methyl-D-aspartate receptor (NMDAR) blocker APV (2-amino-5-phosphonovaleric acid) at development stage 45 abolished the observed decline in retinotectal synaptic transmission, indicating an NMDAR-dependent mechanism. In contrast, the strength of RGC input onto tegmental neurons did not display a transient peak, remained constant across the 3 developmental stages, and was unaltered by NMDAR blockade. Paired pulse recordings indicate that, across the three stages of development studied, RGC input onto tegmental neurons display a higher probability of transmitter release compared to the input onto tectal neurons, suggesting that different populations of RGCs may project to the different visual centers. To begin to study tegmental outputs, a bipolar stimulation electrode was placed on the tegmentum and evoked responses recorded in different brain regions. We found monosynaptic evoked responses in the midbrain tectum and hindbrain, indicating that tegmental neurons send direct projections to those areas. Furthermore, stimulation of tegmental neurons resulted in contraction of extraocular eye muscles and eye movement, showing that the tegmentum may be involved in the optokinetic response. Overall, these results suggest that these two visual projections are built differently and carry out different functions as part of the visual system.

Title: Genetic Interactions between Insm1 and Ikzf2 in Cochlear Outer Hair Cell Development

Authors: *S. LI[1,2], S. HE[1], Y. LU[1], Z. LIU[1,3];
[1]Inst. of Neuroscience, CAS Ctr. for Excellence in Brain Sci. and Intelligence Technol., Chinese Acad. of Sci., Shanghai, China; [2]Univ. of Chinese Acad. of Sci., Beijing, China; [3]Shanghai Ctr. for Brain Sci. and Brain-Inspired Intelligence Technol., Shanghai, China

Abstract: The development of cochlear outer hair cells (OHCs) and inner hair cells (IHCs) in the mammalian inner ear is orchestrated by a complex genetic program. In Insm1 mutants,

approximately half of the OHCs undergo transdifferentiation into converted IHCs (cIHC), while OHCs in Ikzf2-deficient mice exhibit dysfunctional characteristics and maintain partial IHC gene expression. Although recent HC multi-omics sequencing studies suggest the repressive activity of Insm1, there are pronounced similarities between the phenotypes of Insm1 and Ikzf2. We hypothesize that Insm1 determines OHC fate and activates the expression of Ikzf2, which is crucial for OHC maturation. However, direct evidence supporting this hypothesis is currently lacking. In this study, we employed multiple genetic tools to test this hypothesis. First, we generated *Ikzf2*$^{3*V5\text{-}P2A\text{-}tdTomato}$ (*Ikzf2*^{V5}) and *Rosa26-loxp-stop-loxp-tdToamto* (*Rosa26*^{Insm1}) mouse models and characterized Ikzf2 expression in *Atoh1*$^{Cre/+}$*; Rosa26*$^{Insm1/+}$*; Ikzf2*$^{V5/+}$ mice at postnatal day 7 (P7) (n=3). Our results demonstrate that ectopic Insm1 induces the expression of both Prestin (an OHC marker) and Ikzf2 in 94.7% ± 1.8% and 22.2% ± 4.4% of IHCs, respectively. Second, we analyzed *Atoh1*$^{P2A\text{-}Cre/+}$*; Insm1*$^{flox1/flox}$*; Ikzf2*$^{V5/+}$ mice at P5 and P30 (n=3). Immunostaining assays revealed that the expression of Ikzf2 in OHCs is dependent on normal Insm1 expression. OHCs lacking Insm1 downregulated Ikzf2 as early as P5, leading to upregulated expression of vGlut3 (an IHC marker) and downregulated expression of Prestin. Third, we overexpressed Ikzf2 in the absence of Insm1 using *Atoh1*$^{Cre/+}$*; Insm1*$^{flox/flox}$*; Rosa26*$^{Ikzf2/+}$ mice at P21 (n=3). Quantification revealed that the percentage of vGlut3+ cIHCs (6.9% ± 1.0%) in the *Atoh1*$^{Cre/+}$*; Insm1*$^{flox/flox}$*; Rosa26*$^{Ikzf2/+}$ model was significantly lower ($p<0.05$) than that (16.6% ± 2.3%) in *Atoh1*$^{Cre/+}$*; Insm1*$^{flox/flox}$ mice. Finally, double knockout of Insm1 and Ikzf2 resulted in similar OHC defects as observed with Insm1 ablation alone. Collectively, our findings elucidate an indirect transcriptional cascade from Insm1 to Ikzf2, providing valuable insights for future investigations into the molecular mechanisms underlying OHC development and regeneration.

Title: Sema5a regulates spontaneous neural activity in developing cochlea.

Authors: *S. GHIMIRE, R. CHERELSTEIN, T. COATE;
Georgetown Univ., Washington, DC

Abstract: In the pre-hearing cochlea, spiral ganglion neurons (SGN) fire spontaneously in the absence of external stimuli following the glutamate release from the hair cell. The pattern of spontaneous firing by SGNs becomes more refined from infrequent and uncoordinated during embryonic stages, to more frequent and coordinated by early postnatal stages. The underlying

molecular mechanism pertaining to the generation and refinement of spontaneous activity is not well known. Our data show that SEMA5A acts as an inhibitor of spontaneous activity in the developing cochlea. SEMA5A belongs to a large family of proteins called semaphorins, which signal through neuropilin and/or plexin receptors and play important role in wiring of neural circuits in the brain. SEMA5A, is also associated with Autism Spectrum Disorder in humans. In the brain, loss of *Sema5a* is reported to have increased neuronal excitation in mice.
In-situ hybridization shows a wider expression of *Sema5a* in SGNs and mesenchyme of developing cochlea. To evaluate the effect of SEMA5A on spontaneous activity of SGNs, we utilized *Snap25-GCaMP6s*$^{+}$ cochlear explants and recorded calcium transients before and after the application of recombinant SEMA5A-Fc protein. We found that the application of SEMA5A-Fc protein resulted in reduced area of activity, frequency and coordinated events compared to baseline data. Analyses of cochlear explants from *Sema5a*$^{-/-}$;*Snap25-GCaMP6s*$^{+}$ mice showed increased fluorescence levels of calcium compared to littermate controls. We also observed increased phosphorylated CREB in SGNs, cochlear epithelium and mesenchymal cells in *Sema5a*$^{-/-}$ samples as an indicator of elevated activity. Supporting these findings, we also observed reduced terminal branches of type I SGNs in *Sema5a*$^{-/-}$ cochleae suggesting a homeostatic mechanism. It is possible that SEMA5A interacts with one or more ionic channels, which directly regulate SGN excitability. Interestingly, SEMA5A contains a motif that shares partial analogy with spider venom, hanatoxin, which acts as an inhibitor of potassium and calcium channels. We have found that the hanatoxin analog heteropodatoxin (HpTx2) inhibits calcium transient in SGN, similar to the effects of SEMA5A-Fc.
We are currently examining the effects of hanatoxin-like domain (HD) of SEMA5A by generating mutated protein in the context of SGN spontaneous activity and protein pull-down experiments designed to discover SEMA5A binding partners.

Title: Cortical Reorganization and Cognitive Outcomes in Young Adults with Cochlear Implants

Authors: *G. KARTHEISER[1], D. BELL-SOUDER[2], M. W. DYE[3], A. SHARMA[4];
[1]Sensory, Perceptual, and Cognitive Ecology Res. Ctr., Rochester Inst. of Technol., Rochester, NY; [2]Univ. of Colorado, Boulder, Boulder, CO; [3]Sensory, Perceptual, and Cognitive Ecology Res. Ctr., Rochester Insitute of Technol., Rochester, NY; [4]Univ. Colorado, Boulder, Boulder, CO

Abstract: As of 2012, approximately 38,000 American children had received a cochlear implant (CI) with mixed spoken language and cognitive outcomes (Barnard, 2015). There is some debate about the factors that contribute to variability in outcomes, with some studies suggesting that exposing deaf children to a sign language prior to implantation is disadvantageous (Geers, 2017), and yet others showing evidence that children with CI who are exposed to a sign language outperform CI children who were not exposed to a sign language on a variety of spoken language assessments (Hassandazeh, 2012). Furthermore, there are also studies that show children's auditory systems develop differently based on the timing of implantation (e.g. Kral & Sharma, 2012). Here, we examine the effect that the timing of CI has on cortical reorganization of the central auditory and visual systems in young adults with CI and how this, alongside the timing of language exposure, impacts linguistic and cognitive development.
In this study we compare the outcomes of early and late implanted groups of young (aged 18-32) adult CI users (n=17). The early implanted group had received their CI by the age of 3.5 years of age, which has previously been shown to be within the critical period for developing typical auditory cortical development, with late implanted individuals implanted after this age. All were given the cognitive fluidity battery from the NIH Toolbox. All were administered the American Sign Language Comprehension Test and Test of Silent Contextualized Reading Fluency. Cortical development was measured using electroencephalography (EEG) using two paradigms: cortical auditory evoked potentials (CAEP) to examine auditory cortex maturation, and cortical visual evoked potentials (CVEP) to measure cross-modal recruitment of the auditory cortex.
The findings did not show a difference between these two groups in cognition, English language exposure, and English reading fluency. There was a significant difference in ASL comprehension ($t(15) = 5.25$, $p < 0.001$), with the late CI group having significantly higher ASL comprehension. Cortical auditory development, as measured by CAEP P1 latencies and estimated sources, was found to be delayed in the late CI group. In the late CI group, there was some evidence of cross-modal recruitment from the visual system as well as persistent changes in EEG spectral power that could be consistent with constant use of attentional control networks in the brain to listen. Overall, these results suggest that some compensation is possible in the brain that enables typical cognitive ability even in the face of different trajectories of sensory and central auditory development.

Title: Differences in high frequency power spectral density in pre-linguistic infants due to exposure to an interactive auditory experience.

Authors: *B. MAHMOOD, K. WOLFERT, A. A. BENASICH;
Rutgers Univ. Behavioral and Neural Sci., Newark, NJ

Abstract: Spontaneous brain activity has recently garnered much attention for its posited utility as an early biomarker of atypical neural development. Previous studies have shown that spontaneous electroencephalographic (sEEG) data from infants that are at higher risk for developmental delay demonstrate differences in spectral power composition when compared to infants who are at lower risk, and that these differences may correspond to later cognitive deficits. However, no study to date has examined whether spectral power composition can be impacted by early behavioral intervention. In the present study, we examine longitudinal dense-array sEEG data collected from infants at 7, 9, 12 and 18 months. This study consisted of three participant groups: (1) infants in the Active group were presented with an interactive acoustic experience (IAE) between 4-7 months of age, (2) infants in the Passive group were exposed to the acoustic stimuli but no infant response or overt attention was required and (3) a Naïve group which consisted of age-matched infants who had no previous exposure to the sounds. We hypothesized that spectral power in high frequency, such as gamma, would differ by group. Absolute Power Spectral Density (PSD) values were calculated for each infant for alpha, beta, theta, and gamma frequency ranges and the three groups were compared across age. Consistent with previous literature, our results showed that overall Frontal PSD values in the higher frequency ranges increased across age. Group differences were seen in the higher frequencies at 12 and 18 months of age between the Active and Naïve groups and the Active and Passive groups. Interestingly, the Passive and Naïve groups did not show significant differences across age. Additionally, group differences were seen in standardized cognitive assessment scores between the Passive and Active groups. These findings begin to identify important features in early auditory experiences that can impact learning and how these experiences support the development of auditory networks in a manner that can enhance later cognitive and language ability.

Title: Acute administration of a biased serotonin 1A receptor agonist NLX-101 improves auditory temporal processing in a mouse model of fragile X syndrome during early development

Authors: *X. TAO[1], K. CROOM[1], A. NEWMAN-TANCREDI[2], M. A. VARNEY[2], K. RAZAK[1];
[1]UC Riverside, Riverside, CA; [2]Neurolixis SAS, Castres, France

Abstract: Fragile X syndrome (FXS) is a neurodevelopmental disorder caused by the loss of fragile X messenger ribonucleoprotein (FMRP). Humans with FXS show altered sensory processing, which is also seen in the *Fmr1*KO mouse model of FXS. Our previous findings showed that activating serotonin 1A receptors (5-HT1ARs) acutely with NLX-101, a biased agonist that preferentially targets post-synaptic 5-HT1ARs, strongly protected *Fmr1* KO mice from audiogenic seizures (Tao et. al. 2023). Here we tested whether activating 5-HT1ARs acutely with NLX-101 is beneficial in improving translation-relevant electroencephalographic (EEG) phenotypes in *Fmr1* KO mice. The EEG deficits found in humans with FXS and *Fmr1* KO mice include deficits in temporal processing and hypersensitive responses to sounds as measured using inter-trial phase clustering (ITPC), event-related potentials (ERP) and background single-trial power (STP). We recorded epidural EEG signals from auditory and frontal cortex of FVB *Fmr1* WT and KO mice (both males and females) at two age points: postnatal (p)21 and p30. Saline or NLX-101 fumarate salt (at 1.8 mg/kg) was given through intraperitoneal (i.p.) injection immediately before EEG recording. Narrow band noise and 40 Hz gap-in-noise auditory steady state response (gap-ASSR) stimuli were used to evoke ERP and ASSR. Gap-ASSR inserts “gaps” in the continuous background noise at 40Hz to induce resonant auditory cortical steady-state oscillations. Gap-ASSR tests the ability of cortex to respond to narrow gaps in sounds, a measure commonly used to test auditory temporal acuity. We measured ERP peak amplitudes (P1, N1 and P2), STP in ERP and ITPC in gap-ASSR. Acute administration of NLX-101 significantly rescued the ITPC deficit in response to gap-ASSR in *Fmr1* KO mice at both p21 and p30, suggesting improved temporal processing. NLX-101 also significantly reduced gamma band STP in *Fmr1* KO mice at p30, but not at p21. NLX-101 did not correct elevated N1 amplitudes in *Fmr1* KO mice at either age point. Taken together, the results indicate that 5-HT1AR activation regulates auditory temporal processing and background noise, but not ERP amplitudes, in developing mice. Given the relationship between temporal processing and speech recognition, these data suggest that activation of 5-HT1AR may be a promising therapeutic avenue to enhance language function in humans with FXS.

Title: Upstream to Atoh1, the Msx genes are new candidates to play critical roles in establishing cell lineage in the developing cerebellum

Authors: I. GUPTA[1], J. YEUNG[2], M. RAHIMI-BALAEI[2], S.-R. WU[3], ***D. GOLDOWITZ**[2]; [2]Ctr. for Mol. Med. and Therapeut., [1]Univ. of British Columbia, Vancouver, BC, Canada; [3]Neurosci., Baylor Col. of Med., Houston, TX

Abstract: The understanding of cerebellar development, particularly the spatio-molecular signatures that define the GABAergic (Ptf1a+) and Glutamatergic (Atoh1+) lineages that colonize the cerebellum, has evolved dramatically in the last 20+ years. Our examination of the transcriptome in the Pax6-null cerebellum has provided a new view of the molecular players in the cells that arise from the rhombic lip (RL)/Glutamatergic lineage (PMID: 27581449, 25209290). While Pax6 is required for the development of cells committed to the glutamatergic lineages, within the RL it is repressed mutually by Wls expression. Wls expression demarcates the interior face of RL (iRL), and this region is populated by cells that are yet to committed to glutamatergic lineages (i.e. Atoh1-negative). These findings have recently been confirmed in the early development of the human cerebellum (PMID: 31624095).Our current work examined the homeobox containing Msx gene family in the cerebellum. The three genes in the Msx family in mouse are candidates for mediating BMP signaling in cerebellar development and known transcriptional repressors. They are predominately expressed in the germinal zones in the early developing cerebellum. Msx1 and Msx2 are expressed in the RL region, while Msx3 expression is found in the ventricular zone (VZ). We found that Msx1 is co-expressed with Wls in the iRL and do not overlap with Atoh1 expression in the RL. In contrast, Msx2 expression overlaps with Atoh1 in the RL; forming an interesting Msx1-Msx2-Msx1 banding in the RL. We showed that Msx1 and Msx2 expression is independent of Atoh1 as their expression persisted in the Atoh1-null cerebellum. There is, however, an altered banding formed by Msx1 and 2 expressions in the Atoh1-null cerebellum, such that Msx1 expression is expanded into the presumptive Atoh1-positive region in the RL.In the ventricular zone, Msx3 expression largely overlaps with Ptf1a, the marker of VZ. Msx3 expression, however, extends beyond the posterior limit of Ptf1a and shares the VZ/RL border with Atoh1 expression. Thus, between the germinal zones, there is a region between Ptf1a and Atoh1 expressions, that is positive for Msx3, exclusively. In the Atoh1 null, the expression of Msx3 expands to the RL into the Atoh1-positive region. Despite the overlapping expansion of Msx1+ and Msx3+ cells, this does not result in cells that co-express Msx1 and Msx3.The current study highlights the molecularly distinct compartments that are demarcated by the interaction between cells that express Msx genes, Atoh1 and Ptf1a; and places Msx1 (and 2) upstream to Atoh1 in the developmental genetics of the Glutamatergic lineage.

Abstract: Locus coeruleus (LC) neurons are intimately connected with diverse brain functions, most prominently attention, arousal, stress responses, and cognition. Published studies of LC activity cover many traits (species, sex, etc.) but rely on small sample sizes (usually tens of neurons), which has precluded a systematic and robust assessment of how these features affect LC activity. Here, we leverage a pooled dataset of 1,855 single units from 20 laboratories to comprehensively compare LC activity. Verified LC activity was recorded from deafferenated brain slices and intact animals during wakefulness or under different anesthetics. Samples included male non-human primates and rats and mice of both sexes. In some cases, LC activity was recorded from disease models and cell-type selective genetic modifications. We used a negative binomial regression model to identify the individual and combined effects of various attributes on firing rate. This powerful analysis revealed important species-, sex-, age-, and disease model-specific activity, as well as significant effects in Cre-expressing lines. Lastly, in contrast to the foundational concept of two-mode (tonic-phasic) LC activity, we discovered multiple bursting sub-modes and complex second order spike train patterns associated with different LC preparations. In sum, inherent differences in LC activity result from species-, age- and sex-dependent factors, as well as genetic modification. Our findings offer insight into why LC-dependent behavioral and cognitive functions depend on sex and age and may help explain the known association of sex and age with psychiatric disorders.

Abstract: Zinc (Zn^{2+}) is an essential element that affects proper organ function, cell growth, and immune function. However, it can also be present in too great a quantity, with zinc toxicity resulting in both minor and major physiological effects. This study examined the effects of $ZnCl_2$ on both nervous and cardiac function through a number of different experimental methods, using crawfish and *Drosophila* as model organisms. Cardiac function, activity at the neuromuscular junction, and survival were all assessed following the organisms' exposure to zinc. Function of the crawfish sensory muscle receptor organ (a proprioceptive organ analogous to the mammalian muscle spindle) was also examined. Dose-response was used to examine any changes in *Drosophila* larval crawling rates, mouth-hook movement rates, and touch sensitivity. Increased exposure to zinc generally led to decreased survival rate, in both crawfish and *Drosophila*; similarly zinc exposure led to depressed or even eliminated heart rates in both models. The neuromuscular junctions in both organisms saw varying effects: high concentrations (1mM, 10mM; n=6, $p>0.05$) eliminated synaptic transmission without affecting spontaneous quantal events, while lower concentrations (0.1mM, 0.5mM) merely depressed that transmission. At the crawfish MRO, high concentrations of $ZnCl_2$ (that is, 5mM; n=6, $p>0.05$) depressed neural activity (but this returned during washout), while lower concentrations (0.1mM and 1mM) saw MRO activity increase. No consistent effect was yet observed in *Drosophila* behavior with differing zinc concentrations.

Abstract: The claustrum is extensively connected with the whole cerebral cortex, yet its function remains to be clarified. A comprehensive and quantitative characterization of the gene expression in various cell types, and their spatial distributions could help to elucidate the connectivity and function of various claustrum neurons. Using single-nucleus RNA sequencing (snRNA-seq) of more than 300,000 claustrum cells and spatial transcriptomic analysis (Stereo-seq) over 89 sections in 6 macaque monkeys (M. fascicularis), we obtained a spatially resolved, transcriptome-based single-cell atlas of the macaque claustrum. We identified 39 cell clusters in the claustrum, including 24 glutamatergic, 10 GABAergic, and 3 non-neuronal cell clusters. We also characterized the spatial distribution patterns of these cell clusters across the entire claustrum, and found that the distribution of several glutamatergic cell clusters exhibited distinct dorsoventral or core-shell preferences. These spatial distribution patterns correlated with the topographic patterns of claustrum-cortical connectivity, based on retrograde labeling of claustrum neurons by fluorescent dye-injections in 70 cortical areas. Additionally, by comparison with similar data from neighboring putamen and the insula cortex, we identified a set of claustrum-specific cell clusters. Together, these data began to reveal the cellular and molecular organization of the claustrum.

Title: Spatial transcriptomics reveals the convergent evolution of mammalian and avian pallium

Authors: *S. LIU, *S. LIU;
BGI-Research, Shenzhen, China

Abstract: Amniotes have evolved a complex brain organization, particularly in the telencephalon. However, the identity and evolutionary conservation of the telencephalon at the genoarchitecture scale remains largely unknown. We constructed zebra finches, turtles, mice, and macaques using the Stereo-seq with single-cell resolution spatial transcriptome telencephalon atlases. For the first time, we presented a complete single-cell and spatial atlas of the turtles and birds, where we identified some novo brain sub-regions and predicted the mechanism of function or structures change with the gene expression pattern. Moreover, comparative analysis of spatial atlas across the species in amniotes, we identified two major types of gene regulatory models during the evolution of the dorsal ventricular ridge (DVR) in sauropsids: changes in the expression of transcription factors (TF), and changes in the binding motifs of TFs with no difference in expression. We reveal the mechanism by which avian DVR and mammalian neocortex recruit the same effector genes under different transcription factors, indicating their convergent evolution. Overall, our analysis yields insights into the evolutionary relationships of the telencephalon across amniotes.

Title: Profiling cellular diversity in sponges informs the evolutionary origin of neurons and coordinated behavior in animals

Authors: *J. MUSSER[1], L. L. MOROZ[2], D. ARENDT[3];
[1]Yale Univ., New Haven, CT; [2]The Whitney laboratory for Marine Biosci., Univ. of Florida

Dept. of Neurosci., Saint Augustine, FL; [3]Develop. Biol. Unit, European Mol. Biol. Lab., Heidelberg, Germany

Abstract: The evolutionary origin of neurons and coordinated behaviors in animals is a major unresolved question. Using whole-body single-cell RNA sequencing in a sponge, an animal without nervous system and musculature, we identified 18 distinct cell types. These include myoepithelial cells responsive to nitric-oxide and secretory neuroid cells that reside in close proximity to digestive cells expressing postsynaptic scaffolding and receptor proteins. Visualizing neuroid cells by correlative x-ray and electron microscopy revealed secretory vesicles and cellular projections enwrapping digestive cell microvilli and cilia. Our data show a communication system that is organized around sponge digestive chambers, using conserved modules that became incorporated into the pre- and postsynapse in the nervous systems of other animals.

Abstract: Background: As post-mitotic cells of the central nervous system, neurons rely heavily on quality-control pathways to promote cellular homeostasis. Through seminal works in autophagy-deficient mice brains, autophagy has emerged as a critical proponent in a neuron’s repertoire in maintaining the cellular homeostasis and function. Autophagy is the quality-control catabolic pathway wherein cellular components are engulfed in a double membraned vesicle and degraded in a lysosome-dependent manner. As increasing lines of evidence have converged on

autophagy's significant role in maintaining neuronal homeostasis, our project sought to understand the degradative landscape of autophagy in neurons. **Methods**: To enrich for putative autophagy cargoes, we generated autophagy-deficient stem cell-derived neurons by knocking down *ATG7* and *ATG14* using CRISPR-inhibition technology. In addition, we established a neuron-specific *ATG7* and *ATG14* conditional knock out (cKO) mouse line to validate our findings in our stem cell-derived human-induced neurons. To profile putative autophagy cargoes in these models, we subjected our neuronal models to liquid-chromatography tandem mass spectrometry, and defined autophagy cargoes to be proteins with significant accumulations in autophagy-deficient neurons compared to controls. In addition to these models, we also performed affinity purification from *ATG7* cKO mice expressing GFP-LC3 to identify autophagy cargoes who interact with LC3, an autophagy receptor. We utilized our autophagy-deficient human-induced neurons and mouse brains for downstream experiments, including immunostaining and immunoblotting, to validate our computational findings. **Results**: By highlighting proteins significantly accumulated in autophagy-deficient neurons, our quantitative proteomic analyses identified multiple cellular organelles and pathways as autophagy targets. Our results suggest that endoplasmic reticulum (ER), synaptic vesicles (SV), and protein kinase A (PKA) pathway components as major targets of neuronal autophagy. Following up with *in vitro* experiments in the same models, we have validated the significant increase of ER, SV, and PKA pathway proteins in autophagy-deficient neurons compared to controls. **Conclusion**: Through these findings, we have conducted a comprehensive, multi-disciplinary analysis to profile the regulatory landscape of neuronal autophagy. By generating a list of putative autophagy cargoes, we hope to shed light on the molecular mechanisms for neurodevelopmental and neurodegenerative disorders associated with autophagy deficiency.

Title: A parasympathetic neurotransmitter contributes to the formation of functional neuro-myoepithelial cell junctions in submandibular salivary glands.

Authors: *T. NAKAMURA[1,2], Y. SHINDO[3], H. M. NAKAMURA[4], J. NAKAI[2], K. TAKAHASHI[2], T. IWAMOTO[3], M. WAKAMORI[2];

Abstract: The parasympathetic nervous system via muscarinic receptors mainly regulates serous saliva secretion from the salivary glands (SGs) by controlling myoepithelial cell (MEC) contractility. In the developed SGs, MECs derived from epithelial cells acquire mesenchymal properties by epithelial-mesenchymal transition (EMT) and are located on the end buds and ducts of SGs as a thin layer above the basement membrane. The formation of the nerve-MEC junction is important for the parasympathetic response of SGs. During the embryonic stage, the mouse SG with neural responsiveness develops, but how the nerve-MEC junction is formed during the development remains unclear. In this study, we used *ex vivo* organ culture system of submandibular glands (SMGs) to analyze the role of parasympathetic neurotransmitters during nerve-MEC junction formation in mouse SG development. *Chrm1*, which encodes muscarinic ACh receptor M1 (mAChR M1), was preferentially expressed in developing SMG of E13 embryos. Inversely, *Chrm3*, which encodes mAChR M3 receptor, was predominantly expressed in developed SMGs of postnatal 7-day mice. In addition, the expression of neuronal tubulin beta 3 (*Tubb3*), a marker of parasympathetic nerve in developing SMG, was increased at E13.5. qPCR analysis in *ex vivo* organ culture system revealed that carbachol (CCh), a chemical that mimics ACh, promotes the expression of marker genes for EMT and *Acta2*, a marker for MECs, suggesting CCh induces the epithelial cell differentiate into MECs. On the other hand, CCh-mediated MEC induction was canceled by mAChR M1 inhibitor. Immunohistochemical analysis showed MECs were identified at the surface of endbuds close to Tubb3-positive neurons. Taken together our results suggest that ACh, secreted from parasympathetic neurons, promotes MEC differentiation limited in mAChR M1-expressing epithelial cells. This regulation could contribute to the formation of nerve-MEC junctions in neuro-innervating SGs.Our findings provide novel insights into neuro-regulated organ development and also a clue for the development of a therapeutic approach in age-related dry mouth and dysfunction SGs related to oral sarcopenia.

Title: THRA isoform expression profile in healthy human tissues and cortical brain organoids: insights into thyroid hormone signaling during early cortical development

Authors: *E. GRACEFFO[1], R. OPITZ[2], H. KRUDE[3], M. SCHUELKE[1];
[1]Dept. of Neuropediatrics, [2]Inst. of Pediatric Endocrinol., [3]Charite Universtätsmedizin Berlin, Berlin, Germany

Abstract: Thyroid hormone receptor α (THRA) is a nuclear hormone receptor that acts as a transcription factor for genes involved in cell growth and metabolism and therefore mediates the effects of thyroid hormone at the cellular level. There are two main splice isoforms that arise from alternative splicing, the canonical THRα1 and the less-known THRα2. While both isoforms share a high degree of sequence homology and retain key functional domains, only THRα1 can bind to thyroid hormone Triiodothyronine (T3) and hence activate gene expression. In contrast, THRα2 lacks the T3-binding site and consequently acts as an inhibitor. We hypothesize that the local ratio of the two isoforms dictates the overall local action of *THRA*. Limited data is available on the isoform expression levels in different tissues. For this reason, we set out to characterize the *THRA* isoform expression pattern in various healthy human tissues with a specific focus on cortical brain organoids. Considering the lack of antibodies specific for the respective isoforms, we used a bioinformatic pipeline to analyze four bulk RNA-sequencing datasets: **(A)** Newly generated dataset of pooled healthy adult human tissues (10 neuronal and 14 non-neuronal); **(B)** Publicly available human cortical organoids from Testa's lab (E-MTAB-8325) including biological triplicates at 3 time points; **(C)** Newly generated dataset of human cortical organoids including biological triplicates at 3 time points and two T3 conditions and **(D)** Publicly available human and gorilla cortical organoids (GSE153076) including 7 time points. FastQ files were mapped to the reference genome (GRCh30 v13 and Kamilah GGO v6 respectively) using STAR, QC was performed with FastQC and MultiQC, isoform abundances were quantified with StringTie and visualization was done in R. We found that *THRA* expression steadily increases over time in human cortical organoids, with a strong predominance of THRα2 at all stages. This trend was conserved in Gorilla cortical organoids. In adult human tissues, we observed a predominance of THRα2 in all the central nervous system tissues and thyroid, while THRα1 was predominant in adipose tissue and skeletal muscle. Additionally, we observed no difference in *THRA* expression in cortical organoids treated with high T3 levels. These results shed light on the enigmatic role of THRα2 and point at an additional layer of gene regulation. Considering THRα2 is T3-independent, results suggest that the brain requires protection from thyroid hormone during early development. This study may contribute to the development of targeted therapeutic interventions for neurodevelopmental disorders associated with thyroid hormone imbalances.

Title: Analysis of subplate marker genes that could lead to expansion of the human subplate layer

Authors: *Y. MATSUMURA[1], K. HIRAI[1], K. MORIYA-ITO[1], M. OKAMOTO[2], C. MARUYAMA[1];

Abstract: During brain development, transient neurons provide the basis for developing neural networks. Subplate neurons (SpN), below the cerebral cortex, are born and mature early in the developing brain. Previous studies, including ours, have suggested that SpNs play a role in constructing neural networks, such as regulating radial migration and building connections between the thalamus and the neocortex. Furthermore, the subplate layer (SP layer) is much enlarged in primates compared to mice, indicating that SpNs in the primate have acquired a new and primate-specific function and play an essential role in neocortex enlargement. However, the molecular mechanisms that could lead to the expansion of the SP layer remain elusive. To verify the extent to which gene expression profiles in SpNs are conserved among humans, marmosets, and mice, we analyzed the expression patterns of SpN markers using spatial transcriptome data in the mouse, marmoset, and human cerebral cortex. As a result, we found some subplate marker genes commonly expressed between primates and mice. On the other hand, *Suppression of Tumorigenicity 18* (*ST18*), which encodes a transcription factor, is more expressed in the human SP layer than in the marmoset and mouse ones. This result indicates a correlation between ST18 expression and the expansion of the SP layer. Moreover, to clarify the function of *ST18*, we induced overexpression of *ST18* in mouse SpNs by *in utero* electroporation and analyzed its effect on the SP layer. Elucidating the molecular role of subplate marker genes, including *ST18*, may lead to understanding the enlargement of the SP layer and the development of the neocortex in humans.

Abstract: The remarkable increase in human cortical pyramidal neurons (PyNs) is mainly because human cortical radial glial (RG) cells generate PyNs for ~130 days, whereas the same process takes only ~7 days in mice. The molecular mechanisms underlying this difference are largely unknown. Here, we found that BMP7 is expressed by increasing numbers of cortical RG cells during mammalian evolution (mouse, ferret, monkey, man). BMP7 expression in cortical RG cells promotes neurogenesis, inhibits gliogenesis, and thereby increases the length of neurogenic period, whereas SHH signaling promotes cortical gliogenesis. We demonstrate that BMP7 signaling and SHH signaling mutually inhibit each other through regulation of GLI3 repressor formation. We propose that BMP7 drives the evolutionary expansion of the mammalian cerebral cortex by increasing the length of the neurogenic period.

Title: Semi-quantitative analysis neurotrophic factors and their receptors in regenerating mesentery of the sea cucumberH. glaberrima

Authors: *G. WICKERSHAM GARCIA[1,3], J. E. GARCIA-ARRARAS[2];
[1]Univ. de Puerto Rico, Rio Piedras, San Juan, PR; [2]Univ. Puerto Rico, Univ. de Puerto Rico, Rio Piedras, Rio Piedras, PR; [3]Hlth. and Sci., Univ. del Sagrado Corazon, San Juan, PR

Abstract: The field of regenerative medicine and precision medicine aims to use growth factors, transcription factors, and other regulators to target specific cellular mechanisms to regenerate tissues and organs. In humans, the ability to regenerate their nervous system is highly limited by many issues that are not yet fully understood. In contrast, other animal species have amazing regenerative capacities. The sea cucumber *H. glaberrima*, like other echinoderms, has been shown to be a potential model to understand nervous system regeneration. One of the components we are exploring is the reinnervation of the regenerated intestinal tissue and possible nerve-dependent regeneration initiated by the blastema. We hypothesize that fibroblasts and mesenchymal cells inside the blastema are sending growth factors and motility factors to the neurons in the mesentery, thus modulating their behavior. Exploration of these putative factors identified from regeneration transcriptomes has allowed the identification of several holothurian orthologues of vertebrate genes. Two differentially spliced sequences were discovered for the

growth factor neurotrophin-3 and two sequences were also found for the GDNF family related receptor 4. These were present in both radial nerve cord and intestine transcriptomes. GFRα-4 sequences contained the binding domains for the GFRα family as well as two hydrophobic regions at the end and beginning of the sequence. NT-3 sequences contained the binding domains for the NGF superfamily. Neighbor-Joining Trees demonstrated groupings of TrkC receptors, GFRα-4 and NT-3 among echinoderm sequences. Using differential gene expression sets generated from RNA-sequencing log-2-fold change analysis, the expression levels of the holothurian GFRα-4 and NT-3 genes were determined at different intestinal regeneration stages. Both were found to be underexpressed before 7 days-post evisceration (dpe) and overexpressed at 14 dpe suggesting their association with intestinal re-innervation. Further studies of these genes could lead to the determination of their roles in regenerating tissue and their possible importance in the regeneration of the organs.

Title: The Long-Term Molecular Effects of Tributyltin on Estrogen Signaling In The Zebrafish Retina

Authors: *M. SANDERS[1], V. CONNAUGHTON[2];
[1]Biol., American Univ., Rockville, MD; [2]Biol., American Univ., Washington, DC

Abstract: The development of the retina involves a delicate process that requires careful completion to prevent disruption in proper functioning. A vital component of this careful process involves the production of aromatase, an enzyme that is required for the synthesis of estrogen. Endocrine Disrupting Compounds (EDCs) affect the inhibition or upregulation of hormones like estrogen, which can cause cell apoptosis (cell death), thinning of the retina and cornea, as well as delayed development that emphasizes the importance of estrogen during this process. Unfortunately, not much is known about the long-term implications of changing the estrogenic signaling involved in retinal development. The purpose of this work was to examine if transient developmental exposure to tributyltin (TBT), an antifouling EDC and aromatase inhibitor, can disrupt estrogenic signaling pathways in the brain and retinas of adult zebrafish (Danio rerio*)*. Zebrafish larvae aged 72 hours postfertilization (hpf) or 7 days (d) pf were exposed to either water, vehicle (0.1% ethanol), low TBT (0.2uM) or high TBT (2uM) for 24 hr. After exposure, larvae were returned to control conditions and raised to adulthood, when retinal and brain tissue was collected. qPCR analysis examined expression of estrogenic genes of interest: aromatase B,

estrogen receptor alpha (ERalpha), and ERbe*ta. Our results indicate that developmental TBT exposure at 72hpf had little effects on brain and retina gene expression.* One-way ANOVA was used for statistical analysis. At 72hpf, Aromatase expressions in retina and brain were statistically insignificant (retina; p=.437, brain; p=.939). Similarly, at 7dpf aromatase expression was also statistically insignificant (retina; p=.334, brain; p=.486) However, the results at 7dpf were slightly more significant than 72hpdf. These results indicate the possibility of deeper biological processes triggered by TBT to compensate for the effects of TBT. It is also possible that TBT may be acting on non-genomic pathways. This work will help to uncover estrogen signaling mechanisms in the retina by better understanding aromatase regulation, as aromatase inhibitors are used clinically as a breast cancer therapeutic.

Title: Ketamine's rapid antidepressant effects are mediated by ca^{2+}-permeable ampa receptors

Authors: *M. WILES, A. ZAYTSEVA, E. BOUCKOVA, M. H. WUSTRAU, H. MENDEZ-VASQUEZ, I. G. SCHMIDT, S. KIM;
Colorado State Univ., Fort Collins, CO

Abstract: Ketamine is shown to enhance excitatory synaptic drive in multiple brain areas, which is presumed to underlie its rapid antidepressant effects. Moreover, ketamine's therapeutic actions are likely mediated by enhancing neuronal Ca^{2+}signaling. However, ketamine is a noncompetitive NMDA receptor (NMDAR) antagonist that reduces excitatory synaptic transmission and postsynaptic Ca^{2+} signaling. Thus, it is a puzzling question how ketamine enhances glutamatergic and Ca^{2+} activity in neurons to induce rapid antidepressant effects while blocking NMDARs in the hippocampus. Here, we find that ketamine treatment in cultured mouse hippocampal neurons significantly reduces Ca^{2+} and calcineurin activity to elevate AMPA receptor (AMPAR) subunit GluA1 phosphorylation. This phosphorylation ultimately leads to the expression of Ca^{2+}-Permeable, GluA2-lacking, and GluA1-containing AMPARs (CP-AMPARs). The ketamine-induced expression of CP-AMPARs enhances glutamatergic activity and glutamate receptor plasticity in cultured hippocampal neurons. Moreover, when a sub-anesthetic dose of ketamine is given to mice, it increases synaptic GluA1 levels, but not GluA2, and GluA1

phosphorylation in the hippocampus within one hour after treatment. These changes are likely mediated by ketamine-induced reduction of calcineurin activity in the hippocampus. Using the open field and tail suspension tests, we demonstrate that a low dose of ketamine rapidly reduces anxiety-like and depression-like behaviors in both male and female mice. However, when *in vivo* treatment of a CP-AMPAR antagonist abolishes the ketamine's effects on animals' behaviors. We thus discover that ketamine at the low dose promotes the expression of CP-AMPARs via reduction of calcineurin activity, which in turn enhances synaptic strength to induce rapid antidepressant actions.

Title: Ketamine's rapid action on chronic stress-induced mental disorders

Authors: *E. BOUCKOVA, M. WILES, M. WUSTRAU, J. FLOWERS, P. VETTER, R. LEE, S. KIM;
Colorado State Univ., Fort Collins, CO

Abstract: Repeated stress affects brain functions, which contributes to the development of anxiety and depression, cognitive dysfunction, and social avoidance. After demonstrating rapid and robust antidepressant efficacy, the FDA approved esketamine (the S enantiomer from of ketamine) for the treatment of depression in 2019, sparking a surge in clinical and public interest around the world. In addition to reducing depression, some research indicate that ketamine may have neuroprotective effects against chronic stress-related neuropsychiatric conditions in both humans and animals. However, the effects of ketamine on these behaviors have not been fully investigated. Low-dose ketamine can enhance excitatory synaptic drive and neuronal Ca^{2+} signaling in the hippocampus, which are presumed to underlie its rapid antidepressant effects. However, ketamine is a noncompetitive antagonist for NMDA receptors (NMDARs), major Ca^{2+} channels in excitatory synapses. Therefore, it is a puzzling question how ketamine enhances glutamatergic and Ca^{2+} activity while blocking NMDARs. Our recent work has discovered a new mechanism of ketamine's antidepressant effects, in which ketamine at the low dose promotes the

expression of Ca^{2+}-Permeable AMPA Receptors (CP-AMPARs) a rare subtype of AMPARs that have larger single channel conductance. Therefore, the ketamine-induced expression of CP-AMPARs can compensate for reduced NMDAR-mediated synaptic Ca^{2+}signaling and enhance synaptic strength enabling ketamine's rapid antidepressant actions in naïve mice. This further suggests that the ketamine-induced expression of CP-AMPARs can enhance synaptic activity to be neuroprotective against chronic stress. Here, 3-month-old C57Bl6 female and male mice received chronic restraint stress (CRS) for 2 weeks, and we performed 4 behavior tests - open field test, reciprocal social interaction, contextual fear conditioning (CFC), and tail suspension test (TST), to determine whether CRS induced behavioral dysfunction. We found that CRS was sufficient to induce anxiety- and depression-like behaviors, fear memory loss, and social dysfunction in mice. Next, we injected 10 mg/kg and 5 mg/kg ketamine to male and female mice following CRS, respectively, and performed social interaction tests, CFC, and TST and found that ketamine treatment improved these behaviors in stressed mice. These demonstrate that ketamine shows strong neuroprotection against chronic stress.

Title: Interaction of GluA2 and NSF regulates Ca^{2+} permeable AMPA receptors

Authors: *Q. ZHU[1], H. L. TAN[2], R. R. JOHNSON[1], R. L. HUGANIR[1];
[1]Johns Hopkins Univ. Sch. of Med., Baltimore, MD; [2]Rockerfeller Univ., New York, NY

Abstract: Synaptic plasticity at excitatory synapses relies on the mobilization of AMPA receptors, which is known to be mediated by the interaction of GluA2 and NSF. Previous studies have shown that NSF facilitates the synaptic insertion of AMPA receptors by directly binding to GluA2. However, there is little comprehensive characterization regarding how the GluA2-NSF interaction impacts synaptic transmission and rodent behaviors. To address it, we generated a knock-in (KI) mouse line called GluA2ΔNSF, in which endogenous GluA2 does not bind to NSF. First, we quantified the basal levels of AMPAR subunit in hippocampus through biochemical analysis. We found that synaptic GluA1 number and its S831 phosphorylation were increased in KI mice compared to WT, but the amount of GluA2 remained unchanged. These findings were consistent with the electrophysiological data obtained from spontaneous release rather than evoked release, suggesting that the disruption of GluA2-NSF interaction may promote the synaptic insertion of calcium-permeable AMPARs (CP-AMPARs) primarily at

spontaneous release sites. Since an enriched environment (EE) can modify synaptic plasticity, we placed both KI and WT mice in EE cages as well as normal control cages. In the WT, EE led to a higher insertion of CP-AMPARs at evoked release sites. However, in the KI mice, EE did not have any significant effects on AMPAR number and synaptic transmission, suggesting GluA2-NSF interaction is required for EE-induced synaptic plasticity. Thus, this study implies that the GluA2-NSF interaction plays a role in regulating the trafficking of a specific pool of AMPARs, potentially involved in the modulation of AMPAR nanodomains.

Title: Electrophysiology of AMPA receptors in individuals resilient to Alzheimer's disease Neuropathology

Authors: *B. GUTIERREZ GREBENKOVA[1], S. WIDEN[1], W. RUSSELL[1], C. KEENE[2], A. LIMON[1];
[1]Univ. of Texas Med. Br., Galveston, TX; [2]Univ. of Washington, Seattle, WA

Abstract: Alzheimer's disease (AD) is a prevalent form of dementia characterized by the accumulation of amyloid beta and pTau proteins in the brain. While clinical observations are typically used for AD diagnosis, postmortem studies have revealed individuals without dementia symptoms but with high AD pathology, referred to as resilient individuals. Calcium permeable AMPA receptors (CP-AMPARs) have been implicated in the calcium dyshomeostasis of AD, but their presence and electrophysiological response in resilient individuals remain unknown. To address this, we analyzed proteomic and transcriptomic data from a cohort of 30 individuals, including resistant (3M,4F; non-demented/no neuropathology), AD match resistant (2M, 5F; age-matched AD individuals), resilient (2M, 6F; non-demented with AD neuropathology), and AD match resilient (2M, 5F; age-matched AD individuals). Our analysis demonstrated alterations in the expression, organization, and synaptic remodeling of AMPARs across all groups. Notably, resilient individuals exhibited robust involvement in cellular respiration pathways, indicating compensatory mechanisms and enhanced energy management. We further investigated the synaptic responses of CP-AMPARs in these groups by isolating and transplanting synaptic membranes from the parietal cortex into Xenopus laevis oocytes for analysis. Through activation and subsequent inhibition of AMPARs, we determined the contribution of CP-AMPARs to the overall response, revealing reduced CP-AMPARs responses

in resilient individuals. Collectively, our findings provide insights into the structural and functional differences of CP-AMPARs in resilient individuals, potentially reflecting underlying structural or signaling changes identified in our proteomic analysis. Further investigations are warranted to fully understand the mechanisms underlying these alterations and their implications for the progression of AD.

Title: The insulin-like peptide INS-27 mediates an inter-tissue feedback pathway that couples muscle activity with AMPA receptor trafficking in distal upstream neurons in C. elegans

Authors: B. J. RENNICH[1], M. HODUL[2], ***P. JUO**[2];
[1]Grad. Program In Neuroscience, Tufts Univ. Sch. of Med., Boston, MA; [2]Tufts Univ. Sch. of Med., Boston, MA

Abstract: Regulation of the number of AMPA receptors (AMPARs) at the synapse controls synaptic strength and is a major mechanism underlying synaptic plasticity. While much has been learned about the intracellular trafficking mechanisms that control AMPAR levels at synapses, less is known about extracellular factors that control AMPAR trafficking, especially those secreted from distal, non-neuronal tissues. Here, we identify an inter-tissue signal in *C. elegans* that couples muscle activity with GLR-1/AMPAR surface levels at synapses in AVA pre-motor interneurons, which reside two synaptic layers upstream of the neuromuscular junction (NMJ) in a circuit that controls locomotion. Mutants lacking NMJ acetylcholine receptor (AChR) subunits *unc-29*/AChR or *unc-38*/AChR exhibit a compensatory increase in surface GLR-1 levels in AVA neurons. This increase in GLR-1 can be rescued by expressing wild-type *unc-29*/AChR specifically in muscle, revealing a feedback pathway that couples NMJ signaling with GLR-1 trafficking in AVA neurons. Similarly, chronic loss of muscle contraction in *unc-54*/muscle myosin mutants results in increased surface GLR-1 levels in AVA, suggesting that loss of muscle activity is sufficient to trigger the feedback pathway. Acute inactivation of muscle, using conditional mutations in *unc-54*/muscle myosin or *twk-18*/potassium channels, is also sufficient to increase surface GLR-1 levels after development is complete. Interestingly, mutations in *unc-31*/Calcium Activator of Protein Secretion (CAPS), which mediates the release of neuropeptide-

containing Dense-Core Vesicles (DCVs), blocks the feedback pathway. This block can be rescued by expressing wild-type *unc-31*/CAPS specifically in muscle suggesting that a muscle-secreted factor contained in DCVs mediates the feedback pathway. We performed a focused RNAi screen of muscle-expressed neuropeptides and identified the insulin-like peptide INS-27 as a potential mediator of the feedback pathway. Consistent with this role, we found that INS-27 is secreted from muscle in an *unc-31*/CAPS-dependent manner. Furthermore, *ins-27* loss-of-function mutants block the feedback pathway and this defect can be rescued by expression of wild-type *ins-27* in muscle. Together, our data reveal a novel inter-tissue feedback pathway mediated by INS-27 that couples muscle activity with AMPA receptor trafficking in upstream neurons. We propose that muscle-secreted INS-27 mediates a compensatory signal to adjust motor circuit excitability in response to changes in muscle activity.

Title: Afferent convergence to a shared population of synaptic AMPA receptors

Authors: *R. PENNOCK[1], X. YAN[2], L. S. OVERSTREET-WADICHE[3], J. I. WADICHE[4]; [1]Neurobio., Univ. of Alabama at Birmingham Chapter, Birmingham, AL; [2]Univ. of Alabama Birmingham Chapter, Birmingham, AL; [3]Neurobio., Univ. Abstract: Precise alignment of pre- and postsynaptic elements optimizes the activation of glutamate receptors at excitatory synapses and is thought to maintain synapse specificity. Nonetheless, glutamate that diffuses out of the synaptic cleft can have actions at distant receptors, a mode of transmission called spillover. To uncover the extrasynaptic actions of glutamate, we localized AMPA receptors (AMPARs) mediating spillover transmission between climbing fibers and molecular layer interneurons (MLIs) in the cerebellar cortex. Climbing fibers provide a functional synaptic connection to MLIs where neurotransmission is mediated entirely by glutamate spillover in the absence of anatomically defined synapses. Using electrophysiology and 2-photon imaging in ex vivo murine brain slices, we show that climbing fiber-MLI transmission occurs in restricted microdomains along MLI dendrites that are reminiscent of parallel fiber synapses. Using pharmacological and physiological manipulations, we found that

spillover transmission is indeed mediated by activation of synaptic Ca^{2+}-permeable AMPA receptors at parallel fiber synapses. Despite the convergence of these afferent pathways to a common population of postsynaptic receptors, release from each pathway is differentially modulated by presynaptic GABAB receptor activation. This allows activation of synaptic AMPARs even when glutamate release from parallel fibers is suppressed. Additionally, activation of either pathway in close temporal and spatial proximity to the other facilitates recruitment of perisynaptic NMDA receptors. Together, these findings demonstrate a circuit motif that relies on the activation of a common population of synaptic receptors by two separate afferent pathways, which contrasts with the notion of synapse specificity.

Title: Activity dependent induction of presynaptic homeostatic potentiation

Authors: *C. BECKERS, J. YU-STRZELCYZK, C. ZHANG, S. GAO, M. HECKMANN, S. DANNHÄUSER;
Inst. of Physiol., Julius Maximilians Univ. of Würzburg, Würzburg, Germany

Abstract: The neuromuscular junction (NMJ) of *Drosophila melanogaster* is a versatile model for the study of glutamatergic transmission. At the NMJ of *Drosophila* four subunits assemble to one heterotetrametric receptor. Each receptor contains GluRIIC, GluRIID, GluRIIE and additionally GluRIIA or GluRIIB as a fourth subunit. Receptors containing GluRIIA as fourth subunit and receptors which incorporate GluRIIB as fourth subunit, differ in their functions and their physiological parameters. The perturbation of the postsynaptic glutamate receptor subunit GluRIIA leads primarily to a decrease of the postsynaptic response, which is consequently rescued by an increase in presynaptic transmitter release (referred to as presynaptic homeostatic potentiation, PHP)[1].One of the most basic questions has remained elusive so far: Why does the knockout of GluRIIA leads to the induction of PHP and a knockout of GluRIIB does not? A recent study laid focus on the intracellular tail of GluRIIA which recruits CamKII and activates it to pCamKII which then serves as a stop signal for PHP [2].In this study we describe the effect of a GluRIIA-pore-chimera which resembles a native GluRIIA receptor with the pore building region of GluRIIB. Beginning with outside-out-patch-clamp analysis of these receptor constructs in *Xenopus laevis* oozytes, we show that the desensitization kinetics of the GluRIIA-pore-chimera assimilates to the kinetics ofGluRIIA (10.8 ± 0.3 ms vs 14.4 ± 3.2 ms, n=4). In the next step we expressed this GluRIIA-pore-chimera with an additional ALFA-tag and a wildtype GluRIIA with an ALFA-tag at the endogenous locus of GluRIIA in *Drosophila melanogaster*.

Both constructs are expressed at the NMJ, shown by applying SIM-imaging. Interestingly a strong fluorescens signal for pCamKII could be detected as well in GluRIIA-ALFA and GluRIIA-pore-chimera-ALFA. To check how the pore chimera behaves functionally, we applied two-electrode-voltage-clamp (TEVC) of the larval NMJ. The GluRIIA-pore-chimera leads to a decrease of the postsynaptic response to a singly released vesicle. The evoked response is fully restored, thereby undergoing PHP. These findings are giving rise to the idea that an activity-dependent induction mechanismfor PHP exist.References(1) Graeme W. Davis and Martin Müller. Title: Does prolactin induce neuroprotection against Kainic Acid excitotoxicity by modulating intracellular Ca^{2+}concentration?

Authors: *V. RODRIGUEZ CHAVEZ[1], G. MOLINA-SALINAS[1], E. FLORES-SOTO[2], B. ROMERO MARTÍNEZ[2], L. MONTAÑO RAMÍREZ[2], M. CERBÓN CERVANTES[1]; [1]Dept. de Biología, [2]Dept. de Farmacología, Univ. Nacional Autónoma De México, Ciudad de Mexico, Mexico

Abstract: It has been described that PRL induces neuroprotection against kainic acid (KA) excitotoxicity damage, both *in vivo* models and *in vitro* models, but this mechanism is not fully described. This study aimed to determine the neuroprotective role of PRL administration in primary cultures of hippocampal neurons assessing intracellular Ca^{2+} concentration and iGluRs expression. For this study, immunofluorescence, and Western Blot methods were used to assess the expression of iGluRs and their cellular localization. To determine the effect of PRL on iGluRs and intracellular Ca^{2+} concentration, primary hippocampal neurons obtained from 17.5-day-old rat embryos were used. Cultures were divided into Control (CTRL, saline), PRL 20 ng/ml, glutamate (20 μM), PRL+Glu (20 ng/ml/ 20μM), kainic acid (20 μM), and PRL+AK (20 ng/ml/ 20μM) groups. It was found that PRLR localizes to hippocampal neurons, iGluRs subunits are observed at the protein level in primary cultures of hippocampal neurons, and the intracellular Ca^{2+} concentration was modulated by excitotoxic events. Understanding the

neuroprotective effects of PRL will allow the generation of new therapeutic targets for damage caused by the excitotoxicity of iGluR agonists.

Title: Auxililaty protein Neto-a modulates subcellular distribution and functional properties of KaiR1D autoreceptor

Authors: *W.-C. HSIEH[1], T. HAN[3], R. VICIDOMINI[4], P. NGUYEN[2], Z. LI[5], M. SERPE[6]; [2]NICHD, [1]Natl. Inst. of Mental Hlth., Bethesda, MD; [6]NIH, NIH, Bethesda, MD

Abstract: At excitatory synapses, glumatergic autoreceptors provide a feedback mechanism that modulate glutamate release and ensure stable neuronal networks. Disruptions of this feedback have been linked to various neuronal disorders. Detection and functional investigation of these low abundant presynaptic proteins have been challenging. At *Drosophila* NMJ, an autoreceptor containing the KaiR1D subunit has been implicated in the control of glutamate release; *KaiR1D*^{null} animals have reduced basal neurotransmission. We and others previously showed that KaiR1D requires at least two auxiliary proteins, Neto-α and Sol1. Here, we focus on the roles of Neto-α in modulating KaiR1D properties and distribution. Neto-α limits KaiR1D *in vivo* activities: Basal neurotransmission is reduced by 50% in *neto-α*^{null} and neuronal overexpression of KaiR1D cannot rescue this defect. At molecular level, Neto-α modulates homotetrameric KaiR1D channel properties, including desensitization rates and polyamine-induced channel rectification. Neto proteins are highly conserved auxiliary subunits with conserved extracellular domains, including two CUB domains and a LDL motif, and divergent intracellular domains (CTD). We demonstrated that CUB1 domain is required for modulation of KaiR1D gating properties as well as *in vivo* autoreceptor activities, while the CTD modulates KaiR1D gating properties. We found reduced KaiR1D presynaptic distribution at *neto-α*^{null} NMJs. To investigate how Neto-α modulates the subcellular distribution of KaiR1D, we expressed *Drosophila* protein in primary rat hippocampal neurons and examined KaiR1D localization. KaiR1D localizes to dendrites, with or without Neto-α, but it cannot efficiently enter the axon by itself even when overexpressed. Neto-α or ΔCUB1, but not ΔCTD, promote KaiR1D axonal localization,

indicating the intracellular domain of Neto-α promote KaiR1D axonal entry. All Neto variants distributed at both neurites and formed puncta largely colocalizing with KaiR1D. Also, Neto-α and KaiR1D colocalize in the proximity of the active zones suggesting that Neto-α may stabilize KaiR1D at the site of autoreceptor function. Our data indicate that auxiliary protein Neto-α modulates multiple aspects of KaiR1D distribution and function to ensure proper autoreceptor activities.

Title: A pathogenic mutation in GluK2 kainate receptor alters dendritic and neuronal excitability through dysregulation of K+ channels in the hippocampus

Authors: *T. NOMURA[1], S. TANIGUCHI[2], Y.-Z. WANG[2], N.-H. YEH[2], A. WILEN[3], C. C. CASTILLON[2], K. FOOTE[2], J. XU[2], J. N. ARMSTRONG[2], J. N. SAVAS[2], G. T. SWANSON[2], A. CONTRACTOR[2];

Abstract: Human genetic studies have identified several pathogenic mutations in the *GRIK2* gene, encoding for the GluK2 subunit of kainate receptors (KARs), in individuals with neurodevelopmental disorders. Several pathogenic missense mutations cause amino acid substitutions clustered in critical functional domains of the receptor protein associated with channel gating (Guzman et al. 2017; Stoltz et al. 2021). We engineered a GluK2 mutant mouse model which carries a homologous mutation described in humans; GluK2(A657T) mouse. The present study focused on *in vitro* electrophysiological analyses of heterozygous GluK2(A657T) mice to better understand the synaptic and circuit level pathology in *GRIK2* related disorders. The KAR-mediated EPSC ($EPSC_{KAR}$) at the hippocampal mossy fiber (MF) - CA3 synapse had significantly slower decay kinetics in GluK2(A657T) mice, which is consistent with previous studies in non-neuronal cells (Kohda et al. 2000; Guzman et al. 2017) and suggests that mutant GluK2 subunits are incorporated into functional KARs in these mice. While there was a clear alteration in KAR channel function, neither short-term nor long-term synaptic plasticity, in which KARs play a critical role, was affected in GluK2(A657T) mice. Unexpectedly, we found that CA3 neurons fire spontaneous action potentials (APs) at an abnormally high frequency in

GluK2(A657T) mice. Examination of this hyper-excitability phenotype of CA3 neurons revealed that the coupling of distal associational-commissural (AC) - CA3 EPSPs to AP firing was elevated suggesting an increase in dendritic excitability. This was confirmed by the analysis of back-propagating action potential (bAP) by measuring the dendritic Ca^{2+} signal which demonstrated less attenuation more distal to the soma in mutant mice. There was a reduction in the activity of Ca^{2+} activated K^+ channels (SK), which is known to regulate dendritic excitability, in mutant mice. Pharmacological inhibition of SK channels in wild type mice in part mimicked cellular phenotypes of GluK2(A657T) mice, increasing EPSP-AP coupling and the propagation of dendritic bAPs. These results indicate that a disease causing A657T missense mutation in *Grik2* does alter KAR function, but the consequences directly attributable to KAR malfunction are relatively inconsequential. Instead, the dominant circuit pathophysiology in this *Grik2* disorder is through an unexpected alteration in K^+ channels, which results in a change in dendritic excitability and neuronal firing.

Title: Activation of glutamate receptors increases activity of female kisspeptin neurons.

Authors: *R. BEARSS[1], R. PIET[2];
[1]Sch. of Biomed. Sci., [2]Biol. Sci. Dept., Kent State Univ., Kent, OH

Abstract: Kisspeptin (kiss1) neurons in the arcuate nucleus (ARN) stimulate gonadotropin releasing hormone (GnRH) neuron activity and GnRH release, which subsequently promotes luteinizing hormone (LH) release from the anterior pituitary gland. ARN^{kiss1} neurons co-release kiss1, neurokinin B (NKB), dynorphin A (dyn A), and the neurotransmitter glutamate. ARN^{kiss1} neurons are thought to coordinate their activity through reciprocal connections, thereby generating episodic bouts of activity and driving GnRH and LH pulsatile secretion. This is necessary in both sexes for fertility and gonadal function. Ionotropic glutamate receptor antagonists suppress ARN^{kiss1} neuron coordinated activity and pulsatile LH release. Although these lines of evidence indicate a role of glutamatergic neurotransmission in kisspeptin neurons, little is known about the impact of glutamate receptor activation on these cells. We sought to examine the effect of ionotropic AMPA and NMDA receptors, and group 1 metabotropic glutamate receptors (mGluRs) on ARN^{kiss1} neuron activity in female mice.

We used calcium imaging to monitor the activity of kiss1 neurons in brain slices. We crossed Kiss1-Cre mice—expressing Cre recombinase (Cre) in kisspeptin neurons—with Cre-dependent GCaMP6f mice to generate Kiss1-Cre x GCaMP6f mice that express GCaMP6f in kiss1 neurons. Coronal brain slices (200 µm thickness) obtained from female diestrus Kiss1-cre x GCaMP6f mice containing the ARN were placed in a recording chamber. Changes in individual kisspeptin neuron GCaMP6f fluorescence were measured using epifluorescence microscopy to estimate variations in intracellular calcium concentrations ($[Ca^{2+}]_i$) as a proxy for electrical activity. Kiss1 neurons were exposed for 2 minutes, via bath application, to either AMPA (10µM), NMDA (50µM), or DHPG (50µM). On average, applications of AMPA (10 µM), DHPG (50 µM), or NMDA (50 µM) to female ARN^{Kiss1} neurons transiently increased normalized fluorescence by 0.386 ± 0.016 (161 cells, 6 slices, and 4 animals), 0.076 ± 0.007 (111 cells, 7 slices, and 4 animals), and 0.150 ± 0.011 (103 cells, 6 slices, and 4 animals), respectively. The proportion of cells activated for each drug was 100 (n=161), 94 (n=111), and 100% (n=103) for AMPA, DHPG, and NMDA application, respectively. This indicates that activation of ionotropic AMPA and NMDA receptors as well as group 1 mGluRs increases $[Ca^{2+}]_i$ in female ARN^{kiss1} neurons and, thus, stimulates activity in these cells. Further investigation into the role of endogenous glutamatergic signaling and into the respective role of glutamatergic receptors in regulating kiss1 neuron activity is needed.

[1]Axxam S.p.A, Milan, Italy; [2]Univ. of Queensland, Brisbane, Australia; [3]Nanion Technologies GmbH, Munich, Germany; [4]Nanion Technologies Inc., Livingston, NJ; [5]Anatomic Inc., Anatomic Inc., Minneapolis, MN

Abstract: P2X receptors are ligand-gated ion channels activated by extracellular ATP. They are permeable to small monovalent cations, some having significant divalent or anion permeability. The $P2X_2$ and $P2X_3$ subunits are predominantly expressed in primary sensory neurons and have been proposed to play a role in thermal sensation, taste and pain. They form functional hetero- or homotrimers which are activated by αβ-methylene ATP (αβmeATP). The stoichiometry of $P2X_{2/3}$ heteromers appears to be dependent on the relative abundance of the two subunits. A

mixture of $P2X_2$ and $P2X_3$ homomers as well as $P2X_{2/3}$ heteromers are likely to exist, which can be distinguished through their biophysical and pharmacological properties. The receptors open in response to an increase in extracellular ATP which occurs under pathological conditions such as tissue damage. The resulting depolarization leads to propagation of the pain signal. Due to its role in nociception and pain signaling, these receptors are considered to be important targets for pain management. Here we present data collected on automated patch clamp (APC) systems with ranging throughput from 1 up to 384 cells simultaneously. We show activation and inhibition of $P2X_{2/3}$ and $P2X_3$ receptors expressed in CHO cells with rapid and brief application of ligand. ATP was applied using the perfusion system of the Port-a-Patch or the pipette(s) of the Patchliner or SyncroPatch 384. The EC_{50} values for αβmeATP or ATP activation of $P2X_{2/3}$ receptors, and the IC_{50} of suramin, were comparable across the three devices. The kinetics of currents mediated by homomeric $P2X_3$ receptors were distinctly faster than those of heteromeric $P2X_{2/3}$ receptors. $P2X_3$-mediated currents were activated by αβmeATP and could be repetitively activated at least 6 times in the same cell with similar peak amplitudes. The $P2X_3$-selective compound A-317491 blocked $P2X_3$-mediated currents activated by αβmeATP with an IC_{50} of approximately 90 nM and was similar on all three devices. Recording at physiological temperature resulted in a faster recovery but had negligible effects on tachyphylaxis. We also recorded P2X-mediated current responses from human induced pluripotent stem cell-derived sensory neurons on higher throughput automated patch clamp devices. The fast kinetics of the ATP-activated responses is consistent with $P2X_3$ homomeric receptors, and currents could be repetitively activated with a recovery time of 10 minutes between activation with ATP. Studying $P2X_3$ and $P2X_{2/3}$ receptors in heterologous cell lines and hiPSC-derived neurons using automated patch clamp provides physiologically relevant and high throughput tools for drug discovery.

Abstract: It is crucial to rapidly form episodic memories for unfolding experience with regards to spatial environments in the brain. The pyramidal neurons of the dorsal hippocampal CA1 exhibit powerful synaptic potentiation triggered by calcium plateau potentials initiated in the dendrites, which provides an elegant candidate mechanism for one-shot hippocampal learning. In this so-called behavioral time-scale synaptic plasticity (BTSP), it is commonly believed that conjunctive dendritic input processing, which reflects dynamics of the upstream circuits during spatial navigation, is critically important for the induction of plasticity. However, the exact circuit and biophysical mechanisms are largely unknown. We hypothesized that the activation kinetics of synapses to CA1 pyramidal cells constrains BTSP induction in the context of circuit operations, and focused on the particular aspect of input frequency dependence of this plasticity in acute hippocampal slices. We found that CA3 activation frequency was a strong determinant for BTSP, which might not be explained simply by the peak postsynaptic depolarizations resulting from activation patterns. Modeling approach will be taken to refine the mechanistic model proposed by Milstein et al. (2021; *eLife* **10**:e73046) through reducing the free parameter space, and identify potential biophysical mechanisms to test pharmacologically. This quantitative description may be a necessary step toward linking the natural statistics of circuit properties to a neurobiological basis of versatile memory processes under navigation in space.

Title: Interval learning and spontaneous replay in ex vivo cortical circuits using a dual optical training protocol

Authors: *B. LIU, D. V. BUONOMANO;
Neurobio., UCLA, Los Angeles, CA

Abstract: The ability to process the duration, interval, and temporal structure of stimuli is critical to most forms of learning, behavior, and sensory processing. While the neural mechanisms underlying temporal processing on the subsecond scale remain unknown, they have been proposed to rely on the inherent synaptic and network dynamics of all cortical circuits rather than specialized mechanisms present in specific circuits. To test this hypothesis, we differentially trained isolated cortical organotypic slice cultures on two specific temporal patterns using a chronic dual-optical stimulation approach. Excitatory neurons in the cortex were sparsely transduced with either ChR2 or ChrimsonR. Our temporal training paradigm consisted of either an Early or Late pairing. A 440 ms long train of red light pulses (25 Hz, 625nm)—representing presynaptic neurons—was paired with a 80 ms long train of blue light pulses (50 Hz, 455nm)—representing postsynaptic neurons. In the Early group, both pathways were activated with similar onset times, while in the Late group both pathways were activated with similar offset times. Slices were trained for 24 hrs in the incubator. After training, whole-cell recordings revealed differential network dynamics in response to the red stimuli. Specifically, the median event time of the evoked polysynaptic events was significantly shorter in neurons in the Early group compared to the Late group (81 and 323 ms respectively, $p < 0.001$). Similarly, there was a significant difference in the peak time of the polysynaptic responses (77 and 387 ms, $p < 0.001$). Thus, the networks appeared to have learned the temporal structure of the patterns they were exposed to during training, specifically the median peak times of the polysynaptic events were closely aligned with their respective early (10-90ms) or late (370-450ms) training intervals. Suggesting the networks were predicting or expecting the early or late arrival of the blue light. Finally, consistent with the notion of replay and consolidation, we also observed spontaneous replay of activity in the networks which mirrored the differential polysynaptic responses of early or late training. Specifically, spontaneous activity in the early group peaked early, and spontaneous activity in the late group peaked late (47 and 215 ms respectively, $p<0.001$). Our findings suggest that cortical circuits in a dish are intrinsically capable of learning temporal information, and that the learning rules and algorithms underlying spontaneous replay are functional in a dish and thus not necessarily dependent on inter-areal interactions.

Title: Inhibitory circuitry underlying plasticity in motor cortex during skill acquisition

Authors: *T. KIM, B. M. HOOKS;
Univ. of Pittsburgh, Pittsburgh, PA

Abstract: Learning motor skills requires structural and functional plasticity in the primary motor cortex (M1). Cortical inhibitory circuitry is important for motor function. In addition to their proposed role in cortical plasticity in sensory areas, cortical interneurons are required in motor skill acquisition because disruption of the activity of inhibitory neuronal populations interferes with motor learning. But there is a gap in our understanding of how inhibitory synaptic connections change during skill acquisition. This study aims to determine the normal developmental trajectory of motor learning and to address the inhibitory connectivity changes after motor learning. We focus on two major inhibitory interneuron types: somatostatin-expressing (SOM+) interneurons and parvalbumin-expressing (PV+) interneurons. To investigate the difference in inhibition meditated by specific interneuron types during motor learning, animals are trained to run on an accelerating rotarod at ages from postnatal day(P) 20 to P120. Learning is assessed by changes in gait pattern and time to fall. Estimated position of paws and other body parts are obtained from high speed video. To label the task-active and task-inactive cells during motor learning, CaMPARI2, a genetically encoded activity marker, is injected in M1 perinatally to distinguish neurons in an activity-dependent manner. Upon task completion, inhibitory responses (IPSCs) are optogenetically evoked in either PV+ or SOM+ neurons to measure inhibitory synaptic strength to excitatory cells that are task-active (red) or task-inactive (green). Based on time to fall, rotarod task performance improved most rapidly between P30-60. Paw position and gait patterns change with learning, though differently between age groups. PV-mediated inhibition is greater in the active cells, while SOM-mediated inhibition is not different between inactive and active cells on the first day of training. These results suggest early changes in PV-mediated inhibition may support motor skill acquisition in mice. We hypothesize that changes in SOM+ connectivity may occur at longer training periods when learning is consolidated. Further, future experiments will test whether stronger PV-mediated inhibition persists in task-active cells during longer training periods or returns to baseline.

Title: The role of the dyslexia-associated gene KIAA0319 in regulating intrinsic excitability in the zebra finch (Taeniopygia guttata) auditory cortex

Authors: *T. M. BYRON[1], C. D. DEPPMANN[2], C. D. MELIZA[2];
[1]Psychology, Univ. of Virgina, Charlottesville, VA; [2]Program in Fundamental Neurosci., Univ. of Virginia, Charlottesville, VA

Abstract: Nearly 8% of American children ages 3-17 suffer from speech- and language-learning disorders, including dyslexia. Individuals with these disorders often exhibit deficits in processing phonemes, the fundamental units of words, suggesting underlying impairments in central auditory processing. Dyslexia is strongly associated with loss-of-function mutations in *KIAA0319* (Galaburda et al., 2006), but the function of this gene remains poorly understood. Knocking down *KIAA0319* in rats produces deficits in auditory processing and dysregulation of intrinsic excitability in the auditory cortex (Centanni et al., 2014). In zebra finches, an impoverished acoustic environment during the critical period for song memorization also disrupts intrinsic excitability in the auditory cortex via the low-threshold potassium channel Kv1.1 (Chen and Meliza, 2020). We therefore hypothesized that *KIAA0319* may be involved in experience-dependent plasticity of intrinsic dynamics during early auditory development. In this exploratory study, we characterized how co-expression of *KIAA0319* and Kv1.1 depend on age and acoustic environment in fledgling and juvenile zebra finches of both sexes using in situ hybridization and immunofluorescence. We also developed adeno-associated viruses (AAVs) carrying short-hairpin ribonucleic acid (shRNA) constructs targeting *KIAA0319*, with the goal of testing whether knocking down *KIAA0319* during auditory development impacts Kv1.1 expression, intrinsic plasticity, and song memorization. Preliminary data *in vitro* demonstrate that knocking down *KIAA0319* causes overexpression of Kv1.1. These studies can reveal a mechanistic understanding of how dyslexia-associated mutations contribute to deficits in the processing of complex vocal signals used for communication.

Title: Increased synaptic connection in corticocortical circuit in rodent motor skill learning

Authors: *Y. KIM[1], B.-K. KAANG[2];
[2]Sch. of Biol. Sci., [1]Seoul Natl. Univ., Seoul, Korea, Republic of

Abstract: In order to adapt to changing environments, rodents actively learn new motor skills for survival. Although the central cortical region mediating motor skill learning remained elusive, it is recently shown that the primary motor cortex (M1) plays a significant role in motor learning, unlike its classical role as a simple muscle controller. The secondary motor cortex (M2) is also recently shown to be a critical region for motor learning on top of its well-known function for motor execution and planning. Although these two regions are known for their role in motor learning, the role of direct connection and synaptic correlate between these two regions still remain elusive. Here, we show that accelerating rotarod task successfully induces motor skill acquisition in mice which recruited neuronal activity in the motor cortex during their acquisition. We also show increased synaptic density between activated neurons of M2-M1 compared to synapses with unactivated random neurons using the dual-eGRASP technique. To sum up, this study suggests the potential importance of synapses during motor learning.

Title: Brain-wide measurement of synaptic protein turnover during learning in mice

Authors: *B. MOHAR[1], G. MICHEL[1], V. HERNANDEZ[1], P. W. TILLBERG[1], K. SVOBODA[2,1], N. P. SPRUSTON[1];
[1]Janelia Res. Campus, Ashburn, VA; [2]Allen Inst., Allen Inst., Seattle, WA

Abstract: Cellular functions are regulated by synthesizing and degrading proteins on time scales ranging from minutes to weeks. Protein turnover varies across proteins, cellular compartments, cell types, and tissues. In the brain, circuit-specific protein turnover is thought to underlie synaptic plasticity, but current methods to track protein turnover lack cellular or subcellular resolution. We are using our recently described pulse-chase method (DELTA) to measure protein turnover with high spatial and temporal resolution throughout the body. DELTA relies on the rapid covalent capture by HaloTag of fluorescent ligands that were optimized for bioavailability *in vivo* and thus overcome the unique challenges associated with labeling in the brain. DELTA allows measurement of protein turnover with subcellular resolution and at brain-wide scales. We found that the nuclear protein MeCP2 shows brain-region- and cell-type-specific turnover, and the synaptic protein PSD95 is destabilized in specific brain regions and dendritic compartments following behavioral enrichment. We are now using DELTA in knock-in mice expressing GluA2-HaloTag fusions, to localize brain regions associated with learning a virtual reality task.

Title: Attempt to quantify the segmentation of continuous input by a cultured neuronal network

Authors: *K. NITTA[1], S. KUDOH[2];
[1]Kwansei Gakuin Univ., Sanda Shi/Akashiadai, Japan; [2]Kwansei Gakuin Univ., Sanda, Hyougo, Japan

Abstract: Analysis of the cultured neural network, considered to be the smallest unit of the brain, will lead to an understanding of fundamental functions of the human brain, such as learning. Previous studies have shown that a cultured neural network can retain the history of the previous two stimuli when they are applied continuously at 2-second intervals. In this study, we hypothesized that the human brain learns by segmenting a sequence of stimuli into smaller units, and we tested this hypothesis by applying continuous stimuli to a cultured neural network, a model of the human brain. The stimuli applied in uniform frequency of occurrence for all stimulus patterns consisting of a set of three stimuli (triplet), and analyzed the evoked responses to each stimulus. A sequence of 974 stimuli at 2-second intervals was used as a single sequence. The bursts immediately after the stimuli were detected from the spike group at 100 ms after the stimuli, and the firing patterns of the evoked responses to the stimuli were extracted as cell assemblies. Hierarchical clustering was performed by defining each pattern as a set of firing electrodes and calculating the distance between the sets using Jaccard coefficients. The clustering threshold was set as the average of all distance values. We analyzed the response reproducibility to stimuli using our original clustering evaluation indexes, CPI (Class Purity Index), PCA (Pattern Classification Acuracy), and SiC (Similarity in Class). We analyzed the response reproducibility to stimuli using CPI (Class Purity Index), PCA (Pattern Classification Accuracy) and SiC (Similarity in Class). The results showed that the variance of all the indices in the evoked response patterns to each [triplet] set of stimuli decreased between the first and second sequences, while there was no change in the mean value of each index in the evoked response patterns to all 27 types of [triplets]. This suggests that the cultured neural network may have learned each triplet equally as a segment from the successive stimuli with equal frequency of occurrence. The number of classes obtained by hierarchical clustering using the mean of all distance values as the threshold was around 30, which was close to the number of [triplet] types. This result suggests that the clustering method used in this study is effective in classifying the electrical activity induced by the 27 triplets according to their characteristics.

Title: Cmtr1 regulates hippocampus-related long-term synaptic plasticity and memory consolidation through promoting NMDA receptor signaling

Authors: *S. AZEEM[1,2], N.-H. YEH[1], Y.-S. HUANG[1];
[1]Inst. of Biomed. Sciences, Academia Sinica, Taipei City, Taiwan; [2]Taiwan Intl. Grad. Program in Interdisciplinary Neuroscience, Natl. Yang Ming Chiao Tung Univ. and Academia Sinica, Taipei, Taiwan

Abstract: Eukaryotic mRNA is 5′-end capped with m7 guanosine, known as cap0 (m7GpppNpNp, N:any nucleotide). Cap methyltransferase (CMTR1) further catalyzes 2′-O-ribose methylation of the first transcribed nucleotide (N1 2′-O-Me) to produce the cap1 (m7GpppNmNp)structure in all eukaryotes except yeasts. Although the cap0 structure is essential for mRNA stability and cap-dependent translation, it is not known whether cap1 modification also plays a role in regulating posttranscriptional gene expression.Our previous study found that CMTR1 deficiency affects dendritic arborization and cortical development. Because CMTR1 is highly expressed in the hippocampus, I investigated whether CMTR1 modulates synaptic plasticity and spatial memory by using conditional knockout (cKO^{Camk2}, *Cmtr1*$^{f/f, Camk2\text{-}Cre/+}$) mice whose Cmtr1 gene is ablated in the hippocampal CA1 and certain forebrain regions after postnatal 3-4 weeks, so dendritic development is not affected in CMTR1-cKO^{Camk2} mice. We found that CMTR1-cKO mice showed impaired memory consolidation in Morris water maze assay. Although one train of high-frequency stimulation (HFS) and theta-burst stimulation (TBS)-evoked long-term potentiation (LTP) was comparable between cWT and cKO mice, protein synthesis-dependent long-lasting LTP elicited by 4 trains of HFS and TBS was diminished in the cKO group. Moreover, I found that the number but not the size of dendritic spines was reduced in CMTR1-knockdown cortical neurons, suggesting the role of CMTR1 in synaptogenesis. My transcriptome study projects the possibility of that downregulated N-methyl-D-aspartate receptor (NMDAR)-related pathways may account for behavioral and electrophysiological defects. The reduction of NMDAR subunits, NR2A and NR2B, was confirmed by qRT-PCR.Intraperitoneal injection of D-cycloserine, a NMDAR coagonist, right before spatial learning seems to rescue the behavior defect. Further study is required to understand the molecular mechanism underlying impaired memory consolidation in CMTR1-cKO mice and whetherthe catalytic activity of CMTR1 is crucial for synaptic plasticity

and memory.Keywords: CMTR1, mRNA capping, NMDARs, synaptic plasticity, hippocampus, memory

Title: Biliverdin Reductase Facilitates Synaptic Plasticity via Redox Homeostasis

Authors: *S. J. TRIPATHI[1], C. VASAVDA[2], R. KOTHARI[2], R. TOKHUNTS[2], S. CHAKRABORTY[1], S. H. SNYDER[1,2,3], B. D. PAUL[1,2,3,4];

Abstract: Bilirubin, an essential product of heme catabolism, is a potent antioxidant and exerts protective effects at physiological concentrations. Biliverdin reductase A (BVRA) is the main biosynthetic enzyme that converts biliverdin to bilirubin. Although bilirubin is one of the most commonly measured metabolites in the blood, its exact functions in the brain are less explored. Given that the brain is lipid-rich, metabolically active, and especially susceptible to oxidative stress, we hypothesized that optimal bilirubin concentrations might complement the actions of the hydrophilic antioxidant glutathione. Here, we show that bilirubin, being lipophilic, protects the lipid-rich compartments of cells and prevents lipid peroxidation and ferroptosis. In addition, we demonstrate that mice lacking BVRA display elevated lipid peroxidation in the hippocampal CA3 region, markers of ferroptosis, mitochondrial dysfunction, enlarged ventricles, and compromised ability to neutralize free radicals and are highly susceptible to neuronal damage. Interestingly, bilirubin directly scavenges superoxide radicals (O2•−) generated during mitochondrial respiration, indicating a direct neuroprotective mechanism. In addition to oxidative stress, we show that BVRA facilitates learning and long-term potentiation in CA3-CA1 synapses through the focal adhesion kinase (FAK) and modulates phosphorylation of the N-methyl-D-aspartate (NMDA) receptor, a crucial posttranslational modification for synaptic plasticity. In summary, we demonstrate BVRA and bilirubin facilitates synaptic plasticity via redox homeostasis. Moreover, pharmacotherapies enhancing BVRA and bilirubin-mediated

effects at physiological levels may afford therapeutic benefits in the management of neurodegenerative diseases.

Title: Binge drinking induces cross-species plasticity in the orbitofrontal cortex

Authors: *A. MEYERS[1], C. JOHNSTON[2], M. M. PINA[3];
[1]Neuroanatomy, Univ. of Maryland, Baltimore, Baltimore, MD; [2]Univ. of Maryland Sch. of Med. Program In Neurosci., Reisterstown, MD; [3]Anat. & Neurobio., Univ. of Maryland Sch. of Med. Program In Neurosci., Baltimore, MD

Abstract: According to the CDC, an estimated 17% of adults have engaged in binge drinking, where blood alcohol concentration (BAC) exceeds .08% within a short period of time. Binge drinking is associated with increased risk of Alcohol Use Disorder (AUD) and can induce alterations in brain regions important for executive function, specifically the orbitofrontal cortex (OFC). Alterations in OFC function have been previously associated with chronic, heavy alcohol consumption in humans and animal models. In the present work, we looked at the impact of binge alcohol drinking on different cell populations of the OFC to determine how it impacts components of this structure's microcircuitry. We used whole-cell patch clamp electrophysiology to measure binge-alcohol induced changes in intrinsic properties, excitability, and synaptic drive in OFC interneurons (IN) and pyramidal neurons (PN) in mice and rhesus macaques. In mice, binge drinking was modeled using a Drinking in the Dark (DID) paradigm. In short, mice were given access to both a 20% v/v alcohol solution and H2O for 2-h sessions (three days a week) followed by a four-hour session (fourth day) for three cycles. Following the final day of DID, mice were separated into 2 groups: 1) a 24-h withdrawal and 2) a 7-d withdrawal. In rhesus macaques, drinking was assessed using an alcohol self-administration model, in which 4% w/v alcohol was available under 22h/d open access conditions over a one-year period. In this paradigm, rhesus macaques self-select into stable drinking categories, which allowed us to compare monkeys categorized as low-drinkers to binge-drinkers. In mice, OFC PN were hyperpolarized at 24-hr and 7-day following DID as compared to water controls. This effect was not observed in PN of binge drinking macaques or IN. Membrane resistance was differentially altered in PN of mice and monkeys, with increased resistance in mice at both withdrawal timepoints and decreased resistance in binge drinking monkeys. Finally, rheobase

(minimum amount of current required for firing) in OFC PN was decreased in mice at 24h but not 7d after DID. Conversely, we found that the rheobase was increased in OFC PN of binge drinking macaques as compared to low drinkers. Our ongoing work in mice and macaques indicates that binge alcohol drinking does not substantially alter the intrinsic properties or excitability of OFC IN. Findings here demonstrate that binge drinking contributes to differential alterations in OFC neuronal subpopulations, which may help explain the persistence of binge drinking behavior and its risk.

Title: Synapse activity differentially regulates mitochondrial and lysosomal-related organelles bidirectional trafficking between synapse and soma of Aplysia presynaptic sensory neurons

Authors: *K. K. BADAL[1], Y. ZHAO[2], K. E. MILLER[3], S. PUTHANVEETTIL[4];
[1]Neurosci., The Herbert Wertheim UF Scripps Inst. for Biomed. Innovation & Technol., Jupiter, FL; [2]Scripps Res. Inst., Jupiter, FL; [3]Michigan State Univ., East Lansing, MI; [4]UF Scripps Biomed. Res., Jupiter, FL

Abstract: Cell-to-cell communication requires bidirectional trafficking of signaling and materials between the neuron's soma and axon terminal to support synapse formation and plasticity. Organelles such as mitochondria help provide energy to the cell, and lysosomes assist in recycling and degrading macromolecules and are transported bidirectionally between the soma and synapse. However, whether and how their direction, flux, and velocity of transport are modulated for synapse formation, maintenance, and plasticity remain elusive. Here, we show that in the presynaptic sensory neurons of the Aplysia gill withdrawal reflex, the formation of functional synapses leads to a bidirectional enhancement in mitochondrial flux and density and a decrease in retrograde lysosome flux and density. Enhanced mitochondrial and reduced retrograde lysosome trafficking is highly regulated by cAMP-PKA signaling in the presence of a functional synapse. Moreover, synaptic plasticity specifically increases anterograde mitochondrial transport, whereas it decreases retrograde lysosomal transport. Importantly, we find that regulation of this transport requires modulation of PKA activity. These results demonstrate the specific regulation of two different groups of organelles during various synaptic activities.

Abstract: Neurological injuries such as stroke, spinal cord injury, and traumatic brain injury usually result in chronic impairments in motor function. It is widely held that approaches that enhance synaptic plasticity in spared networks after neurological injury can advance recovery. Vagus nerve stimulation (VNS) paired with rehabilitation has emerged as one such approach. VNS evokes an increase in the release of plasticity-inducing neuromodulators which results in an increase in the cortical representation of areas activated during the paired task. As such, increasing the amount of plasticity could result in an increased degree of recovery. Several studies indicate that the stimulation parameters utilized during stimulation impact the degree of plasticity observed. In this study, we sought to identify the VNS frequency that results in the greatest enhancement of plasticity when delivered during a simple jaw training model in rats. Rats received 20Hz, 30Hz, and 45Hz of VNS concurrent with chewing in a jaw training task. After 5 days of VNS pairing, all rats underwent intracortical microstimulation (ICMS) to evaluate cortical movement representations. Current findings show a plateau effect in the jaw cortical area representation as a result of VNS induced plasticity at stimulation frequencies closer to 30Hz. The results of this study help further establish the optimal stimulation parameters for VNS and depict the importance of delivering VNS at the right frequency when used in conjunction with rehabilitation therapy.

Title: Inter-areal Routing Dynamics in Spiking Networks Depend on Local Network Activity and Cognitive States

Authors: *K. BANAIE BOROUJENI[1], T. WOMELSDORF[2];
[1]Princeton Univ., Princeton, NJ; [2]Vanderbilt Univ., Vanderbilt Univ., Nashville, TN

Abstract: In spiking neuronal networks, single neurons act simultaneously as receiver and router of information. Neurons receive synaptic information, integrate and translate local depolarization levels into spiking output that influences postsynaptic neurons. The mechanisms by which spiking networks balance the receiving and the routing functions of single neurons is only poorly understood and requires addressing two key unresolved questions. First, what is the timescale within which neuronal spiking activity engages in routing of information to neurons in distant regions of the brain? Secondly, what are the network activity states that determine whether a neuron is primarily an information receiver or a router? We addressed these questions by first using computational modeling of spiking networks which illustrated that routing states emerge dynamically as directional interactions of spiking activity at a fast ~20 ms timescale. The temporal lead and lag of routing states between interconnected networks were dynamically gated by narrow band burst events of the local field potential (LFP). These simulation results suggest that coherent network activity states facilitate the transition from receiving to directional routing in spiking networks. In a second step, we analyzed the dynamics of routing states in electrophysiological recordings of the lateral prefrontal cortex (LPFC), anterior cingulate cortex (ACC), and striatum of nonhuman primates during a task that separated attention and decision-making processes. As predicted from simulations, routing states emerged across ACC, LPFC and striatum at a fast timescale. Spike events in the LPFC led multiunit activity (MUA) in the ACC and striatum, and in the ACC, spikes preceded stronger MUA in the striatum. These routing states dynamically switched and amplified depending on the LFP state and on cognitive demands. During oscillatory bursts and at a narrow phase range of theta/alpha frequency (8-14 Hz) activity in ACC, neural spikes switched and amplified their temporal lead relative to MUA in the LPFC and striatum. During beta band (15-25 Hz) bursts in the LPFC, spikes amplified their lead over the striatum. The cognitive state likewise switched interareal routing states. Attention increased the size of a neuronal ensemble in the ACC that led LPFC and striatum during theta/alpha LFP bursts, while decision-making increased ensembles of temporally leading neurons in the ACC and LPFC over the striatum. In summary, these results show that routing states emerge in spiking networks at fast timescales and dynamically transition based on local population activity and cognitive states.

Title: Can auditory gratings excite the neuronal circuitry the way visual gratings do?

Authors: *D. GULATI, S. RAY;
Ctr. for Neurosci., Indian Inst. of Sci., Bengaluru, India

Abstract: Sensory inputs modulate local excitatory-inhibitory neuronal interactions, which, for some visual stimuli such as cartesian gratings, induce narrow-band gamma oscillations (30-70 Hz) in the visual cortex. They appear as a bump centred between 30-70 Hz with a bandwidth of 10-20Hz in the power spectra and depend highly on stimulus properties such as size and contrast (Ray & Maunsell, 2011). Interestingly, the amplitude of these oscillations has been observed to decline with healthy ageing (Murty et al., 2020) and in patients with mild cognitive impairment and Alzheimer's disease, indicating their role as a potential biomarker for detecting cognitive decline (Murty et al., 2021). However, such studies require cumbersome procedures like eye fixation and tracking, which are challenging, especially for elderly subjects. This problem can be resolved using an auditory stimulus, delivered to subjects effortlessly using loudspeakers. But it is unclear what kind of stimulus can induce such narrow-band gamma oscillations in the auditory modality.A potential stimulus can be an auditory ripple or auditory grating sounds, an acoustic analogue of visual gratings (Shamma, 2001). We hypothesized that these sounds might excite the cortex like a large-high contrast grating. Ripples span a broad frequency range, activating many neurons in the primary auditory cortex (like a large visual stimulus). Furthermore, the presence of sharp boundaries in the structure of ripples can also engage lateral inhibitory networks. To investigate if auditory ripple stimuli can generate narrow-band gamma oscillations and if they are comparable to visual gratings, we collected 64-channel EEG data from 36 subjects (mean age of 26.1±3.8 years; 18 females) as they passively listened to ripple stimuli played using loudspeakers with their eyes closed or passively fixated on the screen while presenting full-screen grating stimuli on a monitor. For the visual gratings, we observed a robust narrow-band gamma response (22-66Hz, $p<0.01$ Wilcoxon sign rank test) and alpha suppression (8-14Hz, $p<0.01$ WSR) in occipital and parieto-occipital electrodes. Contrary to our expectations, auditory gratings did not elicit narrow-band gamma. Instead, they elicited a strong broadband "high-gamma" response (70-150Hz, $p<0.05$ WSR) in the temporal electrodes near the mastoids and suppression in beta rhythm (14-26Hz, $p<0.01$ WSR) across all the electrodes. High -gamma reflects increased firing activity, indicating that the sound stimuli did excite the auditory cortex but did not engage the neural circuitry like visual gratings do.

Title: Induction of Cortical Gamma Activation through applied Electromagnetic Fields: Influence on cognitive functioning and cerebral dynamics

Authors: *B. T. DOTTA;
Laurentian Univ., Sudbury, ON, Canada

Abstract: Cognitive functioning has been repeatedly shown to be associated with gamma band activity. In fact, learning disorders and Alzheimer's disease are both associated with significant decreases in gamma activity in the brain. Recent research has demonstrated that the application of an electromagnetic field (EMF) at 40 Hz significantly reduces Alzheimer's pathologies in mice (Arendash *et al*., 2010). Because 40 Hz rests within the gamma band, we hypothesized that the application of a low frequency EMF patterned at 40 Hz would facilitate gamma activity in the brain. To test if the application of a low intensity EMF would alter cortical activity, cerebral dynamics were assessed pre- and post- EMF exposure though the use of an electroencephalogram (EEG). The EMF application geometry was placed directly on the subjects' head, and the EMF was applied via CPU to the application geometry through customized software. The duration and intensity of the EMF were 30 minutes and 5 μT respectively. Following EMF exposure, psychometric testing from the WAIS-IV was administered to assess participant's short term and working memory scores. In total, 58 healthy participants (aged 18 - 40 years) were measured in this study. Statistical analyses indicated significant increases in gamma activity in multiple brain regions following the application of a 40 Hz EMF. These increases were seen in the: left inferior frontal gyrus, the right inferior frontal gyrus, the left superior temporal gyrus, and the right superior temporal gyrus [$p<0.05$]. Additional analysis demonstrated a significant increase in working memory scores when the EMF was applied unilaterally to the left hemisphere [$t(29)=2.001$, $p<0.05$]. In summary, our results provide support that cortical gamma activity can be entrained through application of a 40 Hz EMF. The areas affected by the EMF application are also reported in the literature as correlates of working memory and cognitive functioning. That unilateral left hemisphere EMF application was associated with increases in working memory scores supports the proposed relationship between cerebral dynamics, applied EMF, and cognitive functioning.

Title: Effects of oscillating weak electromagnetic fields on EEG frequency localization in the brain following bilateral temporal electromagnetic field stimulation

Authors: *A. ZANETTI, K. SAROKA, B. DOTTA;
Laurentian Univ., Sudbury, ON, Canada

Abstract: The purpose of this study was to determine if electromagnetic field exposure modelled from physiological data would increase instances of flow in participants playing a computer game, and to determine if these fields will change the relationship between challenge and skill necessary for flow. Participants (n = 39, 18-65 years, n_{female} = 20) played the arcade game *Snake* for two ten-minute periods (each with a ten-minute rest period immediately following) at the difficulty corresponding to treatment conditions (easy, medium, and hard). For one of the trials, an electromagnetic field was applied bilaterally to the temporal lobes, with the other serving as the control. Brain activity was measured using quantitative electroencephalography, flow experience was measured using the Flow Short Scale and game play scores were also recorded. Results showed deceased beta 1 activity in the left cuneus [$t = 4.650$, $p < .01$] and left precuneus [$t = 4.603$, $p < .01$], left posterior cingulate [$t = 4.521$, $p < .05$], insula [$t = 4.234$, $p < .05$], and parahippocampal gyrus [$t = 4.113$, $p < .05$] for trials when the field was active, compared to controls during rest periods irrespective of difficulty. Deceased gamma activity was found in the right inferior temporal gyrus [$t = 6.147$, $p < .05$], right middle temporal gyrus [$t = 6.118$, $p < .05$], right superior temporal gyrus [$t = 5.861$, $p < .05$] and right fusiform gyrus [$t = 5.596$, $p < .05$] for trials when the field was active, compared to controls during play periods in the easy difficulty condition. Results from the Flow Short Scale showed a statistically significant difference in mean “concentration ease” scores across electromagnetic field conditions, irrespective of difficulty [$t = 2.131$, $p < .05$]. In all, these results seem to provide evidence supporting the ability of burst pattern EMF (6 - 20 Hz) to elicit neurological correlates of flow in brain regions previously reported in the literature and facilitate concentration.

Title: Emotionally valenced scripts and electromagnetic field effects on cerebral dynamics and working memory scores

Authors: *K. BRANIGAN, K. SAROKA, M. LARIVIERE, P. CORRADINI, B. DOTTA; Laurentian Univ., Sudbury, ON, Canada

Abstract: Current scientific literature has demonstrated that emotion has a significant influence on cognitive processing in humans. These processes include perception, attention, learning, memory, reasoning, and problem solving. Language is a pertinent facet in the processing and understanding of emotions in humans. Utilizing Whissel's *Dictionary of Affect in Language* (DAL), three stories were constructed with either positive, negative, or neutral emotional valences. Participants' cerebral dynamics were assessed using an electroencephalogram (EEG), one of the three stories were read and then participants were exposed to 30 minutes of an electromagnetic field (EMF). Following EMF exposure psychometric testing from the Wechsler Adult Intelligence Scale (WAIS-IV) was administered. A subtest of the WAIS-IV that was used was Digit Span Forward (DSF) which assesses short term memory. Majority of volunteers (N=58) were university students with an average age of 24.08 ± 4.51 (range: 19-39; gender distribution: 24 male, 34 female). Each participant was randomly assigned a condition as well as a different story. A SINE wave EMF oscillating at 40Hz was utilized because gamma activity in the brain which oscillates at 40 Hz is highly correlated with cognitive functioning in the brain. Statistical analysis revealed that with the application of a 40 Hz-based EMF the individual emotionally valenced stories had significant influences on participant's performance on cognitive assessments of the WAIS-IV. However, the control group who did not receive any EMF, were not affected on their cognitive assessment through the different stories. Volunteers who received a 40 Hz-based EMF and were read the Positive story (N=12) performed significantly higher than those who received EMF and were read the Negative story (N=14) on the DSF subtest [$t(24)=2.548$, $p=0.018$]. Additionally, those who received the Positive story and EMF performed significantly higher on the DSF than those who received the Neutral story and EMF [$t(20)=2.258$, $p=0.035$]. Following the application of EMF, those who received a positive story had significantly higher Beta activity (20-25 Hz) in the right anterior insula, when compared to those who received the negative or neutral story. The anterior insula plays a role in supporting subjective feeling states, with the ability to regulate the introduction of feelings into cognitive and motivational processes (Namkung *et al.*, 2017). In summary, these results indicate that different emotionally valenced scripts when paired with an EMF have significant effects on short term and working memory as well as areas in the brain responsible for these processes.

Title: Waveform dissociates cortical rhythms

Authors: *J. GIEHL[1,3,2], M. SIEGEL[1,3,2];
[1]Dept. Neural Dynamics and MEG, Hertie Inst. for Clin. Brain Res., [2]MEG Ctr., Univ. of Tübingen, Tübingen, Germany; [3]Ctr. for Integrative Neurosci., Univ. of Tübingen, Tübingen, Germany

Abstract: Neural oscillations have been associated with different cognitive functions and brain disorders. Recently, the non-sinusoidal waveform of oscillations has gained interest, as the waveform of neural rhythms may be closely associated with the underlying network physiology. However, waveform analysis in the time domain has been limited to dominant neuronal oscillations and by pre-selection of waveform features. Here, we contribute a novel Fourier-series based waveform analysis that allows for a comprehensive analysis of non-sinusoidal waveforms. We applied Fourier-based waveform analysis to human cortical oscillations recorded using magnetoencephalography (MEG). This approach allowed us to robustly dissociate multiple spectrally and spatially overlapping cortical rhythms across theta, alpha and beta frequency ranges in the human brain. Fourier-based waveform analysis is a powerful new tool to distinguish neuronal rhythms, and to study their spectral fingerprints in health and disease.

Title: Disambiguating phase resets from additive event-related potentials by their inter-frequency phase alignment

Authors: *A. M. HARRIS;
Queensland Brain Inst., The Univ. of Queensland, Brisbane, Australia

Abstract: Phase resets are discontinuities in ongoing neural oscillations, whereby the wave abruptly transitions to some default phase (e.g., a peak), regardless of the phase of the wave a

moment earlier. Oscillations can have their phase reset by external stimulation or internal signals, and these resets are theorised to flexibly align the oscillatory activity of different brain regions for enhanced intercommunication in response to task requirements. As such, phase resets play a key role in theoretical accounts of sensory processing, attention, multi-sensory integration, speech processing, and many other areas of cognition. They have also been hotly debated as one possible generator of the event-related potential (ERP). The role of phase resets in cognition and neural processing has been difficult to study, however, because phase resets in electrophysiological data have been impossible to disambiguate from additive wave-like signals (additive ERPs) using available analysis methods. This is a problem for our understanding of neural processing because phase resets and additive ERPs have quite different computational and theoretical implications. I will present work describing a method for detecting phase resets in electrophysiological data using an inter-frequency phase alignment metric. This method works well on simulated data, giving strong responses to phase resets but not to additive ERPs with very similar spectral properties. I will also present the results of applying this method to several real datasets (visual stimulation, eye movements, and speech processing tasks), including showing that the P1 ERP component of the EEG is caused, in part, by a reset of ongoing oscillations, whereas later ERP components are not. This method provides an exciting avenue for the empirical examination of phase resets, and to begin testing theories of the roles of phase resets in cognitively-relevant neural processing.

Title: Electroencephalographic activity patterns evoked by colors and associated emotions

Authors: *P. VALDÉS-ALEMÁN, B. TELLEZ-ALANIS;
Univ. Autónoma del Estado de Morelos, Cuernavaca, Mexico

Abstract: Over the last five decades, electroencephalographic (EEG) activity patterns have been correlated with emotional responses in terms of brain hemispheric lateralization: Frontal Alpha Asymmetry (FAA) (Davidson et al., 1979). That is, increased left frontal brain activity (characterized by alpha suppression), relative to right frontal brain activity, is associated with positive emotions, and the inverse occurs with the negative ones. This has been observed with several emotional stimuli (e.g., music), but color-evoked emotions appear to be left behind. This study assessed the 37 colors from the Berkeley Color Project, which have been previously scored by subjective emotions (Palmer & Schloss, 2010), but never with EEG. In that sense, 32 participants (19 females), M = 21.4 years, SD = 3.3, right-handed, and with normal color vision, observed each color in random order for 15 s, while EEG was recorded from their right and left

frontal areas (F4 and F3, respectively), and referenced to Cz. After each color, they evaluated them subjectively with the following seven bipolar continuous scales, ranging from −100 to +100: green-red, yellow-blue, brightness, saturation, valence, arousal, and pleasure. All participants read and accepted the informed consent. EEG data was corrected for eye movement artifacts, segmented into 1 s epochs, and normalized. The absolute power of the alpha band (8—13 Hz) was calculated (Alpha Power), and natural logarithm (*ln*) was then applied. Regarding the subjective data, Valence, Arousal, and Pleasure ratings per stimulus were averaged (VAP index), meaning that greater values represent joyful and pleasurable colors, whereas sad and unpleasant colors are indicated by lower ones. The results showed that *ln*(Alpha Power) at F3 was negatively correlated with Brightness ($r_s = -.35$, $p = .03$), Arousal ($r = -.38$, $p = .02$), and the VAP index ($r = -.32$, $p = .046$). Finally, no significant correlations were found at F4. It should be noted that Brightness was positively correlated with Valence ($r_s = .68$, $p = <.001$). With these results, we found that bright, joyful, and pleasurable colors were associated with an increase of left frontal brain activity (alpha suppression), as proposed by the FAA model. On the other hand, we could argue that, in general, colors are more prone to evoke positive emotions, rather than strong negative ones, which are linked to right frontal cortex activity. These findings will help to better understand the role of FAA as a model to assess electrophysiological responses to emotions. Particularly, this study fills a gap in the study of FAA with colors as emotional stimuli in the fields of cognitive psychology and neuroscience.

Title: Synchrony of ripple oscillations in the mouse visual cortex

Authors: I. VERZHBINSKY[1], Y. BU[2], *E. HALGREN[3];
[1]Univ. Of California San Diego Neurosciences Grad. Program, San Diego, CA; [2]UCSD, San Diego, CA; [3]Radiology and Neurosci., Univ. of California at San Diego, San Diego, CA

Abstract: Conscious perception of visual stimuli involves the precise coordination of many cortical centers. In the visual cortex, information generally flows along an anatomical and functional hierarchy, but how different visual elements are seamlessly integrated into a perceptual whole remains largely a mystery. High frequency oscillatory bursts (i.e., ‘ripples’) have recently emerged as a potential substrate for the binding of neuronal activity across distributed cortical centers. Originally described in the rodent hippocampus, ripples riding on sharp waves (SWRs) have been shown to couple with ripples in the posterior parietal cortex and

index the reconstruction of spatiotemporal neuronal firing patterns essential for the consolidation of memories during non-rapid eye movement sleep. It is not clear, however, whether ripples exist in the rodent visual cortex and whether their properties are consistent with a role in binding of visual information. Here, we analyzed local field potential and spiking data in the visual cortex of mice collected as part of the Allen Brain Observatory Visual Coding study. We found that ripples occur and co-occur with zero phase lag in primary visual cortex and all higher visual areas with a stereotyped frequency of ~160 Hz and duration of ~70ms (similar to ripples found in the hippocampus). Surprisingly, spontaneously-evoked ripples in the deeper layers of visual cortex co-occurred more frequently with ripples in other cortical parcels than with ripples in higher layers within the same parcel. Ripple co-occurrence was most pronounced between the deepest layers of posteromedial area (VISpm) and anteromedial area (VISam), which both sit atop the visual cortex hierarchy. Ripple co-occurrence also increased co-firing between involved cortical sites. These results provide preliminary evidence that ripples occur in the murine visual cortex and may help integrate neuronal activity between separated cortical centers. Future work should: (1) explore which mechanisms generate visual cortex ripples and facilitate their co-occurrence; (2) further examine the focality of ripple events; (3) characterize how ripples may facilitate neuronal interactions; and (4) quantify how ripple occurrence in different cortical sites lock to visual stimuli.

Sch., Chestnut Hill, MA; [9]Dept. of Neurol., VA/Mass.General Hosp./Brown U, Boston, MA; [10]Dept Neurol, Mass Genl Hosp, BOSTON, MA

Abstract: Synchronous bursts of high frequency oscillations (‘ripples’) are hypothesized to contribute to binding by facilitating integration of neuronal firing across cortical locations. We tested this hypothesis using local field-potentials and single-unit firing from four 96-channel microelectrode arrays in supragranular cortex of 3 patients. Neurons in co-rippling locations showed increased short-latency co-firing, prediction of each-other’s firing, and co-participation in neural assemblies. Effects were similar for putative pyramidal and interneurons, during NREM sleep and waking, in temporal and Rolandic cortices, and at distances up to 16mm. Increased co-prediction during co-ripples was maintained when firing-rate changes were equated and were strongly modulated by ripple phase. Co-ripple enhanced prediction is reciprocal, synergistic with local upstates, and further enhanced when multiple sites co-ripple. Together, these results support the hypothesis that trans-cortical co-ripples increase the integration of neuronal firing of neurons in different cortical locations, and that enhanced integration is not secondary to increased firing but does depend in part on phase-modulation.

Title: Visual working memory content is encoded by weak but spatiotemporally coordinated oscillatory power fluctuations

Authors: *V. LIMA CORDEIRO[1], S. J. HOFFMAN[2], N. DOTSON[3], C. M. GRAY[4], A. BROVELLI[1], D. BATTAGLIA[1];
[1]Aix-Marseille Univ., Marseille, France; [2]Montana State Univ., Bozeman, MT; [3]6455 LA JOLLA BLVD, UNIT 140, Salk Inst. for Biol. Studies, LA JOLLA, CA; [4]Montana State Univ. Bozeman, Montana State Univ. Bozeman, Bozeman, MT

Abstract: Working memory requires large-scale coordination among widespread brain regions. Long-range coherence between the oscillatory activity of cortical regions, arising in multiple frequency bands, may be a mechanism supporting information routing and integration across distributed networks.
Here, we perform a time-resolved spectral analysis of local field potentials (LFPs) recorded simultaneously from dozens of cortical areas in non-human primates performing a visual delayed match-to-sample task. We define a novel type of neural activity events, which we call “crackles”. A crackle is a transient upward modulation of the average oscillatory power (spatially and spectrally localized). A minority of “crackles” are also “bursts” as they correspond to strong transient increases of power. However, most crackles are not bursts, because the power remains overall weak even at the fluctuation peak (and thus unlikely to generate modulations of postsynaptic excitability).
We find that a multiplicity of regions undergo task-related modulations of crackling intensity and probability across many frequency bands (alpha to gamma), with a subset of frontoparietal regions exhibiting a ramping crackling probability through the delay period of the task. Furthermore, these modulations of crackling activity carry mutual information about the identity of the visual stimulus held in working memory.
Remarkably, the nodes whose crackling modulations convey the most mutual information are not always the ones with the strongest oscillatory power and the more prominent oscillatory activity. On the contrary, the nodes with the highest stimulus-related mutual information have weak average oscillatory power, but tend to crackle in a temporally coordinated manner with other regions. This creates windows of opportunity where nonlinear integration can take place through the formation of “co-crackling assemblies”. In other words, the regions whose LFP power encodes the most working-memory content are not the one with the strongest, but with the most entangled oscillatory crackles.
We propose alternative scenarios for interpreting our results and favor the hypothesis that stimulus is encoded within low-dimensional subspaces of distributed, but coordinated system's activity. In this view, entangled power fluctuations may be the signature of the system operating within a specifically-adapted processing mode, but they would not necessarily mediate, by themselves, inter-regional communication (even if many weak crackles could still collectively boost integration via their coordination)

Title: Encoding and decoding visuomotor task and behavioral parameters using spectro-laminar beta rhythm patterns in macaque motor cortex

Authors: *L. LÓPEZ-GALDO[1], S. NOUGARET[1], D. BATTAGLIA[2,3], B. E. KILAVIK[1]; [1]Inst. de Neurosciences de la Timone (INT), UMR 7289, CNRS, Aix-Marseille Univ., Marseille, France; [2]Inst. for Systems Neurosci. (INS), UMR 1106, Inserm, Aix-Marseille Univ., Marseille, France; [3]Univ. of Strasbourg Inst. for Advanced Studies (USIAS), Strasbourg, France

Abstract: Beta rhythms are ubiquitous in the motor cortex, and many functional roles were proposed. We recently described a double-dissociation between different beta bands in macaques local field potential (LFP), with low beta (<20Hz) in primary motor cortex (M1) correlating with movement preparation and spontaneous postural dynamics, and high beta (>20Hz) in dorsal premotor cortex (PMd) correlating with temporal task prediction and dynamical visuospatial attention (Nougaret et al. 2023, bioRxiv, doi:10.1101/2023.03.28.534535). Even within the low and high beta bands, individual beta events are highly heterogeneous in their temporal, spectral and spatial dynamics. We here explore single-trial spectro-spatial beta rhythm patterns in motor cortical laminar recordings in two male macaques during visuomotor behavior, to determine their relationship to different aspects of the behavioral task and performance. In order to incorporate the laminar dimension to this analysis, we applied Non-negative Tensor Factorization (NMF) to time-frequency single trial LFP data, to decompose it into spectro-spatial patterns. We found that these patterns underwent fluctuations in amplitude, and we termed moments with relatively high amplitude of a pattern "*crackles*". Crackles resemble "bursts", although their overall amplitude could be weak compared to total LFP power in the beta range. The rates of occurrences of crackles for individual patterns were characteristically modulated by the task, and encoded task-related information. Furthermore, they could be used as features for decoding. Specifically, there was significant Mutual Information (MI) between crackles and task conditions, which allowed us to build a random forest decoder able to extract the identity of the condition cue from the "instantaneous" crackling rate of the patterns within single trials. In conclusion, the power across the total beta range can be decomposed into multiple spectro-laminar patterns that correlate with the behavioral task. These spectro-laminar patterns might reflect specific neuronal subpopulations or network states.

Title: Real-time EEG-TMS motor mapping to evaluate phase-specific trends in mu and beta rhythms

Authors: *Z. HAIGH[1], M. WISCHNEWSKI[1], S. SHIRINPOUR[3], I. ALEKSEICHUK[2], A. OPITZ[2];
[2]Dept. of Biomed. Engin., [1]Univ. of Minnesota, Minneapolis, MN; [3]Univ. of Minnesota Twin Cities, Minneapolis, MN

Abstract: Transcranial magnetic stimulation (TMS) is an increasingly popular neuromodulation technique for therapeutic and diagnostic use in research and clinical settings. However, TMS is susceptible to variability, especially in populations with neurological abnormalities. Therefore, individualized TMS treatment is warranted. The recent development of real-time electroencephalography-TMS (EEG-TMS) created novel pathways toward such patient-specific applications. One limitation to EEG-controlled approaches is the low spatial resolution of the method. As such, it is important to characterize the spatial dependencies of EEG-TMS effects. In this study, we use TMS motor mapping to explore the spatial effects of EEG-TMS in the two prominent sensorimotor EEG rhythms, mu (8-13 Hz) and beta (14-30 Hz). Twenty participants were recruited for participation. Magnetic resonance imaging (MRI) was collected to identify anatomical and functional (fMRI) relationships within the data. Then we performed EEG-TMS over a pseudorandom grid surrounding the primary motor cortex. Four brain states were targeted, specifically, peak, falling, trough, and rising phase of the sensorimotor mu and beta rhythms. Electromyography (EMG) was recorded from the first dorsal interosseus (FDI) and abductor digiti minimi (ADM) muscles to identify changes in cortical excitability. The cortical location and orientation corresponding to the TMS-induced motor evoked potentials (MEP) were recorded using neuronavigation. The spatial data was projected to a 2-D plane the MEP data is fitted to the plane. To quantify the spatial effects of EEG-TMS, we evaluated the motor map in three ways. Traditional motor mapping uses center of gravity, area of activation, and volume of activation. Cortically localized motor mapping uses electric field stimulation to regress standard motor maps to the cortical surface for anatomical comparisons. Task- and resting state-fMRI provide correlations between TMS motor maps and functional connectivity. Preliminary results suggest elevated cortical excitability at the trough of the beta oscillation (1.08 ± 0.05 mV) compared to the peak (0.96 ± 0.06 mV) in and around the center of the spatial map. Ongoing analyses will further explore the spatial extent of this effect, compare frequencies at different spatial locations, and investigate covarying effects of individual differences in MRI and fMRI. Ultimately, this study will characterize spatial heterogeneity of brain states during real-time neuromodulation, which allows us to provide recommendations for accurate translation of EEG-TMS to clinical targets in and outside the motor cortex.

Title: Canonical cortical circuits maximize high-order synergies for multi-frequency communication

Authors: *S. N. CASTRO[1,2], R. HERZOG[3], M. HELMER[4], D. BATTAGLIA[5,2];
[1]Inst. de Neurosciences des Systèmes, UMR1106, Aix-Marseille Univ., Marseille, France; [2]Lab. De Neurosciences Cognitives Et Adaptatives (LNCA), UMR7364/CNRS - Univ. de Strasbourg, Strasbourg, France; [3]ICM Inst. for Brain and Spinal Cord (Institut du Cerveau - Paris Brain Inst. - APHP - INSERM - CNRS - Sorbonne Université), Paris, France; [4]Yale Univ., New Haven, CT; [5]INS, Univ. Aix-Marseille, INS, Aix-Marseille Univ., Marseille, France

Abstract: The functional connectivity between cortical regions can be divided into bottom-up and top-down pathways, each utilizing a specific frequency band. These frequencies emerge at the regional scale through oscillations on different cortical layers. Explanations for the origin and utilization of this frequency communication range from a structural basis, such as specific cellular types (PV, SOM) for each frequency band, to its function as multiplexed communication with high frequency for bottom-up and low frequency for top-down. By employing rate models of coupled regions embedded in a realistic multi-layer cortical organization, we demonstrate that different layers exhibit specific and segregated frequencies. Deep layers display low frequencies, while superficial layers exhibit high frequencies. This finding is surprising because, in our model, each layer includes identical excitatory and inhibitory populations without laminar-specific resonances. We demonstrate that this frequency segregation is a by-product of self-organized collective dynamics rather than hardwired anatomy or interneuronal diversity.
Next, we evaluated the communication between two hierarchically distinct cortical regions using spectral Granger causality. The model confirms empirical results, showing that communication is possible for bottom-up in high-frequencies and top-down in low frequency. However, the model's explanatory power extends beyond this, demonstrating that top-down communication can flexibly change from low to high frequency. This modulation is finely adjusted by contextual inputs (e.g. salience/attention) or the weight of interregional connections.
We find then that the emergence of dynamic regimes with frequency segregation is non-trivial and tightly related to canonic circuit wiring as not arising in randomized multilaminar circuits. We thus speculate that this special connectome has been selected because of the peculiar functional advantages it confers. Through information theoretical analyses (in terms of S- and O-information), we find that the canonical circuit has exceptional information processing properties, since it gives rise to collective dynamics simultaneously maximizing "complexity" (coexistence of integration and segregation) and inter-regional "synergy" (beyond communication). In this view, the emergence of frequency-segregation would not be an aim by itself but rather the unsought-for but necessary consequence -a spandrel- of maximizing inter-layer and inter-regional entanglement.

Title: Brain network hypersensitivity underlies pain crises in sickle cell disease

Authors: *P. JOO[1], U. LEE[1], R. HARRIS[1,2], Y. WANG[3,4];
[1]Anesthesiol., Univ. of Michigan, Ann Arbor, MI; [2]Anesthesiol., Univ. of California, Irvine, CA; [3]Dept. of Anesthesia, [4]Div. of Hematology/Oncology, Dept. of Med., Indiana Univ., Indianapolis, IN

Abstract: Sickle cell disease (SCD) is a genetic disorder characterized by abnormally deformed blood cells causing vessel blockages and vascular occlusion crises (VOCs). During VOCs severe pain occurs when sickle-shaped red blood cells block blood flow in small vessels. The occurrence of VOCs is repetitive and unpredictable in many patients, making it difficult to timely implement preventive strategies. Here we suggest explosive synchronization (ES), a widely observed physical phenomenon characterized by abrupt phase transitions and high sensitivity near the critical point, as a novel approach to address this challenge. We previously demonstrated that a network mechanism of ES and hypersensitivity is involved in chronic pain in patients with fibromyalgia. We hypothesized that, changes in the default mode network (DMN) connectivity as observed in patients with SCD, possibly due to the recurrent VOCs, can potentially disrupt the hub structure, leading to ES and hypersensitivity. In this study, we analyzed EEG data collected from two 24 individuals with SCD pain and 18 pain-free healthy controls. EEG recordings were acquired at rest and during painful pressure cuff application to the left calf. We aimed to investigate the relationship between frequency disassortativity (a condition for ES) of alpha waves, patient reported outcomes (PROs), and VOCs. During the eye-closed resting state, the SCD group exhibited a lower frequency of alpha waves (9.01±0.09Hz) compared to the control group (9.83±0.13Hz). During the painful stimulation, we found that the frequency assortativity of alpha waves in the SCD group displayed a significant negative correlation with three important PROs: BPI Pain Interference score (R=-0.496, p=0.010), PROMISE29 Physical Function (R=-0.539, p=0.005), and HADS Depression (R=-0.509, p=0.008). This suggests that patients with greater pain, depression and poor physical function displayed greater ES features (more disassortative frequencies). Furthermore, patients who had a higher frequency of VOCs in the preceding 12 months presented with decreased frequency assortativity (R=-0.595, p=0.001). Importantly, the occurrence of the VOCs relative to the time of EEG recordings (within 30 days) was significantly correlated with the intensity of the ES condition: the closer of the occurrence of VOCs before or after the EEG recording, the stronger frequency disassortativity. In conclusion, we provided first-of-hand evidence that supports ES as

a novel objective marker for assessing pain and VOCs in SCD. Further studies will help us to understand unique brain network features in SCD with recurrent VOCs and pre-empt the occurrence of VOCs.

Title: Probing Neural Alterations in the Wall of the Abnormal Brain Cavity: An Electrophysiological Investigation in Rats

Authors: *U. KILIC[1], B. ASAMOAH[3], Z. DENG[1], M. MCLAUGHLIN[1], B. NUTTIN[2]; [1]Dept. of Neurosciences, [2]Dept. of Neurosurg., Catholic Univ. of Leuven, Leuven, Belgium; [3]Ctr. for Neurosci. and Dept. of Neurobiology, Physiol. & Behavior, Univesity of California Davis, Davis, CA

Abstract: Cortical stimulation holds promise as an effective approach for addressing post-stroke motor impairment. Previous attempts at stimulating the perilesional cortex using epidural electrodes for post-stroke impairments have encountered challenges, potentially due to limited spatiotemporal precision. Besides, the formation of an abnormal cavity (aBC) following a stroke presents an opportunity for a new strategy involving electrical stimulation to enhance motor recovery. Utilizing more compliant and flexible arrays, the immediate surface of the aBC can serve as a neuromodulation interface for treating post-stroke impairment. However, a deeper understanding of the neuronal dynamics within the aBC wall is necessary for precise targeting, thereby opening avenues for spatiotemporal stimulation of the aBC wall to alleviate post-stroke motor impairment. This project aims to investigate the altered neurophysiological dynamics within the aBC wall. In this study, local field potentials (LFP) in the forelimb motor cortex (MC) of eleven male Sprague-Dawley rats were unilaterally recorded using a 32-channel recording probe. Subsequently, stereotactic aspiration of the MC was performed at that location to mimic an aBC. LFP recordings were repeated using the same probe, both within and around the aBC wall, approximately one hour (acute) and one week (chronic) after inducing the lesion in an anesthetized setup. Pulsed electric stimulation was applied to the contralateral forelimb muscles in all conditions, and evoked potentials were recorded through the same implanted probe. The LFP measurements revealed a sudden decrease in power within the delta and alpha bands in the acute cavity plane compared to healthy conditions, which depended on the depth of electrical contact. Conversely, in the chronic cavity, a more heterogeneous response was observed, with some regions exhibiting recovery through local field potential power in specific frequency bands,

while others experienced further deterioration. Meanwhile, in the acute cavity, the amplitude of evoked potentials was significantly reduced compared to the response observed in a healthy MC. In chronic conditions, partial recovery of the evoked potential amplitude was observed. Our study reveals changes in both spontaneous and evoked neural activity following aBC formation in the rodent motor cortex. Mapping these changes within the aBC wall can help identify optimal stimulation sites to improve motor deficits.

Title: Alpha oscillations mediate directed interbrain synchronization in socially interacting ferrets.

Authors: *M. ZHANG[1,2,3], D. PATEL[3,2,4], S. RADTKE-SCHULLER[3,2], F. FROHLICH[3,2]; [2]Carolina Ctr. for Neurostimulation, [3]Psychiatry, [4]Biol., [1]Univ. of North Carolina Chapel Hill, Chapel Hill, NC

Abstract: Social interaction plays a key role in shaping human cognition and mental health. Canonical paradigms in social neuroscience focus on recording the brain activity of individual subjects performing a specific perceptual or behavioral task. Recently, the social brain has been increasingly studied in more naturalistic and interactive settings, where brain activity from multiple interacting people is simultaneously recorded, a technique known as “hyperscanning.” This has led to the discovery of interbrain synchronization in humans in various types of social interaction, from musical performances to classrooms. Greater interbrain synchronization has been correlated with greater social engagement in humans. Two commonly observed brain oscillations mediating interbrain synchronization in humans are frontal theta oscillations (4-8 Hz) and parietal alpha oscillations (8-12 Hz). To further investigate the neural mechanisms of interbrain synchronization, hyperscanning experiments emerged in the study of animal social interactions. While different forms of synchronization have been observed across the frontal cortex of interacting animals in various species, region- and frequency-specific findings analogous to those of humans are yet to be demonstrated. Here, we introduce domestic ferrets (*Mustela putorius furo*) as a novel animal model for studying interbrain synchronization. Ferrets

are gregarious animals that exhibit strong social-cognitive skills, visuomotor communication, and vocalization. They also exhibit human-homolog theta and alpha oscillations in the frontoparietal network while performing cognitive tasks. Thus, we hypothesized that frontal theta oscillations and parietal alpha oscillations of the ferret brain would mediate interbrain synchronization during social interaction. Electrophysiology in the premotor cortex (PMC) or the posterior parietal cortex (PPC) was simultaneously recorded in pairs of animals during free social interaction. Preliminary analysis of one pair of animals demonstrated that interbrain synchronization during active social interaction is primarily mediated by directed coupling between the alpha oscillations in the PPC of the two animals. We did not observe significant synchronization in PMC between the two animals in any frequency bands, including the theta band. Our findings demonstrate the importance of PPC alpha oscillations, over PMC theta oscillations, in mediating interbrain synchronization during social interaction between ferrets. This work also demonstrates the value of using ferrets as an animal model for studying interbrain synchronization comparable to that of humans.

Title: Causal role of frontoparietal theta oscillations in the ferret during the 5-choice serial reaction time task

Authors: *G. ROSS[1,2,3], A. HUANG[2,3], P. SIEKIERSKI[2,3], M. ZHANG[2,3], J. HOPFINGER[4], S. RADTKE-SCHULLER[2,3], F. FROHLICH[2,3];

Abstract: Introduction: The dorsal frontoparietal network (dFPN), including dorsal frontal cortex (dFC) and posterior parietal cortex (PPC), generates top-down control signals through corticocortical oscillations during cognition. Theta oscillations appear to coordinate activity in the dFPN during cognitive tasks, including sustained attention. Yet, whether theta oscillations within the dFPN play a causal role in sustained attention remains unknown. **Methods:** To

investigate sustained attention, we trained animals in the 5-choice serial reaction time task (5-CSRTT), a preclinical analog of a human sustained attention task. We recorded multi-site electrophysiology and implemented frequency-specific optogenetic perturbations in the freely moving ferret (*Mustela putorius furo*) during the 5-CSRTT. We refined the 5-CSRTT into two behavioral contexts; "hard" and "easy". Task difficulty was determined by length of delay period an animal must wait to respond to a visual stimulus for reward. The peak of frontal theta activity (~5 Hz) for each animal was extracted from endogenous activity. Optogenetic stimulation was delivered via light pulses to the dFC during the 5-CSRTT, while recording local field potential and single-unit activity from dFC and PPC. **Results and Discussion:** We were successful in creating two behavioral contexts of the 5-CSRTT by modulating delay length. The "hard" version of the task significantly degraded task performance, reflected in reduced accuracy ($p = 0.008$) and increased occurrence of premature touches ($p < 0.001$). Animals responded to the visual stimulus faster in the "hard" condition compared to "easy" ($p < 0.001$), indicating that animals were more engaged in the more difficult version. We modulated single unit activity in the dFC with temporal and frequency precision during the delay period of the 5-CSRTT across conditions. We successfully drove network connectivity with theta stimulation in the "easy" task condition, measured by phase locking value. We observed improved task accuracy ($p = 0.0728$) driven by a reduction in omissions ($p = 0.068$) in the "easy" task condition, but did not observe altered functional connectivity or behavior in the "hard" condition. **Conclusion:** We demonstrated a context-dependent effect of rhythmic optogenetic stimulation on dFPN connectivity and identified a potential causal role of theta-frequency coupling within the dFPN during 5-CSRTT performance. Abstract: Accumulating evidence from wide-field imaging suggests the temporal and spatial non-stationarity of brain dynamics. However, the limited spatiotemporal resolution and large-area coverage of available electrophysiological or imaging techniques prevent the complete characterization of these non-stationary dynamics. Particularly, imaging techniques suffer from poor temporal resolution and applicability to freely-moving animals, while electrophysiological recordings are limited to frequencies above ~0.5Hz and to a limited area/dense coverage. Thus, novel methodologies are required to understand the large-scale and wide-band non-stationary dynamics of field potentials. Here, we present the use of an active, multiplexed and flexible micro electrocorticography probe based on graphene transistors, which is operated by a dedicated implantable head stage in freely moving rats. Graphene active sensors provide a stable gain in a wide frequency band, including DC, while enhancing the scalability in terms of channel count. Using 256 and 512 channel probes we recorded broadband local field potential (LFP) across a large fraction of the neocortical surface in freely behaving rats. 3D-tracking and spatio-spectral analysis of recordings over long sessions enabled automatic brain states segmentation. We identified topographic spectral characteristics of distinct states as well as the infra-slow correlates of brain-state transitions. We developed a novel approach for the detection of the spatiotemporally non-stationary LFP sources allowing the decomposition of cortical activity into spatiotemporal waves from infra-slow to gamma time scales clustering in similar topographic regions. We identified topographically localized and frequency-diverse sleep spindle and gamma oscillations that were modulated by infra-slow and slow waves. On a cycle time scale, sleep spindles and gamma oscillations presented complex phase dynamics corresponding to standing, travelling as well as spiral waves. Characterization of non-stationary cortical waves in a wide band challenges traditional views of brain oscillations, providing an alternative framework for cross-frequency coupling analysis across spatiotemporal scales, characterization of the oscillatory dynamics, interpretation of the polarity of the surface LFP signals and their spatiotemporal properties.

Abstract: While highly integrated, large sensor count probe systems have revolutionized neuroscience in recent years, the systems for distributed deployment of such tools on a global brain scale in freely moving animals are still poorly developed. Furthermore the linkage of electrophysiological signals across spatial scales often necessitates the combination of different probe types with highly divergent form factors in the same animal, making implantation challenges currently a main bottleneck for systematic cross-scale investigations. In addition, development cycles of new probe designs and integrated multi-scale sensor systems would benefit greatly from iterative tests of different device types within one animal as well as testing of one device type in quick succession in comparable conditions across different animals. Scientific use and technological development of high sensor count, multi-scale probe systems would therefore benefit greatly from cranial interfaces that combine chronic global brain access with techniques for modular, large-scale and iterative implantation of probes and mounting of supportive equipment for recordings in freely moving animals. We therefore developed such an implantation interface for modular, semi-chronic implantation of high-density surface and depth probes in rats, designed around an easy to implant and standardizable base layer supporting full brain access and head-fixation, development of surgical approaches for large bihemispheric craniotomies, exchangeable and probe penetrable skull prosthesis, and modular chronic mounting approaches for depth and surface probes or combinations thereof.

Title: Alterations of cortical and subcortical high-gamma oscillations in anticipation of reward-associated cues in visual and olfactory operant tasks

Authors: E. B.-L. MANESS[1], J. CHOI[1], M. MACIVER[1], B. KOCSIS[2], J. T. MCKENNA[1], R. E. STRECKER[1], *J. M. MCNALLY[3];

Abstract: Consciousness is comprised of a multitude of brain states that reflect varying degrees of exteroceptive awareness, which depends on specialized functional neural networks that flexibly respond to the demands of the external world. The default mode network (**DMN**) is one such large-scale brain network in humans and non-human animals that is active during introspective behavior, such as resting wakefulness. Suppression of DMN activity is essential to allow task-associated network function for goal-directed behaviors and cognitively-demanding tasks. The basal forebrain (**BF**), a subcortical region which promotes alertness and vigilance, has been hypothesized to facilitate the switch between cortical DMN activity and "task-on" network activity. DMN-like gamma activity (30+ Hz) is enhanced in both the prelimbic cortex (**PrL**), a central node in the DMN, and the BF during quiet wakefulness in the home cage, while such activity is suppressed during exploration of a novel environment, contexts that are presumed to promote or suppress DMN activity, respectively. However, such findings do not address the ability of the BF to provide instant-by-instant regulation of transitions between the DMN and network activity associated with externally guided behaviors. Thus, here we employed multi-site local field potential (**LFP**) recording techniques to measure changes in oscillatory activity in DMN-associated brain regions versus non-DMN regions during performance of two self-initiated operant tasks testing vigilant attention, the rodent psychomotor vigilance task (**rPVT**); and executive control, the odor discrimination Go/No-Go (**GNG**) task. In both tasks, we observed a reduction of broadband high gamma activity (80 - 200 Hz) in anticipation of information-bearing visual and olfactory signals in regions associated with the DMN (PrL, BF, olfactory bulb) and salience network (anterior insula). Interestingly, this suppression was more profound during correctly answered trials, such as when mice released the lever within one second of signal presentation in the rPVT and either retrieved the reward in "go" trials (hit) or refrained from responding in "no-go" trials of the GNG task (correct rejection). Together, these findings support the hypothesis that the BF is an important subcortical regulator of DMN-associated cortical regions, suppressing DMN activity during task-oriented behaviors, such as when awaiting the transient occurrence of a reward-predicting stimulus.

Title: Assessing the role of interhemispheric GABAergic neurons in coordinating cortical activity

Authors: *J. URRUTIA[1], C. MORALES-MORAGA[1,2], N. SANGUINETTI-GONZÁLEZ[1], S. F. ESTAY[1], A. E. CHAVÉZ[1,2], I. NEGRÓN-OYARZO[1,3], C. Q. CHIU[1,2];

Abstract: Inhibitory neurons play an essential role in cortical computation and brain synchronization; however, they have been studied mainly in regard to their local synaptic interactions. We focused on the study of a sub-type of neocortical long-range inhibitory neurons recently described: interhemispheric long-range GABAergic neurons (Int-LRGNs) that interconnect bilateral sensory cortical areas. A substantial population of these neurons co-express parvalbumin (PV) and are fast-spiking neurons, but how they impact interhemispheric coordination of neuronal activity and shape large-scale oscillatory patterns remain unknown. To address this question, we took advantage of cell type-specific optogenetic manipulations, i.e., injection of the Adeno-Associated Virus (AAV) expressing Channelrhodopsin in transgenic mice (PV-Cre). In acute brain slices, optogenetic stimulation of Int-LRGNs evokes inhibitory postsynaptic responses in cortical neurons. In freely moving injected mice that were chronically implanted with bilateral optrodes (arrays of electrodes and optical fibers), Int-LRGNs synchronize large-scale oscillatory activity at gamma, impacting interhemispheric coupling. The results of this research contribute to understanding how Int-LRGNs shape cortical activity and impact interhemispheric coordination. Further research may shed light on their contribution to processes such as sensory perception, as well as their participation in pathological conditions in which interhemispheric synchronization is altered such as schizophrenia and autism.

Title: Gaba transport blockaded in the external globus pallidus disinhibits the thalamic reticular nucleus and desynchronized cortical beta oscillation.

Authors: *N. VILLALOBOS VÁSQUEZ[1], V. M. MAGDALENO MADRIGAL[2];
[1]Academia de Fisiología/Sección de Estudios de Posgrado e Investigación-ESM, Inst. Politécnico Nacional, Ciudad de México, Mexico; [2]Dirección de Investigación en Neurociencias, Inst. Nacional de Psiquiatria, México, Mexico

Abstract: The external globus pallidus (GP) is a GABAergic core that coordinatesfiring and synchronization in the basal ganglia–thalamic–cortical networkthrough afferents and spiking rate. In this sense, the GP sends axons to therostral sector of the reticular thalamic nucleus (RTn); however, thefunctional contribution of this pathway is unknown. The existence of theGP-RTn pathway is important since the RTn controls the flow of informationbetween the thalamus and cortex, suggesting that it contributes to corticaldynamics. In Parkinson's disease, high GABA levels alter electrical activityin the GP and contribute to motor symptoms. Under normal conditions,GABA levels are regulated by GABA transporters (GATs). GAT type 1(GAT-1) is highly expressed in the GP, and pharmacological blockade ofGAT-1 induces tonic inhibition. In this work, we investigated the effect ofincreased GABA levels (by pharmacologically blockading GAT-1 into GPwith 200 nm of tiagabine) on firing pattern in the RTn by obtaining single-unit extracellular recordings from anesthetized rats and on the motor cortex(MCx) by corticography (n=16). Our results show that high GABA levelsincrease the spontaneous activity rate of RTn neurons by 138.02 ± 19.37%and desynchronize oscillations in the beta frequency band in the MCx(diminishing the mean power spectra by 59.89 ± 11.39%). Our findingsprovide evidence that the GP exerts tonic control over RTn activity throughthe GP–RTn pathway and functionally contributes to cortical oscillationdynamics.

Title: Sex differences in LFP bursts and phase discontinuities in the Shank3B-/- mouse

Authors: *L. NELSON, R. PEIXOTO;
Univ. of Pittsburgh, Pittsburgh, PA

Abstract: Autism spectrum disorder (ASD) is a developmental disorder characterized by corticostriatal circuit dysfunction. Hyperconnectivity between frontal cortical regions such as the cingulate cortex and the dorsomedial striatum (DMS) has been found in several ASD experimental cohorts. Corticostrial hyperconnectivity is hypothesized to drive behavioral disturbances in ASD such as repetitive behaviors, language development, motor learning and social development. One model to study corticostriatal hyperconnectivity is the Shank3B loss-of-function model. Shank3B is a highly penetrant cause of ASD and the mouse model has increased corticostriatal structural connectivity during development. However, it is unknown whether there are functional changes in corticostriatal connectivity in the Shank3B mouse. Furthermore, it is unknown whether there is increased functional connectivity in the corticostriatal circuit of both male and female mice. We used dual in vivo setup to record neural activity from the anterior cingulate cortex (ACC) and dorsal striatum (DMS) in juvenile male and female Shank3B+/+ and Shank3B-/- mice. We analyzed different properties of the LFPs such as LFP bursts and phase discontinuities. Bursts represent periods of increased LFP activity and show increased power in the theta and gamma bands. Phase discontinuities may represent the disruption of fluid coordination of neural information processing. Preliminary data suggests that the LFP bursts are less frequent but longer in the Shank3B-/- ACC and DMS with a stronger effect in females. When we analyzed phase discontinuities, we found that females had increased phase discontinuities in the beta band (12-30 Hz). In the DMS we found a potential interaction effect where Shank3B-/- males have increased phase discontinuities in the gamma band (30-80 Hz) and Shank3B-/- females have decreased phase discontinuities in the gamma band (30-80 Hz). These data suggest that there are changes in processing of neural information that differs across sexes. There are very few studies analyzing the differences between sexes in both normal and abnormal circuit thus these studies provide new insights into the functional circuit differences between males and females. Future work will include analyzing spike data from the same recordings to see if there are any changes at the single neuron level and determining synchronization between the ACC and DMS.

Abstract: Glucose represents the principal brain energy source. Thus, not unexpectedly, genetic glucose transporter 1 (Glut1) deficiency (G1D) is synonymous with encephalopathy. G1D seizures, which constitute a prominent disease manifestation, often prove refractory to medications but may respond to therapeutic diets. These seizures are associated with aberrant thalamocortical oscillations as inferred from human electroencephalography and functional imaging. Mouse electrophysiological recordings indicate that inhibitory neuron failure in the thalamus and cortex underlies these abnormalities. This provides the motivation to develop a neural circuit testbed to characterize the mechanisms of thalamocortical synchronization and the effects of known or novel interventions. We used *ex-vivo* mouse thalamocortical slices on microelectrode arrays and characterized spontaneous low (0.1-4 Hz) frequency oscillations and gamma (30-60 Hz) oscillations under near physiological (2.5mM) and high (20mM) bath glucose concentrations. Using the cortical recordings from layer IV, we quantified oscillation epochs via an automated wavelet-based algorithm. Acknowledging that both persons and mice with G1D exhibit neurophysiological changes upon neural fuel administration, we asked if our slice model captured relevant changes in low and high frequency oscillations. Under near physiological bath glucose, G1D slices exhibited low frequency oscillations at a rate of 0.03 ± 0.02 per second (mean ± SEM, n=6 slices from 3 mice) with an average duration of 1.57 ± 0.03 seconds. Gamma oscillations, which were sparser, occurred at a rate of 8 ± 0.7 mHz, with an average duration of 1.63 ± 0.26 seconds. High bath glucose resulted in a significant ($p < 0.05$, paired t-test) decrease in low frequency oscillations by 13.4 ± 7.2 % (or a rate of 24 ± 20 mHz), whereas the gamma oscillatory events rose by 53.2 ± 16.9 % (or a rate of 12 ± 0.1 mHz). There was no significant change in epoch duration for these broad bin low (1.55 ± 0.23 seconds) or high (1.49 ± 0.1 seconds) frequency oscillations under high bath glucose. However, specifically for 2 to 4.8 Hz oscillations a significant decrease in epoch duration under high glucose was exhibited (2.5 mM glucose: 1.34 ± 0.03 seconds; 20 mM glucose:1.19 ± 0.02 seconds, $p < 0.01$, paired t-test). Increased bath glucose reduced the low frequency oscillations while augmenting the gamma oscillations, likely reflecting strengthened inhibitory neuron activity. This approach provides an *ex vivo* method for the evaluation of mechanisms, fuels, and pharmacological agents in a crucial G1D epileptogenic circuit.

Title: Phase lock of gamma wave by aurally presenting tones amplitude-modulated at 40 Hz

Authors: *Y. NAGATANI[1], K. TAKAZAWA[1], K. MAEDA[2], A. KAMBARA[3], Y. SOETA[3], K. OGAWA[2];
[1]Pixie Dust Technologies, Inc., Tokyo, Japan; [2]Shionogi & Co., Ltd., Osaka, Japan; [3]Natl. Inst. of Advanced Industrial Sci. and Technol., Osaka, Japan

Abstract: [Motivations] The gamma-band brain activities or entrainments corresponding to sound stimuli are expected to be effective for preventing cognitive diseases. In many studies, a pulse train, the intermittent sound, is used as the stimuli. In this study, we have focused on the type or the modulation functions. [Methods] Eight stimuli were used: sinusoidal waves at 40 Hz (low frequency sound) and 1 kHz (normal tone as control); sinusoidal waves at 1 kHz which are amplitude-modulated (modulation ratio was 100 %) by 20, 40, and 80 Hz sinusoidal wave, 40 Hz sawtooth wave, and 40 Hz inverse-sawtooth wave; a pulse train containing single 1 kHz sinusoidal pulses with a repetition period of 25 ms. The duration of all stimuli was 500 ms including 0.3 ms tapers. All stimuli were presented to the participants at the A-weighted equivalent noise level of 60 dB via headphones. Each stimulus was randomly presented 100 times. For the measurement of EEG signals, 26 participants with no medical history on hearing were employed (22.7 ± 2.1 years). The experiment was performed in accordance with the protocol approved by an ethical review committee. The result at T6 channel is reported as representative in this abstract. The time-frequency analysis of the EEG signals was performed by using continuous wavelet transform with complex Morlet wavelet. Then, the phase locking index (PLI) of each stimulus was calculated. Finally, the PLI values within the presenting area were temporally averaged with phase adjustment to derive a representative scalar value of the degree of phase locking for each stimulus. [Results and Discussions] First, the temporal mean of the PLI at 35 Hz, which is out of the modulation frequency of the stimuli, is checked. The PLIs of all stimuli was around 0.3 without showing any statistical significance. It implies that the phase was moderately locked to the onset timing of the stimuli regardless of the signal component and/or the shape of the envelope since the duration of the stimuli was short enough to keep the synchronization. The continuing duration of the locking should be checked in the future work. In

contrast, the result of 40 Hz showed different tendency. All stimuli with 40 Hz modulation or 40 Hz pulse as well as the 40 Hz resulted in stronger locking with statistical significance to the non-modulated sound while the 20 Hz and 80 Hz modulation result in no difference. In addition, the inverse-sawtooth modulation did not statistically show difference to the pulse train. The result leads us to the expectation that the target sound to be modulated can be arbitrarily selected for the purpose of brain wave synchronization, which may be useful for the future clinical use for dementia prevention.

Abstract: Human neurons exhibit distinctive structural and functional qualities, making studies using human tissue particularly valuable for gaining mechanistic insights into the functioning and pathologies of the human brain. The use of *in vitro* human brain slices preserves the complex

cytoarchitecture and functional local microcircuits, therefore comprising a close representation of local networks *in vivo*. Here, we aimed to provide a two-dimensional characterization of human cortical dynamics during spontaneous cortical activity and in response to pharmacological and electrical modulation. We resorted to cortical tissue from patients with pharmacoresistant epilepsy and brain tumors undergoing resective surgery, cut into 400 μm thick slices. Local field potentials were simultaneously recorded from multiple cortical columns and layers using 16 and 32 multielectrode arrays. Following electrophysiological recording, cortical layers were histologically reconstructed, enabling a two-dimensional spatiotemporal profiling of spontaneous cortical events. We also studied the progressive effects of blocking $GABA_A$ receptors on cortical activity, which was transformed into epileptiform patterns. Finally, we investigated the effect of cholinergic activation by means of light, using the photoswitchable muscarinic agonist (Phthalimide-Azo-Iper (PAI)). Human slices expressed spontaneous slow oscillations, characterized by alternating periods of activity (Up states) and silence (Down states), at a frequency <1Hz. This activity presented layer-specific dynamics, with Up states initiating preferentially in deep cortical layers. Gradual blockade of $GABA_A$ receptors increased the firing rate and initially shortened Up states, eventually leading to epileptiform discharges with high network synchronization. The horizontal propagation of spontaneous slow oscillations was ca. 50 mm/s, an order of magnitude faster than the one described in other mammals. Slice illumination with white light induced the photoconversion of PAI from inactive (*cis*-) to the active isoform, *trans*-PAI. The subsequent activation of M2 muscarinic receptors of acetylcholine resulted in an increase in slow oscillation frequency. Exploring network dynamics in local circuits broadens our understanding of human cortex network mechanisms and mesoscale organization. Even when structurally the recorded slices showed no signs of dysplasia, the potential impact of patients' epileptic discharges on the tissue will be discussed. Comprehending the fundamental properties of the human cortex is a crucial first step towards the development of effective treatment strategies.

Title: Optimization of a multiplexed, cell-based assay of neuronal function

Authors: P. ELLINGSON, B. STREETER, D. SULLIVAN, A. PASSARO, S. CHVATAL, *D. MILLARD;
Axion Biosystems, Atlanta, GA

Abstract: The flexibility and accessibility of induced pluripotent stem cell (iPSC) technology has allowed complex human biology to be reproduced in vitro at high throughput scales. Indeed, rapid advances in stem cell technology have led to widespread adoption for the development of in vitro models of neuron electrophysiology to be used in screening applications in drug discovery and safety. As in vitro neuronal models become more mature, the functional electrophysiological activity may begin to reproduce low-frequency brain rhythms, in addition to the spiking, bursting, and synchronization already observed. Also, the nature of the functional activity, whether desynchronized or synchronized, may impact the utility of a model for a given application. The objective of this work is to develop and validate a functional neuronal assay that quantifies the relationship between cell health, the spiking activity of individual neurons, and the network activity embedded in the local field potential (LFP). Further, we provide a rationale for optimizing an in vitro model, including the cells and the media system. To accomplish these aims, we utilized multiwell microelectrode array culture plates, with a planar array of microelectrodes embedded into the substrate of each well. Impedance measurements were used to quantify the attachment of cells to the substrate and microelectrodes, as a measure of cell viability. Broadband (1 - 5000 Hz) electrophysiological data was acquired and then separately processed for action potential detection (200 - 5000 Hz) and low frequency oscillations (1 - 50 Hz). The power spectral density was computed from the low frequency signal sampled after network burst events, and then absolute power was computed in the delta (1-4 Hz), theta (4-8 Hz), alpha (8-14 Hz), beta (14-30 Hz), and gamma (30-50 Hz) bands. The spectral power within the LFP was correlated with the emergence of bursting activity within the rodent cortical neurons by 14 days in culture, and intra-burst oscillations in the alpha band were detected at 21 days in culture. Known reference compounds were then added to the cultures and the change in LFP features were quantified and compared with more traditional functional endpoints based on spiking activity. For example, Amoxapine reduced the burst duration and increased the network burst frequency, while also eliminating the intra-burst oscillations and thus decreasing the LFP power in the alpha band. These results support the continued development and use of in vitro neural assays for high throughput drug discovery and safety assessment.

Title: The Effect Of Network Size On The Structure Of Population Activity In Human-iPSC Derived Neurons

Authors: *Y. UZUN[1,3], R. SANTOS[4,5], C. MARCHETTO[6], K. PADMANABHAN[2,3,7,8,9]; [1]Physics and Astronomy, [2]Univ. of Rochester, Rochester, NY; [3]Univ. of Rochester Sch. of Med., Del Monte Inst. for Neurosci., Rochester, NY; [4]Binstitute of Psychiatry and Neurosci. of Paris, Paris, France; [5]Cnrs, Inst. des Sci. Ctr., Univ. of Rochester Sch. of Med., Rochester, NY

Abstract: Cell culture methods for studying population activity in human neural networks offer unprecedented opportunities to understand how the structure of circuits can give rise to complex activity patterns. Although it is generally thought that the size of the network, defined as the number of neurons that comprise the circuit, is critical for determining the dynamics of the population activity, the relationship between this structural parameter and the resultant activity patterns is unclear. Using multi-electrode arrays, we characterized the spontaneous activity in human iPSC-derived neural networks of different size as these circuits matured. We found rather counterintuitively, that networks with fewer neurons generated more complex patterns as compared to networks with a larger density of cells. Furthermore, a model of the global structure built by examining the dynamics and interactions of pairs of neurons was better at predicting the structure of activity in large networks of neurons as compared to cultures with fewer cells, suggesting that larger networks are highly interconnected and therefore more simply organized. Beyond the implications these results have for determining how to experimentally study human brain circuits in vitro, this work illustrates how a property of neuronal cultures such as the size of the network, can self-organize circuits whose dynamics differ not just in degree, but in kind.

Title: Comparative Assessment of Network Level Ca^{2+} Oscillations in 2- and 3-Dimensional hiPSC Derived and Primary Neuronal Cultures with the NeuroDeRisk Compound Set

Authors: *J. IMREDY[1], G. ROUSSIGNOL[2], H. CLOUSE[1], G. SALVAGIOTTO[3], L. MAZELIN-WINUM[2];
[1]Nonclinical Drug Safety, Merck & Co., Inc., Rahway, NJ; [2]Preclinical Safety, Sanofi R&D, Montpellier, France; [3]Fujifilm Cell. Dynamics, Inc., Madison, WI

Abstract: Human induced Pluripotent Stem Cell (hiPSC) derived neural cells offer great potential for modeling neurological diseases and toxicities and have found application in drug discovery and toxicology. As part of the European Innovative Medicines Initiative (IMI2) NeuroDeRisk (Neurotoxicity De-Risking in Preclinical Drug Discovery), we here explore the Ca^{2+} oscillation responses of 2- and 3-dimensional (2D, 3D/neurospheroid) hiPSC derived neuronal networks composed of mixtures of astrocytes and neurons of mixed glutamatergic and GABAergic activity. The test compound set (33 in total) encompasses established seizurogenic tool compounds as well as drugs that have a higher association with seizurogenic adverse events (positive) than other drugs (negative) based on the Food and Drug Administration Adverse Event Reporting System (FAERS) database. Both types of hIPSC networks were scored against Ca^{2+} responses of a mouse neonatal primary cortical neuron 2D network model serving as an established comparator assay. Parameters of frequency and amplitude of spontaneous global network Ca^{2+} oscillations and the drug-dependent directional changes to these were assessed, and predictivity of seizurogenicity scored using contingency table analysis. In addition, responses were compared between both 2D models as well as between 2D and 3D models. Concordance of parameter responses was best between the hiPSC neurospheroid and the mouse primary cortical neuron model (77% for frequency and 65% for amplitude). Decreases in spontaneous Ca^{2+} oscillation frequency and amplitude were found to be the most basic shared determinants of risk of seizurogenicity between the mouse and the neurospheroid model based on testing of the seizurogenic compound set. Increases in spontaneous Ca^{2+} oscillation frequency were primarily observed with the 2D hIPSC model, though the specificity of this effect to seizurogenic clinical compounds was low (33%), while decreases to spike amplitude were more predictive of seizurogenicity. Overall predictivities of the models were similar, with sensitivity of the assays typically exceeding specificity due to high false positive rates. Higher concordance of the hiPSC 3D model over the 2D model when compared to mouse cortical 2D responses may be the result of both a longer maturation time of the neurospheroid (84-87 days for 3D vs. 22-24 days for 2D network maturation) as well as the 3-dimensional nature of network connections established. The simplicity and reproducibility of spontaneous Ca^{2+} oscillation readouts support further investigation of hiPSC derived neuronal sources and their 2D and 3D networks for neuropharmacological safety screening.

Title: Ca^{2+}-induced Zn^{2+}spikes are generated via Zn^{2+}liberations from metallothionein III in neurons

Authors: *L. SALVAGIO[1], C. ZHANG[1], Y. QIN[2];
[2]Univ. of Denver, [1]Univ. of Denver, Denver, CO

Abstract: Ca^{2+}-induced Zn^{2+} spikes are generated via Zn^{2+} liberations from metallothionein III in neuronsCrosstalk between Ca^{2+} and Zn^{2+} ions has been demonstrated in numerous cellular processes, and previous research from our lab showed synchronous Ca^{2+} spikes that occur during critical stages of neurodevelopment can induce large increases in cytosolic Zn^{2+}, termed “Zinc spikes” in primary hippocampal neurons (Chen et al., Journal of Neurochemistry 2021). These Zn^{2+} spikes are always preceded by Ca^{2+} spikes and were found to be dependent on calcium-induced intracellular acidification. Zn^{2+} has the ability to interact with proteins as a structural element or enzymatic co-factor and has recently been thought to act as a signaling molecule. Changes in Zn^{2+} concentration may have the ability to alter the activity of proteins related to neuronal development and activity. The observation of zinc spikes introduces a new form of crosstalk between Ca^{2+} and Zn^{2+} ions and raises the question of uncovering potential roles for Zn^{2+} during neurodevelopment stages where spontaneous and synchronous Ca^{2+} spikes occur. It was hypothesized that intracellular acidification can liberate Zn^{2+} from Zn^{2+} binding proteins, like metallothiones (MT), or ligands, such as antioxidant glutathione or cysteine residues. This work aims to discover the mechanism behind how neuronal Ca^{2+} spikes produce Zn^{2+} spikes. Using fluorescence microscopy imaging, we found that Zn^{2+} spikes were evoked using various methods to induce Ca^{2+} influx, such as depolarization, glutamate activation, and optical activation in primary rat hippocampal neurons. MT3 is a brain specific isoform of the metallothiones Zn^{2+} binding proteins and can sequester up to seven Zn^{2+} ions. Reduction in MT3 expression by shRNAi reduced Zn^{2+} spikes in primary hippocampal neurons. This evidence demonstrates that MT3 may release Zn^{2+} ions upon Ca^{2+} influx and cellular acidification and therefore be responsible for large increases in cytosolic Zn^{2+} in neurons, which may be important signaling events during brain development.

Abstract: Whilst still widely used, animal experimentation shows some limits, especially in the field of neuroscience. In the last few years, cerebral organoids have appeared as relevant alternative solutions to model human cerebral cellular organization and development in 3D. Nevertheless, the implementation of organoids for large-scale drug screening in terms of efficacy and toxicity requires reproducibility and scalability. To address this challenge, we combine cerebral organoid culture with a microfluidic system, called Brain Organoid-on-Chip (Castiglione *et al*., 2022), which enables us to improve organoid culture conditions thanks to the precise modeling of cellular microenvironment. Here we present the establishment of the conditions for cerebral organoid culture in the NETRI Duplex Well microfluidic device, composed of two compartments separated by a porous membrane: 1/ a 3D organoid-culture chamber, and 2/ a perfusion channel enabling medium diffusion. Two different types of human cerebral organoid generation protocols have been assayed: unguided (adapted from Lancaster *et al.*, 2013) and cortical (adapted from Xiang *et al.*, 2017) organoids. Preliminary assays were performed to optimize on-chip cerebral organoids culture conditions, including the medium renewal procedure and an anti-adherence approach. We compared the Brain Organoid-on-Chip system to conventional culture, in terms of morphology, viability, cytoarchitecture, and transcript level of expression. The established procedure for culture medium renewal takes advantage of the perfusion channel to reduce direct medium changes within the organoid culture chamber. Following this procedure, unguided and cortical cerebral organoids were cultured for different long-term time points. They exhibited the characteristic morphologies expected from Lancaster *et al*, 2013 and Xiang *et al*, 2017. Immunofluorescence and RT-qPCR characterizations confirmed the presence of neural progenitors, mature neurons, and astrocytes. The chip design enables a reproducible culture protocol for cerebral organoids. This Brain Organoid-on-Chip platform paves the way for modeling the blood-brain barrier, and ultimately for studying the diffusion of compounds, for toxicological assessments, such as developmental neurotoxicity testing, and for efficacy screening of novel therapeutics.

Title: Diversity of network burst patterns in astrocyte enriched brain organoids

Authors: *S. E. FERNANDES[1], Y.-M. LIN[2], K. S. PRADEEPAN[3], L. ZHANG[4], M. WANG[1], J. MARTINEZ-TRUJILLO[3], F. H. GAGE[1];

Abstract: Brain organoids demonstrate some aspects of spatial-temporal brain development, including complex cytoarchitecture, resulting in a broad diversity of cell types. However, the ratio of neurons to glial cells is often disproportionately higher in brain organoids than in typical brains. Our lab has developed protocols for the generation of astrocyte-enriched organoids (AEO) containing amounts of astrocytes exceeding those of available organoid protocols. The astrocytes exhibit complex morphology by approximately day 150 in culture. Here, we first performed an immunohistochemical analysis to demonstrate that AEOs are composed of a variety of cell types including astrocytes. Second, we used multielectrode array (MEA) technology to explore neuronal and network activity patterns in the AEO. By nine months, astrocyte-enriched organoids showed spontaneous activity consisting of network bursts as well as sparsely distributed spikes. We used a burst detection algorithm that allowed detection of bursting patterns with high temporal resolution. In some AEO we found bursting patterns that evolve to repetitive high frequency reverberations resembling those previously described on monolayer excitatory networks (Abstract #12085; Pradeepan et al., 2023). However, different from patterns isolated in monolayer networks, AEO showed a much greater variety of network bursts and reverberating phenotypes, likely arising from the diversity of cell types. Third, we are exploring mechanisms that may be contributing to the diverse repertoire of network bursting and reverberating burst patterns through pharmacological treatment corroborated with immunohistochemistry. Pharmacological treatments include bicuculline (GABAAR antagonist), EGTA-AM (slow-kinetic calcium chelator), Strontium chloride (calcium-like divalent cation), artificial cerebrospinal fluid, and Sachez-Vivez (SV) solution (mimicking ionic composition of brain interstitial fluid). Our preliminary findings suggest SV solution promotes hyperexcitability in the network, resulting in increased frequency of patterned bursts. Taken together, AEOs provide evidence of mature cellular networks, diverse cell types, and complex,

electrophysiologically active neuronal networks, all of which are essential elements when modeling neurodegenerative to neuropsychiatric disorder pathophysiology.

Title: A blinded compound study on a human cortical tri-culture model using isogenic iPSC-derived cortical excitatory neurons, cortical inhibitory interneurons and astrocytes.

Authors: *S. HUMPHREYS[1], S. BROADBENT[1], S. SPRINGE[1], S. YANG[2], A. GHOSHAL[2], N. DEDIC[3], A. BARNES[1];
[1]Axol Biosci., Cambridge, United Kingdom; [2]Sunovion Pharmaceuticals Inc., Marlborough, MA; [3]Sunovion Pharmaceuticals, Sunovion Pharmaceuticals, Marlborough, MA

Abstract: As the global population ages the prevalence of neurodegenerative diseases (NDD) continues to rise to around 2% in people over 80. Despite this for many of the most common types, such as Alzheimer's, there is no cure and current treatments only management of the declining symptoms. One of the key brain areas affected by NDD is the cortex and as a result, a major area of interest for drug discovery. However, the cortex is also a complex structure and a significant site of potential neurotoxicity leading to 25% of drug attrition in full development and causing major side-effects in over 400 registered medications. The lack of physiologically relevant cortical models is a major challenge for developing better treatments for NDDs and identifying potential neurotoxic liabilities during drug development. In drug discovery, categorising the phenotypic effect of small molecules on a target tissue is a common approach. Axol have used iPSC-derived neuronal and brain immune cells in *in vitro* co-culture to recreate a cortex-like tissue for research and drug discovery approaches. In partnership with Sunovion, Axol performed a blinded study with eight reference compounds on Axol's cortical tri-culture model using an Axion MEA system. The tri-culture was maintained to Day 26 post thaw. On Day 26, 10 minutes baseline data was recorded before adding the first concentration of each compound. 10-minute recordings were taken immediately to capture any acute effects and after 60 minutes to capture longer-term effects. Following this a second concentration of each compound was added to the same wells in an accumulative manner and the process repeated. In total three concentrations of each compound were tested. Axol analysed the data and categorised each blinded compound from their observed actions into one of six groups/sub-groups. The main groups were Group 1 - "Little Effect", Group 2 - "Activators" and Group 3 - "De-Activators" which were further sub-divided into Group 2A - "Hyperpolarising", Group 2B - "Excitatory", Group 2C - "Pro-convulsant", Group 3A - "Blockers" and Group 3B - "Inhibitors". On

unblinding the study, all eight compounds were found to be correctly identified although one compound, *A* was placed into the right group as a “De-Activator” but into the wrong sub-group as it’s mode of action would be expected to be an “Inhibitor” rather than a “Blocker”. Overall, this supports the ability of Axol’s human iPSC-derived cortical tri-culture model in predicting the action of new drugs and identifying potential neurotoxic liabilities.

Title: Functional Interactions of iPSC-Derived Neuronal and Astrocytic Networks: Insights from MEA and Patch Clamp Recordings

Authors: A. MANOLE, A. RHEE, C. GAO, A. PANKONIN, S. CHIN, J. URRESTI, ***N. LIN**; Ixcells Biotechnologies, SAN DIEGO, CA

Abstract: Understanding the complexity of brain function depends on our ability to comprehend the complicated interactions that take place between various cell types in neural networks. In this study, we used multi-electrode array (MEA) and patch clamp techniques to examine the functional characteristics and interconnections of dopaminergic, sensory, motor, glutamatergic and GABAergic neurons, and astrocytes that are capable of releasing cytokines. Our findings give insight into the underlying mechanisms and shed light on the functional effects of astrocyte-neuron interactions. By employing MEA recordings, we evaluated the synchronization patterns and network activity of these neuronal groups using MEA recordings. Every neuronal subtype exhibited unique firing patterns and network dynamics that were indicative of their functional specialization. The electrical characteristics and synaptic connections within these neural circuits were also examined using patch clamp recordings. Notably, we discovered synapse-specific traits and various synaptic transmission patterns in several neuronal populations. Our research also demonstrated the critical part astrocytes play in controlling neuronal activity. We found that astrocytes secreted cytokines that affected the activity and plasticity of the nearby neurons in addition to their well-known supporting roles. The functional impacts of astrocyte-neuron crosstalk were shown by the cytokine-mediated effects on neuronal excitability and neurite outgrowth. Overall, our research offers thorough understandings of the characteristics and

interconnections of dopaminergic, sensory, motor, glutamatergic and GABAergic neural networks produced from iPSCs. Furthermore, we stress the crucial part astrocytes play in determining neuronal activity and the possible influence astrocytic cytokines may have on neuronal function. The intricate dynamics of brain networks are better understood thanks to these discoveries, which also have implications for neurodegenerative and neurodevelopmental diseases.

Title: Calcium dependent reverberating super bursts in human Rett syndrome excitatory neuronal networks

Authors: *K. PRADEEPAN[1], F. MCCREADY[2], W. WEI[3], J. ELLIS[2], J. MARTINEZ-TRUJILLO[4];
[1]Western Univ., London, ON, Canada; [2]Mol. Genet., Univ. of Toronto, Toronto, ON, Canada; [3]Developmental & Stem Cell Biol., The Hosp. for Sick Children, Toronto, ON, Canada; [4]Schulich Sch. of Med. and Dentistry, Robarts Institute, Western Univ., London, ON, Canada

Abstract: Rett syndrome (RTT) is a rare neurodevelopmental disorder caused by mutations of *MECP2*, which encodes a global transcriptional regulator. RTT patients show abnormal developmental trajectories that include epileptic seizures. Previous studies have shown human stem cell derived excitatory *MECP2* mutant single neurons have smaller cell bodies with shorter dendrites and decreased branching, decreased synaptic potentials, and hyperexcitability. Using multielectrode array (MEA) technology, researchers have begun investigating patterns of in vitro spontaneous and synchronous activity that reflect neuronal and synaptic development. Abnormal patterns of spontaneous activity reflect altered normal development. Using MEAs and standard

burst detection algorithms, MEAs demonstrate progressive synchronization between electrodes over development - indicative of neurons connecting within a network. Previously, *MECP2* mutant networks have showed decreased burst frequency interpreted as a decrease in network activity and functional connectivity compared to isogenic controls. Here, we reveal that *MECP2* deletions lead to an increase in frequency of reverberating super-bursts (RSBs), consisting of an initial large amplitude network burst followed by high frequency mini-bursts resulting in an increase in burst frequency and number of bursts - indicating hyper-activity. Pharmacological treatment of Ca^{2+} chelator EGTA-AM selectively eliminated RSBs, implicating elevated pre-synaptic calcium dynamics and rescuing the network burst phenotype. RSB were not affected by bicuculline (GABAAR antagonist). Taken together, reverberating super bursts (RSBs) present as a temporally complex dynamic that warrants careful consideration when defining bursts. Our results show that RSBs emerge early in developing neuronal networks of RTT, likely a consequence of enhanced excitability in single neurons and networks. *MECP2* mutant networks exist in a genetically pre-disposed hyperexcitable state, such that physiologically relevant stimuli are more likely to persist within the network as a reverberation. These abnormal dynamics may lead to deviations from the typical developmental trajectory that facilitate the emergence of hyper-synchronic states that contribute to seizure onset.

Title: An in vitro investigation of cortical network hyperexcitability in mouse models of ALS

Authors: *M. DOULOUDI[1], A. URBANEK[1], A. J. GRIERSON[1], J. WATKINS[2], J. DUCE[2], M. R. LIVESEY[1], R. J. MEAD[1];
[1]Neurosci., Univ. of Sheffield, Sheffield, United Kingdom; [2]MSD (UK) Limited, London, United Kingdom

Abstract: Amyotrophic lateral sclerosis (ALS) is an incurable neurodegenerative disease that leads to the progressive death of cortical and spinal motor neurons that comprise the locomotor circuit. Growing evidence indicates that cortical hyperexcitability, an early detectable electrophysiological disturbance in ALS and a driver of neuronal toxicity, is a strong candidate for driving locomotor circuit dysfunction and neuronal injury/loss. Cortical hyperexcitability, therefore, represents an attractive therapeutic target. However, the underlying drivers and

mechanisms of cortical hyperexcitability are not well understood. Multi-electrode arrays combined with *in vitro* dissociated cortical neuronal cultures provide a powerful platform to decipher mechanisms which drive excitability in transgenic mouse models of ALS and thus, pave the way for the discovery of novel therapeutics and *in vivo* testing. Using this technology, we performed a longitudinal analysis in cortical neuronal networks of different ALS mouse models with the aim of detecting changes in network excitability. We have analysed our excitability data using a multi-parameter approach, which took into consideration spike frequencies, burst duration, inter-burst intervals, individual bursts per array and number of network bursts per array, amongst other parameters. Specifically, we found early and late network excitability alterations in G93A-SOD1 derived cortical neurons consistent with a hyperexcitable phenotype, that were evidenced by decreased burst intervals (days *in vitro* 14: $p = 0.009$, days *in vitro* 21: $p = 0.012$), but not spiking frequency (days *in vitro* 14: $p = 0.396$, days *in vitro* 21: $p = 0.456$) compared to control neurons. Pharmacological interrogation of the G93A-SOD1 network disturbances by glutamatergic and GABAergic receptors blockers, uncovered that cortical hyperexcitability was accompanied by inhibitory circuitry deficits, but not changes in the excitatory input, suggesting that inhibitory transmission-related physiology is a promising therapeutic target for further investigation in rescuing the early hyperexcitable phenotype that is present in the disease. We also extended our analysis to two different C9ORF72-BAC mouse models which present molecular phenotypes only. Our results report early excitability changes in G93A-SOD1, but not in C9ORF72-BAC, cortical neurons, confirming that cortical hyperexcitability is only observed in models which go on to display a motor phenotype associated with motor neuron loss.

Title: Vagus nerve stimulation is differently integrated at the nucleus of the solitary tract (NTS) neurons during heart failure in rats.

Authors: *L. G. FERNANDES, E. BEAUMONT;
Biomed. Sci., East Tennessee State Univ., Johnson City, TN

Abstract: Vagus nerve stimulation (VNS) therapy is currently use to treat heart failure with reduced ejection fraction (HFrEF). VNS is typically used at a frequency of 5 Hz with an intensity that is sufficient to induce a slight bradycardia during stimulation. We previously shown that all

myelinated and none of the unmyelinated afferents are activated during VNS. The current study investigates the integration of vagal afferents on NTS neurons in control and HF rats (ejection fraction &lt 60%) following different VNS protocols. Sprague-Dawley rats with pressure overload underwent a thoracic aortic constriction twelve weeks prior to terminal electrophysiology experiments and were compared to healthy controls. For terminal patch clamp experiments, the brainstem was removed under isoflurane anesthesia and a horizontal brainstem slice containing the solitary tract (ST) and medial NTS was obtained. Brain slice was maintained in physiological CSF and whole-cell voltage-clamp recordings was performed. Electrical shocks to the ST produced fixed latency evoked excitatory postsynaptic currents (eEPSCs) with a jitter &lt 200usec that identified NTS neurons with monosynaptic afferent input. EPSCs with jitter &gt 200usec were considered polysynaptically innervated. ST stimulation protocols were used to mimic in vivo VNS using the following protocols: 1) continuous 5 Hz stimulation for 14 secs, 2) continuous 20 Hz stimulation for 14 secs, 3) 300Hz burst stimulation (4 pulses) for 14 secs, interburst interval (IBI) of 1 sec, 4) 300Hz burst stimulation (7 pulses) for 14 secs, IBI of 1 sec. Results showed that spontaneous EPSCs from second-order neurons in HF rats had smaller amplitude ($p < 0.05$) and frequency (p &lt 0.05) compared to sEPSCs observed control rats. VNS at 300 Hz with 4 pulses elicited an increase in evoked EPSC amplitude compared to other protocols in control rats (p &lt 0.05), but this effect was not observed in HF rats. All VNS protocols elicited asynchronous release of glutamate in TRPV1+ ST terminals, and these events were significantly more frequent (p &lt 0.05) and larger in amplitude (p &lt 0.05) in second-order neurons in controls compared to HF animals. In conclusion, second-order NTS neurons in HF rats showed significantly depressed synaptic features compared to controls. Since VNS therapy is beneficial in improving cardiac function, its effect may rely on restoration of synaptic properties for central integration of vagal afferents at the NTS level.

Title: Learning in closed-loop neural cultures embodied in virtual worlds

Authors: *W. CLAWSON, M. LEVIN;
Allen Discovery Ctr., Tufts Univ., Medford, MA

Abstract: All brains are collectives of cells embodied in a larger collective (the body) that together form an organism, whether non-vertebrate, vertebrate, mouse, or human. These bodies

are in an environment which is detected through a number of sensors, and that sensation is passed to the brain through electrical signaling. Much of learning and memory occurs in, or is directed by, the brain itself, where through neural firing and electrochemical interactions, the brain utilizes its plasticity to adapt to the environment. However, the full extent of brain plasticity - what elements of brain composition change, when, and how - is not fully understood. Additionally, the technical difficulty of in-vivo experimentation leaves much to assumption or indirect measurement. Here we propose to study the environment-brain relationship through closed-loop electrical stimulation of neural tissue culture, which is capable of the sensing, processing, learning, and action loops present in all organisms as well as being experimentally more accessible than in-vivo brains. We grow both primary cultures from wildtype embryonic mice as well as human induced neural stem cells (hiNSCs) as monolayers on a high density multielectrode array (HD-MEA) which records local field potentials (LFPs) and spiking activity in high temporal and spatial fidelity. These cultures are embodied in a virtual world after 21 days in vitro (DIV) via a closed-loop system in which neural electrical activity guides an agent's behavior in a simple computer game and the agent's interactions inside the game are encoded as stimulations given to the culture. Crucially, both the agent-environment stimulation ruleset and the location of the stimulations remain fixed throughout the training. Therefore, any change in behavior comes from the neural cultures' plasticity efforts, rather than a change of software. With this, we aim to probe a form of tissue level intelligence as only a subset of plasticity changes is available to the neural culture. We report and classify a number of traditional electrophysiological measures as cultures develop over weeks, how these measures change in response to embodiment, and propose a novel platform for future study of fundamental principles of learning and memories in neural systems.

Title: Comparative study of neural cell culture conditions and their impact on synchronized bursting

Authors: *J. L. TANCREDI, A. M. IBRAHIMI, M. A. DERR, S. SHIN;
Cell Biol. R&D, Thermo Fisher Scientific, Frederick, MD

Abstract: In vitro culture of neural cells requires an ideal energy source to maintain their viability and functionality. Glucose and pyruvate are commonly utilized as energy sources for sustaining neurons in vitro. However, culturing neurons in a low glucose-containing medium has been associated with significant degeneration. Thus, providing optimal culture conditions to support neural cells in vitro is crucial.

This study compared the effects of different culture conditions on neuronal health and functionality. B27 System was specifically designed to culture neurons while suppressing the growth of glial cells. In contrast, B27 Plus system aimed to support matured neurons and was found to be capable of supporting both neurons and astrocytes. It has been previously reported that glial cells can enhance synchronized bursting, a phenomenon observed in neuronal networks.
To evaluate the impact of culture conditions on synchronized bursting, electrophysiological measurements were conducted. Calcium imaging analysis revealed that B27 Plus system resulted in the development of synchronized bursting when compared to B27 system. The emergence of synchronized bursting signifies enhanced network activity and coordination among neurons. Furthermore, astrocytes, a type of glial cell, were found to produce L-serine and glycine. A subsequent "add back" study was performed, where glycine and L-serine were supplemented in the culture medium. This supplementation led to an increase in both the frequency and amplitude of spontaneous synaptic currents, indicating a positive impact on neuronal communication. These findings emphasize the importance of selecting appropriate culture conditions for neural cell studies in vitro. Understanding the influence of different conditions on neuronal health and functionality can contribute to the development of optimized culture protocols, ultimately enhancing our understanding of neural networks and their dynamics.

Title: Linking physically isolated in vitro neural specimens on separate three-dimensional microelectrode arrays via virtual white matter

Authors: ***M. KHANTAN**[1,2], J. T. LIM[1], A. NAPOLI[1], I. OBEID[2], M. D. SERRUYA[1]; [1]Raphael Ctr. for Neurorestoration, Thomas Jefferson Univ., Philadelphia, PA; [2]Dept. of Electrical and Computer Engin., Temple Univ., Philadelphia, PA

Abstract: Closed-loop stimulation of the nervous system, in which activity recorded from one area triggers focal stimulation in a separate target area, has emerged as a potential therapeutic modality to enhance recovery after neurological disease and injury. In addition to in vivo investigations in non-human animals, e.g., Neurochip3 developed by Fetz and colleagues [1],

this technique has also been applied to individual neural specimens in vitro, such as in the European Project ‘BrainBow’ ‘Bidirectional Bridging’ system developed by Chiappalone et al [2] and closed-loop optogenetic stimulation by Jackson and colleagues [3]. To our knowledge, neural activity-driven microstimulation across two physically separate in vitro specimens has not been reported. If shown to be feasible, a software-driven virtual white matter platform could enable neuroscientists to scale up an increasing number of specimens to link to each other to create more sophisticated circuits and feedback loops, and to test the effects of temporarily virtually disconnecting or reconnecting specimens to each other.We created an in vitro model composed of two ex-vivo brain tissue samples cultured in two separate dishes, and a computer-based system to record and stimulate them. The activity of a neural specimen was recorded from one dish, action potentials (APs) and field potentials (FPs) were identified and used to focally modulate artificial electrical stimulation in the second dish. The neural activity evoked in the second dish is also recorded and used in turn to modulate electrical stimulation delivered back to the first dish. This focal stimulation therefore functions as a bi-directional virtual white matter connection.The system collects APs and FPs from neural specimens with preserved cytoarchitecture (organotypic slices and organoids) using three-dimensional multielectrode arrays (MEAs). The system selectively and focally stimulates desired regions of the brain tissue, and stimulation can be modulated in real-time based on neural activity recordings. Following stimulation, the system can detect changes in neural activity in the surrounding tissue, demonstrating the possibility of virtually recreating white matter.These findings demonstrate the viability of using electrical circuitry to virtually recreate the connections between various neural specimens. In addition to providing a novel methodology to study emergent properties from dynamically linked neural specimens in two or more separate dishes. Furthermore, the system could function as a testbed to develop in vitro brain-computer interfaces that rely on activity-triggered microstimulation and bidirectional feedback.

Abstract: Efficiently establishing *in vitro* neural models that accurately mimic the structural and functional connectivity of neural networks is of paramount importance in neuroscience research. Three-dimensional (3D) bioprinting, an emerging biofabrication technology, offers great potential for constructing sophisticated *in vitro* models. Here, we employed extrusion-based 3D bioprinting to fabricate 7×7×1.5 mm GelMA-based constructs containing E18 rat cortical neurons, which was subsequently referred to as 3DP. ATP quantification and CaM/PI staining indicated favorable neuronal viability within the 3DP over 14 days *in vitro*. Immunofluorescence staining targeting specific markers, such as NeuN, MAP2, and Tuj1, revealed progressive aggregation of neurons into spherical clusters of 50-200 μm in diameter (Figure). These clusters were accompanied by distinct axonal interconnections within and between clusters, resulting in the formation of a brain-like network. Fluo-4 mediated 3DP calcium signal recording enabled the visualization of spontaneous discharges within neuronal clusters at a micrometer scale, as well as synchronized calcium signals at a millimeter scale. Further investigation of pharmacological perturbation by antagonists of glutamate receptor, GABA receptor, and ion channel on the 3DP neurons exhibited significant alterations in firing rates and global correlation. RNA-seq analyses on both 3DP and conventional two-dimensional (2D) cultured neurons were performed. Gene Set Enrichment Analysis (GSEA) showed that the 3DP gene expression profiles were more similar to the adult rat cortex compared to the E18 cortex and 2D-cultured neurons, suggesting that 3DP neurons manifest an adult-like expression pattern despite being originated from fetal rats. These findings demonstrate the formation of multi-scale neural circuits within the 3D bioprinted mini-brain structure.

Title: Label free functional characterization of ipsc derived neurons at subcellular resolution

Authors: *S. OLDANI[1], E. GUELLA[1], S. RONCHI[2], M. J. OBIEN[3];
[1]MaxWell Biosystems, Zurich, Switzerland; [2]ETH Zurich, Basel, Switzerland; [3]MaxWell Biosystems AG, Zuerich, Switzerland

Abstract: In recent years, brain models derived from pluripotent stem cells have become a fundamental tool for studying common neurological disorders, such as epilepsy, Alzheimer's disease, and Parkinson's disease. The ability to measure the electrical activity of human iPSC derived neurons in real time and label free can provide much needed insights into the complexity of the neuronal networks. Nowadays, combining single cell resolution with high throughput physiological assays, which can potentially deepen our understanding of subtype specific neuronal activity, is especially valuable and yet difficult to achieve.In this study, the MaxTwo System (MaxWell Biosystems, Switzerland), a multi well high density (HD) MEA platform was used. MaxTwo HD MEA System allows *in vitro* extracellular recordings of action potentials at different scales, ranging from network through single neuron to subcellular features. Moreover, we showed the advantages of having an HD-MEA system featuring 26,400 electrodes per well, which are key to increase the statistical power of the data collected from iPSC derived neurons over multiple days, weeks and to capture the smallest neuronal signals.Finally, we present the Axon Tracking Assay, a tool for automated recording and analysis of individual axonal arbors of many neurons in parallel. The Axon Tracking Assay enables to measure action potential conduction velocity, axonal length, and number of axonal branches. With this unique method, we characterized the function and axonal structure of different iPSC derived neuronal cell lines.Our HD MEA platforms and the extracted metrics, such as firing rate, spike amplitude, and network burst profile among several others, provide an extremely powerful and user friendly approach for *in vitro* drug screening and disease modelling.

Title: Responsive closed-loop neurostimulation to prevent focal epilepsy progression and associated long-term memory impairment.

Authors: *J. J. FERRERO[1], A. HASSAN[2], Z. YU[2], Z. ZHAO[3], L. MA[2], S. SHAO[2], J. ENGEL[1], D. KHODAGHOLY[3], J. GELINAS[2];
[2]Neurol., [3]Electrical Engin., [1]Columbia Univ., New York, NY

Abstract: Long-term memory impairment significantly impacts patients with temporal lobe epilepsy (TLE), but no targeted treatment exists. The hippocampus and associated mesial temporal lobe structures are essential for declarative memory, and uncontrolled epileptic activity in these brain areas is a strong risk factor for progression of epilepsy and memory dysfunction. Temporal coupling of neural oscillations is critical for physiologic brain functions, and is dysregulated in the presence of interictal epileptiform discharges (IEDs).
We used a rodent kindling model to investigate the electrophysiologic activity patterns in hippocampus and medial prefrontal cortex (mPFC) as animals experienced worsening of seizures and cognitive decline. Progression of epileptic activity in the hippocampus was associated with creation of an independent focus of interictal epileptic activity in the mPFC. Emergence of this independent cortical IED focus was correlated with a defined shift in hippocampal-cortical interactions that promoted intra-cortical hypersynchronous neural spiking. We found that spatiotemporally targeted closed-loop mPFC stimulation triggered on hippocampal IED occurrence eliminated this hypersynchronous response, effectively preventing recruitment of the mPFC into the epileptic network and ameliorating long-term spatial memory deficits.
These results suggest a causal role for IED-mediated hippocampal-cortical communication in epilepsy progression and memory impairment, and propose interictal closed-loop electrical stimulation as a potential therapy for epilepsy and its comorbidities.

Title: Activation of parvalbumin interneurons in the anterior piriform cortex alleviates seizures in temporal lobe epilepsy

Authors: *H. ZHANG, A. CHIU, H. JIANG, H. CHOI, C. G. LAU;
City Univ. of Hong Kong, Hong Kong, Hong Kong

Abstract: Epilepsy is a pathological state that involves altered excitation-inhibition in the brain and exhibits recurrent seizures. The anterior piriform cortex (APC) is a limbic area that is closely associated with temporal lobe epilepsy (TLE). In the APC, parvalbumin-expressing (PV^+) interneurons, which form abundant perisomatic synapses on principal neurons, can provide strong local inhibition. However, the causal relationship between APC-PV neurons and TLE is unclear. Using the pilocarpine model, we first found reduced local inhibition and PV synaptic density in the APC. To examine the causal role of APC in TLE, we applied chemogenetics and multi-site local field potential (LFP) recording in both the pilocarpine (i.p.) and hippocampal kainic acid (KA) injection models. In the pilocarpine model, we showed that APC-PV neuronal activation induced an anti-ictogenic effect and afforded seizure protection but did not influence an ongoing status epilepticus. In the chronic KA model, activation of APC-PV neurons significantly weakened focal seizure (FS) expression in the hippocampus. Additionally, brain dynamics analysis indicated that APC-PV neuronal activation took effect by modulating the long-range functional connectivity of the seizure network. Specifically, we found decreased local excitability and increased phase synchronization in ictal states when APC-PV was activated. Phase synchronization was measured by inter-regional phase locking value (PLV) of LFP. Moreover, there was a strong, negative correlation between FS number and PLV in ictal states. These results identify the APC-PV neuron as a target for treating TLE and highlight long-range functional connectivity as an endophenotype to report seizure severity. Importantly, our research provides novel insights into how a cortical microcircuit can exert antiepileptic benefits.

Title: NRTX-1001: Human inhibitory interneuron cell therapy suppresses seizures and reduces histopathology in a mouse model of chronic focal epilepsy with high repeatability across multiple studies and manufacturing lots

Authors: *P. HAMPEL[1], M. B. PAREKH[2], H. K. KIM[2], E. T. SEVILLA[2], F. PORKKA[2], A. VOGEL[2], S. LEE[2], J. H. JUNG[2], M. W. L. WATSON[2], S. HAVLICEK[2], S. KRIKS[2], M. BERSHTEYN[2], Y. MAURY[2], L. FUENTEALBA[2], A. BULFONE[2], G. BANIK[2], C. A. PRIEST[2], C. R. NICHOLAS[2];

Abstract: One-third of people with epilepsy have drug-resistant seizures. Surgical resection or ablation of a seizure focus can be effective options for chronic focal epilepsy; however, these procedures are tissue-destructive and are not indicated for all. As a restorative therapeutic alternative, the administration of cells that deliver GABA to the seizure focus could suppress chronic seizures without tissue destruction. NRTX-1001 comprises GABAergic, post-mitotic interneurons of a specific MGE pallial-type lineage derived from human pluripotent stem cells. Previous work examining NRTX-1001 transplantation into a mouse model of chronic focal epilepsy demonstrated seizure suppression and reduced hippocampal histopathology. The studies described here demonstrate that the disease-modifying effects of NRTX-1001 transplantation are consistent across multiple studies with independent manufacturing lots of NRTX-1001. Clinically-compliant processes were used to manufacture and cryopreserve NRTX-1001. Multiple preclinical studies were performed in the intrahippocampal kainate mouse model of drug-resistant focal epilepsy using independent lots of NRTX-1001. Single intrahippocampal administration of NRTX-1001 was performed in the chronic phase of the disease model, which is characterized by spontaneous recurrent seizures and hippocampal sclerosis. Focal seizures were detected by continuous (24/7) EEG recording from bipolar hippocampal electrodes at several timepoints up to 7 months post transplantation. Intrahippocampal administration of NRTX-1001 into mice with chronic mesiotemporal seizures resulted in pronounced reduction of focal seizures across multiple independent cell lots and studies. NRTX-1001 transplantation consistently resulted in stable seizure-freedom in approximately two-thirds of epileptic mice. At 7.5 months post transplantation of NRTX-1001, cell engraftment and hippocampal histopathology were assessed. NRTX-1001 interneurons persisted for the duration of the studies and distributed throughout the hippocampus. NRTX-1001 administration led to significantly reduced hippocampal dentate granule cell dispersion. No ectopic tissues, tumors or teratomas were observed following transplantation of NRTX-1001. The results of these preclinical studies support the ongoing phase I/II clinical trial (NCT05135091) to evaluate NRTX-1001 in people with drug-resistant temporal lobe epilepsy. Abstract: Dravet syndrome (DS) is a devastating developmental and epileptic encephalopathy marked by treatment-resistant seizures, developmental and motor deficits, and a high rate of premature death. In over 80% of patients with DS, the disease is caused by heterozygous loss-of-function mutations in SCN1A, the gene encoding Nav1.1 channels. SCN1A mutations impair GABAergic interneuron excitability, and mouse models recapitulate key DS phenotypes when SCN1A mutations are targeted to GABAergic interneurons. Taken together these observations suggest interneurons constitute a promising target for precision gene therapy in DS. Here we developed and validated cell class-specific enhancer AAV gene replacement therapy driving expression of SCN1A in GABAergic interneurons. Using these tools, we overcame the AAV carrying capacity limitations and achieved full-length SCN1A expression in forebrain GABAergic neurons with high efficiency and specificity. Patch-clamp recordings and western blot in cell lines showed that these constructs produce a functional Nav1.1 protein. After packaging these vectors into AAV and administration in mice, immunohistochemical analyses showed dose-dependent biodistribution of the therapeutic cargo in targeted cells and brain regions. Remarkably, these vectors displayed strong dose-dependent protection against mortality

and thermally induced seizures to DS mouse models carrying nonsense alleles of Scn1a. We observed protection in two independent model mouse lines and at two independent research sites, with no overt toxicity observed in littermate control mice. Immunohistochemistry on these testing cohorts allowed us to directly correlate vector biodistribution with functional rescue. Furthermore, we also tested additional vectors for pan-neuronal expression of Nav1.1, and these vectors provided weaker protection from DS symptoms, and showed safety concerns including preweaning lethality. These findings suggest that cell class specificity might not only boost effectiveness of gene therapy in DS but could also enhance the safety of therapy. In summary, these findings demonstrate proof-of-concept that cell class-specific AAV-mediated SCN1A gene replacement therapy could provide an effective precision therapy in DS.

Title: Histological analysis of hippocampal interneuron populations in the Scn1b knockout mouse model of Dravet syndrome

Authors: *J. EDWARDS, J. H. CHANCEY, M. A. HOWARD;
Ctr. For Learning & Memory, Univ. of Texas, Austin, Austin, TX

Abstract: Dravet syndrome (DS) is a severe and devastating developmental epileptic encephalopathy characterized by early age of onset, refractory seizures, and cognitive comorbidities. Homozygous loss-of-function mutations in the *SCN1B* gene have been linked to DS, and *Scn1b* loss specific to interneurons in mice has been shown to cause early mortality. Given the involvement of the protein products of *SCN1B*— β1 and β1B—in neuronal migration and pathfinding, it is possible that loss of *SCN1B* may contribute to the DS phenotype by interfering with the migration and/or integration of GABAergic interneurons. GABAergic parvalbumin (PV), somatostatin (SST), and calretinin (CR) interneurons play significant roles in hippocampal processing and are involved in the pathology of other forms of DS and epilepsy. To address the hypothesis that hippocampal interneuron displacement contributes to DS pathology, we compared the number and anatomical locations of PV, SST, and CR hippocampal interneurons between *Scn1b* knockout DS model mice and their wild-type littermates. We bred

independent mouse lines to label specific interneuron subtypes, crossing *Scn1b*$^{+/-}$ mice with interneuron-specific Cre lines and the Ai-14 TdTomato (TdTom) reporter line. Between ages P15-20, we perfused and fixed the brains of *Scn1b*$^{-/-}$;Cre^{+};TdTom^{+} (knockout) and *Scn1b*$^{+/+}$;Cre^{+};TdTom^{+} (wild-type) mice and performed immunohistochemistry to—in combination with Cre-mediated TdTom labeling—increase the accuracy of PV, SST, and CR interneuron identification. Manual cell counts were conducted using ImageJ software, and the numbers and locations of cells throughout hippocampal subregions were analyzed. Preliminary data (N=2 mice for each interneuron type) showed no obvious difference between the number or placement of PV, SST, or CR hippocampal interneurons in *Scn1b* knockout mice compared to their wild-type littermates. These data indicate that, even in the absence of *Scn1b*, GABAergic PV, SST, and CR interneurons are still able to migrate and incorporate into the expected subregions of the hippocampus. Thus, it is not likely that alterations in hippocampal physiology found in *Scn1b* knockouts are caused by a deficit in GABAergic interneuron migration. Additional detailed cell counts will be performed to verify this conclusion.

Title: Behavior analysis in a Purkinje cell-specific SCN1B deleted mouse model of Dravet syndrome

Authors: *M. GEIST[1], M. TREVIÑO[2], M. HOWARD[3];
[1]Neurosci., Ctr. For Learning & Memory, Univ. of Texas, Austin, Austin, TX; [2]Neurosci., Univ. of Texas at Austin, Austin, TX; [3]UNIVERSITY OF TEXAS AT AUSTIN, Austin, TX

Abstract: *SCN1B* encodes the β1 protein, an auxiliary subunit to voltage-gated ion channels, cell adhesion molecule, and transcriptional regulator, as well as the secreted β1B protein. Mutations in *SCN1B* are associated with developmental epileptic encephalopathies including Dravet syndrome (DS). DS is a severe infantile epilepsy with frequent and difficult to treat seizures and a range of comorbidities including movement disorders, cognitive, and social delays.The cerebellum is involved in coordination of voluntary movements and motor learning, as well as cognition and social behavior. *SCN1B* expression is high in cerebellar Purkinje and granule cells, but the role of this protein in the cerebellum, and the cerebellum's role in DS, are understudied.

We hypothesized that loss of *SCN1B* causes cerebellar dysfunction, leading to the ataxia and social behavioral changes frequently reported in people with DS even after seizures are medically controlled.Global *Scn1b* knockout mice die by age P22, so are inadequate for studying DS in the adult. Thus, we crossed a conditional *Scn1b* knockout mouse with a Purkinje cell-specific Cre line creating an *Scn1b* mouse model that lives into adulthood (>P150). To quantify motor and social deficits, we performed a three-phase behavioral paradigm including open field and 3-chamber tests on Purkinje cell-specific *Scn1b* KO and WT littermate mice, repeated at 8, 10, and 12 weeks of age. Phase 1 was open field testing of locomotor activity. Distance traveled, velocity, and time spent in middle of the arena were scored using Ethovision XT software. In phase 2 the test mouse was placed in a 3-chamber arena with the choice of spending time with either a novel mouse or a novel object. In phase 3, the 3-chamber choice was spending time with a familiar mouse or a novel mouse. Sociability is the propensity of the test mouse to spend more time in the chamber containing the novel mouse vs novel object; social preference is the propensity to spend more time in the chamber containing the novel mouse vs the familiar mouse. Our preliminary findings show that conditional KO mice exhibit clear ataxia and balance issues by 8 weeks of age compared to wild type. These mice moved more slowly than their WT peers and would fall over when rearing up. Importantly, these mice do not show signs of failure to thrive, seizures, or early mortality which severely afflict the constitutive *Scn1b* KO mice. These findings indicate that cerebellar function is directly altered by loss of *Scn1b* from Purkinje cells, which may be an underlying cause of some of the comorbidities of DS.

Title: Sex-specific aggressive behavior in the pilocarpine mouse model of temporal lobe epilepsy

Authors: A. PANT, M. A. HOWARD, *J. H. CHANCEY;
Univ. of Texas At Austin, Austin, TX

Abstract: Temporal lobe epilepsy (TLE) is one of the most common forms of epilepsy, affecting over 50 million people worldwide. In addition to seizures, TLE has a significant impact on quality of life, affecting cognitive function and emotional well-being. While individuals with TLE are not inherently more prone to aggression than the general population, up to 40% experience postictal aggression in the hours or even days following seizures. Understanding the neurophysiological pathways responsible for this behavior is crucial for providing

comprehensive care to individuals with TLE. Although studies have reported aggression in rodent models of TLE, there are a limited number of systematic investigations examining aggressive behavior in relation to the disease state. Additionally, there is a significant lack of TLE studies in females despite existing sex differences in epilepsy and its comorbidities, even in extensively studied animal models of chemically induced TLE. Our objective is to understand sex differences in postictal aggression and establish a correlation between the severity of epilepsy and aggressive behavior in a mouse model of TLE. The pilocarpine mouse model of TLE was employed, wherein a 2-hour episode of status epilepticus (SE) was induced, then pharmacologically stopped. The mice were then continuously monitored using 24-hour video recordings to evaluate the frequency, duration, and intensity of seizures. Aggressive behavior was assessed using the resident intruder test at two time points: 5-10 days after SE, representing the latent period characterized by ongoing epileptogenesis without spontaneous seizures, and 30-35 days post-SE, the epileptic period. In this test, an unfamiliar (intruder) mouse is introduced into the home cage of the test (resident) mouse, creating a social interaction that can trigger territorial aggression. Latency to attack was recorded as a measure of aggressive behavior. We found that males in the pilocarpine group averaged a lower latency, i.e., more aggressive behavior, than controls at both time points. This pattern was not observed in the female mice. These results suggest that there is an increased likelihood of postictal aggressive behavior that is sex dependent, and that the pilocarpine model provides a tool to study the underlying neurophysiological mechanisms of TLE associated aggression.

Title: Thalamic connectivity with epileptogenic neural circuitry in patients implanted with responsive neurostimulators

Authors: *P. REEDERS, N. W. SCHULTHEISS, M. LALLAS, S. WANG, P. JAYAKAR, M. DUCHOWNY, M. FAJARDO;
Nicklaus Children's Hlth. Syst., Miami, FL

Abstract: Responsive Neurostimulation (RNS) is an alternative treatment for patients with drug-resistant epilepsy who are not candidates for surgical resection. RNS detects abnormal electrical activity and delivers targeted electrical stimulation to interrupt seizure propagation. Surgical

therapies using RNS typically target the centromedian nucleus of the thalamus (CM) due to its widespread connectivity. The mechanism by which RNS aborts seizures at CM is not completely understood.
Understanding whether the anatomical network from CM includes epileptogenic zones provides important insight in how RNS reduces seizure burden. One hypothesis is that direct connectivity of CM with the region of highest amplitude of the scalp activity distribution leads to more favorable outcomes with RNS. We investigated 1) structural connectivity of CM in patients with generalized epilepsy and a RNS, 2) whether this network includes epileptogenic brain regions with predominant peaks in the spatial current density distribution (CDR hotspots) of the EEG, and 3) whether there is a relationship with the connectivity measures and seizure burden reduction post RNS.
We performed probabilistic tractography on pre-surgical diffusion weighted imaging using CM of the thalamus as our seed and whole brain cortical regions as our targets. We used streamlines from each voxel in the seed and recorded when they ended in one of the target regions. We created a seed-target distribution to investigate the connectivity profile. We then identified the target regions with direct connectivity to CM and compared them to the brain areas with CDR hotspots. Lastly, we explored whether connectivity between brain regions with early seizure activity to CM, is related to lowering of seizure burden post RNS implantation.Preliminary findings (N=2) in patient 1 revealed CDR hotspots in bilateral superior frontal gyri and left medial orbitofrontal cortex. Tractography revealed corresponding strong connectivity between CM and the superior frontal gyri, as well as to the medial orbitofrontal area. This patient had a reduction in seizure duration and intensity. Patient 2 had CDR hotspots in the rostral area of the middle frontal gyrus, and strong connectivity between CM and this region. This patient had a reduction in seizure intensity and improvement in reported behaviors. Further analyses and a larger sample are necessary to verify initial findings.
These results support a relationship between anatomical connectivity of CM with brain regions involved in early seizure activity, and seizure burden reduction post RNS. This relationship may aid in candidate selection, surgical targeting and outcome prediction.

Title: High frequency stimulation modifies the firing activity of thalamic reticular nucleus

Authors: *V. M. MAGDALENO-MADRIGAL[1], J. VALERIO-MUÑOZ[2];
[1]Inst. Nacional De Psiquiatría Ramón de la Fuente Muñiz, Ciudad De México, Mexico; [2]Inst. Nacional de Psiquiatría, Ciudad de México, Mexico

Abstract: Deep brain stimulation, specifically high-frequency stimulation (HFS), is an alternative and promising treatment for intractable epilepsies; however, the optimal targets are still unknown. The thalamic reticular nucleus (TRN) occupies a key position in the modulation of the cortico-thalamic and thalamo-cortical pathways. High-frequency stimulation (HFS) in TRN retards the generalization of PTZ-induced seizures, however, the mechanisms of action are still unknown. To explore the mechanism underlying HFS-TRN we recorded the multiunit activity of TRN in response to HFS-TRN and PTZ. Male Wistar rats, anesthetized with urethane (1.2 g/kg) and atropine sulfate (0.05 mg/kg), were used. A borosilicate microelectrode (4-8 MOhms) for extracellular recording, and a bipolar electrode for biphasic HFS (100 Hz, 0.1 ms, 200 mA), were introduced, both in the left TRN. At the end of the experiment, the rats were sacrificed and the brain was removed for histological analysis. The total frequency, the firing type, and the firing rate were analyzed. PTZ caused a significant decrease in firing rate, 15 neurons changed their firing from tonic to burst, while an increase in firing rate was observed in another five neurons. HFS decreased firing frequency compared to baseline and the second dose of PTZ, with no change in firing rate observed in three neurons. The results suggest that the TRN participates in the maintenance of the characteristic spike-wave discharges of absence seizures, while the HFS in the TRN can induce the inhibition of the synchronization of oscillatory activity. In conclusion, the HFS in the TRN may block the burst firing in TRN, and may be enough to protect against spread of convulsive seizures.

Title: Cathodal transcranial direct current stimulation decreases the epileptic excitability: From neuronal firings to local field potential oscillations

Authors: *Y.-J. WU[1], C.-C. CHIANG[2], M.-E. CHIEN[1], Y.-J. HUANG[1], S.-F. LIANG[3], K.-S. HSU[4], D. DURAND[2];

Abstract: Seizure is a hyperexcitability brain disorder. Cathodal transcranial direct current stimulation (ctDCS) has been applied to treat refractory seizures. However, the mechanism of how ctDCS modulates seizure excitability remains not fully understood. We used local field potential (LFP) and extracellular single-unit recordings with one session *in vivo* ctDCS in the kainic-acid induced hippocampal seizure animals to investigate the neurophysiological changes following ctDCS compared with sham stimulation. The neuronal unit firings recorded at CA1 coupled with the LFP epileptic discharges. In tDCS-treated rats, the amplitudes of LFP epileptic spikes were reduced and the LFP oscillations were shifted toward delta-to-theta ranged low-frequency oscillations compared with sham. Neuronal unit spike numbers at CA1 were reduced in tDCS-treated rats compared with sham, among which the putative interneuron spikes decreased to a more significant degree than those of the putative pyramidal cells. High unit spike-LFP coherences were observed in the putative interneurons while the coherences decreased during ctDCS treatment. The short-term plasticity measured by paired-pulse stimulation showed enhanced paired-pulse depression and reduced paired-pulse facilitation in ctDCS-treated rats. These ctDCS-induced neurophysiological changes occurred during tDCS and lasted for 90 minutes following stimulation. c-Fos activations increased in GAD^+ inhibitory neurons whereas reduced in $CaMKII^+$ excitatory neurons. Collectively, ctDCS decreases seizure excitability by reducing the neuronal unit firings and altering LFP toward low-frequency oscillations. These underpinnings exert the inhibitory effects of ctDCS with the short-term plasticity changes in an epileptic brain.

Title: Investigation of Therapeutical Potential of Optimized Low Frequency Deep Brain Stimulation at Novel Anatomical Target Area in the Treatment of Epilepsy

Authors: *V. Y. Y. CHU[1], **S. CHAN**[2], G. KUMAR[2], C. H. E. MA[2,3];
[1]City Univ. of Hong Kong, Hong Kong, Hong Kong; [2]Dept. of Neurosci., City Univ. of Hong Kong, Kowloon, Hong Kong; [3]City Univ. of Hong Kong Shenzhen Res. Inst., Shenzhen, China

Abstract: Epilepsy is a debilitating neurological disorder and is caused by abnormal hyperexcitability of neurons which disrupts normal neurocircuitry and brain functions. It affects

over 60 million people globally with more than 40% of the patient population developing antiepileptic drug resistance (ARD). Deep brain stimulation (DBS) is typically prescribed to patients with ARD using Anterior thalamic nucleus (ATN) as the target brain stimulation site. However, stimulation in this area results in side effects such as memory impairment, and depression. We have previously reported a novel anatomical DBS target in the midbrains that has demonstrated therapeutic efficacy when DBS is administered at 20Hz frequency, 100µA pulse amplitude, 80µs pulse width for 1 hour daily for 7 days. To further examine the neurocircuitry involved, an AAV fluorescent tracer is injected at the novel DBS target site, and we observed presence of fluorescent signal in the motor cortex, substantia nigra par reticular (SNr) and ATN; suggesting that the therapeutic effect is largely due to neuronal innervation from the new DBS site. We then optimize DBS parameters by varying DBS current and frequency using acute mouse model of pentylenetetrazol (PTZ)-induced epilepsy. The optimized DBS parameters increased myoclonic latency by ~200% and reduced general tonic clonic (GTC) duration by 80%. Furthermore, our optimized DBS treatment has suppressed hyper excitation in the delta band by ~67% and that of theta band by ~70%. Reduction of GTC duration holds clinical relevance as prolonged sessions often leads to irreversible brain damages and ultimately resulting in death. To dissect the molecular mechanisms involved in the pathogenesis of PTZ or kainic acid (KA) induced epilepsy and the effects of DBS, we investigate the role of excitatory (vGLUT) and inhibitory (GAD67) neurons in the new DBS site and their contribution to the pathogenesis of epilepsy. Immunohistochemical staining of vGLUT and GAD67 demonstrate a 50% reduction of vGLUT-positive neurons and 30% reduction of GAD67-positive neurons after DBS in the new DBS site. Our results suggest the involvement of glutaminergic and GABAergic neurons in disease progression of epilepsy. In summary, our study demonstrates the therapeutic potential of low frequency DBS at our proposed novel DBS site via its neuronal connection to the motor cortex, SNr and ATN. Further molecular and electrophysiological studies are required to investigate the involvement of vGLUT and GAD67 neurons in our proposed target region and their roles in orchestrating the pathogenesis of epilepsy.

Title: Low-frequency deep brain electrical stimulation of callosal white matter tracts provides an antiepileptic effect in the cortex by activating inhibitory $GABA_B$ and slow afterhyperpolarization mechanisms

Authors: *N. PAKALAPATI, D. DURAND;
Case Western Reserve Univ., Cleveland, OH

Abstract: Epilepsy is a neurological disorder characterized by abnormal brain electrical activity and poses significant treatment challenges when it becomes drug resistant. Deep brain stimulation (DBS), particularly low-frequency stimulation (LFS) targeting white matter tracts, has emerged as a potential therapy for drug-resistant epilepsy. However, the precise mechanisms underlying LFS-induced suppression of epileptic activity in the cortex remain unknown. This study investigates how LFS, when applied to the corpus callosum, provides an antiepileptic effect in the cortex in coronal rodent brain slices. We first identified that 5 Hz LFS maximally suppressed epileptic activity in the cortex (>80%) relative to other stimulation frequencies in a 4-aminopyridine (4-AP) seizure model. Upon assessing changes to tissue excitability resulting from LFS using a paired-pulse test, we observed a reduction in tissue excitability across a wide range of interspike intervals (ISI) (20-1000 ms), as indicated by the decrease in the P2/P1 ratio of evoked potentials relative to no stimulation (n = 8). Furthermore, we observed that the maximum reduction in tissue excitability occurs at an ISI of 200 ms, suggesting the involvement of specific receptors or mechanisms contributing to the anti-epileptic effect. Notably, tissue excitability remains depressed at 1000 ms, indicating the activation of persistent long-term inhibitory mechanisms. To explore the underlying mechanisms contributing to the reduction in tissue excitability, we employed various specific and non-specific pharmacological blockers in combination with LFS to study changes in the resulting antiepileptic effect. Independent administration of $GABA_B$ receptor blockers and slow afterhyperpolarization (sAHP) blockers (n = 8 each) reduced the LFS-induced antiepileptic effect by over 85%. When specific blockers for these mechanisms and receptors are used in conjunction, LFS fails to provide an antiepileptic effect—indicating that LFS primarily depends on these two mechanisms to provide an antiepileptic effect. Our findings suggest that $GABA_B$-mediated inhibition maximally reduces tissue excitability at an ISI of 200 ms, while sAHP provides a weaker, persistent antiepileptic effect observed at an ISI of 1000 ms. Overall, our study reveals that 5 Hz LFS targeting white matter tracts activates $GABA_B$ receptors and sAHP mechanisms, leading to a potent reduction in cortical epileptic activity. These insights contribute to the understanding of LFS-induced suppression of epileptic activity and provide a basis for the development of novel therapeutic approaches for drug-resistant epilepsy.

Title: Optogenetic activation of the dorsal striatum suppresses generalized absence epilepsy and limbic seizures

Authors: *W. L. LOPES[1], S. HYDER[2], P. A. FORCELLI[3];
[1]Pharmacol. and Physiol., [2]Dept. of Pharmacol. & Physiol., [3]Dept of Pharmacol., Georgetown Univ., Washington, DC

Abstract: Generalized seizures are the most common type of epilepsy in humans. The striatum is the main basal ganglia input structure, and it has important connections with cortical and limbic brain sites, suggesting that modulation of striatal activity may be a viable approach for control of generalized seizures. Here, we tested if optogenetic activation of the striatum can attenuate generalized absence seizures induced by gama-butyrolactone (GBL) and generalized limbic seizures induced by the amygdala kindling. 25 Sprague-Dawley (SD) rats were submitted to stereotaxic surgery for bilateral cortical electrodes implantation over the frontal, parietal, and cerebellum (reference and ground). 16 SD rats were implanted with bipolar electrode within the basolateral amygdala nucleus (BLA). All animals received a virus injection in the striatum. rAAV-hSyn-ChR2 (H134R)-mCherry was used for activation of striatal neurons and AAV-CAG-GFP was used for control rats (opsin-negative). Viruses were allowed to express for 3 weeks. For limbic seizures, animals were submitted to daily electrical stimulation of the BLA. Once animals were fully kindled, they were tested under different light frequencies (blue light 473 nm, 5 and 100 Hz). For absence seizures, rats received intraperitoneal injection of GBL (100 mg/kg) and were tested under 5 and 100 Hz conditions. In the GBL model we also performed additional test sessions to compare open loop (continuous) and closed loop (responsive neuromodulation) light delivery. In previously kindled rats, both 5 and 100 Hz suppressed the afterdischarge ($p<0.05$) and the behavioral manifestation of limbic seizures ($p<0.05$). In the GBL model of absence epilepsy, the continuous light delivered (open loop, both 5 and 100 Hz) reduced the number of spike-and-wave discharges (SWD), mean SWD duration, and the percentage of time seized during session ($p<0.5$). In the closed loop protocol, 100 Hz attenuated absence epilepsy manifestation, reducing SWD mean duration ($p<0.05$), but 5 Hz was ineffective. Control animals showed no alteration in any of the parameters assessed in the GBL and kindling models. In separate sessions we monitored electrographic activity changes in the cortex and BLA during and after light delivery without evoking seizures; these data suggest an increase in high frequency, low amplitude activity during optogenetic stimulation. These results support our hypothesis that activation of the striatum can attenuated generalized seizures. Additionally, our closed loop data suggest that, under specific testing conditions, on-demand activation of the striatum is sufficient to shorten SWDs displayed in the GBL model of absence epilepsy.

Title: Subthreshold oscillating waves induced by optogenetic stimulation can suppress epileptiform activity in the hippocampal slice

Authors: *C.-C. CHIANG[1], D. M. DURAND[2];
[2]Case Western Reserve Univ., [1]Case Western Reserve Univ., Cleveland, OH

Abstract: Subthreshold oscillating waves have been observed in different regions across the brain and are thought to influence the timing of neural spikes. Our previous study shows that optogenetic stimulation can induce a subthreshold oscillating wave propagating across the whole hippocampal slice, even without synaptic transmission. Moreover, the induced subthreshold waves can generate interference patterns and suggest that the neural tissue could process signals with a very low amplitude below the threshold of firing action potentials. In the current study, we further characterize the induced subthreshold waves and investigate the interaction between the induced subthreshold waves and other endogenous neural activity. We found that the induced subthreshold waves decay in amplitude along the propagating direction. The propagating speed of the subthreshold waves also decreased with reduced amplitude but became constant at very low amplitudes. Furthermore, the speed and amplitude of the subthreshold waves can be modulated by changing the osmolarity in the environment. To study the interaction between subthreshold and suprathreshold neural activity, we generated subthreshold waves in the theta frequency traveling from the septal hippocampus towards an epileptic focus in the temporal region. We found that the subthreshold waves could suppress interictal spiking activity induced by 4-aminopyridine (4-AP). The suppression of epileptiform activity is dependent on the amplitude of subthreshold waves. These results suggest that the low amplitude subthreshold waves traveling by ephaptic coupling non-synaptically could suppress much larger amplitude epileptiform activity. The mechanism of this effect is not known, but it suggests that theta waves are involved in promoting a low excitability level in the brain. The subthreshold waves and epileptiform activity could possibly explain the seizure suppression by theta waves.

Title: Short-term calorie restriction reduces the spectral power of seizures induced by microinjection of kainic acid in rat hippocampus

Authors: D. SIERRA-LEON[1], ***O. MERCADO-GOMEZ**[2], J. SANCHEZ-HERNANDEZ[1], V. ARRIAGA-ÁVILA[1], R. GUEVARA-GUZMAN[1];
[1]Physiol., Univ. Nacional Autonoma de Mexico, CDMX, Mexico; [2]Physiol., Univ. Nacional Autonoma de Mexico, Mexico city, Mexico

Abstract: Calorie restriction (CR) defines as a reduced calorie intake from food without causing nutritional deficiencies. Even though long-term CR has been described to have an anticonvulsant effect in generalized seizure models, the mechanisms that produce this effect are not clear in short-term. The objective of the present work was to evaluate the effect of short- term CR (SCR) on seizures induced by microinjection of kainic acid (KA) in the hippocampus of anesthetized rats. Male Wistar rats (250-300g) were divided into two groups: the first received food and water ad-libitum; the second, a short-term CR schedule that consisted of restricting calories to 40% in each animal for 30 days. A recording electrodes and microinjection by cannula system directed to the right hippocampus was implanted. Subsequently, each group was subdivided into two: one received the vehicle microinjection (0.9% NaCl) and the other the KA microinjection (1µg/µl). The electroencephalogram (EEG) was recorded at the microinjection site in the animals. The percentage of protection against status epilepticus (SE) was determined and the EEG signal was analyzed at different times (30,60 and 120 min). In the group subject to SCR, an increase in protection was found when presenting SE. In the spectral analysis of the EEG signal, the spectral power was lower in SCR rats compared to ad-libitum [$F(30,60) = 3.182$, $P<0.05$] at 120 min. These results suggest that SRC reduces the voltage of seizures induced by KA microinjection in the rat hippocampus.

Title: Downregulation of Wnt/B-catenin pathway in kindled rats subjected to caloric restriction

Authors: *E. URIBE[1], A. PORTILLA[1], D. HUERTA[1], W. MORENO[1], M. RUBIO-OSORNIO[2], C. RUBIO[1];
[1]Neurophysiol., [2]Neurochemistry, Inst. Nacional de Neurologia y Neurocirugia, Mexico City, Mexico

Abstract: Several of the antiepileptic effects of caloric restriction (CR) have been described, however, no relationship has yet been established within the *Wnt* molecular pathway, whose

status has been observed to be particularly altered in epilepsy in recent years. Continued research into these types of adjuvant therapies is essential as they could unveil new therapeutic targets for better disease control. We analyzed electroencephalographic changes and Racine´s stages behavior using the amygdalin Kindling experimental model (t-test), as well as the concentrations of key proteins within the *Wnt*/β-catenin signaling pathway (β-catenin, cyclin D, *GSK3β, Wnt*) using Western Blot and immunofluorescence technique in hippocampus and motor cortex of male Wistar rats (n=24) randomly divided into a control group (n=6), a Sham group (n=6) and two groups subjected to the Kindling model, one with CR (n=6) and the other *Ad libitum* (n=6). Data were analyzed using the software ImageJ for obtaining arbitrary optical units for protein´s density in grayscale and then analyzed in Excel using ANOVA and Tukey post hoc. After the Kindling model, we observed both a decrease in the duration of epileptic activity and the behavioral threshold in rats kindled with CR compared to those kindled *ad libitum* ($p<0.05$). Statistically significant differences were obtained in the densitometric analysis of proteins with an elevated concentration of all proteins in the Kindling *ad libitum* group compared to the rest ($p<0.01$) in both the motor cortex and hippocampus. Likewise,
a marked decrease of proteins close to control levels was observed in the Kindling group with CR ($p<0.01$), particularly in the hippocampus. Our results evidence a clear stabilizing effect of the *Wnt*/β-catenin pathway in rats subjected to CR after being exposed to seizures with the Kindling model, promoting a downregulation of the pathway in general, thus exerting a counterbalance to the overregulation obtained in the *ad libitum* Kindling group. It is important to consider the regulation of this intracellular signaling pathway as another molecular target within the antiepileptic effects of caloric restriction, as well as to continue investigating its potential relationship with other intracellular pathways such as mTOR, the ubiquitin-proteasome system or mitochondrial biogenesis.

Title: Female sex influences microRNA-silencing and anti-seizure efficacy of an antagomir in mice

Authors: *D. TIWARI[1,4], V. RAJATHI[2], J. RYMER[2], L. N. BEASLEY[1], A. MCGANN[2,5], A. BUNK[2], E. V. PARKINS[2,5], M. F. RICE[2], K. SMITH[3], D. M. RITTER[2], A. WHITE[2], C. M. DOERNING[3], C. GROSS[2,4];

Abstract: About one third of individuals living with epilepsy have treatment-resistant seizures. Alternative therapeutic strategies are thus urgently needed. One potential novel treatment target is microRNA-induced silencing, which is differentially regulated in epilepsy. Inhibitors (antagomirs) of specific microRNAs have shown therapeutic promise in preclinical epilepsy studies; however, these studies were mainly conducted in male rodent models, and research into microRNA regulation in females and by female hormones in epilepsy is scarce. This is problematic because female sex and the menstrual cycle can affect the disease course of epilepsy and may, therefore, also alter the efficacy of potential microRNA-targeted treatments. Here, we used the proconvulsant microRNA miR-324-5p and its target, the potassium channel Kv4.2, as an example to test how microRNA-induced silencing and the efficacy of antagomirs in epilepsy are altered in female mice. We showed that Kv4.2 protein is reduced after seizures in female mice similar to male mice; however, in contrast to male mice, microRNA-induced silencing of Kv4.2 is unchanged, and miR-324-5p activity, as measured by the association with the RNA-induced silencing complex, is reduced in females after seizure. Moreover, a miR-324-5p antagomir does not consistently reduce seizure frequency or increase Kv4.2 in female mice. As a possible underlying mechanism, we found that miR-324-5p activity and silencing of Kv4.2 in the brain were differentially correlated with plasma levels of 17β-estradiol and progesterone. Our results suggest that hormonal fluctuations in sexually mature female mice influence microRNA-induced silencing and could alter the efficacy of potential future microRNA-based treatments for epilepsy in females.

Title: Identification of non invasive biomarkers to improve diagnosis and prognosis of subjects with suspected autoimmuno encephalitis with seizure.

Authors: *L. LIBRIZZI[1], D. VILA VERDE[2], F. DELEO[1], G. D'AMBROSIO[1], C. REGONDI[1], M. DE CURTIS[1];
[1]Epilepsy Unit, Fondazione IRCCS Inst. Neurologico "C. Besta", Milan, Italy; [2]UCB Biopharma SRL, Braine-l'Alleud, Belgium

Abstract: Seizures frequently occur in Autoimmune Encephalitis (AE), but the factors underlying their development have not been fully identified. AutoAbs, indeed, could in principal account for the synaptic dysfunction, but only incompletely explain the generation of seizures that does not invariably occur in all the AE patients sharing the same autoAb, and can occur even in AE-seronegative cases (Bien,2017; Dalmau and Graus,2018). Growing evidence suggests that inflammatory mediators contribute to seizure development in epilepsy (Vezzani,2019; Librizzi,2021). In this study we investigated the specific role of peripheral blood mononuclear cells (PBMCs) in combination with serum albumin in initiating brain inflammation and in inducing seizure-like events (SLEs). We propose to identify novel mechanisms of seizure generation and new immunological markers specific to AE subtypes. We used the in vitro guinea pig brain preparation (de Curtis,2016) to investigate the effect of blood brain barrier impairment consequence, such as PBMC and serum albumin extravasation, on brain inflammation and excitability. We collected plasma samples from healthy volunteers and from AE patients who respond to these inclusion criteria: a) age 18 years; b) clinical onset no more than 9 months before inclusion in the study and at least one seizure (Graus,2021); c) APE2 score 4 (Dubey, 2019). HPBMCs were isolated and cultured in a standard medium. At t0 and at t6, supernatants were analyzed by ELLA® system, for IL10, IL17A, IL1β and IL6. Healthy volunteers (20) and AE patient-derived (7) hPBMCs ($10x10^6$) and their supernatant were perfused intra-arterially in the in vitro brain preparation. LPS (100ng/ml) and human recombinant albumin (4mg/ml) were previously perfused into the arterial stream to respectively favor and mimic a mild BBB impairment (Librizzi,2021). The specific ability of the experimental treatment to induce SLEs and brain inflammation was investigated. Morphological analysis and reconstruction of GFAP- and Iba1-positive glial cells were performed. Only AE patient-derived PBMCs treatment was able to evoke seizure activity and glial cells activation in the isolated brain preparation. ELLA immunoassay revealed an increased level of inflammatory mediators such as IL10, IL1β and IL6 in AE patient- derived PBMC supernatants compared with healthy ones.Preliminary results suggest an impact on brain inflammation and excitability by intrinsically activated, AE patient-derived PBMCs. Our experiments might shed light on identifying key mediators involved in seizure generation in order to identify novel treatments in epilepsies due to inflammatory and dysimmune causes.

Abstract: Chronic pain following peripheral nerve injury is accompanied by increased neuronal activity in the somatosensory cortex. However, whether and how cortical microglia contribute to these changes are less understood. To this end, we applied the optogenetic strategy to specifically target cortical microglia and their function in pain behavioral sensitization. We found that in vivo optogenetic activation of cortical microglia via red-activated channelrodopsin (ReaChR) triggered pain hypersensitivity and spontaneous pain in mice. Remarkably, S1-targeted microglial optogenetic stimulation increased microglial landscape change and ATP release events. In addition, optogenetic stimulation of cortical microglia up-regulated neuronal c-Fos expression and neuronal Ca^{2+} hyperactivity in the S1. We further found that optogenetic stimulation increased number of microglia derived extracellular vehicles (EVs) with proteomic alterations. The data obtained from the profiling of differentially expressed proteins (DEPs) provides mechanistic evidence how cortical microglia involved in development of chronic pain. Together, our results suggest that cortical microglia are critical in regulating neuronal activity, which is implicated in pain hypersensitivity.

Abstract: Microglia are key players in maintaining brain homeostasis and exhibit phenotypic alterations in response to epileptic stimuli. However, it is still relatively unknown if these alterations are pro- or anti-epileptic. To unravel this dilemma, we employed chemogenetic manipulation of microglia via of the artificial Gi-Dreadd receptor within a kainic acid (KA) induced murine seizure model. Our results indicate that Gi-Dreadd activation can reduce seizure severity. Additionally, we observed increased interaction between microglia and neuronal soma, which correlated with reduced neuronal hyperactivity. Interestingly, prolonged activation of microglial Gi-Dreadds by repeated doses over 3 days, arrested microglia in a less active, homeostatic-like state, which associated with increased neuronal loss after KA induced seizures. RNAseq analysis revealed that prolonged activation of Gi-Dreadd interferes with interferon β signaling and microglia proliferation. Thus, our findings highlight the importance of microglial activation not only during *status epilepticus* (SE) but also within later seizure induced pathology.

Title: Microglial volume regulated anion channel (VRAC) in epilepsy

Authors: *A. S. BARATH[1], A. DHEER[2], D. BOSCO[2], K. HARUWAKA[2], R. SAH[3], L.-J. WU[2];
[1]Neurosci., [2]Dept. of Neurol., Mayo Clin., Rochester, MN; [3]Cardiovasc. Div., Washington Univ. Sch. of Med., St. Louis, MO

Abstract: Microglia modulate neuronal activity during acute seizures as well as phagocytose injured neurons. They are thus attractive targets for anti-epileptic interventions. However, the mechanisms of their anti-epileptic effects are not completely understood. RNA sequencing data from our lab has shown upregulation of the volume regulated anion channel (VRAC) subunits in mice microglia at 3-7 days following seizures. The VRAC channel classically helps cells deal with hypoosmotic stress. However, it has multiple cell-type and context dependent functions. Therefore, we sought to study the role of microglial VRAC in the context of epilepsy. We used an inducible Cre-lox system to selectively delete SWELL1, the obligatory subunit of VRAC in microglia of adult mice. Acute status epilepticus was induced in these mice through an intra-

cerebroventricular injection of kainic acid (a glutamate agonist). Our preliminary results show a reduced CD68 expression in hippocampal microglia 3 days following seizures in SWELL1 cKO mice compared to their littermate controls. *In vitro* investigations revealed impaired phagocytosis of opsonized beads by SWELL1 cKO microglia. We functionally validated SWELL1 cKO *in vitro* by observing impaired microglial volume regulation and reduced taurine release in response to a hypotonic challenge. We continue to investigate the mechanism by which VRAC/ SWELL1 affects phagocytosis and its downstream effect on post seizure memory and learning.

Title: Chemogenetic manipulation of CX3CR1^{+} cells transiently induces hypolocomotion independent of microglia

Authors: *S. ZHAO[1], J. ZHENG[1], L. WANG[1], A. D. UMPIERRE[1], S. PARUSEL[1], M. XIE[1], A. DHEER[1], K. AYASOUFI[1], A. J. JOHNSON[1], J. R. RICHARDSON[2], L.-J. WU[1]; [1]mayo clinic, rochester, MN; [2]florida international university, miami, FL

Abstract: Chemogenetic approaches using Designer Receptors Exclusively Activated by Designer Drugs (DREADD, a family of engineered GPCRs) were recently employed in microglia. Here, we used *Cx3cr1*$^{CreER/+}$*:R26*$^{hM4Di/+}$ mice to express Gi-DREADD (hM4Di) on CX3CR1^{+} cells, comprising microglia and some peripheral immune cells, and found that activation of hM4Di on long-lived CX3CR1^{+} cells induced hypolocomotion. Unexpectedly, Gi-DREADD-induced hypolocomotion was preserved when microglia were depleted. Consistently, specific activation of microglial hM4Di cannot induce hypolocomotion in *Tmem119*$^{CreER/+}$*:R26*$^{hM4Di/+}$ mice. Flow cytometric and histological analysis showed hM4Di expression in peripheral immune cells, which may be responsible for the hypolocomotion. Nevertheless, depletion of splenic macrophages, hepatic macrophages, or CD4^{+} T cells did not affect Gi-DREADD-induced hypolocomotion. Our study demonstrates that rigorous data analysis and interpretation are needed when using *Cx3cr1*$^{CreER/+}$ mouse line to manipulate microglia.

Abstract: Microglia are resident immune cells of the central nervous system, constantly monitor the brain environment, and can regulate neuronal circuits through their interactions with neurons. Typical roles for microglia-synapse interactions include synaptic pruning and promoting spine formation, resulting in relatively persistent changes to neuronal circuits. Recently, several studies have demonstrated that microglia dampen neuronal hyperactivity in a P2Y12 receptor-dependent manner during acute brain injury and seizures. Previous studies reported that microglia increase their dynamic process surveillance and interact more closely with neurons depending on norepinephrine reduction during anesthesia. However, the functional significance of microglial process dynamics and neuronal interaction has remained unclear. Our hypothesis is that microglia promote neuronal activity to maintain homeostasis during hypoactive periods. To test this possibility, we investigated the role of microglia in regulating neuronal activity during recovery from general anesthesia. Using in vivo two-photon imaging, we discover that microglia enhance neuronal activity after the cessation of general anesthesia. We found that during anesthesia emergence, the excitatory neurons increased their spontaneous calcium activity, which correlated with enhanced sensory perception and animal locomotion. During anesthesia, microglial processes increased their contact with neuron somas and exhibited bulbous process endings at their contact sites. To study how microglial contacts may promote neuronal activity, we assessed excitatory and inhibitory synapses present on neuronal soma together with microglial processes with immunostaining. Hyperactive neuron somata are directly contacted by microglial processes, which specifically co-localize with GABAergic boutons rather than excitatory synapses. Three-dimensional electron microscopy-based synaptic reconstruction after two-photon imaging reveals that microglial processes enter the synaptic cleft to shield

GABAergic inputs. Two-photon live imaging further revealed that the interaction of microglial processes with GABAergic boutons was temporary and reversible, rather than phagocytosis. Microglial ablation or loss of microglial β2-adrenergic receptors prevents shielding GABAergic inputs and post-anesthesia neuronal hyperactivity. Together, our study demonstrates a previously unappreciated function of microglial process dynamics, which allow microglia to transiently boost neuronal activity by physically shielding axo-somatic inhibitory inputs.

Title: Alterations in microglia morphology and expression following in vitro traumatic brain injury

Authors: ***E. BLICK**, C. FRANCK, A. HAI;
Univ. of Wisconsin - Madison, Madison, WI

Abstract: Neuroinflammation following traumatic brain injury (TBI) remains an understudied link between primary injury and neurodegenerative disease, with post-mortem analysis of TBI patients demonstrating a brain-wide immune response up to 18 years after injury. Microglia, the resident immune cells of the brain, are crucial in this process as their prolonged activation is associated with driving secondary injury, cognitive decline, and cell death. Microglia are sensitive to their microenvironment and undergo functional and morphological transitions in response to inflammatory signals, adopting either anti- or pro-inflammatory roles. Most research on microglia activation relies on using lipopolysaccharide (LPS), a bacterial membrane component that targets microglial-specific receptors, but the research investigating the response of microglia to mechanical impacts is lacking. Furthermore, most TBI studies are conducted *in vivo* and, although biologically complex, they preclude reliable application of strain with the accuracy required to determine a correlation between impact and inflammatory response at a single cell level. In this study, we utilize a novel and highly precise *in vitro* model of TBI to evaluate alterations in microglia morphology and cytokine expression in response to controlled mechanical stress. Microglia are isolated from primary glial cultures derived from P0/P1 Sprague Dawley rats and seeded onto a customized dogbone-shaped polydimethylsiloxane (PDMS)

substrate treated with poly-d-lysine (0.1 mg/mL) and laminin (0.4 mg/mL). The geometric design and substrate properties enable the use of high strain rates without disrupting the gripping points and allow the gauge area hosting the cells to experience a realistic and uniform strain field. The dogbone is adhered between two grippers that are contacted by a custom-built tension device that applies programmed uniaxial stress. Strain rates between 10 s^{-1} to 50 s^{-1} are evaluated at 30 % strain. Live-cell fluorescent imaging is utilized before, during, and after the strain is applied and is analyzed in conjunction with images of fixed samples stained for Iba-1 to examine changes in microglial morphology. Additionally, an ELISA panel measures changes in relevant pro- and anti-inflammatory cytokines. Our approach enables us to investigate the effect of precise and reproducible mechanical strain on microglia and better understand their response to injury magnitudes experienced during TBI. This work offers valuable insights into the mechanosensitive response of microglia and could improve our understanding of TBI-related neuroinflammation.

Abstract: Alzheimer's Disease (AD) is a progressive neurodegenerative disorder characterized by cognitive decline, brain network alterations, and pathological changes, including extracellular amyloid-beta (Aβ) deposits and gliosis. AD-related network alterations include deficits in network hyperexcitability and gamma oscillatory (30-90 Hz) activity, which are canonically linked to alterations in interneuron activity. However, the contribution of non-neuronal cells to these disease-related network alterations is still unknown. Microglia have emerged as a potential mediator of neuronal network dynamics, as they respond to neuronal activity via activation of inflammatory pathways such as NF-κB. Previously, it has been shown that constitutive activation of microglial NF-κB contributes to tau spreading and toxicity in a mouse model of tauopathy. We built upon these findings to investigate the impact of microglial NF-κB activation on other cell types and behavior. To do this, we used mice with cre-dependent, constitutive activation of *ikbkb*—the upstream regulator of NF-κB—in microglia (*Cx3cr1*$^{CreERT2/+}$*;ikbkbCA*$^{F/F}$). To assess the functional impact of this manipulation, we performed *in vivo* LFP/single-unit recordings and

machine learning behavioral phenotyping (DeepLabCut and VAME) in mice with or without microglial NF-κB activation. Using these methods, we discovered state-dependent alterations in neuronal synchrony and behavioral deficits. Collectively, these findings elucidate a novel mechanism by which aberrant microglia NF-κB signaling contributes to AD-related network dysfunction and behavioral alterations.

Title: Sepsis increases complement pathway expression in the mouse and human brain and is associated with increased microglial synaptic pruning in amyloid-burdened mouse brains

Authors: *K. GIFFIN[1], A. C. BUSTAMANTE[2], P. K. CRANE[4], B. H. SINGER[3];
[1]Neurosci. Grad. Program, [3]Div. of Pulmonary and Critical Care Medicine, Dept. of Intrnl. Med., [2]Univ. of Michigan, Ann Arbor, MI; [4]Med. - Gen. Intrnl. Med., Univ. of Washington, Seattle, WA

Abstract: Sepsis is associated with both acute and long-term brain dysfunction, including cognitive deficits and mental health disorders, especially in the elderly. Multiple mechanisms drive sepsis-induced brain dysfunction and are not fully characterized. We previously used bulk RNA-sequencing (RNA-seq) to explore transcriptomic changes acutely caused by sepsis in the human brain. RNA-seq was completed on 12 sex-matched postmortem parietal cortex samples

from older patients from the Adult Changes in Thought (ACT) brain bank (Bustamante et al. 2020, DOI:10.1164/rccm.201909-1713LE). In bulk RNA-seq sepsis was correlated with several gene modules, including ones involving inflammatory response ($\rho = 0.51$, P = 0.01) and synaptic function ($\rho = 0.41$, P = 0.05). Here, we present single-nucleus RNA-seq, performed on a subset of 8 sex-matched brain samples used in the bulk RNA-seq study, to identify cell types driving the immune pathway changes. Cytokine and damage-associated molecular pattern signaling (e.g., *TNFRSF1A*, *TLR4*) and complement system (e.g., *C1QB, C1QC, C5AR1*) genes were differentially expressed by sepsis in astrocytes and microglia.
The complement system is a mediator for both neuroinflammation and synaptic pruning, as microglia phagocytose synapses tagged with complement proteins. To further investigate complement and microglia activity in the brain after sepsis, we turned to a mouse model of abdominal sepsis, cecal ligation and puncture (CLP). We investigated complement expression via whole-brain bulk RNA-seq and microglia-mediated synaptic phagocytosis as measured by proportion of microglia ($CD11b^{+}/CD45^{mid}$) positive for synaptic protein (SNAP25) by flow cytometry. To investigate the potential synergistic interaction of sepsis and amyloid pathology, we assessed complement expression and synaptic phagocytosis in sex-matched wild-type and 5xFAD mice. *C1QA-C* gene expression was elevated in the brain after sepsis acutely and long term (5- and 25-days post CLP). We did not find changes in microglial synaptic phagocytosis in wild-type mice. However, 5xFAD sepsis survivor mice had increased levels of synaptic phagocytosis relative to 5xFAD controls acutely (5-days post CLP) that persisted 6 weeks after sepsis. We were underpowered to assess sex differences.
We found that sepsis increases the expression of complement system genes in the brains of both humans and mice. Furthermore, microglial phagocytosis of synapses was increased in 5xFAD sepsis survivors. In vulnerable patients with underlying amyloid pathology, complement-driven, microglial-mediated synaptic pruning may be a mechanism driving brain dysfunction after sepsis.

Abstract It is likely that multiple mechanisms interact to cause the dysfunction and loss of substantia nigra and other vulnerable neurons in Parkinson's disease (PD). Growing evidence supports the hypothesis that activation of the immune system contributes to PD pathogenesis. In the brain, microglia are the main local actors of immune responses. These cells constantly probe their local microenvironment and interact with neurons through secreted factors. In PD postmortem tissue and in animal models of PD, evidence for microglial activation has been reported. Due to growing evidence suggesting the implication of Parkin in innate and adaptive immunity, we hypothesize that loss of function of this gene product could lead to increased activation of microglia following infections, with subsequent detrimental effects on dopamine neurons. Studying primary microglia obtained from neonatal Parkin KO mice, we observed that, as expected, these cells drastically change their morphology following exposure to the bacterial endotoxin LPS, switching from a polarized to an amoeboid shape, and show. increased expression of pro-inflammatory genes, such as MHC1, MHC2, iNOS and COX-2 . Interestingly, we observed that Parkin KO microglia show increased secretion of IL-6 and other cytokines and chemokines in response to LPS. They also show increased survival under culture conditions when compared to WT cells. Short-term co-culture of activated Parkin KO microglia with DA neurons did not induce loss of DA neurons. Functional studies are now required to examine their functionality. These initial results support the hypothesis of increased innate immune responses in the brain under conditions of Parkin loss of function in PD.

Title: Trem2 deficiency in microglia ameliorated neuroinflammation and photoreceptor loss at middle- and later-stages of retinitis pigmentosa disease

Authors: *R. LI[1,2], J. M. WU[2], J. Q. FAN[1], J. ZHANG[1], B. LIN[1,2];

Abstract: Purpose: Neuroinflammation plays a critical role in various neurodegenerative diseases. Similarly, increasing evidence indicates the involvement of microglia-derived neuroinflammation in the pathogenesis of retinitis pigmentosa (RP). Triggering receptor expressed on myeloid cells 2 (TREM2) is specifically expressed by microglia in the brain. Previous studies have reported that loss-of-function mutations of TREM2 compromise microglial phagocytosis and result in chronic neurodegenerative diseases. However, the functional role of TREM2 in RP remains unclear. Here, we investigated the role of TREM2 in mediating neuroinflammation and photoreceptor degeneration in a mouse model of RP. **Methods:** To investigate the role of TREM2 in regulating neuroinflammation in RP, we crossed $TREM2^{-/-}$ mice with rd10 mice, a mouse model of autosomal recessive RP, to generate $TREM2^{-/-}$/rd10 mice. We evaluated temporal expression of TREM2, microglia activation and photoreceptor degeneration in the retina of $TREM2^{-/-}$/rd10 mice using immunohistochemistry, qPCR, western blot, flow cytometry and electroretinography (ERG) approaches. Moreover, we performed single-cell RNA sequencing to explore transcriptional changes in TREM2-deficient microglia in rd10 mice. **Results:** We found that TREM2 was significantly upregulated in the retina of rd10 mice after postnatal day 22 (P22), the middle-stage of the disease. Meanwhile, we found that most of TREM2- positive microglia were localized at the outer nuclear layer (ONL) and retinal pigment epithelium (RPE) layer of the retina. Moreover, we observed that TREM2 deficiency significantly reduced microglia activation and the release of proinflammatory cytokines, while preserved photoreceptor cells in rd10 retinas. In addition, we found that TREM2 deficiency accelerated cell apoptosis of activated microglia at p25 of rd10 retinas by flow cytometry analysis. Furthermore, we performed single-cell RNA sequencing of microglial cells and found that TREM2 deficiency significantly induced transcriptional alteration in microglia in rd10 retinas. Bioinformatics analysis revealed that one subtype of disease-associated microglia (DAM) expressed most of differential expressed genes (DEGs), in which inflammation-related DEGs were downregulated and apoptosis-associated DEGs were upregulated. **Conclusion:** We demonstrated that TREM2 participated in the pathogenesis of RP. TREM2 regulated neuroinflammation and photoreceptor loss at middle- and later-stages of RP. Targeting TREM2 signal could be a new therapeutic strategy for RP.

Title: The impact of pharmacological depletion of microglia on alcohol-induced corticolimbic neurodegeneration in male rats

Authors: J. K. MELBOURNE, ***E. R. CARLSON**, K. NIXON;
Pharmacol. and Toxicology, The Univ. of Texas at Austin, Austin, TX

Abstract: Corticolimbic damage is a consequence of heavy drinking in individuals with an alcohol use disorder (AUD). Reactivity of microglia, the brain parenchymal macrophages, has been suggested as a mechanism underlying this damage, but causality has not been established. The aim of this study is to determine the role of microglia in alcohol-induced neurodegeneration in a rat model of alcohol dependence. We utilized the CSF1R inhibitor PLX-5622, an established tool for microglial depletion in mice, but infrequently used in rats. Adult male Sprague-Dawley rats were treated with PLX-5622 or vehicle (50mg/kg; MedChemExpress), by chow plus intraperitoneal injection or intragastric gavage (i.p., i.g. every 12 hours), for 7 days. For depletion plus alcohol exposure, rats received i.p. PLX-5622 or vehicle every 12 hours for 11 days, plus 4-day binge alcohol (25% (w/v) ethanol, i.g.) or isocaloric control diet every 8 hours in the final 4 days. Importantly, PLX-5622 did not significantly impact blood ethanol concentrations, which were 389.2 ± 23.98 mg/dl in the ethanol plus vehicle (Veh-EtOH) and 331.3 ± 42.49 mg/dl in the ethanol plus PLX-5622 (PLX-EtOH) groups. Rats were saline perfused, then brains were post-fixed in PFA and sectioned at 40 µm. Depletion was confirmed with immunohistochemistry for the microglial marker IBA1. Images were acquired in the hippocampus and peri/entorhinal cortex and counts performed to estimate % depletion. Histology and profile counts for FluoroJade B (FJB), a marker of dying neurons, were carried out in the hippocampus, peri/entorhinal and piriform cortices. Data were log transformed due to unequal group variance and analyzed by one-way ANOVA with Tukey's *post hoc*. 7 days of PLX-5622 i.p. plus chow resulted in ~90-94% microglial depletion, whereas there was no apparent depletion with PLX-5622 i.g. plus chow (n=2/group). In the alcohol experiment, 11 days of i.p. PLX depleted microglia ~97-98% (n=2/group). FJB+ cell counts were significantly increased for all rats that received ethanol diet (PLX-EtOH n=4; Veh-EtOH n=5) versus control diet (PLX-CON n=4; Veh-CON n=4) across all regions examined ($p<0.05$). In the peri/entorhinal cortex there were fewer FJB+ cells in the PLX-EtOH compared to Veh-EtOH group ($p<0.05$). While not statistically significant, fewer FJB+ cells were also noted in the other regions of PLX-EtOH rats. These data suggest that microglia may indeed contribute to ethanol-induced neurodegeneration. However, as neuronal death was observed in ethanol exposed rats depleted of >97% of their microglia, microglia-mediated mechanisms are unlikely to be the sole cause of corticolimbic damage in AUD.

Title: Microglial attenuate excitotoxicity in vitro by altering neuronal NMDA receptor subunit GluN2B expression independent of neuroprotection by an EP1 prostaglandin receptor antagonist

Authors: *N. G. CARLSON[1,3], L. SCHMIDT[2], B. WOOD[2], M. ROJAS[2], J. W. ROSE[4]; [1]Neurobio., [2]Neurovirology Lab., Univ. Utah, Salt Lake Cty, UT; [3]Grecc, VA SLCHCS, Salt Lake City, UT; [4]Neurol., VASLCHCS/University of Utah, Salt Lake Cty, UT

Abstract: Background: Microglia modulation of neuronal function is important in the pathogenesis of neurodegenerative diseases. Our previous study revealed that microglial cells co-cultured on transwells above neuronal cultures made neurons more resistant to NMDA-mediated excitotoxicity. Also, Neuroprotection mediated by an EP1 receptor antagonist was lost when neurons were co-cultured with microglia. Here we examine whether neuronal EP1 played a role in microglial-mediated neuroprotection and what changes in neuronal gene expression are induced by co-culturing neurons with microglia.
Methods: Cortical neurons were from E15 mouse embryos were cultured under conditions to produce nearly pure neuronal cultures. Microglia cultures were prepared from P1 post-natal mice and plated on transwells. After 1 week in culture, microglial transwells were placed above pure neuronal cultures for 48 hours. Neuronal viability was assessed following NMDA exposure to neuronal cultures in the presence or absence of microglial. In other experiments, neurons were transfected with EP1 shRNA to knock down expression of EP1. RNA was isolated from pure neurons grown with and without microglia and examined by transcriptome analyses for microglial induced changes in gene expression. Expression of GluN2B transcripts and protein was examined by real-time PCR and western blot respectively.
Results: To test whether the neuroprotective effect of microglia was mediated by altering the EP1 response in neurons, we knocked down neuronal EP1 expression by transfecting EP1 Sh RNA constructs into neurons and examined NMDA mediated excitotoxicity in the presence and absence of microglial trans-wells. Both control and EP1 knockdown neuronal cultures exhibited robust neuroprotection when co-cultured with microglial. As a positive control, protection by an EP1 antagonist in pure neuronal cultures was eliminated following Sh RNA mediated inhibition of EP1 expression. These results indicate that microglial-mediated neuroprotection occurs independent of neuronal EP1. To evaluate if microglia elicit neuroprotective effects through changing gene-expression in neurons, transcriptome analyses were conducted on neurons cultured in the presence and absence of microglia. The only difference in gene expression was GluN2B. A 1.5 fold decrease in expression of GluN2B was seen with RT-PCR and 2 fold change in expression by western blot analysis.
Conclusions: Our results showed that microglia can decrease neuronal expression of GluN2B. This in vitro system can facilitate future studies to examine microglial interactions that could play an important role in normal physiology and disease.

Abstract: Microglia are the immune resident cells of the central nervous system (CNS). They are known to be involved in phagocytosis of cellular and myelin debris, remyelination, and formation of a neuroprotective scar in the context of injury and disease. Insulin-like growth factor 1 (IGF-1) is known to activate various signaling pathways regulating cell proliferation, differentiation, migration, and survival. Since mechanisms by which microglia can repair CNS tissue remain unclear, we studied the effects of microglia-derived IGF-1 in different contexts such as spinal cord injury (SCI) and cuprizone-mediated brain demyelination. We hypothesize that IGF-1 is a key mediator for microglia to adopt a regenerative phenotype, thus contributing to CNS protection and repair. To test this hypothesis, we produced transgenic mice whose microglia are conditionally invalidated in IGF-1 after tamoxifen treatment, namely *Cx3cr1*^{CreER}::*Igf1*$^{fl/fl}$ mice. RNA-sequencing experiments revealed that genes (adj.p-value <0.05) and gene set supporting fibrotic scar formation are upregulated in conditional knockout mice at 7 days post-SCI, which corresponds to the peak of *Igf1* mRNA expression in wild-type (WT) littermates (GeneSet Enrichment Analysis with p-value <0.0001). Immunofluorescence data further showed that deletion of the *Igf1* gene in microglia slightly reduced the area occupied by Iba1^{+} signal outside of the primary lesion and was associated with changes in lesion morphology. In the cuprizone model, where microglia rather than peripheral macrophages are the predominant responders and key effectors of demyelination and myelin debris clearance, RT-qPCR analysis performed on dissected corpus callosum tissue samples revealed that *Igf1* mRNA levels are significantly decreased in *Cx3cr1*^{CreER}::*Igf1*$^{fl/fl}$ mice compared to WT littermates after tamoxifen and cuprizone treatment (p-value <0.005, n=3-4/group). Notably, reduced myelin staining was observed in the forebrain of *Cx3cr1*^{CreER}::*Igf1*$^{fl/fl}$ mice compared to WT mice at the peak of demyelination, i.e. after 5 weeks post-cuprizone feeding (p-value <0.05, n=5-7/group). In sum, our data reveal that microglia-derived IGF-1 could regulate formation of the glial and fibrotic

scars in SCI, while it may play a role in the activation/proliferation of microglia and clearance of myelin debris in areas of CNS demyelination.

Title: Sleep fragmentation alters microglial function leading to lethal neuroinflammation during sepsis-like inflammation

Authors: *A. WANI[1,2], A. RICKMAN[2], P. SHARMA[1], B. HECKMANN[2], D. R. GREEN[1]; [1]St. Jude Children's Res. Hosp., Memphis, TN; [2]USF Hlth. Byrd Alzheimer's Ctr. and Neurosci. Institute, Dept. of Mol. Medicine, Morsani Col. of Medicine, Tampa, FL, USA., Floida, FL

Abstract: It is well established that infection can promote slow wave sleep, but the functional importance of this phenomenon remains unclear. In this study, we utilized sleep fragmentation, i.e., intermittent disruption of sleep throughout the day, to explore the relationships between sleep and inflammatory disease. We found that sub-lethal injection of a bacterial lipopolysaccharide (LPS), prior to sleep fragmentation (SF) invariably resulted in dramatically increased mortality compared to LPS only or SF only controls, highlighting the importance of sleep following an inflammatory challenge. Further investigation revealed hyperactivation of microglia in the hypothalamus and other brain areas in mice subjected to LPS plus sleep fragmentation. As Toll-like receptor-4 (TLR4) is crucial for responses to LPS, we examined animals with microglia-specific deletion of TLR4 and found that it completely protected mice from the combination treatment. To further explore the role of sleep, we generated Dec2 (BHLHE41) mutant mice that display decreased sleep and found that these animals are protected from low dose LPS plus SF. We are currently extending our results to bacterial infection.

Title: Microglial removal of dying cells after status epilepticus

Authors: *P. HEMAN BOZADAS, N. H. VARVEL, R. J. DINGLEDINE;
Pharmacol. and Chem. Biol., Emory Univ., Atlanta, GA

Abstract: Microglia are the resident immune cells of the Central Nervous System. In addition to responding to injuries and aiding in recovery, microglia also promote a healthy environment through a process known as efferocytosis, which is the clearance of apoptotic cells. If efferocytosis is not efficient, the cell membrane of an apoptotic cell can lose integrity, spilling intracellular content and leading to a secondary necrosis of the surrounding tissue. One important role of efferocytosis is to prevent inflammation by quickly removing apoptotic cells. Neurodegenerative diseases and stroke can result in inefficient clearance of apoptotic cells if the capacity of microglia is overloaded. However, in Status Epilepticus (SE) the role of efferocytosis in recovery has not been explored. The goal of this study is to identify the cells undergoing efferocytosis after SE. Male C57BL/6 mice experienced pilocarpine-induced SE that was interrupted by diazepam after 1 hr. Four days later, 35 micron frozen sections were prepared through hippocampus and immunohistochemistry was performed to identify specific cell types (NeuN for neurons; Iba1 for reactive microglia) in conjunction with TUNEL labeling to identify nuclei of dying cells. Z-stack confocal images were obtained from the hippocampus using an A1R HD Nikon Confocal Microscope and the images were processed using Imaris V10.0 software. NeuN and TUNEL positive cells were counted and the cell volume overlapped (i.e., engulfed) by microglia was analyzed. In the CA3 region a histogram of Tunel volume was bimodal, with peak means of 6.4 ± 7.0 and 112 ± 43 μm^3, suggesting two populations of Tunel+ objects: smaller debris and larger actively apoptosing cells. Of all TUNEL-positive cells 33% were neurons. For Tunel+ cells, 77% of neurons and 56% of non-neuronal cells were larger than 25 μm^3. Microglia had engulfed 35% (median) of neuron volume but only 1.6% of non-neuronal volume ($p=.0029$, Mann-Whitney test). By contrast, the more numerous neurons *not* undergoing apoptosis, lacking the Tunel stain, experienced only 1.06% (median) of engulfment volume. These data suggest that efferocytosis by microglia in the CA3 region is mainly restricted to neurons undergoing apoptosis, and the small neuron fragments that are Tunel negative are being cleared possibly because they already have passed through necrotic process. These data are also consistent with the notion that non-neuronal cells undergoing apoptosis might eventually be redirected to a necrotic pathway, increasing neuroinflammation.

Abstract: Microglia reactivity in sensory and affective brain regions after peripheral nerve injury Rafael A. Cazuza[1], Jane C. Morphett[2], Michail Laoumtzis[2], Michael J. Lacagnina[1], AnamariaGrieco[1], Sever M. Zagrai[1], Mark Hutchinson[2], Peter M. Grace[11] Laboratories of Neuroimmunology, Department of Symptom Research, University of Texas MDAnderson Cancer Center, Houston, TX 77030, USA.[2] Australian Research Council Centre of Excellence for Nanoscale BioPhotonics and AdelaideMedical School, University of Adelaide, Adelaide, South Australia 5005, Australia.Microglia are resident macrophages in the central nervous system, responsible for cellsurveillance, phagocytosis, and release of soluble factors. These cells can change theirmorphology from a ramified to the most unramified amoeboid phenotype once reactive. Inaddition, microglia are very heterogeneous and can display distinct phenotypes depending ontheir location in the central system. In the context of nerve injury, microglia become reactive andalter their morphology in the spinal cord, releasing inflammatory mediators which maintainneuropathic pain. However, the sensory inputs that are carried through the spinal cord constituteonly one dimension of pain. Pain is a multidimensional experience that is encoded by verycomplex brain circuitry. Thus far, microglial reactivity has been incompletely mapped in thebrain after a nerve injury.In this work we explored microglia reactivity across time in brain regions that are associatedwith pain processing, using both males and females rats. Chronic constriction injury (CCI) orsham surgery of the sciatic nerve was performed in rats (N=6/sex/group) and the whole brainwas collected at 7 or 28 days after the surgery. The entire brain was coronally cryosectioned at30µm and stained for CD11b using immunohistochemistry. An advanced software for automatedanalysis (HALO – Indica Labs) was used to assess microglia morphological changes after thenerve injury. The morphological assessment was compared to a densitometry method.The densitometry analysis showed that affective brain regions display sustained microgliareactivity while areas responsible for sensory processing have a transient response. The HALOdetection of reactive microglia is still under analysis and it could provide further informationhidden in the densitometry assessment. These results suggest a possible role of microglia in long-lasting disruptions in affective states in neuropathic pain.

Title: Mif nuclease contributes to neuronal death in a mouse model of neuroinflammation

Authors: *S. GADANI, J. MACE, D. GALLEGALIOUS, M. SMITH, T. DAWSON, V. DAWSON, P. CALABRESI;
Johns Hopkins Hosp., Baltimore, MD

Abstract: Neuronal loss in the central nervous system is an irreversible outcome of many neuroinflammatory illnesses, and while several cellular and humoral factors have been implicated, the final mechanism(s) of cell death remain unclear. Parthanatos is a novel form of programmed cell death that is triggered when excessive DNA damage, induced by various stimuli including ROS, leads to overactivation of the PARP1 enzyme. PARP1 catalyzes the addition of poly-ADP-ribose (PAR) to numerous proteins including macrophage migration inhibitory factor (MIF), which then traffics to the nucleus and cleaves DNA through endogenous nuclease activity. Parthanatos was recently found to mediate α-synuclein related neurodegeneration in Parkinson's disease, but it had not been studied in the context of inflammation. Here, we present evidence for an important role of Parthanatos in the mouse model of neuroinflammation, experimental autoimmune encephalomyelitis (EAE). We find high baseline expression of MIF in neurons and accumulation of PAR within the spinal cord after EAE corresponding with neuronal cell death. We also found preservation of spinal cord neurons and retinal ganglion cells in mice where MIF nuclease activity is inhibited through a point mutation of its catalytic domain (MIF-E22Q). MIF-E22Q mice develop less severe neurologic impairment in the chronic stage of EAE compared to wild-type mice, though importantly they have similar peak EAE severity and immune infiltration, supporting a specific role for this pathway in neuroprotection. Treatment with C831, a novel small molecule inhibitor of MIF-nuclease, also leads to increased neuronal survival in the retina and spinal cord after EAE. Future studies will be aimed at assessing markers of Parthanatos in human multiple sclerosis samples, cell type-specific alteration of the Parthanatos pathway, and defining optimal C831 treatment paradigms. This work is the first to explore Parthanatos as a mediator of inflammatory neuronal cell death, and it contributes to a growing understanding of the role of Parthanatos in neurodegeneration and neuroinflammation.

Title: Inhibition of multifunctional MIF protein prevents inflammatory- and parthanatic-mediated neurodegeneration in the context of multiple sclerosis

Authors: *J. W. MACE[1], S. P. GADANI[2], D. GALLEGUILLOS[2], M. D. SMITH[2], B. KANG[3], T. GARTON[1], M. GHARAGOZLOO[2], V. L. DAWSON[3], T. M. DAWSON[3], P. A. CALABRESI[2];

Abstract: Nearly three million people worldwide are living with multiple sclerosis (MS), an autoimmune condition characterized by peripheral immune cell infiltration into the central nervous system (CNS) and reactive gliosis, demyelination, and neuroaxonal degeneration. Existing therapies target adaptive immune cells and treat relapsing MS, but are not effective in halting neurodegeneration in progressive MS. Numerous studies have identified prominent dysregulation of macrophage migration inhibitory factor (MIF), a multifunctional protein with cytokine and enzyme activity, in MS. MIF has two discrete enzymatic functions, as a tautomerase and a nuclease, that have not been well studied in MS. Our lab has shown that MIF nuclease acts as the final executioner of the caspase-independent cell death pathway, parthanatos, that is triggered upon DNA damage and contributes to neuronal loss in Parkinson's disease and stroke. Because neuroinflammation and parthanatos-inducing conditions, such as high ROS concentrations, are pathologically prevalent across many neurological diseases including MS, we hypothesized that MIF contributes to neurodegeneration in MS. Our lab used a commercially available mouse line (P2G) with its MIF tautomerase activity selectively ablated and created a mouse line (E22Q) with its MIF nuclease activity selectively ablated. We have also synthesized a compound (PAANIB1) that specifically inhibits MIF nuclease. These tools were used to assess the therapeutic efficacy of blocking MIF activity in an experimental autoimmune encephalomyelitis (EAE) mouse model of MS. Our data showed that P2G-EAE and E22Q-EAE mice had a decreased clinical disease severity over time. P2G-EAE mice had less peripheral immune cell infiltration into the CNS, whereas E22Q-EAE mice did not undergo a change in peripheral immune cell infiltration into the CNS. We further determined that E22Q-EAE mice, P2G-EAE mice, and PAANIB1-treated EAE mice were protected against retinal ganglion cell death. Lumbar spinal cord neuroprotection was also evident in E22Q-EAE mice and PAANIB-treated EAE mice. Both enzymatic activities of MIF appear to act in concert in EAE, as MIF global knockout EAE mice had the most protection from clinical disease severity and neurodegeneration, while E22Q-EAE and P2G-EAE mice were only partially protected. Altogether, if neurons degenerate by MIF-mediated inflammatory or parthanatic processes in the context of MS as indicated by our data, this research could establish a pharmacological target to treat the ongoing loss of grey matter in patients with this disease.

Title: Feasibility of prolyl oligopeptidase (PREP) as tumor biomarker in glioblastoma patients: a pilot study

Authors: *E. ESPOSITO[1], G. CASILI[1], M. CAFFO[2], S. SCUDERI[1], R. BASILOTTA[1], M. LANZA[1], A. FILIPPONE[1], I. PATERNITI[1], M. CAMPOLO[1], S. CUZZOCREA[1];

Abstract: Prolyl oligopeptidase (PREP) is a serine protease that hydrolyzes biologically active oligopeptides on their carboxyl side. PREP has been connected with multiple physiological and pathological conditions. Increased PREP activities have been found in tumors, although its involvement in the modulation of cancer mechanism is still unclear. Thus, the identification of PREP and clarification of its clinical significance are important for improving the diagnosis and treatment of brain tumors. The purpose of this study was to analyze the expression of PREP and its diagnostic and prognostic value in patients with glioblastoma (GBM). In this study, GBM patients and controls were enrolled and clinical data and PREP expression, from serum and biopsies, were analyzed. Moreover, the relationships between PREP, Protein phosphatase 2A (PP2A), signal transducer and activator of transcription (STAT3) and Transforming growth factor-β (TGF- β) were also examined. Our study demonstrated that PREP was significantly upregulated in both serum and in biopsy from GBM patients compared with controls. This upregulation was negatively correlated with survival, but significantly correlated with age and Mindbomb Homolog-1 Index (MIB1). Also, PREP expression was inversely correlated with tumor suppressor PP2A in biopsy from GBM patients, while PREP protein levels resulted to be positively correlated with STAT3 and TGF-β protein expression. The detection of PREP in serum and biopsies have the potential to serve as diagnostic and prognostic biomarker in GBM patient. The findings may provide diagnostic and therapeutic target for GBM.

Title: Reprogramming of Astroglioma Cells for Redirecting the Tumor Cell Fate as a Potential Anti-Cancer Gene Therapy

Authors: *T. ESTABA[1], M. Q. JIANG[1,3], S. DHARANENDRA[1], X. GU[1,3], A. WU[1], K. BERGLUND[2,3], S. YU[1,3], L. WEI[1];

Abstract: Gliomas are primary central nervous system tumors derived from glial cells. Glioblastoma (a type of glioma derived from astrocytes) is considered a grade 4 astrocytoma and is the most common type of adult brain malignancy that can be very aggressive with a very poor prognosis. Because of their highly vascularized nature, along with their predilection for widespread invasions of brain tissues, glioblastomas present a uniquely life-limiting illness. Direct reprogramming or direct conversion of glial cells to non-glial cells such as neurons has provided a genetic tool to manipulate cell fate as a potential therapy for neurological diseases. NeuroD1 (ND1) is a master transcription factor for neurogenesis with critical roles in regulating neuronal differentiation and maturation during nervous system development. In the present study, we tested the hypothesis that overexpression of the master transcription factor ND1 can redirect the fate of malignant glioma cells to postmitotic neuronal cells for slowing down or ceasing glioblastoma tumor progression. Our in vitro experiments used cell cultures of human glioblastoma cell lines LN229 and U87 as temozolomide (TMZ)-sensitive cells and T98G as TMZ-insensitive cells. ND1-initiated cell reprogramming was induced by adding an AAV carrying ND1 and mCherry. Three to 14 days after reprogramming, ND1-treated cells showed evidence of successful reprogramming and neuronal lineage conversion with significantly increased MAP2, TUJ1, and BDNF expression. TUNEL staining identified increased apoptotic cells co-labeled with ND1 overexpression in U87 and T98G cultures. Western blot analysis confirmed restoration of anti-tumor and cell cycle regulatory protein p53 in reprogrammed cells. Consistently, cultures with overexpressed ND1 had significantly fewer BrdU+ cells, indicating decreased cell proliferation. In an in vivo experiment, ND1-treated human U373 glioma cells were orthotopically transplanted into the fornix of cyclosporine-induced immunocompromised C57 mice. Immunohistochemical staining revealed increased neuronal markers such as TUJ1 expression of transplanted cells in the tumor area. The transplantation of ND1-converted cells also resulted in much-reduced tumor formation in the animal. The study provides evidence of successful reprogramming and conversion of glioblastoma tumor cells into postmitotic neuron lineage cells, suggesting that the direct reprogramming strategy using ND1 is an effective treatment for an extremely deadly cancer.

Title: Inhibition of WNT and TBK1 induces changes in cell cycle and cellular viability in human glioblastoma cells

Authors: *G. CONTRERAS CHÁVEZ[1], J. ESTRADA[2], L. ZAPI-COLÍN[2], I. CONTRERAS[2]; [1]Univ. Autonoma del Estado de Mexico, Metepec, Mexico; [2]Univ. Autonoma del Estado de Mexico, Toluca, Mexico

Abstract: Glioblastoma multiforme (GBM) remains difficult to treat, with current therapeutic options failing to significantly improve long-term life expectancy in patients. GBM is frequently accompanied by alterations in signaling pathways involved in inflammation, cellular proliferation, angiogenesis and survival. Hence, pharmacological modulation of cell signaling is commonly used as a therapeutic alternative for different types of cancer.WNT and TBK1 signaling pathways are involved in essential cellular processes, such as regulation of cell proliferation and apoptosis. The objective of this study is to determine the effects of pharmacological blockage of WNT and TBK1 signaling pathways on cell cycle progression and cell viability in U-87 MG human glioblastoma-derived cells. U-87 MG cells were cultured and supplemented with WNT (IWP12) and TBK1 (BX795) inhibitors at 0.1, 1, 5 or 10 μM concentrations, for 24, 48 and 72 hrs. Changes in cell cycle progression and cellular viability were evaluated by flow cytometry and crystal violet assays.Addition of BX795 to cell cultures increased cell cycle progression in U-87 MG cells, with the 10 μM concentration nearly doubling the frequency of cells at G2/M phase after 24 and 48 hours, compared to untreated controls (55.16% vs. 29,97%, respectively). However, after 72 hours, this effect disappeared, causing treated cells to behave like untreated controls. Treatment with IWP12 did not appear to influence cell cycle progression, regardless of dose and exposure time.Concerning cell viability, our results show reductions in viability using either inhibitor at all concentrations and exposure times, with the greatest effect observed being a 13.92% reduction in viability using BX795 at 10 μM concentration for 72 hours, compared to untreated cells.Our results suggest that pharmacological inhibition of TBK1 signaling using BX795 initially promotes proliferation of U-87 MG cells, but this effect becomes reduced after 72 hours of exposure, leading to increased apoptosis of treated cells in a dose-dependent manner.Further analyses to determine the mechanisms underlying these observations are currently underway.

[1]Mayo Clin., Rochester, MN; [2]Duke Univ., Durham, NC; [3]Albert Einstein, New York, NY; [4]MIT, Cambridge, MA

Abstract: With more than 13,400 adults diagnosed in the United States in 2022, Glioblastoma (GBM) is responsible for 49% of all primary malignant brain tumors. Despite decades of research, the median life expectancy for patients who undergo the current standard of care is between 12 and 16 months. α-PD-1 checkpoint blockade is a promising immunotherapeutic approach for many solid tumors; however, this strategy is minimally effective for GBM patients as a monotherapy. A potential explanation of why α-PD-1 checkpoint blockade is ineffective for GBM is the tumor microenvironment and systemic derangements of the immune system prevalent in these patients. We have successfully modeled peripheral immune suppression in experimental murine GBM models. These include low peripheral blood CD4 T cell counts, reduced MHC class II expression on monocytes, and atrophy of primary immune organs in animals harboring gliomas. We therefore hypothesized that extended half-life IL-2, a potent cytokine which promotes the proliferation, differentiation, and killing activity of T cells, could overcome immune derangements and potentially synergize with α-PD-1 checkpoint blockade inhibitor. In cohorts of C57Bl/6 mice, we supplemented α-PD-1 checkpoint blockade with multiple bio-engineered extended half-life IL-2 molecules to treat GL261-Luc and CT2A orthotopic glioma models, which are historically resistant to monotherapy. We demonstrate a statistically significant extended survival in GL261-bearing animals receiving the combination therapy of an extended half-life IL-2 reagent and αPD-1 relative to control-treated mice. Some animals receiving this combination therapy had a reduction in tumor burden to levels below detection. These long-term survivors underwent a rechallenge experiment with a second inoculation of GL261-Luc and effectively cleared tumor without further therapeutic intervention. This synergistic intervention causes a significant shift in the immune profile, including the formation of mature T cell responses, as well as restoring the diminished peripheral immune cell

counts in GL261-bearing animals. Finally, combining extended half-life IL-2 with α-PD-1 checkpoint blockade is effective independently of the CD8 T cell responses. Together, these data suggest that combination immunotherapies employing extended half-life IL-2 fusion proteins are translational to the clinic for GBM treatment and do not require the identification of tumor specific antigens for efficacy.

Title: Trem2 mediates mhcii-associated cd4^{+} t cell response against gliomas

Authors: *J. ZHENG[1], L. WANG[1], S. ZHAO[1], W. ZHANG[1], H. DONG[2], L.-J. WU[3]; [1]Mayo Clin. Grad. Sch. of Biomed. Sci., ROCHESTER, MN; [2]Immunol., [3]Neurol., Mayo Clin., ROCHESTER, MN

Abstract: Myeloid cells comprise up to 50% of the total tumor mass in glioblastoma (GBM) and have been implicated in promoting tumor progression and immunosuppression. Therefore, modulating the response of myeloid cells to the tumor has emerged as a promising new approach for cancer treatment. In this regard, we focus on the Triggering Receptor Expressed on Myeloid cells 2(TREM2), which has recently emerged as a novel immune modulator in peripheral tumors. We showed that brain tumors exhibit significantly higher levels of TREM2 expression, predominantly in tumor-associated myeloid cells. In a pre-clinical model of glioma, TREM2 deficiency did not have a beneficial effect, but instead accelerated glioma progression. Through

the integration of in vivo two-photon imaging, spectrum flow cytometry, quantitative real-timepolymerase chain reaction (qRT-PCR), and immunofluorescence staining, we discovered that TREM2 deficiency impair tumor-myeloid phagocytosis and MHCII expression. Furthermore, we found that deficiency of TREM2 significantly reduced CD4 + T cells in tumor hemispheres. Our results revealed a previously unrecognized protective role of tumor-myeloid TREM2 in promoting MHCII-associated CD4 + T cell response against gliomas.

Abstract: Glial-derived tumors account for most of the central nervous system (CNS) tumors. The initiating cell of glial-derived tumors is still elusive. However, state-of-the-art studies point towards immature oligodendrocytes as a possible source of gliomagenesis. Thus, studying markers related to oligodendrocyte precursors has become of great interest. Breast carcinoma amplified sequence 1 (BCAS1) has emerged as a novel marker that defines an immature oligodendrocyte population in the human CNS. The expression of this protein has been described as a key marker for tumorigenesis in non-CNS tumors, such as prostate cancer. However, its role and expression in gliomas is still underexplored. In this study, we analyzed the expression of BCAS1 in a series of oligodendrogliomas (n = 17), astrocytomas (n = 8) and glioblastomas (n = 60) surgically removed from patients, as well as four primary cell lines derived from patient tumors. The distribution, microenvironment, genetic alterations, and proliferative status of this cell subpopulation were analyzed, and further stereological quantifications were performed. Additionally, $BCAS1^{+}$ cells ultrastructure was studied by immunoelectron microscopy. Our

results show that BCAS1$^+$ cells constitute a morphologically heterogeneously distributed population in glial-derived tumors. BCAS1$^+$ cells exhibit stellate or spherical morphology. Stellate and spherical cells were detected in all studied gliomas as isolated cells. Interestingly, only stellate cells proliferate and form tightly packaged nodules in oligodendrogliomas, but not in glioblastomas or astrocytomas. We did not detect any BCAS1 gene amplification in any of the studied tumors. In conclusion, our findings suggest that BCAS1 defines a specific subpopulation within glial-derived tumors, which could correspond to a transient amplifying neoplastic cell state due to the proliferative features of BCAS1$^+$ stellate cells, thus contributing to tumor malignancy.

Title: Optimizing functional neuroimaging analysis in glioma patients

Authors: ***K. PARK**[1], J. SHIMONY[2], E. C. LEUTHARDT[3], A. Z. SNYDER[4];
[1]Washington Univ. in St. Louis Neurosci. PhD Program, SAINT LOUIS, MO; [2]Washington Univ. Sch. of Med., Saint Louis, MO; [3]Washington Univ. Sch. of Med., St. Louis, MO; [4]Radiol Dept, Washington Univ. Sch. Med., Saint Louis, MO

Abstract: Resting-state fMRI is becoming increasingly used to study the effects of gliomas on the functional organization of the brain. A variety of image processing and functional connectivity (FC) analysis techniques is represented in the literature but, to date, there has been no systematic examination of how this diversity affects observed results. To this end, we evaluated the impact of atlas registration option, parcellation granularity, and parcellation scheme in contrasting FC between patients and age-matched reference subjects. We analyzed data representing 59 glioma patients and 163 age-matched reference subjects. Differences between the two groups strongly depended on the methodologic choices. Our key findings are as follows: (1) Nonlinear atlas registration is required to compensate for anatomical distortions in glioma-bearing brains. Use of affine atlas registration leads to the false appearance of FC abnormalities. Theoretically, tumor masking could impact the results. However, in our data, the impact of tumor masking was not significant. (2) Functional parcellation schemes, as opposed to

anatomical parcellation schemes (AAL/Brainnetome), maximize sensitivity for the detection of glioma-induced FC abnormalities. (3) FC variability in normal subjects must be considered when identifying FC abnormalities in glioma patients. FC abnormalities in glioma patients are most evident in analyses based on fine parcellations. (4) Much prior work evaluates FC in glioma patients using graph-theoretic measures. As previously noted, not all such measures are equally sensitive to FC abnormalities in glioma patients. In particular, modularity appears to be unchanged in glioma patients. Importantly, the differences between patients and the reference subjects as assessed with graph-theoretic measures were only evident at fine parcellation granularities.

Title: Investigating the evolution of neuron-glioma circuit dynamics using an in vivo imaging method

Authors: *K. SHAMARDANI[1], M. B. KEOUGH[1,2], M. MONJE[1,3];
[1]Neurol., Stanford Univ., Stanford, CA; [2]Neurosurg., Univ. of Alberta, Edmonton, AB, Canada; [3]Howard Hughes Med. Inst., Stanford, CA

Abstract: Pediatric high-grade gliomas (pHGG) are aggressive primary brain neoplasms with a dismal prognosis, making them the leading cause of brain tumor-related deaths in children. pHGGs occur in specific anatomical locations at specific ages underscoring their origin in neurodevelopment and the critical importance of the brain tumor microenvironment. Activity-regulated mechanisms such as neurotransmitter, neurotrophin, and calcium-mediated signaling are major regulators of neural development and plasticity. Many pHGGs originate from oligodendroglial precursor cells (OPC) and, like OPCs, neuronal activity promotes pHGG proliferation. Recent work has demonstrated that pHGG cells form calcium-permeable AMPAR-mediated synapses with neurons analogous to the axo-glial synapses that form between neurons

and OPCs. Neuronal activity drives pHGG growth through the secretion of activity-regulated mitogens and through electrochemical communication with pHGG cells that integrate into neural circuits. In turn, pHGG increases neuronal excitability and remodels functional neural circuits. The interconnected network of glioma cells and neurons is fundamental to pHGG progression. However, how these neuron-glioma networks evolve over time remains to be fully understood. We hypothesize that as gliomas progress, the neuron-glioma malignant circuitry evolves chiefly through synaptogenesis to promote activity that fosters glioma progression. Thus, we developed a two-color in vivo imaging method to study neuron-glioma cell interactions over time in freely behaving mice enabling us to record the frequency, pattern, and synchronicity of calcium transients in neurons, glioma cells, and their coactivity giving us a comprehensive view of the changes in neuron-glioma circuit dynamics over time. We have observed increasing neuronal activity throughout the disease, consistent with increasing neural hyperexcitability over time, and have observed that different types of gliomas exhibit unique patterns of calcium transients (rise time, peak amplitude, decay time, and half-width). Our imaging paradigm offers a unique ability to study neuron-glioma interactions at the systems level and will allow us to study how pharmacological inhibitors and neuronal experience shape neuron-glioma malignant circuit dynamics.

Title: Glioblastoma-neuronal circuit integration is modulated by interleukin-6

Authors: *A. G. S. DANIEL, S. KRISHNA, S. L. HERVEY-JUMPER;
Neurolog. Surgery, Univ. of California San Francisco, San Francisco, CA

Abstract: The pleiotropic cytokine interleukin-6 (IL-6) is known to be involved in both pro- and anti-inflammatory signaling cascades. In glioblastoma studies using animal and human models, IL-6 promotes immunosuppression and tumor progression and is negatively associated with survival. Intriguingly, IL-6 also contributes to increased synaptogenesis during development and following focal brain injury. Glioblastoma remodeling of neuronal circuits influences patient survival; therefore, it is possible that IL-6 has mechanistic significance. Here, we investigated IL-6 as a driver of activity-dependent glioblastoma proliferation using patient-derived xenograft (PDX) mouse and human glioblastoma models. We assessed neuronal activity by microelectrode arrays and in vitro calcium imaging using weighted mean firing rate (WMFR), network burst frequency (NBF), and synchrony index. Next, we used bulk and single-cell RNA sequencing on 13,731 cells from ten tumors including pair-matched samples to identify differentially expressed genes in intratumoral regions with elevated functional connectivity and found IL6 to be highly upregulated. Mouse embryonic cortical neurons and cerebral organoids co-cultured with primary patient-derived glioblastoma cells demonstrated concentration-dependent neuronal hyperexcitability (increased WMFR and NBF) in IL-6-overexpressing conditions compared to the neuron-only condition. Pharmacological inhibition using the humanized IL-6 receptor antibody tocilizumab reduced network synchrony across models. These findings suggest that IL-6-induced glioma-neuronal hyperexcitability may be inhibited by the FDA-approved tocilizumab, thereby providing preclinical support for its use to treat activity-dependent mechanisms of glioblastoma proliferation. Future studies are needed to uncover mechanisms and clinical efficacy.

Title: Sodium pump activity in the cerebral cortex of rats fed with a high-calorie diet.

Authors: *R. MERCADO[1], O. GUZMAN-QUEVEDO[2], R. MANHÃES-DE-CASTRO[3], M. FLORES, Jr[4];
[1]Univ. Michoacana, Tarimbaro, Michoacan, Mexico; [2]Inst. Tecnológico Superior de Tacámbaro, Tacámbaro, Mexico; [3]Dept. de Nutrição, Univ. Federal de Pernambuco, Recife, Brazil; [4]Univ. Michoacana de San Nicolás de Hidalgo, Morelia, Mexico

Abstract: The central nervous system coordinates all the functions of the organism and its main function is the transmission of the nerve impulse, with the help of neurotransmitters. On the other hand, the Na+/K+-ATPase (sodium pump) is a membrane-bound enzyme responsible for maintaining the ionic gradients across the membrane, also it is part of the cellular signaling pathway so we know that is stimulated by serotonin. In Mexico and the world, metabolic related

diseases are a public health problem, especially diabetes mellitus, a disease related to a high-calorie intake and which is part of the metabolic syndrome. To this day it is unknown if a high-calorie intake would alter the sodium pump activity and its effect in the metabolic of lipids and carbohydrates, therefore our main goal is to determinate the effect of a high-calorie intake in the lipid profile, the tolerance of glucose and the activity of the sodium pump. A diet model of high carbohydrates and high lipids intake was established in male Wistar rats and its effect was compared against a control group. Meanwhile this model was implemented, body weight and blood glucose levels were recorded, also oral glucose tolerance test and insulin resistance test were executed. Lipid profile and activity of the sodium pump were determined. Results show an increase in body weight in animals with high-calorie diet, also an increase in blood lipids level was observed. Fasting blood glucose levels were not different between groups, meanwhile oral glucose tolerance curves and insulin resistance test in fact shows hints about an impaired glucose tolerance in rats with high-calories diet. In relation with the activity of the sodium pump, we observed that there was a statistically significant decrease in the experimental group as compared with the control group. These results suggest us that a high-calorie diet decreased sodium pump activity although without signals of hyperglycemia, altered lipid profile.Acknowledgements: The present work was partially supported by CIC-UMSNH, ICTI-Michoacán.

Title: Transient exercise-induced changes of circulating factors in the mouse muscle-brain axis

Authors: *J. JUERGENSMEYER[1], C. DESAI[2], S. MORET[2], J. MURRAY[2], E. KANG[2], S. VILLARINO[2], K. ALVIÑA[2];
[2]Neurosci., [1]Univ. of Florida, Gainesville, FL

Abstract: Exercise promotes healthy cognitive aging and could be an effective non-pharmacological alternative to prevent or delay pathology associated with neurodegenerative disorders such as Alzheimer's disease (AD). However, mechanisms underlying such positive effects are not fully understood. Irisin, a myokine that is secreted from skeletal muscle during exercise, is linked to mechanisms that are dysfunctional in AD, such as glucose metabolism and hippocampal neurogenesis. Nevertheless, there have been contradictory reports on changes in irisin levels following exercise. Such inconsistencies might be a result of variability in

experimental conditions, such as duration of exercise protocols (e.g., acute or chronic) and/or timing of tissue collection (e.g. immediately after or hours later).
To determine the precise timespan of exercise-induced changes in circulating irisin, we designed exercise protocols that tested the effect of these experimental variables. We hypothesized that changes in circulating irisin concentration occur during or immediately after exercise and return to baseline shortly thereafter. Moreover, we predict the irisin-mediated benefits of exercise will not be represented by changes in baseline levels. To test these hypotheses, we subjected adult male and female mice to swimming or running exercise for 20 min and measured post-exercise serum irisin concentration (via ELISA) at four different time points: 0, 30, 60, or 120 min after. Compared to sedentary controls, we observed a ~20% increase in male mice immediately after either exercise protocol, which decreased to baseline levels within 60 min. No changes were detected in female mice. Next, we performed a chronic exercise protocol (swimming for 20min/day for 21 days) with a separate group of male and female mice, and measured serum irisin 24 h after the last exercise session. As expected, our results show no difference between the exercise group and the sedentary controls. Our results suggest that irisin is released during exercise and circulating levels return to baseline within an hour. Therefore, the timing of sample collection should be carefully considered to reliably detect exercise-induced changes in circulating irisin. In addition, we observed robust sex-dependent differences that should be further explored, including the potential relationship between Irisin release and stress.

Title: Evaluating dietary and synthesized agents associated with modulation of the autophagy-lysosomal pathway for improving synaptic resilience and reducing aging-related cognitive deficits

Authors: M. F. ALMEIDA[1,2], K. N. ADAMS[1], R. HICKS[1], M. GREENE[1], S. T. KINSEY[2], R. DAVIDSON[1], J. ENRIQUEZ[1], M. VIANA[1], K. L. G. FARIZATTO[3,1], *B. A. BAHR[4];

Abstract: Cognitive health is a major research focus for pharmaceutical and nutraceutical studies. Cognitive decline is strongly associated with aging, and it can be attenuated by physical exercise and a healthy diet which were recently associated with the modulation of proteostasis. Neuronal compromise signifies vulnerability that fosters cognitive impairment, whether facilitated by aging, excitotoxicity, cholinergic crises, or traumatic events. These risks to cognition negatively affect proteostasis and synaptic integrity, and they are known to compromise the autophagy-lysosomal protein clearance pathway. Natural products have been linked to cognitive health, thus a range of agents were tested for the ability to amplify cathepsin B (CatB), a lysosomal hydrolase that degrades pathogenic proteins and is synaptoprotective. After three daily infusions into hippocampal explants, extracts of bacopa and the ginseng *P. quinquefolius* enhanced the CatB-30 active form by over 3-fold; several other natural products were ineffective. Only *P. quinquefolius* produced correlative enhancements of CatB-30, LC3-II, and synaptic markers. Interestingly, this ginseng and the exercise mimetic β-GPA both protected synapses in cultured explants subjected to age-related stress induced by a lysosomal inhibitor. From subsequent translational work, *in vivo* studies identified cognitive defects in middle-aged rodents, and the measured cognitive decline was offset by the two different treatments. Currently, chemoproteomics techniques are being utilized for protein target discovery to decipher the potential mechanistic pathway for the lysosomal enhancement produced by unique compounds that are sensitive to brefeldin A with the apparent involvement of the AMPK/SIRT1 axis. Note that disruption of lysosomal function has been linked to neurodegenerative disorders (Wang et al. 2018 *Curr Opin Neurobiol* 48:52), while the polyphenol-type compounds that upregulate/promote CatB maturation provide protective enhancement of protein clearance capacity in models of AD, PD, and MCI (Viswanathan et al. 2012 *ACS Med Chem Lett* 3:920; Hwang et al. 2019 *International J Mol Sci* 20:4432). We are particularly interested in whether targets of the protective compounds are also compromised by organophosphate toxicity (Farizatto et al. 2019 *Scientific Reports* 9:6532), seizure induction, and/or primary blast exposures (Almeida et al. 2021 *Brain Pathology* 31:e12936), all of which cause dementia-related synaptopathy. These studies suggest that dietary and other agents act via a similar pathway as does exercise, promoting protein clearance activation and corresponding synaptic protection.

Title: Exercise Modalities Improve Motor Coordination and Balance Skills in Aged Rats

Authors: *I. SIQUEIRA[1], L. MEIRELES-MORAES[1], L. C. RECK[1], F. GALVÃO JÚNIOR[1], L. HOLT[2], P. MEWS[2], E. J. NESTLER[2];

Abstract: Although several lines of evidence suggest that exercise has neuroprotective effects, there are few reports comparing different exercise modalities in an aged model. In addition, the prefrontal cortex (PFC), which is involved in cognitive control including motor functions, may have a central role in exercise-induced improvements on brain functions. Our aim was to investigate the protective effects of different exercise modalities on age-related declines in cognitive skills, specifically on motor function. The Local Ethics Committee at UFRGS approved all handling and experimental conditions (CEUA-UFRGS, no. 29818). Adult and aged male Wistar rats (2 and 22 months old) were subjected to aerobic, acrobatic, resistance, or combined exercise modalities for 20 min, 3 times a week, for 12 weeks. Beam balance and rotarod tests were used to investigate motor function. All rats were decapitated 1 h after the last exercise session. The PFC was quickly isolated by punch dissection, immediately snap-frozen in liquid nitrogen, and then stored at −80°C until the nuclear-FACS procedure. PFC nuclei were isolated and sorted into NeuN+ and the remaining NeuN- fractions by fluorescence activated cell sorting (FACS). Total RNA was isolated, cDNA libraries were constructed, and RNA-seq was performed. Aged rats had worse motor performance. All exercise modalities, except acrobatic, showed a trend to improve rotarod index. Sedentary aged rats were unable to stay on the rotarod apparatus even at a relatively slow speed (10 rpm), while all modalities improved rotarod performance at this speed. Aerobic, acrobatic, and combined exercise modalities improved beam balance performance. All exercise modalities improved postural stability and balance and represent a potential approach to reduce the incidence and severity of falls in older people. Moreover, our evolving RNA-seq data will provide insight into the molecular mechanisms in PFC by which exercise improves motor performance.

Title: Anabolic effects of dexamethasone on hippocampal lipidome

Authors: *F. I. AGUAYO[1], J. KUHN[2], J. CIDLOWSKI[2];
[1]Signal Transduction Lab., [2]Mass Spectrometry Res. and Support group, NIEHS, Durham, NC

Abstract: Background: Dexamethasone (DEX) is a synthetic glucocorticoid broadly used for treatment of inflammatory affections, such as rheumatic problems, allergies, asthma, chronic obstructive lung diseases, brain swelling, among others. However, its chronic use has been related to the development of mood disorders, including depression and anxiety; and less commonly with seizures, euphoria, sleep disorders and psychosis. This drug exerts its actions by binding to the glucocorticoid receptor (GR), a member of the nuclear receptor family of ligand-activated transcription factors that modulate the expression of numerous genes either by repressing or increasing their transcription. These genes mostly regulate inflammation process and catabolism of carbohydrates and lipids. In a recent analysis of transcriptomic data from mice depleted from hippocampal GR, our laboratory has shown a decrease in mRNAs related to the biosynthesis of phosphoinositides, diacylglycerol, fatty acids, ethanolamines, and sphingolipids. **Hypothesis:** Dexamethasone has an anabolic effect on the hippocampal lipidome **Methodologies:** HT-22 mice hippocampal cell line was incubated with DEX 10 nM, RU-486 100 nM (RU, a GR antagonist), the co-incubation with DEX and RU, and the vehicle solution by 48 hours. Then lipids were isolated by the Bligh and Dyer method, and semi-quantified by non-targeted lipidomic. Additionally, adrenalectomized male mice were administrated with DEX 2.5 mg/L in the drinking water. After 8 weeks of drug administration, mice were euthanized and hippocampi were dissected, followed by lipid extraction the Bligh and Dyer method, and semi-quantified by non-targeted lipidomic. After initial data collection, PCA and hierarchical clustering analysis were used as a non-supervised classification method. Differential lipid levels were determined by using Partek suite software, and lipid enrichment analysis was performed in LION database. **Results:** Dexamethasone incubation of HT-22 cells induce a general increase in levels of phosphatidylcholine, phosphatidylserine, phosphatidylethanolamine, phosphatidylinositol, sphingomyelin, and ceramide. These effects are blunted by GR antagonist co-incubation. On the other hand, the hippocampi from DEX treated mice showed increases and decreases in phosphatidylethanolamine, phosphatidylcholine and phosphatidylserine, along with a decrease in sphingomyelin and triglycerides. **Conclusions:** Dexamethasone presents an anabolic effect on lipidome in the *in vitro* mice hippocampal model. However, this drug displayed both anabolic and catabolic effects on lipids from our *in vivo* model.

Title: The multifaceted impact of APOE genotype on the benefits of calorie restriction during aging

Authors: *W. QIAO[1], Y. CHEN[2], Y. REN[3], T. IKEZU[2], S. JOHNSON[2], F. LI[2], K. CHEN[2], M. PAN[6], A. MENESES[2], A. KURTI[4], J. CHEN[5], X. HAN[7], G. BU[2], N. ZHAO[8];
[1]Neurosci., [3]Hlth. Sci. Res., [4]Neurosci. Res. Dept., [2]Mayo Clin., Jacksonville, FL; [5]Mayo Clin., Rochester, MN; [6]Med., [7]Univ. of Texas Hlth. Sci. Ctr. at San Antonio, San Antonio, TX; [8]Mayo Clin. Jacksonville, Jacksonville, FL

Abstract: Introduction: Calorie restriction (CR) is known to promote healthy aging and extend lifespan. However, the influence of different apolipoprotein E (*APOE*) genotypes on the outcomes of CR intervention remains unclear. **Methods:** To address this question, we conducted an 8-month CR study in APOE-targeted replacement (TR) mice expressing human *APOE2*, *APOE3*, or *APOE4* gene. The CR treatment involved a 30% reduction in caloric intake starting at 12 months of age until 19.5 months, while control littermates received a normal diet *ad libitum* (AL). We also examined the effects of CR in a separate cohort of mice with a history of 3.5-month high-fat diet (HFD) exposure. We conducted a battery of behavioral tests to assess the anxiety, working memory, and associative memories. We then harvested brains and blood and collected fecal samples from these animals and performed multi-omics profiling, including transcriptomics, lipidomics, and microbiomics. **Results:** We found that CR reduced anxiety and improved associative memory in *APOE3* and *APOE4* mice but not *APOE2* mice compared to the AL group. Transcriptome analysis of the brain identified an activation of the cholesterol synthesis pathway and predicted changes in myelination through the activation of oligodendrocyte precursor cell differentiation in *APOE3* and *APOE4* mice upon CR. CR also had significant effects on brain and blood lipid metabolism, with APOE genotype-dependent alterations mainly observed in the blood lipidome, particularly in APOE2 mice. Microbiota profiling showed that CR increased the abundance of Bifidobacteriaceae species in *APOE3* and *APOE4* mice, correlating with memory improvement, while APOE2 mice exhibited increased abundance of Lactobacillus species without memory-related correlations. These effects of CR were also observed in mice with prior HFD exposure and were specific to *APOE3* and *APOE4* mice. **Conclusions:** Our study demonstrates that *APOE* genotypes play a differential role in mediating the multifaceted effects of CR on behavior, gene expression, lipid metabolism, and microbiome diversity, providing important implications for early prevention strategies targeting aging and aging-related disorders.

Title: Propofol attenuates surgery induced cognitive impairment in aged mice via α5-$GABA_A$ receptors

Authors: *R. NAGARAJAN[1], J. LYU[2], M. KAMBALI[1], M. WANG[2], R. A. PEARCE[3], U. RUDOLPH[1];
[1]Dept. of Comparative Biosci., Univ. of Illinois at Urbana-Champaign, Urbana, IL; [2]Dept. of Comparative Biosci., Neurosci. Program, Univ. of Illinois at Urbana-Champaign, Urbana, IL; [3]Dept. of Anesthesiol., Univ. of Wisconsin, Madison, WI

Abstract: Postoperative neurocognitive disorder (poNCD), i.e., cognitive deficits present more than four weeks after surgery and anesthesia that may lead to increased morbidity and mortality, are relatively common in aging human patients. Propofol, the most commonly used intravenous anesthetic, exerts its anesthetic actions primarily via $GABA_A$ receptors. However, it has also been shown to have neuroprotective effects in aged mice and in a mouse model of Alzheimer's disease. We wanted to test the hypothesis that chronic intermittent propofol prevents or reverses postoperative cognitive deficits in aged mice via α5-$GABA_A$ receptors. Abdominal surgery was performed under isoflurane anesthesia in 21-24 months-old wild-type mice and global α5 knockout mice. Animals received either chronic intermittent propofol (CIP, 75 mg/kg i.p.) or vehicle (Intralipid^R) every 5th day throughout the experiment. CIP led to a sustained redistribution of the $GABA_A$ receptor α5 subunit to the surface membranes. Laparotomy performed on day 17 impaired learning and memory functions, as determined using a behavioral test battery that included Y maze alternation, novel object recognition, water maze learning, reversal learning, and cued and contextual fear conditioning, compared to no surgery controls. Strikingly, CIP improved cognitive function postoperatively and attenuated surgery-induced mitochondrial dysfunction and the oxidative stress marker nitrite in the hippocampus. Western blots on hippocampal tissues showed that CIP attenuated the surgery-induced apoptotic cell death and microglial activation in the aged mice. Importantly, these protective effects of propofol were absent in aged global α5 knockout mice, indicating that α5-$GABA_A$ receptors are involved in mediating the cognitive benefits of propofol. The current study suggests that perioperative intermittent propofol administration might prevent or attenuate surgery-induced cognitive dysfunction and thus potentially reduce the liability for undesired long-term outcomes. Our results reveal that chronic intermittent propofol
administration increases the surface expression of α5-$GABA_A$ receptors, improving cognitive function in aged mice after surgery.

Title: Ipsc-derived mononuclear phagocytes rescue cognitive impairment and improve neural health in aging mice

Authors: *V. MOSER[1], L. J. DIMAS-HARMS[2], J. INZALACO[2], S. BELL[2], R. M. LIPMAN[4], H. S. GOODRIDGE[3], C. SVENDSEN[3];
[1]Regenerative Med. Inst., Cedars-Sinai Med. Ctr., West Hollywood, CA; [2]Regenerative Med. Inst., [3]Regenerative Med. Ctr., Cedars-Sinai Med. Ctr., Los Angeles, CA; [4]Univ. of Maryland, College Park, MD

Abstract: A number of studies have demonstrated the ability of young blood or plasma to improve cognitive function in aged animals, and we have previously shown that bone marrow transplanted from young to aging mice has beneficial effects on cognition and neural health in aging recipients. In the current study, we sought to evaluate the cell type that might be responsible for the observed effects, focusing on mononuclear macrophages as these cells are known to become dysfunctional in aging. We used human induced pluripotent stem cells (iPSCs) to generate mononuclear macrophages (iMPs), as this enables the generation of a renewable and scalable cell therapy. iMPs were administered to aging mouse models via tail vein injection. Aging-associated cognitive deficits were significantly improved in iMP-treated mice. Moreover, relative to vehicle-treated aging mice, aging mice treated with iMPs showed improvements in several neural health outcomes, including increased synaptic marker expression, and reduced microglial activation. A proteomic analysis of plasma revealed that several proteins increased in aging plasma but were restored to levels observed in young animals after iMP treatment. Interestingly, several of these same pathways were altered with aging and after iMP treatment in hippocampal single nucleus RNA sequencing (snRNA-seq) data, suggesting potential targets through which iMPs may be acting. iMPs present a promising novel therapeutic for aging-associated declines in cognition and neural health.

Title: Tlr4 mediates development of persistent post-operative cognitive dysfunction following short-term high-fat diet consumption in male rats

Authors: *S. MUSCAT, M. BUTLER, M. BETTES, J. DEMARSH, R. BARRIENTOS;
Inst. for Behavioral Med. Res., The Ohio State Univ., Columbus, OH

Abstract: Background: Gradual declines in cognition are associated with normal aging but can turn precipitous following peripheral immune insults. Post-operative cognitive dysfunction (POCD) is an abrupt decline in neurocognitive function - difficulty with executive functions, memory impairment, confusion - experienced following surgery, lasting days-to-months after surgery. Importantly, longer-lasting POCD can develop into dementia. Advanced age and obesity & other comorbidities linked to high-fat diet (HFD) consumption are identified as risk factors for POCD, although underlying mechanisms remain unclear. We previously showed that just 3-days of HFD can evoke neuroinflammation sufficient to cause memory deficits in aged rats. Therefore, we hypothesized that HFD consumption before surgery would potentiate the neuroinflammatory response & memory deficits via activation of the innate immune receptor TLR4, which both insults are known to stimulate. **Methods:** Young-adult (3mo) & aged (24mo) rats were fed chow or HFD for 3-days immediately before sham surgery or laparotomy. 2-weeks later, rats underwent contextual fear conditioning to assess hippocampus- & amygdala-dependent long-term memory. Expression of neuroinflammatory molecules was assessed. In a separate experiment, rats were administered the TLR4-specific antagonist LPS-RS immediately before HFD onset; surgery & memory tests were performed as before. Additionally, the efficacy of DHA supplementation to mitigate HFD and surgery-induced neuroinflammation and memory deficits was assessed. **Results:** Aged rats who received both HFD & laparotomy had impaired hippocampus-dependent memory compared to all other groups, and both aged & young-adult rats fed HFD before surgery experienced amygdala-dependent impairment. Interestingly, protein expression of the pro-inflammatory cytokines IL-1β, IL-6, & TNF was significantly increased in aged rats who received both HFD & surgery in the hippocampus, but not amygdala, 3-weeks after surgery. The HFD+surgery-induced memory impairments are dependent on activation of TLR4, as LPS-RS pre-treatment completely prevented this effect. Additionally, pre-operative DHA supplementation effectively prevented HFD and surgery-induced neuroinflammation and memory impairments. **Conclusions:** These findings suggest that HFD may 1) increase risk of persistent POCD-associated memory impairments following surgery in rats in 2) a TLR4-dependent manner, which 3) can be targeted by DHA supplementation to mitigate development of persistent POCD.

Title: Efficacy of microalgae extract from Phaeodactylum tricornutum on cognitive function in elderly

Authors: *J. MAURY[1], C. SEXTON[2], V. BARBOSA[2], G. DUNNGALVIN[2], T. G. DINAN[3], R. PRADELLES[1];
[1]Res. & Develop., Microphyt, Baillargues, France; [2]Atlantia Food Clin. Trials, Cork, Ireland; [3]APC Microbiome Ireland, Univ. Col. Cork, Cork, Ireland

Abstract: In developed countries, a rapidly ageing population is being observed due to declining birth rates and increased life expectancy, and it has a direct impact on public health policies from on a societal and economic perspectives. One of the critical health and societal issues facing an ageing population is the maintenance of cognitive function. In this regard, some pharmacological, behavioural and dietary preventive approaches have been evaluated to improve age related decline in the cognitive function. Microalgae is a promising approach as they are able to produce bioactive molecules, such as pigments, fatty acids, peptides and sterols. Fucoxanthin is one of the major carotenoid found in microalgae as *Phaeodactylum tricornutum* (PT), well known for its neuroprotective effect. There are no human studies to our knowledge, however, results from an *in vivo* study showed a significant improvement in learning, short term and spacial memory, a decrease in brain inflammation and oxidative stress following microalgae extract from PT in a mice model of ageing (article submission in progress). The objective of the present double-blind, placebo-controlled study was to evaluate in healthy older adults the effect of daily supplementation of microalgae extract *PT* during a 24-week period on cognitive function of healthy older adults with age-related mild cognitive decline (NCT04832412). In total, 66 males and females, aged between 55 and 75 years old were randomly assigned to ingest placebo (PL) or 550mg of *PT* extract (including 0.8% of fucoxanthin, Brainphyt™). The definition of age-related mild cognitive impairment was a score of ≥24 on the Mini Mental State Examination (MMSE) and a score of ≥25 on the Memory Assessment Clinic-Q (MAC-Q). Participants performed a battery of cognitive tests using Computerised Mental Performance Assessment System (COMPASS) to measure spatial, working, episodic, long term memory, attention and vigilance and executive function. Sleep quality, mood and stress states were also evaluated using validated questionnaires. In addition, blood samples were collected to evaluate the effect of supplementation on neuro-inflammatory markers (e.g. BDNF, CCL2, IL6, IL18, TNFa, VEGF) and identify their potential mechanism of actions. All endpoints were collected at baseline, week 12 and week 24, and the interventional phase has been completed. This study is now in the statistical analysis and interpretation phase, which is expected to be completed in Q3 2023.

Title: Tamsulosin impairs object recognition without affecting anxiety-related behaviors in mice

Authors: *C. D. MOURA[1], V. A. HOLANDA[2], M. C. OLIVEIRA[1], C. I. TORRES[1], E. D. JUNIOR[1], E. C. GAVIOLI[1];
[1]Dept. of Biophysics and Pharmacol., Federal Univ. of Rio Grande do Norte, Natal, Brazil; [2]Neurosurg. Departament, Johns Hopkins Univ., Baltimore, MD

Abstract: Tamsulosin is an uroselective α1-adrenoceptor blocker used to treat benign prostatic hyperplasia. This drug displays high affinity for α1A and α1D-receptors subtypes, which are also expressed in the brain. Dementia symptoms after administration of tamsulosin in humans have been reported, but studies on its brain-derived effects are still lacking. On that account, this study aimed to investigate the effects of tamsulosin on cognitive performance and anxiety, by using object recognition task (ORT) and elevated plus-maze (EPM) test in mice. For this, tamsulosin (0.001-0.01 mg/kg) was orally administrated in male Swiss mice (12-16 weeks old) at three separate time points: 60 min before training session (TS), immediately after TS and 60 min before test session (TES). Biperiden (BPD; 2-4 mg/kg, ip) was used as an amnesic standard. The elevated plus-maze (LCE) was conducted after oral administration of tamsulosin (0.0001-0.1 mg/kg, 60 min prior to the test). Diazepam (DZP; 1 mg/kg, ip) was used as an anxiolytic standard. BPD impaired object recognition when injected both pre- (Recognition index, RI - interaction between treatment and sessions: $F(1,26)=11.8$, $p<0.05$, 2-way ANOVA, Bonferroni's test) and post-training (time: $F(1,28)=13.2$, $p<0,05$, 2-way ANOVA, Bonferroni's test). Tamsulosin 0.01 mg/kg impaired object recognition at all times measured, while at the dose of

0.001 mg/kg did not affect mouse performance in the ORT (RI-pre-training: $F(2,42)=36.4$; post-training: $F(2,42)=43.5$; for both $p<0.05$, 2-way ANOVA, Bonferroni's test). In the EPM, DZP was able to increase the percentage of time spent in the open arms compared to the control ($F(5,40)=5.7$, $p<0.05$, 1-way ANOVA, Bonferroni's test). However, tamsulosin did not affect mouse behavior at any dose tested ($p>0.05$). The sample size was 7-8 animals per group. In conclusion, tamsulosin impaired memory performance by affecting acquisition and consolidation of memory in mice. The cognitive impairment of tamsulosin is not related to anxiety. Previously, we reported that tamsulosin (0.01 mg/kg) increases susceptibility to depressive-like behaviors in mice (Holanda et al. 2022). Altogether, behavioral effects of tamsulosin contribute to understand its potential side effects, and it can also add to the role played by α1-adrenoceptor in the etiology of psychopathologies.

Title: Effects of acute and chronic administration of intranasal oxytocin on large-scale brain networks in older adults

Authors: *P. LIU[1], T. LIN[2], R. POLK[2], H. FISCHER[3], D. FEIFEL[4], N. C. EBNER[2,5,6,7]; [1]Dept. of Psychology, Univ. of Florida, GAINESVILLE, FL; [2]Dept. of Psychology, Univ. of Florida, Gainesville, FL; [3]Psychology, Stockholm Univ., Stockholm, Sweden; [4]Kadima Neuropsychiatry Inst., La Jolla, CA; [5]Inst. on Aging, Gainesville, FL; [6]Dept. of Clin. and Hlth. Psychology, Ctr. for Cognitive Aging and Memory, Gainesville, FL; [7]Florida Inst. for Cybersecurity Res., Gainesville, FL

Abstract: Intranasal oxytocin (IN-OT) is a key modulator of social-cognitive capacities such as emotion identification (*Horta et al., 2019)*, social memory (*Tse et al., 2018)*, animacy perception (*Valdes-Hernandez et al, 2021)*. IN-OT has also been shown to modulate resting-state functional connectivity (rs-FC) between key nodes of the salience network (e.g., insula and amygdala; *Ebner et al., 2016; Brodmann et al., 2017*), known to gate attention (*Uddin, L. Q., 2016).*

However, not well understood yet are IN-OT's effects on large-scale brain networks: (i) among older adults, despite robust evidence of age-related differences in brain network function and increasing evidence of age-differential effect of IN-OT on both brain and socioemotional behavior (*Ebner et al., 2013; Horta et al., 2020);* (ii) for chronic (i.e., repeated) in addition to acute (i.e., single-dose) administration regimens, to determine OT's therapeutic potential (*Horta et al., 2020)*. Given that, the research aim in the present study is to determine the extent to which IN-OT (relative to placebo) modulates rs-FC between the salience network and its key nodes in the aging brain both after acute (*Study 1*) and chronic (*Study 2*) IN-OT. The results were shown that (i) acute IN-OT decreased rs-FC of right insula with the salience network in both young and older adults; (ii) chronic IN-OT decreased rs-FC of right insula with the salience network in older adults; (iii) OT reduced rs-FC of the right insula with the salience network was more pronounced after chronic than acute IN-OT.

Title: Genkwa Daphne flower extract (GFE) and the major compounds restored neuroprotective functions of disease-associated senescent microglia.

Authors: S. PARK[1], D. GUPTA[1], Y.-S. LEE[1], ***G. SONG**[2,1];
[1]Translational Brain Res. Ctr., Intl. St. Mary's Hospital, Catholic Kwandong Univ., Incheon, Korea, Republic of; [2]Dept. of Med., Catholic Kwandong Univ., Incheon, Korea, Republic of

Abstract: The population is facing an era of super-aging, and the number of patients with degenerative brain diseases such as dementia is rapidly increasing. Neuroinflammation, commonly observed in degenerative brain disorders, is closely related to microglial dysfunction. Microglia are the innate immune cells in the central nervous system that play a crucial role in neuroprotection by releasing neurotrophic factors and removing pathogens through phagocytosis and regulating brain homeostasis. The extract from Daphne Genkwa plants were reported to have neuroprotective effects in animal models of neuroinflammation. This study aims to study the anti-inflammatory and neuroprotective effect of GFE and major compounds in disease-associated senescent microglia (DASM). First, we developed in vitro model of DASM. GFE inhibited LPS-induced inflammatory factors in DASM, supporting the anti-inflammatory effect of GFE. Arg1 and BDNF mRNA was increased in primary microglia treated with GFE, supporting the neuroprotective effect of microglia. In vivo effects of GFE were also found in mouse brain as oral administration of GFE significantly inhibited the LPS induced neuronal loss and inflammatory activation of microglia. This study suggests that oral GFE may be a promising approach that may promote neuroprotection, and anti-inflammatory effects can be a preventive measure for neurodegenerative diseases via promoting microglial neuroprotective effects.

Title: Presentation and loss of environmental enrichment toys: effects on stress and affective behaviors in male and female mice

Authors: *M. RHODES[1], M. L. JENKINS-ANDREWS[1], M. R. BISIGNANI[1], C. M. MONROY[1], S. A. LIVELSBERGER[1], G. C. NOEL[1], R. T. RUBIN[2];
[1]Biol. Sci., St. Vincent Col., Latrobe, PA; [2]David Geffen Sch. of Med. at UCLA, Oxnard, CA

Abstract: Structural aspects of housing and husbandry conditions can influence the physiology and behavior of laboratory animals. We previously demonstrated that housing jugular vein-cannulated (JVC) rats with commonly used environmental enrichment (EE) toys resulted in lower hypothalamic-pituitary-adrenal (HPA) axis activity before and after mild stress. Other studies indicated that removal of EE in these animals resulted in sexually diergic HPA activity before and after restraint stress: male HPA responses increased, and female HPA responses decreased. The goal of the present study was to extend these studies in male and female mice by determining the influences of presenting and removing EE toys on adrenal hormone responses and on anxiety and depressive behaviors, as an animal model of stress and mental health changes

following significant loss in humans.
The EE toys, Nesting Sheets™, Gummy Bones, and Mouse Igloos® and Arches™, were chosen because of their potential to enhance nesting, gnawing, playing, and sheltering behaviors. Following a one week acclimation period, the mice were presented with EE for two weeks. At the end of the two weeks, EE was removed randomly from selected cages to form two experimental groups: 1) male and female mice that remained housed with EE, and 2) male and female mice that had lost EE. Control mice were housed without EE under standard husbandry conditions throughout. Each week, marble-burying and sucrose preference tests were performed, and fecal samples were collected. Five days after EE removal, the mice in each group were restrained for 10 min, followed by blood collection. Fecal and serum corticosterone (CORT) concentrations were determined by highly specific immunoassays.
EE increased, and EE removal decreased, anxiety and depressive behaviors in female mice. In contrast, EE decreased, and EE removal increased, anxiety and depressive behaviors in male mice. Consistent with our previous findings, removal of EE resulted in sexually diergic CORT concentrations in fecal samples as well as CORT responses after restraint stress: male CORT concentrations increased and female CORT concentrations decreased.
These data indicate that sudden changes to the housing environment of laboratory mice can affect their physiology and behavior in sexually diergic ways: Housing male mice with EE may lower their stress and affective behaviors, whereas housing female mice with EE may increase their stress and behavioral responses. In contrast, removal of EE may lower stress and affective behaviors in female mice, while increasing them in male mice.

Title: Running to remember: The effects of exercise on perineuronal nets, microglia, and vascularization in female and male mice

Authors: *M. G. MAHEU[1], N. JAMES[1], Z. CLARKE[2], A. YANG[1], S. M. BEAUDETTE[1], R. PATEL[3], R. E. K. MACPHERSON[1], P. DUARTE-GUTERMAN[4];
[1]Hlth. Sci., [2]Psychology, [3]Neurosci., [4]Psychology, Ctr. for Neurosci., Brock Univ., St Catharines, ON, Canada

Abstract: Exercise is accepted as a positive health behaviour; however, the mechanisms underlying its role in neuroprotection and cognitive health are less well understood. The purpose of this investigation was to explore the neurobiological benefits of treadmill exercise in female and male mice through its role in regulating microglia (Iba-1), cerebral vascularization (CD-31), and perineuronal net (PNN, with WFA) expression. We aimed to examine how these neurobiological changes relate to spatial memory outcomes. C57BL/6J mice were assigned to a sedentary (12F/12M) or exercise group (11F/12M). Mice were treadmill-trained for an hour per day, five days per week, at increasing speeds and incline for eight weeks. During the final week of the exercise intervention, all mice were trained on a spatial memory task (Barnes Maze) for five consecutive days. A probe trial was conducted, after which brains were perfused for immunohistochemical analysis. Exercised mice incurred fewer errors than sedentary mice during the first two days of training as well as the probe. Females, regardless of exercise regimen, made fewer errors during training, had shorter latencies, and had a greater frequency of spatial strategy use compared to males. Exercised mice, regardless of sex, expressed fewer PNNs in the dentate gyrus compared to sedentary controls. Dorsal PNNs were positively correlated with greater errors on the first day of training, and this effect was strongest among females. PNNs were negatively correlated with microglia in the ventral dentate gyrus, and this effect was greatest among the exercised females. Microglia count and cerebral vascularization were not affected by exercise. Our study suggests that exercise improves spatial memory and decreases PNNs in the dentate gyrus, but may pose greater cognitive benefits to females compared to males.

Title: Glutamatergic synapse properties are rapidly modulated by ERα but not ERβ or GPER1 activation in female rat nucleus accumbens core medium spiny neurons

Authors: A. KRENTZEL, C. MILLER, ***J. MEITZEN**;
North Carolina State Univ., Raleigh, NC

Abstract: Sex steroid hormones such as 17β-estradiol (estradiol) modulate the nucleus accumbens core (NAcc), a sexually differentiated brain region integral for motivated behaviors and addiction and mental health disorders. Estradiol action upon the NAcc is sex-specific, with increased sensitivity exhibited by adult females compared to males. One estradiol action in adult female rat NAcc is rapid modulation of excitatory synapse properties of medium spiny neurons

(MSNs), the predominant neuron type of the NAcc. Topical estradiol application acutely and rapidly decreases the frequency of MSN miniature excitatory postsynaptic currents (mEPSCs), mimicking natural fluctuations in mEPSC properties observed across estrous cycle phases. We tested whether activation of estrogen receptor α (ER), ERβ, or GPER1 was sufficient for inducing changes in mEPSC properties assessed via whole-cell patch clamp in acute brain slices of adult female rat NAcc. The ERα agonist PPT induced robust decreases in mEPSC frequency, while the ERβ agonist DPN and the GPER1 agonist G1 did not. These data indicate that activation of ERα is sufficient for inducing changes in mEPSC frequency, implicating this receptor as a primary target for future research.

Title: Impact of estrogen on gut microbiome and their metabolites and cognitive function in young adult rats following adolescent stress

Authors: M. XU[1], K. KROLICK[1], J. ZHU[2], *H. SHI[1];
[1]Biol., Miami Univ., Oxford, OH; [2]Human Sciences; James Comprehensive Cancer Ctr., The Ohio State Univ., Columbus, OH

Abstract: Adolescence is a period with hormonal changes and continuing brain maturation. Chronic stress with elevated glucocorticoids due to disruption of the hypothalamic-pituitary-adrenal (HPA) axis during this developmental stage increases the risk for psychological and cognitive maladies. The brain-gut axis serves as two-way communication connecting the central nervous system (CNS) that regulates behaviors and the gastrointestinal tract where a diverse population of microorganisms resides. The gut microorganisms constantly produce metabolites that provide feedback to the CNS. Both rodents and humans display estrogen-dependent stress responses. It is unclear how estrogen affects gut microbial population and their metabolites and cognitive behavior following stress. Female rats at 4 weeks of age, sham or ovariectomy (OVX), with or without estradiol (E2) replacement, underwent 13 days 1 hour/day restraint stress. Plasma corticosterone (CORT) levels during stress were measured using ELISA. After chronic stress or no-stress in 6-week-old rats, a complex-paradigm reward-nose-poke design known as reversal learning behavioral test was used to assess cognitive flexibility, which represents the ability of behavioral adjustment in new environmental challenges and is associated with

increased resilience to negative life events such as stress. The gut microbial population and their metabolites were characterized in cecum fecal samples using integrated genomic analysis and mass spectrometry (MS)-based metabolic profiling. Stress increased CORT levels of sham and OVX+E2 rats compared to their respective no-stress rats at the beginning of the stress period, but such increase disappeared at the end of the stress period. When estrogen level was reduced in OVX+Oil rats, the HPA axis stress response persisted, indicated by increased CORT levels throughout the entire stress period. Stress OVX+E2 rats, but not OVX+Oil rats, showed an increased rate of reversal learning compared to their no-stress counterparts, suggesting that E2 enhances coping following stress. Beta diversity of microbial community indicated distinctly separated clusters between no-stress and stress rats in sham and OVX+E2 groups, but not OVX+Oil group. Microbial metabolic analysis revealed a similar attribute, with differences in major metabolic pathways between stress and no-stress rats of sham and OVX+E2 groups, but not OVX+Oil group. The findings suggest that estrogen may benefit brain-gut homeostasis and improve cognitive functioning, at least partially via relieving prolonged stress response involving the HPA axis and maintaining changes in gut microbiota and their metabolites.

Title: Lepr-pirt neurons of the hypothalamic arcuate nucleus promote pituitary reproductive function

Authors: Y. WANG[1], A. TOMLINSON[1], J. G. SANTINGA[1], Q. WEIWEI[1], A. C. RUPP[1], C. F. ELIAS[2], S. M. MOENTER[3], *M. MYERS, Jr[1];
[2]Mol. and Integrative Physiol., [3]Mol. and Integrative Physiology, Intrnl. Medicine, and Obstetrics and Gyne, [1]Univ. of Michigan, Ann Arbor, MI

Abstract: Secreted by adipocytes, leptin acts on leptin receptor (LEPR) neurons in the central nervous system to signal the repletion of body fat/energy stores. In addition to decreasing appetite and food intake, adequate leptin concentrations permit the expenditure of energy on a host of energy-intensive processes, including basal metabolism, immune function, and the neuroendocrine reproductive and growth axes. The specific Lepr cell types that mediate each effect have yet to be defined, however. Our recent single nucleus RNA sequencing analysis identified several novel populations of hypothalamic Lepr neurons, including an arcuate nucleus (ARC) populations marked by the expression of Pirt (LeprPirt neurons). While LeprPirt neurons reside in the ARC, they are distinct from other well-known populations of ARC Lepr neurons,

including those that contain POMC, AgRP, or kisspeptin/dynorphin. While these other populations of ARC neurons mainly project into the hypothalamus, ARC Pirt neurons (a surrogate for LeprPirt cells) project mainly into the median eminence, suggesting their potential role in the control of pituitary function. We used the stereotaxic injection of cre-dependent AAVs to express Designer Receptors Exclusively Activated by Designer Drugs (DREADDs) in ARC Pirt cells to examine their function. Activating these cells did not alter food intake or energy balance. In contrast, this stimulus increased circulating concentrations of luteinizing hormone (LH) and follicle stimulating hormone (FSH) while decreasing growth hormone (GH); ACTH, TSH, and Prolactin were unaltered. Consistently, the activation of ARC Pirt neurons in diestrous female mice promoted entry into estrus as measured by vaginal cytology. These data are consistent with the notion that ARC Pirt neurons project into the median eminence to activate the pituitary reproductive axis, linking energy balance and other signals to the neuroendocrine control of reproductive function.

Title: Presynaptic Dopamine Synthesis Capacity during the Menstrual Cycle in Healthy Women Studied with Positron Emission Tomography

Authors: *C. RECTO[1,2], S.-M. WEI[2,3], D. P. EISENBERG[2], P. D. KOHN[2], M. D. GREGORY[2], J. B. CZARAPATA[2], M. N. GOLDBERG[2], I. M. WILDER[2], P. J. SCHMIDT[3], K. F. BERMAN[2];

Abstract: Background: Sex differences in the course and prevalence of dopamine-related neuropsychiatric disorders such as schizophrenia and Parkinson's disease have raised the possibility of clinically important effects of sex hormones on the central dopamine system. Preclinical experiments have identified a number of sex hormone-dopamine interactions, including rodent studies finding that estradiol may facilitate presynaptic dopamine function, though human data are limited. In menstruating women, we hypothesized that presynaptic

dopamine synthesis capacity would be increased in the follicular phase of the menstrual cycle, when estradiol levels are both higher and unopposed by progesterone compared to the luteal phase.
Methods: To directly measure presynaptic dopamine synthesis capacity, [^{18}F]-FDOPA PET scans were obtained for thirty-one healthy, regularly menstruating women. A separately-collected T1-weighted anatomical MRI scan was segmented to provide a cerebellar reference region and was co-registered to each participant's realigned, attenuation-corrected PET data. Using the Gjedde-Patlak method, extracted cerebellar time activity curves were used to calculate the specific uptake constant K_i. Voxel-wise analyses ($p=0.005$, uncorrected) were performed using SPM within the striatum to compare eleven women studied during the follicular phase (days 4-11 of menstrual cycle; mean age=39.0±11.5 years) to twenty women studied during the luteal phase (days 18-39; mean age=35.0±9.0 years).
Results: We observed greater [^{18}F]-FDOPA K_i in the follicular relative to luteal phase in bilateral striatum, specifically within the left putamen, right caudate, and right ventral striatum (peak $p=0.001$). No effects were observed in the opposite direction ($p<0.05$).
Conclusions: Compared with the luteal phase, greater [^{18}F]-FDOPA uptake was found in women assessed during the follicular phase, which is associated with relatively higher estradiol levels. Our results align with preclinical evidence suggesting estradiol's modulatory role within the dopamine system, and, if confirmed longitudinally, may provide impetus for more directed studies in clinical populations. Future work will additionally explore associations between the menstrual cycle and other aspects of the dopamine system, such as dopamine receptor density.

Abstract: Age is a risk factor for the development of breast cancer. Breast cancer patients frequently report alterations in behavior and cognition. Foundational science studies have supported associations among neuroinflammation, breast cancer, and chemotherapy, but to date, these associations are based on studies using young adult rodents. The current study examined the neuroinflammatory effects of chemotherapy in aged, tumor-naïve and tumor-bearing mice with or without social enrichment. We hypothesized that chemotherapy increases neuroinflammation via increased peripheral immune cell trafficking within the brain and predicted this effect would be modulated by social enrichment. Mice received two intravenous injections of doxorubicin (A; 9mg/kg) and cyclophosphamide (C; 90mg/kg) separated by two weeks. Brain immune cells were enriched and assessed via flow cytometry seven days following the second chemotherapy injection. Contrary to our hypothesis, social enrichment enhanced peripheral immune cell trafficking in aged tumor-naive mice treated with AC. However, group-housed aged tumor bearing mice receiving AC displayed a reduced percentage of IL-6+ monocytes and granulocytes relative to their singly- housed counterparts, demonstrating the ability of social enrichment to attenuate some aspects of neuroinflammation in aged mice. There was no effect on tumor growth when aged social enrichment partners were used. In contrast, social enrichment with young mice reduced TNF^{+} monocytes, tumor volume, and tumor mass in aged tumor bearing mice relative to their singly-housed counterparts. These data add to the literature detailing the beneficial effects of social enrichment and are the first to demonstrate that social support with young housing partners reduces tumor growth in aged mice.

Title: Mitochondrial fission inhibition by isoliquiritigenin ameliorates LPS-induced Inflammation in BV-2 microglial cells

Authors: *S. LEE[1,2], D. LEE[1,2];
[1]Sch. of Life Sci. & Biotechnology, Col. of Natural Sci., [2]Sch. of Life Sciences, BK21 FOUR KNU Creative BioResearch Group, Kyungpook Natl. Univ., Daegu, Korea, Republic of

Abstract: Excessive microglial cell activation in the brain can lead to the production of various neurotoxic factors (e.g., pro-inflammatory cytokines, nitric oxide) which can, in turn, initiate neurodegenerative processes. Recent research has been reported that mitochondrial dynamics regulate the inflammatory response of lipopolysaccharide (LPS). Isoliquiritigenin (ISL) is a compound found in Glycyrrhizae radix with anti-inflammatory and antioxidant properties. In this study, we investigated the function of ISL on the LPS-induced pro-inflammatory response in BV-2 microglial cells. We showed that ISL reduced the LPS-induced increase in pro-inflammatory mediators (e.g., nitric oxide and pro-inflammatory cytokines) via the inhibition of ERK/p38/NF-κB activation and the generation of reactive oxygen species (ROS). Furthermore, ISL inhibited the excessive mitochondrial fission induced by LPS, regulating mitochondrial ROS generation and pro-inflammatory response by suppressing the calcium/calcineurin pathway to dephosphorylate Drp1 at the serine 637 residue. Interestingly, the ISL pretreatment reduced the number of apoptotic cells and levels of cleaved caspase3/PARP, compared to LPS-treated cells. Our findings suggested that ISL ameliorated the pro-inflammatory response of microglia by inhibiting dephosphorylation of Drp1 (Ser637)-dependent mitochondrial fission.

Title: Amyloid beta oligomers intensify ER stress-associated apoptotic cell death by upregulating of Parkin expression levels.

Authors: *S.-M. JUNG[1,2], D. LEE[1,2];
[1]Sch. of Life sciences & Biotechnology, Col. of Natural Sci., Kyungpook Natl. Univ., Daegu, Korea, Republic of; [2]Sch. of Life Sciences, BK21 FOUR KNU Creative BioResearch Group, Kyungpook Natl. Univ., Deagu, Korea, Republic of

Abstract: Recently, Parkin has been reported to induce endoplasmic reticulum (ER) stress. In addition, amyloid beta oligomers (AβO), hallmarks of Alzheimer's disease (AD), also increase ER stress in neurons. Because a mutation in the Parkin gene is a well-known predominant cause of familial Parkinson's disease (PD), Parkin has been well studied in PD but has not been well researched in AD. In this study, we investigated the role of AβO-mediated Parkin associated with ER stress in AD. For AD-based research, we used AβO treatments in mouse hippocampus derived HT-22 cells. We stably expressed Parkin in HT-22 cells to confirm the hypothesis and used siParkin for downregulation of Parkin expression. Moreover, using hippocampi from amyloid precursor protein/presenilin 1/Tau triple transgenic mice (3xTg-AD mice), which are used for AD models, we confirmed the relationship between ER stress and Parkin in vivo. We observed that ATF4 upregulated AβO-increases in Parkin. Parkin overexpression aggravated ER stress in AβO-treated HT-22 cells and the hippocampi of 3xTg-AD mice. Parkin downregulation led to no significant change when compared to AβO-treated cells. Moreover, Parkin-mediated ER stress was not related to oxidative stress. Our study indicates that AβO-induced ATF4 upregulated Parkin levels and that Parkin increases ER stress as a positive feedback loop. Through this study, our findings provide a foundation for future studies on the specific mechanisms related to the role of Parkin in AD.

Title: Peroxiredoxin 2 relives amyloid-beta oligomer associated autophagy through ROS-NRF2-p62 pathway in N2a-APP Swedish cells

Authors: *G. KIM[1,2], D. LEE[1,2];
[1]Kyungpook Natl. Univ., Daegu, Korea, Republic of; [2]Sch. of Life Sciences, BK21 FOUR KNU Creative BioResearch Group, Kyungpook Natl. Univ., Daegu, Korea, Republic of

Abstract: In Alzheimer's disease, reactive oxygen species (ROS) are generated by the deposition of amyloid-beta oligomers (AβOs), which represent one of the important causes of neuronal cell death. Additionally, AβOs are known to induce autophagy via ROS induction. Previous studies have shown that autophagy upregulation aggravates neuronal cell death. In this study, the effects of peroxiredoxin 2 (Prx2), a member of the peroxidase family of antioxidant enzymes, on regulating AβO-mediated autophagy were investigated. Prx2 decreased AβO-mediated oxidative stress and autophagy in N2a-APPswe cells. Further, we examined the relationship between the neuronal protective effect of Prx2 and a decrease in autophagy. Similar to the effects of N-acetyl cysteine, Prx2 decreased AβO-induced ROS and inhibited p62 protein expression levels by downregulating the activation of NRF2 and its translocation to the nucleus. In addition, treatment with 3-methyladenine, an autophagy inhibitor, ameliorates neuronal cell death. Overall, these results demonstrate that the Prx2-induced decrease in autophagy was associated with the inhibition of ROS via the ROS-NRF2-p62 pathway in N2a-APPswe cells. Therefore, our results revealed that Prx2 is a potential therapeutic target in anti-Alzheimer therapy.

Title: Expression and activity of rat esterases in response to a high fat diet

Authors: Z. F. FARAZ, *R. SVARCBAHS, E. S. WIRES, L. GREER, E. H. TRESSLER, J. C. M. VENDRUSCOLO, L. F. VENDRUSCOLO, B. K. HARVEY;
Natl. Inst. on Drug Abuse, Baltimore, MD

Abstract: The endoplasmic reticulum (ER) contains the highest level of intracellular calcium. Calcium is imperative to proper protein folding, modification, processing, and secretion. Perturbations to ER calcium have previously been shown to activate the unfolded protein response (UPR) and elicit a mass departure of ER resident proteins in a phenomenon called exodosis. Exodosis has been associated with increased extracellular esterase activity, mediated by ER-resident carboxylesterase (Ces) proteins. Ces proteins metabolize ester containing compounds and drugs. Previous work from our lab showed that a high-fat diet (HFD) causes increased blood levels of Ces activity. To test whether the HFD only increases the secretion of esterases or alters the expression of Ces1 in the liver and brain, we measured mRNA expression of the different Ces1 isoforms from rats on HFD compared to the standard chow diet. Consistent with previous results, we found that HFD increased esterase activity in the plasma. Liver and brain tissue were analyzed for Ces1 mRNA expression using digital polymerase chain reactions (dPCR). Using multiplex dPCR assays that we developed to measure multiple Ces1 isoforms and other genes related to ER stress, we found that expression of Ces1 isoforms and ASNS, a gene associated with the unfolded protein response (UPR) increased in rat tissue that underwent HFD. Studying how HFD can influence esterase activity may advance our understanding of medicinal and illicit drug metabolism and pharmacology.

Title: Does Xanthine Oxidase accelerate Alzheimer's Disease-related pathologies in a high fat and fructose diet?

Authors: *N. M. EMINHIZER[1], A. HANSHEW[1], S. PRABHU[1], S. BALL[1], A. GIROMINI[1], R. KING[1], E. KELLEY[2], P. CHANTLER[3];
[1]West Virginia Univ., Morgantown, WV; [2]Physiolgoy & Pharmacol., West Virginia University, Ctr. for Basic and Translational Stroke Res., Morgantown, WV; [3]Exercise Physiol., WVU Robert C. Byrd Hlth. Sci. Ctr., Morgantown, WV

Abstract: Approximately 42% of individuals in the United States suffer from obesity, widely caused by low activity and poor diet. This percentage is only predicted to grow and leaves countless Americans at risk for other serious comorbidities, including an increased risk for

Alzheimer's Disease (AD). The main hallmarks of AD are cognitive decline, neuroinflammation, and oxidative stress that worsen as the disease progresses. Nonalcoholic steatohepatitis (NASH), another comorbidity of obesity, is characterized by an irreversible fat build-up in the liver and the increased presence of reactive oxygen species. We hypothesized that oxidative stress driven by xanthine oxidase (XO) is a main factor for the accelerated accumulation of AD-related pathologies caused by a NASH diet. In order to test this theory, we used a hepatic xanthine dehydrogenase knockout (XDH-KO), floxed control (FLX), and wild-type control (WT) mouse model and induced obesity through a NASH diet. We administered a 40% fat and 25% fructose diet for 9 months to the XDH-KO and FLX groups, while the WT group was given normal chow. At 12 months of age, the mice were euthanized, and whole brain samples were collected. These samples were homogenized and processed for protein quantification using western blot analysis and detection by fluorescence. Tau had a 74% increase in the FLX NASH diet group compared to the WT control diet groups. However, Tau was elevated only by 13% in the XDH-KO NASH diet compared to the WT control diet. Additionally, significantly higher levels of amyloid beta were found in the FLX NASH diet compared to the XDH-KO NASH diet ($p<0.05$). Tau and amyloid beta are two major proteins associated with AD, and our study supports the previous literature that has shown the upregulation of these compounds within a high fat and fructose diet. However, our data show that knocking out XO production hepatically in mice on a NASH diet decreases the levels of these two major products of AD. This data suggests that XO is a driving factor that leads to the accumulation of AD-related pathologies within high fat and fructose diets.

Title: Molecular analysis of neural mechanisms controlling organismal responses to oxidative stress

Authors: *K. BISWAS[1], M. M. FRANCIS[2], J. B. RAND[3];
[1]Neurobio., UMass Chan Med. Sch., Worcester, MA; [2]Neurobio., Univ. of Massachusetts Med. Sch., Worcester, MA; [3]Oklahoma Ctr. For Neurosci., Norman, OK

Abstract: Organisms have evolved protective strategies that are geared toward limiting cellular damage and enhancing organismal survival under environmental stresses. There is considerable emerging evidence for neuronal regulation of organismal stress responses, but the underlying

molecular mechanisms remain unclear. Reactive Oxygen Species (ROS) such as superoxide and peroxides can cause oxidative stress and cellular damage by reacting with biomolecules. We are exploring neuronal mechanisms for initiating or regulating responses to oxidative stress, using the nematode *Caenorhabditis elegans* as a model. The neurotransmitters and signaling mechanisms used by *C. elegans* neurons are highly conserved. From a survey of six neurotransmitter systems (glutamate, acetylcholine, GABA, serotonin, dopamine and octopamine), we found that cholinergic and glutamatergic transmission have significant roles in promoting antioxidant defenses. Specifically, we observed that animals carrying null or hypomorphic mutations in genes related to vesicular loading of these two transmitters have increased susceptibility to the toxic effects of prolonged exposure to the ROS generator paraquat (PQ). Importantly, these mutations have no effects on lifespan in the absence of PQ, suggesting that glutamate and acetylcholine neurotransmission are important for coordinating organismal protective responses. To determine how specific receptor types may be involved in antioxidant signalling, we measured the survival of *C. elegans* strains carrying mutations in candidate genes encoding various receptor subunits during prolonged oxidative stress. We found that mutations in the metabotropic glutamate receptor genes *mgl-1* and *mgl-2* increased susceptibility to oxidative damage while mutation of genes encoding ionotropic AMPA- and NMDA-type glutamate receptor subunits had little effect. Null mutations that affected the metabotropic acetylcholine receptor *gar-3* also increased susceptibility to PQ. In contrast, a null mutation in the *ric-3* gene that encodes a chaperone broadly required for assembly of ionotropic nicotinic acetylcholine receptors had little effect. Survival assays following cell specific inactivation of the vesicular acetylcholine transporter gene *unc-17* suggested cholinergic motor neurons are particularly important for protection from oxidative damage. We are now using RNA sequencing to investigate how loss of cholinergic and glutamatergic neurotransmission affect transcriptional activation of oxidative stress response pathways and are excited to explore downstream signalling mechanisms in neural regulation of these pathways.

Title: Are Glx and GABA levels changed in type 2 diabetes patients?

Authors: *K. CUYPERS[1,2], J. VANDERSMISSEN[1], K. PUUSTINEN[1], T. GOJEVIC[1,2], V. CORNELISSEN[2], D. HANSEN[1,3];
[1]Hasselt Univ., Diepenbeek, Belgium; [2]KU Leuven, Leuven, Belgium; [3]Jessa Hosp., Hasselt, Belgium

Abstract: Background: Next to the cardiovascular complications, type 2 diabetes mellitus (T2DM) also affects brain function, structure and metabolism. Mild cognitive impairment (MCI) is prevalent in around 45% of all T2DM patients (Chakraborty et al., 2021), and T2DM is causally related to the development of unspecified or vascular dementia (Benn et al., 2020). Recent studies reported significant unfavourable changes in the brain of T2DM patients, such as a decreased regional grey matter volume, and altered intrinsic activity mainly in the default mode network (Li et al., 2022). Additionally, there is evidence that the brain's neurometabolites change dramatically, suggesting disturbances in metabolism and neurotransmission (Zhao et al., 2018). Hence, T2DM patients are at high risk for brain complications. **Aim:** To determine differences in neurometabolite levels between T2DM patients and healthy controls using HERCULES (Oeltzschner et al., 2019), a novel magnetic resonance spectroscopy (MRS) sequence. This may help to determine better how T2DM mechanistically contributes to brain disorders, such as Alzheimer's disease and MCI. **Methods:** The data were derived from 18 T2DM patients and 9 healthy controls, with a male to female ratio of 3 to 1 and an age range between 51 and 73 years. By means of a 3T MRI scanner, we compared neurometabolite levels in the posterior cingulate cortex (PCC), the left primary sensorimotor cortex (LSM), and the medial prefrontal cortex (mPFC) between patients and controls. Although a full spectrum analysis was performed, we focussed on glutamine/glutamate (Glx) and GABA. **Results:** The data was analysed using the GANNET pipeline (Edden et al., 2014). Visual inspection of the data revealed that the spectral quality and fit was insufficient for data-analysis in the PCC and mPFC. For LSM the data quality was sufficient, however, there were no significant group differences nor for GABA (P = 0.897) neither for Glx (P = 0.105) levels (Figure 1). **Conclusion:** Our results suggest that GABA and Glx levels in the LSM do not differ between T2DM patients and healthy controls.

Title: Prolactin regulate the antioxidant response of astrocytes through the activation of STAT3 signaling pathway.

Authors: ***M. ULLOA**[1], F. MACÍAS[1], C. CLAPP[1], G. MARTÍNEZ DE LA ESCALERA[1], E. ARNOLD[1,2];
[1]Inst. de Neurobiología, UNAM, Queretaro, Mexico; [2]CONACYT-Instituto de Neurobiología de la UNAM, Querétaro, Mexico

Abstract: Astrocytes exert a wide variety of functions in health and disease, including regulating defense against oxidative stress. Agents that improve astrocytes antioxidant defenses could be potential therapies for brain pathologies associated with oxidative stress The STAT3 signaling is a key pathway through which astrocytes regulate their antioxidant response. In this regard, prolactin (PRL) displays antioxidant and cytoprotective effects in retinal pigmented epithelial cells and JAK/STATs are an important pathway associated with prolactin receptor (PRLR) signaling. This study sought to determine the protective effect of PRL against hydrogen peroxide (H_2O_2)-induced cytotoxicity in primary rat cortical astrocytes in culture. PRL treatment led to increased expression of the long PRLR isoform, and this response was associated with upregulation of STAT3 phosphorylation/activation, increased antioxidant capacity, and both the transcriptional upregulation and increased enzymatic activity of the antioxidant enzymes: superoxide dismutases, glutathione peroxidase and peroxiredoxins. H_2O_2 induced cell death, increased ROS generation, lipid peroxidation and protein oxidation. Preincubation with PRL protected astrocytes against H_2O_2-induced cell death and increased lipids and proteins oxidative damage. Pharmacological blockade of STAT3 (S31-201) or genetic deletion of the long PRLR isoform ($Prlr^{-/-}$) suppressed the protective effect of PRL against H_2O_2-induced cell death and oxidative damage, by decreasing both antioxidant capacity and the activity of antioxidant enzymes. Our data suggest that PRL might represent a promising strategy for the treatment of brain pathologies associated with oxidative stress.

Title: Selective impairment of interaction of ADP and ATP synthase by anesthetics

Authors: *F. LIANG[1,2], K. KURMI[3], S. JOSHI[3], M. HAIGIS[3], Y. GUO[4], Z. XIE[2]; [1]Massachusetts Gen. Hosp., Charlestown, MA; [2]Dept. of Anesthesia, Critical Care and Pain Med., Massachusetts Gen. Hosp. and Harvard Med. Sch., Charlestown, MA; [3]Dept. of Cell Biology, Blavatnik Institute, Harvard Med. Sch., Boston, MA; [4]Swansea Univ., Swansea, United Kingdom

Abstract: Introduction: General anesthesia has been reported to be associated with a higher risk of developing dementia in patients and cognitive impairment in animals. Our research has demonstrated that anesthetic isoflurane, but not desflurane, can induce apoptosis and promote the generation of Aβ by impairing mitochondrial function. However, the underlying mechanism remains largely unknown. We, thus, employed nanobeam technology and other methodologies to investigate the potential differences between isoflurane and desflurane on the interaction between ATP synthase and ADP at single molecular level, and the associated changes in mitochondrial function. **Method**: Human H4-APP cells were subjected to 2% isoflurane or 12% desflurane treatment for 6 hours. LC-MS based metabolomics analysis were used to differentiate the effects of isoflurane and desflurane. Mitochondrial respiration was assessed using a Seahorse XFp Extracellular Flux Analyzer. Nanobeam technology was used to investigate the interaction between ADP and ATP synthase at the single molecular level. Additionally, molecular dynamics simulation was employed to identify the specific amino acids involved in the binding of isoflurane or desflurane with ATP synthase. Through the use of CRISPR/Cas9 technology, we mutated the identified amino acid and conducted rescue studies using the mutant cells and peptides. **Results**: Isoflurane and desflurane exhibit distinct metabolic profiles, as desflurane only increased the levels of four metabolites, whereas isoflurane increased the levels of 13 metabolites and decreased 10 compared to the control. Moreover, isoflurane, but not desflurane, reduced mitochondrial metabolic function. Nanobeam technology demonstrated the impairment of the interaction between ATP synthase and ADP at the single molecular level by isoflurane, but not desflurane. Molecular dynamics simulation identified the 549th amino acid residue, alanine, of ATP synthase as the site of action for isoflurane. Finally, the mutation of alanine 549 residues of ATP synthase attenuated the effects of isoflurane. **Conclusion**: Our data provide compelling evidence of the distinct effects of isoflurane and desflurane on the alterations linked to the pathogenesis of Alzheimer's disease. The findings indicate that the mutation of a specific amino

acids residue, alanine 549 of ATP synthase, to cysteine or serine, can attenuate the impairment caused by isoflurane in the interaction between ATP synthase and ADP, as well as mitochondrial function. These significant findings serve to promote further investigation into the relationship between anesthesia and the pathogenesis of Alzheimer's disease.

Title: MICAL2: Bridging synaptic function and the antioxidant system in bipolar disorder

Authors: *K. KRUTH[1], P. SURYAVANSHI[2], J. B. MEHR[3], A. KARKI[4], A. WILLIAMS[1]; [1]Psychiatry, Univ. of Iowa, Iowa City, IA; [2]Pediatrics, Univ. of Iowa, Iowa city, IA; [3]Rutgers Brain Hlth. Inst., Piscataway, NJ; [4]Rutgers Univ. Behavioral and Neural Sci., Edison, NJ

Abstract: Bipolar disorder remains one of the most severe and least treatable of all neuropsychiatric illnesses, but new treatments have remained elusive due to poor understanding of its etiology. Lithium remains the gold standard of treatment, but its use comes with many caveats, including numerous side effects, a narrow therapeutic window, and the potential for life-threatening toxicity. Better treatments are desperately needed, but the mechanism behind lithium's effectiveness remains unclear, limiting our ability to improve upon its action. In 2014, Beech et al. identified MICAL2 in a screen as a top hit for genes associated with lithium responsiveness in bipolar patients, suggesting it may play a crucial role in bipolar disorder treatment. MICAL2 is an NADPH-dependent enzyme that reversibly oxidizes actin, leading to rapid cytoskeleton collapse. Intriguingly, its reliance on NADPH, the primary electron donor of the antioxidant system, ties its function to the cell's redox balance, which has been shown to be altered in patients with bipolar disorder. However, to our knowledge, MICAL2 has never before been studied in brain, and its role in neuronal function—and bipolar disorder—remains completely unknown. Here, we have begun to characterize the role of MICAL2 in human stem cell-derived neurons in an effort to ascertain whether it may be a viable new treatment target in bipolar disorder. Via immunofluorescence, MICAL2 appeared to precisely colocalize with synapsin 1, suggesting its role may be primarily synaptic. Western blots on synaptosomes isolated from adult mouse brain confirmed this result, showing that MICAL2 is present in both synaptic and nuclear/cytosolic cellular fractions, though the banding pattern suggests there may be synapse-specific isoforms of MICAL2. We then knocked down MICAL2 in human iPSC-derived neurons and analyzed structural changes via super resolution microscopy and functional

changes through calcium imaging and patch clamp. Our results suggest that MICAL2 may play an important role in synaptic function, and further research is warranted to ascertain whether it may be a viable treatment target for bipolar disorder.

Title: Impact Of Mitochondrial G13513A Heteroplasmic Mutation On Mitochondrial Function

Authors: *D. LIN, T.-Y. WU, T.-H. LEE, Y.-W. HUANG, Z.-D. HUANG, C.-S. HO; Mackay Mem. Hosp., Taipei, Taiwan

Abstract: Mitochondria play a vital role in cellular energy production through oxidative phosphorylation (OXPHOS) in the respiratory complexes. Mitochondrial DNA alterations have the potential to disrupt mitochondrial function and contribute to the development of heterogeneous diseases. Leigh syndrome (LS) is a progressive neurodegenerative disorder commonly observed in infants and children, characterized by bilateral symmetric necrosis of the basal ganglia and/or brain stem. The G13513A mutation in mitochondrial DNA is a frequent cause of LS with isolated complex I deficiency, although its impact on mitochondrial function remains poorly understood. In this study, we determined the heteroplasmy of the mitochondrial G13513A variant in leukocytes, buccal mucosa, hairs, urine sediments, and dermal fibroblasts derived from two LS patients (LS1: 2 years and 5 months old boy and LS2: 1-year-old boy). We investigated various mitochondrial functions, including bioenergetics, ATP production, reactive oxidative species (ROS) generation, and mitochondrial membrane potential (MMP), in fibroblasts. The heteroplasmy of the mt G13513A variant (M1/M2) was found to be 36%/47%, 43%/58%, 31%/58%, 70%/82%, and 67%/33% in leukocytes, buccal mucosa, hairs, urine sediments, and dermal fibroblasts, respectively. Bioenergetic profiles, measured by real-time oxygen consumption rate (OCR) using a Seahorse Extracellular Flux Analyzer, revealed significant differences in basal, ATP-production, maximal respiration, and spare respiratory capacity between control and LS fibroblasts (C/M1/M2). The corresponding values for these parameters were 9.9/4.2/6.4, 7.8/1.7/5.3, 15.7/5.3/9.6, and 5.8/1.1/3.2 pmol/min/protein, respectively. ATP production in C/M1/M2 fibroblasts was 33.7/29/31 nmol/mg protein. MMP and ROS levels in C/M1/M2 fibroblasts were measured as 1/0.88/0.72 and 1/1.49/0.98 fold of the normal, respectively, using flow cytometry and fluorescent dyes TMRE and DCFDA. Our

results demonstrate that complex I deficiency caused by mt G13513A mutation leads to impaired mitochondrial bioenergetics, elevated ROS levels, reduced MMP, and decreased ATP production. Furthermore, heteroplasmy of mt G13513A above 60% exhibited a more pronounced impact on mitochondrial function. These findings validate the pathogenic role of mt G13513A variants in LS and provide insights into the pathological mechanisms involved, using primary fibroblasts derived from LS patient

Prevention of Blindness

Title: Pgc-1α Repression dysregulates lipid metabolism and induces lipid droplet accumulation in retinal pigment epithelium

Authors: S. ZHOU, ***K. TASKINTUNA**, J. HUM, J. GULATI, S. OLAYA, J. STEINMAN, N. GOLESTANEH;
Ophthalmology, Georgetown Univ., Washington, DC

Abstract: The purpose of this study is to investigate the role of peroxisome-proliferator-activated receptor-γ coactivator 1α (PGC-1α) in lipid metabolism in the retinal pigment epithelium (RPE). As the leading cause of blindness in the elderly, age-related macular degeneration (AMD) is a debilitating late-onset neurodegenerative disease which results in loss of central vision. Drusen are a hallmark characteristic of AMD and lipid droplets are reported in RPE from AMD donors. However, the mechanisms underlying these disease phenotypes remain elusive. Previously, we showed that PGC-1α repression, combined with a high-fat diet, induces AMD-like phenotypes in mice. We also reported increased PGC-1α acetylation and thus deactivation in the RPE derived from AMD donor eyes. Here, through a series of *in vivo* and *in vitro* experiments we show that PGC-1α plays an important role in RPE and retinal lipid metabolism and functions. For *in vivo* experiments, we used the whole-body *Pgc-1α* heterozygous and knockout mice on a C57BL/6J background. We performed electroretinography to test retinal function and fundus photography to assess drusen-like deposits. For *in* vitro experiments, CRISPR-Cas9 gene editing was used to generate the ARPE19-*PGC1A* KO cell line. qPCR, Western Blotting, cell viability experiments, various assays to measure mitochondrial activity, fatty acid oxidation (FAO), and lipid peroxidation assays were performed. *In vivo* analyses showed increased accumulation of drusen-like deposits as well as impaired

photoreceptor and RPE function in both heterozygous and knockout mice compared to wild-type controls. In addition, the drusen-like deposits seemed to be bigger in size in KO compared to heterozygous. *In vitro* inhibition of PGC-1α by CRISPR-Cas9 gene editing in human RPE (ARPE19- *PGC1A* KO) reduced expression of genes responsible for lipid metabolism, fatty acid β-oxidation (FAO), and lipids biosynthesis. Furthermore, inhibition of *PGC-1α* in the RPE cells caused lipid droplets accumulation and increased lipid peroxidation. ARPE19-*PGC-1A* KO cells also showed reduced mitochondrial biosynthesis, mitochondrial dynamics and activity, FAO, mitochondrial membrane potential, loss of cardiolipin, and increased susceptibility to oxidative stress. Our data reveal an important role for PGC-1α in regulating lipid metabolism in the RPE, and shed light on mechanisms involved in lipid and drusen accumulation in the RPE and retina during aging and AMD.

Title: Reversibly oxidized thiols on metabolic enzymes support compartmentalization of redox homeostasis in the brain and expose a transient reductive stress following global ischemia

Authors: *T. FOLEY, W. HUANG, E. PETSCHE, E. FLEMING, J. HORNICKLE;
Univ. Scranton, Scranton, PA

Abstract: Perturbations in metabolism and associated redox homeostasis have been implicated in brain aging and disease but fundamental tenets of redox biology operating in the brain, including the relevance of reversible oxidations of protein thiols, which can function as metabolic regulatory switches, remain to be established. Using redox phenylarsine oxide-affinity chromatography to capture proteins from rat brain forming reducible (i.e., potential regulatory) disulfide bonds, we report that creatine kinase B, alpha-enolase, and glyceraldehyde-3-phosphate dehydrogenase contained thiols that were selectively oxidized compared to other metabolic enzymes of interest, including neuron-specific (gamma) enolase, under experimental conditions designed to trap *in vivo* protein thiol redox states. In addition, short-term delays to tissue freezing, to allow perturbations in metabolism triggered by decapitation-induced global ischemia, exposed an early reductive shift marked by transient decreases in the extents of oxidizations of protein thiols. The results of this study (i) establish metabolic enzymes containing thiols that are preferred targets of reversible oxidations in the healthy brain, (ii) support the largely unrecognized view that neurons and astrocytes may operate at distinct protein thiol-linked redox potentials, *in vivo*, and (iii) suggest that reversals of thiol oxidations on metabolic

enzymes may occur during the earliest stages of ischemic injury, promoting rapid increases in anaerobic ATP production from glucose and creatine phosphate stores.

Title: Novel therapeutic strategies to enhance DNA repair in neurodegenerative diseases

Authors: *S. SHADFAR, F. FARZANA, M. VIDAL, C. JAGARAJ, S. PARAKH, A. S. LAIRD, J. D. ATKIN;
Motor Neuron Dis. Res. Ctr., Macquarie Univ., Sydney, Australia

Abstract: Background: DNA damage and defects in DNA repair are increasingly implicated in neurodegenerative conditions. However, there are no therapeutic approaches to prevent DNA damage in these disorders. Double-stranded DNA breaks (DSBs) are the most toxic type of damage, particularly for post-mitotic neurons because they rely entirely on the error prone non-homologous end joining (NHEJ) mechanism of repair. Previous studies in our group have established that protein disulphide isomerase (PDI) is protective against dysfunction to proteostasis induced by multiple mutant proteins *in vitro* in ALS. However, it remains unclear if PDI is also protective against DNA damage.
Objectives: In this study, we aimed to examine whether PDI is protective against DNA damage both *in vivo* and *in vitro*, to determine if it has potential as a novel therapeutic approach in ALS and/or other neurodegenerative diseases.
Methods: Two cell lines, NSC-34 and Neuro-2a, were transfected with PDI or PDI with ALS-associated mutant, TDP-43^{M337V}. Immunocytochemistry was performed to detect DNA damage induction. For *in vivo* studies, zebrafish embryos were microinjected with either RNA encoding PDI WT or a PDI mutant lacking redox activity (QUAD). At 24 hours post fertilization, embryos were incubated with 3mM H_2O_2 for 24 hours, then lysed to perform western blotting analysis.
Results: PDI was protective against DNA damage induced by etoposide and H_2O_2 in both Neuro-2a and NSC-34 cells, detected by a widely used marker, the formation of γH2AX foci. Moreover, PDI was also protective in cells expressing mutant TDP-43^{M337V}, implying it is protective against DNA damage induced during neurodegeneration. This was also confirmed using 53BP1, a specific marker for NHEJ. PDI also translocated from its normal location in the endoplasmic reticulum into the nucleus following etoposide treatment, where it was recruited

directly to sites of DNA damage, implying that it has a direct role in DNA repair. In addition, PDI was also protective *in vivo* against DNA damage induced by H_2O_2 in zebrafish. We also identified that the redox activity of PDI mediates these protective functions. From these findings, we then developed novel therapeutic peptides based on the redox activity of PDI that prevented key behavioural phenotypes in two mouse models of ALS. Hence, these data reveal that PDI and our novel therapeutic peptides are protective against DNA damage *in vivo* and *in vitro*. **Conclusion:** These results demonstrate the protective role of PDI against DNA damage both *in vivo* and *in vitro*. This study therefore has implications for future therapeutic studies based on preventing induction of DNA damage in neurodegenerative diseases.

Title: Mitochondrial responses to estrogen withdrawal in human neural cells

Authors: *P. SINCLAIR, N. LEBERT, N. KABBANI;
Neurosci., George Mason Univ., Fairfax, VA

Abstract: Estrogen is an important steroid hormone mainly produced in the ovaries but also in non-reproductive tissue including the brain and is important for the development and function. At the cellular level, estrogen signaling has been shown to regulate molecular signaling through various organelles including the mitochondria and nucleus. While there are several forms of estrogen in mammals, E2 is the most dominant form in premenopausal human females and is involved in synaptic function and brain neuroprotection. In order to explore the role of estrogen decline in neuronal health, I utilized an in vitro method that models E2 loss within the human SH-SY5Y neuronal cell line. Based on published evidence that estrogen decline is associated with mitochondrial oxidative damage. I examined how estrogen reduction impacts the mitochondrial proteome. Cells were treated with E2 for 3 days and then E2 was continued (E2+) or withdrawn (E2#) for another 3 days. Matching control cells did not receive E2 (E2-) throughout the 6-day period. Mitochondrial fractionation was used to obtain the mitochondrial enriched fraction (MEF) from cells under the 3 different treatment conditions. An LC-ESI MS/MS analysis of the MEF was used to identify proteomic changes in response to E2. The results indicate a significant effect of E2# on mitochondrial protein expression and function including increased reactive oxygen species (ROS) and cardiolipin (CL) levels. Our results also show an effect of E2 on estrogen receptor expression within the MEF. Taken together, the data reveal modifications to mitochondria in response to estrogen decline supporting the involvement of mitochondria in age-related neurodegeneration.

Title: Preservation of an aging-associated mitochondrial signature in advanced human neuronal models: iPSCs derived neurons and directly converted neurons from human fibroblasts

Authors: *N. VARGHESE[1,2], L. SZABO[1,2], A. GRIMM[1,2], Z. CADER[3], I. LEJRI[1,2], A. ECKERT[1,2];
[1]Res. Cluster Mol. and Cognitive Neurosciences, Univ. of Basel, Basel, Switzerland; [2]Neurobio. Lab. for Brain Aging and Mental Hlth., Univ. Psychiatric Clinics Basel, Basel, Switzerland; [3]Nuffield Dept. of Clin. Neurosci., Univ. of Oxford, Oxford, United Kingdom

Abstract: Background information: Aging is a risk factor for several of the world's most prevalent diseases, including Alzheimer's disease (AD). Understanding the aging process in the human brain, particularly the role of mitochondria, is still poorly investigated. The main challenge is to find suitable human models to study brain aging. Animal models, brain biopsies, or carcinomic cell lines are indispensable but subject to transferability limitations, inaccessibility, and ethical constraints. Therefore, the advanced neuronal in-vitro models are of interest, including iPSCs-derived neurons (iPSCsN) or directly induced neurons (iNs) from human fibroblasts. By transiting an embryo-like state, the iPSCsN are suspected of undergoing a rejuvenation leading to a reset of the aging-associated phenotype, whereas directly converted neurons seem to retain an aging-associated donor signature. This study aimed to investigate how well the advanced neuronal models (iPSCsN and iNs) are preserving the aging donor signature, focusing on the neuronal powerhouse, the mitochondria. Methods: The bioenergetic profile of iPSCsN and iNs, both derived from the same young (n=3, Age_{mean} = 29 years) vs. aged (n=3, Age_{mean}= 67 years) donors respectively were compared by measuring the total ATP level, mitochondrial membrane potential (MMP), reactive oxygen species (ROS), mitochondrial respiration, glycolysis, mitochondrial mass, mitochondrial morphology, and mitophagy. Results: Our preliminary findings, showed that both the iNs and the iPSCsN, could maintain an aging-associated phenotype by comparing to the corresponding young neurons. With this, a decline in ATP, MMP, and mitochondrial respiration and a rise in ROS, glycolysis, and mitochondrial mass were measured in aged neurons compared to young neurons. The mitochondrial dynamics were characterized by a more fragmented mitochondrial morphology and a lower mitophagy rate in age. Conclusion: Our preliminary findings showed that the iNs preserve an aging-associated phenotype. More surprisingly, the iPSCsN also showed an aging-associated phenotype contrary

to the idea that the embryonic state of the iPSCs would lead to a rejuvenation of iPSCsN from aged donors. Nevertheless, the extent to which the iPSCsN and iNs preserve this aging-associated signatures is currently under investigation. Overall, this study will deepen our understanding of how well ‘‘aged” iNs and iPSCsN represent human brain aging. It may help to establish remarkable tools for identifying pharmaceutical targets to improve human health during aging and in various aging-related diseases.

Title: Altered brain microvascular bioenergetics by chronic stress: a pathway to cerebrovascular dysfunction and cognitive decline?

Authors: *A. A. HANSHEW[1], S. PRABHU[2], N. M. EMINHIZER[1], E. N. BURRAGE[3], J. CRAWFORD[1], D. THAPA[1], R. W. BRYNER[1], W. GELDENHUYS[4], P. CHANTLER[5]; [1]Exercise Physiol., [2]Pharmaceut. and Pharmacol. Sci., [4]WVU Sch. of Pharm., [3]West Virginia Univ., Morgantown, WV; [5]Exercise Physiol., WVU Robert C. Byrd Hlth. Sci. Ctr., Morgantown, WV

Abstract: Dementia is a progressive neurodegenerative disorder associated with oxidative stress. Chronic stress is linked to cognitive decline, but the role of the cerebrovasculature on the disease progression of cognitive decline has not been fully elucidated. Specifically, the role of mitochondrial and glycolytic energy pathways which are critical to cerebrovascular function is unknown. This study aimed to determine the impact of UCMS on cerebrovascular energetics. Four-month-old C57Bl/6 male and female mice were randomized into control (non-UCMS) and UCMS groups for 8 weeks. Control mice remained in home cages, while UCMS mice were exposed to chronic stress for 5 days/week for 7 Hrs/day for 8 weeks. At 6 months of age, mice were euthanized and the middle cerebral artery (MCA) was removed and positioned in a pressurize myobath and exposed to increasing concentrations of acetylcholine (ACh; 10^{-9}M to 10^{-4}M) to measure endothelial-dependent dilation (EDD). The remaining brain microvessels (BMVs) were homogenized to assess for hydrogen peroxide (H_20_2) production and bioenergetics using the coumarin boronic acid assay and Seahorse Bioflux Analyzer, respectively. Our data show that BMVs from UCMS mice had a significant ($p<0.05$) increase in H_20_2 production and a decrease in the rate of oxidative phosphorylation compared to control mice. This decrease corresponded to a decrease in ATP production ($p<0.05$) in mice experiencing UCMS vs. controls. This altered BMV bioenergetics coincided with a 57% reduction in the EDD of the MCA in UCMS vs. control mice ($p<0.01$). Taken together, our data suggest that the BMVs are susceptible to chronic stress with elevated vascular oxidative stress, and reduced vascular bioenergetics which affects the cerebrovascular functions and opens up avenues for therapeutic targeting of novel therapies to support the cerebrovascular function.

Title: Sexual dimorphism in the effect of high-fat diets on the sphingolipid composition of mouse hippocampus

Authors: *E. SANCHEZ-HITA[1], B. FERNANDEZ-REQUENA[2], C. GONZALEZ-RIANO[2], A. GARCIA[2], M. RUIZ-GAYO[1], B. MERINO[1], V. CANO[1], A. PLAZA[1];
[1]Hlth. and Pharmaceut. Sci., [2]Ctr. de Metabolómica y Bioanálisis (CEMBIO), Univ. San Pablo-CEU, CEU Universities, Madrid, Spain

Abstract: High-fat diets (HFD) promote the accumulation of ceramides and other sphingolipids in different organs, including the brain, a circumstance that has been related with lipotoxicity and cell aging. HFD also trigger memory deficits both in humans and rodents. Related with that, hippocampal synaptic plasticity has been shown to be impaired in the hippocampus of mice consuming HFD. Nevertheless, a relationship between cognition performance and the sphingolipid composition of the hippocampus has not been established. Otherwise, sexual differences in the effect of HFD have not been so far investigated. Our Aim was to analyse the effect of a regular intake of HFD enriched with either oleic acid (40% high-oleic sunflower oil; Unsaturated OiL-enriched Food, UOLF) or lauric/palmitic acids (40% palm kernel oil; Saturated OiL-enriched Food, SOLF) on the sphingolipid composition of the hippocampus. Methods: Five-week old male and female C57BL mice fed either SOLF, UOLF or standard diet for 8 weeks. Hippocampi were dissected and analysed using an Agilent 1290 Infinity II UHPLC system coupled to an Agilent 6546 quadrupole time-of-flight (QTOF) mass spectrometer in both MS and iterative-MS/MS modes using a reversed-phase lipidomics-based strategy [1]. Briefly, tissue was homogenized with MeOH:H2O 50% (v/v) and extracted with MeOH:methyl tert-butyl ether 4:1 (v/v)[2]. After data reprocessing using Agilent MassHunter Profinder B.10.0.2 and Lipid Annotator v1.0 (Agilent Technologies Inc., Santa Clara, CA, USA), 32 Cer, 20 SM and 45 HexCer lipid species were accurately annotated and statistically compared. Results: Compared to standard diets, SOLF increased the content of i) ceramides and dihydroceramides in males, and ii) cerebrosides in females, while UOLF i) diminished ceramide and dihydroceramide concentration in females, and ii) enhanced cerebrosides in males. Otherwise, the lauric acid-derived ceramide, Cer18:1/12:0, was specifically detected in animals that consumed SOLF (males 0.05±0.01 µg/g tissue; females 0.05±0.02 µg/g tissue; p&lt0.001). Conclusion: Our data show that both SOLF and UOLF differently affect male and female brain sphingolipid pattern.[1] C. Gonzalez-Riano et al. Journal of Chromatography Open, 1, 100018 (2021).[2] C. Gonzalez-Riano et al. Brain Structure and Function, 222, 2831-2853 (2017).

Title: Characterizing ATP:ADP using PercevalHR in mixed hippocampal cultures

Authors: *S. L. SIMS, S. L. CASE, R.-L. LIN, N. A. WRIGHT, J. RHINEHART, O. THIBAULT;
Pharmacol., Univ. of Kentucky, Lexington, KY

Abstract: Brain homeostatic equilibrium is a well-maintained and orchestrated metabolic process which, when lost, is associated with brain aging or neurodegenerative diseases, and is often detected as hypometabolism in aging and AD. It is, therefore, integral to maintain this homeostasis on a second-to-second basis and across multiple cell types. Major energetic processes can be addressed through the measurement of ATP levels within a single cell. In addition to the well-established role of glucose metabolism in the CNS, more recently, insulin has also been recognized to play an essential role in the regulation of cognitive function, particularly in the hippocampus, where it can ameliorate spatial memory recall. Using mixed primary hippocampal cultures (neurons and astrocytes), we tested the hypothesis that PercevalHR, an ATP:ADP biosensor, could reliably quantify bioenergetics with single cell resolution. Embryonic rat hippocampi (E17) were extracted and maintained for 12-16 days *in vitro* (DIV). Cultures were treated with lentivirus (Human Ubiquitin C promoter) containing the PercevalHR nanosensor. To control for PercevalHR's pH sensitivity, some experiments were conducted concomitantly with the intracellular pH sensor pHrodo. We attempted to normalize glucose transporter function following ~12 days in high glucose concentration (35 mM), by returning the cells to a serum-free 5.5 mM glucose media ~24 h prior to imaging. PercevalHR emission was filtered at 525 nm and pHrodo emission at 580 nm. After an initial baseline, cells were treated with one of several compounds (0.5 mM, 5.5 mM, and 10 mM glucose; 50 mM KCl; 20 µM glutamate; 10 nM insulin). Glutamate and KCl resulted in rapid decreases in ATP:ADP ratios. Insulin only demonstrated a slight drop in ATP:ADP. PercevalHR seems to reliably report on cell energetics in mammalian cultures and surprisingly, appears to indicate that neurons display higher baseline ATP:ADP compared to astrocytes. These data help evaluate bioenergetic status in two closely associated cell types that are known to share intermediates. Ongoing studies are investigating PercevalHR imaging in astrocytes using *in vivo* 2P microscopy in a mouse model of amyloidosis during ambulation (i.e., awake).

Title: Neuronal reactive oxygen species resistance in Caenorhabditis elegans mutants and its role in neurodegenerative disease

Authors: *N. PINZON[1,2], R. EL BEJJANI[1];
[1]Davidson Col. Neurosci. Program, Davidson, NC; [2]Davidson Col. Genomics Program, Davidson, NC

Abstract: Amyotrophic Lateral Sclerosis (ALS) is a progressive neurodegenerative disease characterized by motor neuron (MN) degeneration that currently has no cure. Previous research has found morphological defects in patients' MNs to correspond with damage caused by oxidative stress mediated by Reactive Oxygen Species (ROS). ROS detoxification has remained a primary therapeutical target, leading the way for one of the only three FDA-approved treatments for ALS (Edaravone: a free radical scavenger molecule). Yet, oxidative stress has remained a challenging mechanism to study due to ROS's general and spreading nature. Previously in our lab, we developed an optogenetic tool (KillerRed) that allows for selective, non-invasive, and neuron-specific induction of ROS using light. We used forward genetic screens to isolate six neuronal ROS-resistant strains of Caenorhabditis elegans, which this work seeks to characterize fully. Utilizing Paraquat as a general ROS inducer, we confirmed one strain to be resistant and one to be hypersensitive, suggesting a mechanism through which these overcome ROS damage in all types of cells and specifically in neurons, respectively. We seek to further describe morphological neurodegeneration differences between our strains upon chemical and optogenetic-induced oxidative stress. Future work will focus on strain outcrossing and genomic sequencing to find single-gene mutations responsible for neuronal oxidative stress resistance. Through this research, we aim to identify therapeutically targetable pathways in ALS and further the understanding of ROS' role in neurodegenerative disease.

Title: Chaperon-mediated autophagy suppresses glioblastoma via degradation of E2F1

Authors: *W. TANG, K. KIANG, G. LEUNG;
Dept. of Surgery, The Univ. of Hong Kong, Hong Kong, China

Abstract: Chaperon-mediated autophagy (CMA) is a selective form of autophagy, which has been widely studied in neurodegenerative diseases like Alzheimer's disease and Parkinson's disease. However, the roles of CMA in brain tumors are still poorly understood. By using an orthotopic animal model, we showed that CMA blockade promotes glioblastoma progression, accompanied by the upregulation of glioma promoters, i.e., E2F1, and activated metabolic

pathways. Furthermore, we found that long-term Temozolomide treatment would upregulate the expression of LAMP2A, the indicator of CMA, both *in vitro* and *in vivo*. However, the inhibition of LAMP2A had no significant impact on the sensitivity of glioblastoma cells in response to Temozolomide. In summary, CMA plays a critical role in the regulation of glioblastoma growth via selective degradation of glioma-promoting proteins, and chemotherapy would affect the activity of CMA. These findings might broaden the knowledge of CMA and provide insights into how the modulation of CMA contributes to the treatment of brain diseases.

Title: Self-regulating noradrenergic activity influences cortical excitability and neuroplasticity

Authors: *W. POTOK[1], S. MEISSNER[2], N. WENDEROTH[2,3];
[1]Dept. of Hlth. Sci. and Technol., ETH Zurich, NCM Lab., Zurich, Switzerland; [2]ETH Zurich, Neural Control of Movement Lab., Zurich, Switzerland; [3]Campus for Res. Excellence And Technological Enterprise (CREATE), Future Hlth. Technologies, Singapore-ETH Ctr., Singapore, Singapore

Abstract: The arousal state of the brain is determined by the neuromodulatory activity of several brainstem nuclei and, particularly, by the noradrenergic (NA) transmission from the locus coeruleus (LC). Activity of the LC-NA system causally influences the eye's pupil diameter. We have recently shown that pupil-based neurofeedback enables participants to acquire mental strategies for volitionally controlling LC activity. Pharmacological studies confirm that activating β- or α1-adrenoreceptors facilitates cortical excitability and neuroplastic effects. However, it is unknown whether self-regulation of noradrenergic activity has a similar effect. We use a multimodal approach combining (i) pupil diameter-based neurofeedback training that enables participants to control LC-activity, (ii) anodal transcranial direct current stimulation (a-tDCS) for inducing neuroplastic changes in the primary motor cortex, and (iii) single-pulse transcranial magnetic stimulation with electromyography for measuring cortical excitability using motor evoked potentials (MEP) as our main outcome parameter. We observed significant changes in cortical excitability when applying mental strategies to modulate the pupil size, reflected in 35±44% increase in MEP amplitude relative to rest during up-regulation and 2±12%

decrease in MEP amplitude relative to rest during down-regulation of the pupil size ($t_{(14)}$=3.2, p=0.006 (2-sided) d=0.8, N=15, 11 females). Moreover, our preliminary results indicate that applying plasticity-inducing a-tDCS to the primary motor cortex while participants up-regulate pupil diameter caused an increase in cortical excitability. Down-regulating pupil diameter, by contrast, reduced this a-tDCS effect on cortical excitability (d=0.5, N=5, 4 females, data collection in process). Together, we provide first evidence that pupil-based neurofeedback may be a new, non-invasive, and non-pharmacological tool for modulating cortical excitability, and potentially also neuroplasticity, most likely by changing the NA levels in the brain.

Title: The role of the intraparietal sulcus in numeracy: a review of parietal lesion cases

Authors: *E. DURICY, C. DURISKO, J. A. FIEZ;
Univ. of Pittsburgh, Pittsburgh, PA

Abstract: We reviewed single case studies of acalculia following focal damage to examine the similarities and differences between cases and how they compare to the primary theory of numerical processing: the Triple Code Model (Dehaene, 1992). According to the Triple Code Model, different brain regions contribute to magnitude, verbal, and visual coding of number, with the intraparietal sulcus (IPS) supporting representations of magnitude that undergird an internal number line and meaningful calculation. Our goal was to examine numeracy-focused single case studies with parietal damage to test for causal relationships between damage to the IPS and impairments in different components of numeracy. We identified a set of 27 single case studies with parietal lesions and then assessed the role of the IPS across four key numeracy domains: Approximation, Calculation, Transcoding, and Ordinality/Cardinality. We compared individual-level published images by drawing a sphere at the estimated center of mass of each case's lesion on a standard template. These spheres were then overlapped with an IPS region-of-interest (ROI), and cases were grouped (IPS or Parietal) based on ROI overlap and original anatomical description. A Fisher's Exact Test was performed to compare behavioral performance on each numeracy domain between lesion groups. We then followed up these tests with an Activation Likelihood Estimation (ALE) analysis. We assessed the frequency of numeracy impairment between the IPS group and Parietal case groups and found that Approximation deficits were significantly more frequent in the IPS group. Further exploration using an ALE

analysis revealed that only Approximation deficit cases significantly overlapped with the IPS, while the other domains were localized to different regions of the parietal lobe. Based on the pattern shown across parietal-damage single case studies we conclude that damage to the left IPS is both necessary and sufficient to impair approximation ability, but not other components of numeracy. Thus, its contributions to numeracy seem more circumscribed than proposed in the Triple Code Model, and may be more compatible with models of dissociable circuits of numerical and verbal/visual processing in the parietal lobe.

Title: Early sensory overstimulation leads to behavioral dysfunctions predominantly in male CD-1 mice: a mechanism for male vulnerability in ADHD?

Authors: *J. MERZ[1], T. FU[1], H. BACKHAUS[1], R. GUIMARAES-BACKHAUS[1], S. SCHWEIGER[2], A. STROH[3];
[1]Leibniz Inst. for Resilience Res., Mainz, Germany; [2]Inst. for Human Genet., Univ. of Mainz, Mainz, Germany; [3]Univ. Med. Ctr. Mainz, Mainz, Germany

Abstract: Sensory overstimulation (OS), caused by the increased consumption of audiovisual media usage, is a widespread phenomenon and runs through all areas of our society. The COVID-19 pandemic has further exacerbated this. OS is believed to be an important factor in the development of neuropsychiatric disorders such as attention deficit/hyperactivity disorder (ADHD) in children. Yet, the neuronal mechanisms and the temporal window of vulnerability linking ADHD and OS are largely unexplored. In this study, we used a mouse model of excessive sensory stimulation (ESS) to investigate the impact of OS on behavioral outcome and its underlying neuronal mechanisms. Male and female CD-1 mice at P10, prior to weaning, were overstimulated for 42 consecutive days, 6 hours per day. Subsequently, we investigated anxiety-like behavior in the Elevated Plus maze (EPM) and in the Light/Dark test (LDT), locomotor activity in the Open Field test (OFT), and cognitive functions in the 24-h Novel Object Recognition (24-h NORT) and Y-maze (YM). For assessing cortical microcircuit dynamics, we employed awake two-photon calcium imaging in the primary visual cortex (V1). ESS impacts anxiety-like and risk-taking behavior in OS mice. OS mice tend to explore the open arms of the EPM longer than the control group. Notably, we observed a gender-specific vulnerability in terms of the behavioral outcomes in the LDT, where male OS mice spent significantly more time in the brightly lit light chamber of the testing arena than male controls indicating an increase in risk-taking behavior in the OS male group. Female OS mice did not show this behavioral aberration. These findings reflect the human condition of ADHD, where male patients are more

likely to engage in risky behavior, which is associated with physical injuries, reckless driving, and substance abuse. Our data suggests that early sensory overstimulation leads to a durable shift in behavior, with a higher vulnerability in males.

Title: Relationships among cognitive variables in Puerto Rican children using the Cognitive Assessment System 2 - Spanish Version

Authors: *A. L. BERRIOS-NEGRON, C. CENTENO-ROMAN, Y. PEREZ, J. MARTINEZ-TORO, G. CORDERO-ARROYO, M. MORENO-TORRES, M. BERMONTI-PEREZ; Clin. Psychology, Ponce Hlth. Sci. Univ., Ponce, PR

Abstract: The Cognitive Assessment System 2 – Spanish Version (CAS 2: SP) is a comprehensive test that assesses a range of cognitive variables, including planning, attention, simultaneous processing, and successive processing (PASS). Understanding the relationships among these variables can offer valuable insights into the interconnectedness of cognitive processes and their impact on overall cognitive functioning in children. However, there is a notable scarcity of research specifically examining these relationships in Puerto Rican children. Therefore, our study aims to fill this gap by exploring patterns, associations, and dependencies among different cognitive domains to deepen our understanding of how specific cognitive abilities influence one another and contribute to overall cognitive performance in children. To achieve this, we conducted a secondary data analysis with a sample of 34 children, ranging from first to fourth grade, representing 11 schools across the metropolitan and southern areas of Puerto Rico (IRB #1314-085). Employing bivariate correlation analysis, we examined the relationships between the PASS variables. The analysis revealed significant positive correlations between planning and attention ($r = 0.523$, $p < 0.001$), attention and successive processing ($r = 0.458$, $p = 0.003$), planning and successive processing ($r = 0.393$, $p = 0.011$), planning and simultaneous processing ($r = 0.387$, $p = 0.012$), and simultaneous processing and successive processing ($r = 0.330$, $p = 0.028$). However, no positive correlation was found between attention and simultaneous processing ($r = 0.282$, $p = 0.053$). By establishing these meaningful relationships, our study provides a more comprehensive understanding of the cognitive skills of Puerto Rican children. Ultimately, our research aims to contribute to enhancing the cognitive assessment and intervention practices specific to Puerto Rican children.

Title: Modeling the content of event representations along the cortical hierarchy during natural vision

Authors: *Y. CHEN[1], Z. ZADA[2], R. E. RICE[3], S. A. NASTASE[2];
[1]MIT, Boston, MA; [2]Princeton Univ., Princeton, NJ; [3]Univ. of California, Santa Barbara, Goleta, CA

Abstract: How are multimodal event representations constructed in the brain from different stimulus features? This study explicitly modeled the content of neural event representations along the cortical processing hierarchy during natural vision. We developed a framework for combined voxelwise encoding models and event segmentation to quantify the contribution of different visual and linguistic features to event representations in brain activities. We employed an open fMRI dataset comprising 25 participants viewing the second half of the Grand Budapest Hotel in five 10-minute runs (Visconti di Oleggio Castello et al., 2020). fMRI data were preprocessed using fMRIPrep and organized according to a 1000-parcel cortical atlas (Kong et al., 2021). Three types of features were extracted from the stimulus: low-level visual motion energy, higher-level visual embeddings from VGG, and linguistic subtitle embeddings from GPT-2. Voxelwise encoding models were estimated for each feature space in order to predict BOLD time series in left-out runs. These model-predicted time series reflect components of the brain activity captured by the feature space of the respective encoding model. Event segmentation was then performed on both the original BOLD time series and the model-predicted time series for each encoding model. In line with prior work (Geerligs et al., 2022), we found a hierarchical distribution of events across brain regions, with higher-level brain regions having fewer and longer events than low-level brain regions. Model-predicted time series yielded more events than the original BOLD time series but with numerous matching event boundaries. Lower-level features (i.e., motion energy) yielded the most numerous model-predicted event boundaries, many of which matched the original event boundaries in early visual areas; higher-level features (i.e., VGG, GPT-2) yielded fewer event boundaries that better matched the original boundaries in higher-level visual and language areas. This suggests a hierarchical organization in brain responses to naturalistic stimuli, with different encoding models capturing different aspects of this hierarchy. Critically, this approach also allows us to compare model-predicted event representations (i.e., activity patterns) derived from a given feature space to event representations derived from the original BOLD data and quantify the relative contribution of each feature space

to the event representations in a given cortical area. This framework provides novel insights into the multidimensional structure of event representations and their hierarchical organization in the human brain.

Title: Different cognitive domain induces different pattern of task-evoked negative BOLD response

Authors: Q. RAZLIGHI[1], *S. GHOLIPOUR PICHA[2];
[1]Cornell Univ. / Weill Cornell Medic Neurosci. Program, Mamaroneck, NY; [2]Cornell Univ. / Weill Cornell Medic Neurosci. Program, New York, NY

Abstract: Introduction:This study explores the overlooked negative blood-oxygen-level dependent (BOLD) responses (NBR) and their unique spatial pattern for each cognitive domains, advancing our understanding of the neurophysiological mechanisms underlying cognitive processes.
Method:Two separate cohorts (n=100, 30) of young participants from different institutes, and different scanners and pulse sequences were imaged with functional magnetic resonance imaging (fMRI) during 12 tasks targeting four cognitive domains (3 tasks per domain). We investigate variations in the spatial pattern of the NBR patterns. Our univariate first-level analysis employs multiple regression with task timing as the predictor, followed by voxel-wise one-sample t-tests at the second level to identify responsive voxels. Cluster-wise multiple comparison correction identifies patterns of deactivated regions. Dice overlap measures the similarity between each pair of task deactivated pattern, generating a 12x12 similarity matrix. Statistical significance is assessed using permutation tests to compare "within domain similarity" and "across domain similarity" of deactivation patterns.
Results:Fig. 1(a and b) presents a color-coded similarity matrix from the first and second cohorts, indicating that patterns of deactivated regions are similar within domains but less so between domains. The permutation test demonstrates significant differences between within-domain and across-domain similarity in both cohort data (∇=0.243/0.114, $p<0.001/0.002$). The data suggests task-specific patterns of deactivated regions, indicating active regulation rather than a biomechanical shutdown of the known default mode regions.
Conclusion: These findings enhance our understanding of neurophysiological signatures linked to cognition, uncovering interconnections and shared neural substrates across functions. They

underscore the significance of task-evoked NBR in studying cognitive domains and contribute to our knowledge of the neural underpinnings of cognition.

Title: Selective Attention Modulates Cortical but not Subcortical Responses

Authors: *V. FIGAROLA[1], A. L. NOYCE[1], A. T. TIERNEY[3], R. K. MADDOX[4], F. DICK[5], B. SHINN-CUNNINGHAM[2];
[2]Carnegie Mellon Univ., [1]Carnegie Mellon Univ., Pittsburgh, PA; [3]Birkbeck College, Univ. Col. London, London, United Kingdom; [4]Univ. of Rochester, Univ. of Rochester, Rochester, NY; [5]Birkbeck/UCL Ctr. For NeuroImaging, Birkbeck/UCL Ctr. For NeuroImaging, London, United Kingdom

Abstract: Individuals often need to attend to one signal within a crowded acoustic scene. The phenomenon of attending to an important auditory source while ignoring other stimuli is known as the cocktail party effect. While attentional effects are well-documented in the auditory cortex, it is still unclear how the function of auditory subcortical nuclei is affected by attention.

This study combines two previous electroencephalography (EEG) paradigms to evaluate the effects of attention on brainstem and cortical physiological responses. The first paradigm replicated is by Dr. Adam Tierney (Birkbeck College, University College London) that requires top-down attention. Competing, interleaved melodies are played and the subjects are asked to attend to a high- or low-pitched melody, listening for 3-note repeats. To test attentional modulation in the brainstem, we modified the stimuli so that each complex tone evokes an auditory brainstem response (ABR) using a paradigm by Dr. Ross Maddox (University of Rochester). Specifically, we created two isochronous impulse trains (2Hz rate), one for the low and one for the high melody, offset in time by 250ms. Each was convolved with different narrowband tone complexes with different pitches (low and high).
We have recruited 19 subjects thus far (12F/7M) all with normal hearing thresholds. We extracted both subcortical ABRs and cortical evoked responses to each note, as well as the phase and inter-trial phase coherence (ITPC) at 2Hz. We found robust ABRs evoked by each tone pip, one per pitch period, within each note, especially wave V. However, there is little evidence suggesting attention modulates ABRs given that wave V latency and amplitude did not change while attending versus ignoring the distractor. On the other hand, each note onset evoked cortical activity, specifically enhancement of every other note depending on which stream was being attended. Additionally, the ITPC showed peaks at the within-melody repetition rate (2 Hz). Furthermore, the best attending listeners showed ~180 degree phase separation between conditions. By simultaneously recording cortical responses and ABRs, we are able to track attention-mediated changes in the neural signals in the cortex and brainstem, respectively.

Abstract: Humans use complex multimodal information to build a rich dynamic interpretation of social environments. Multisensory integration may thus be key for effective social functioning. How are complex naturalistic features integrated and flexibly represented across brain networks? Which features are most relevant for social cognition? We used diverse naturalistic viewing paradigms with rich audiovisual social information [1] and fit encoding models to study how complex stimuli features (audio, visual, abstract semantic) predict brain activity. We used a functional magnetic resonance imaging (fMRI) dataset of healthy adults (n = 79, 23 females, mean(SD) age = 26.8(7.7) with six passive video watching scans (5-21 minutes) of different genres (black/white thriller, diverse movie trailers, animated family movie, TV sitcoms). MRI data processing (described in [1]) included rigorous quality control and parcellation of the cortex into 360 regions in 12 networks [2]. Semantic features (e.g., presence of speech, speaker identity, distance between interacting people) were denoted manually, object-level visual features were extracted with a deep neural network, and audio features were derived from sound statistics (e.g., spectral centroid, power). We fit cross-validated regularized linear regression models [3] using different subsets of features and tested which features best predicted held-out fMRI data. To address overfitting, we included null models (time reversed, block scrambled, within-block-scrambled features). We found robust encoding accuracy in language, visual, and auditory networks for most movies. Across movies, we found the lowest performance in the animated movie (which lacked speech). Across features, visual features alone often performed no better than null models, some of which yielded surprisingly high encoding performance, emphasizing the need for careful overfitting control. Interestingly, models using auditory features outperformed the null models not only in auditory and language networks, but also in visual and the posterior multimodal network across multiple movies. Our results indicate cross-modal integration of complex audiovisual information in semi-naturalistic movies beyond unimodal regions. Efforts to further characterize complex feature spaces and improve encoding models are currently underway with the aim to identify candidates which most reliably predict atypical social behavior.

Title: Automated estimation of participant engagement during computerized cognitive training from facial expressions in older adults at risk for dementia

Authors: *A. TURNBULL[1], Y. WANG[1], Y. XU[2], E. ADELI[3], F. V. LIN[4];
[1]Stanford Univ., Palo Alto, CA; [2]Univ. of Rochester, Stanford Univ., Rochester, NY; [3]Stanford Univ., Stanford Univ., Palo Alto, CA; [4]Stanford Univ., Stanford Univ., Sunnyvale, CA

Abstract: Computerized cognitive training is a frontline non-pharmacological intervention for slowing cognitive decline and brain aging in dementia. The effectiveness of computerized cognitive training in dementia is often limited by the engagement of participants. Monitoring at-risk older adult users' real-time engagement in the domains of attention, motivation, and affect is crucial to understanding and addressing heterogeneity in cognitive training outcomes. In the current project, we predicted engagement (measured using an established mental fatigue measure assessing perceived attention, motivation, and affect during computerized cognitive training sessions) in older adults with mild cognitive impairment (MCI), by monitoring their real-time video-recorded facial gestures in training sessions. Our novel Recurrent Video Transformer (RVT) model, which combines a clip-wise transformer encoder module and a session-wise Recurrent Neural Network (RNN) classifier, achieved the highest balanced accuracy, F1 score, and precision compared to other state-of-the-art models for both detecting mental fatigue/disengagement cases (binary classification) and rating the level of mental fatigue (multi-class classification). The fatigue feature derived from this model also significantly related to slower reaction times at the session level (B=.04, SE=.02, p=.016), providing further validation. By leveraging dynamic temporal information, the RVT model demonstrates the potential to accurately predict engagement among computerized cognitive training users, which lays the foundation for future work to modulate the level of engagement in computerized cognitive training interventions in MCI.

Title: Resolving interindividual propagation dynamics of slow wave events in human EEG/fMRI recordings

Authors: *M. ILHAN-BAYRAKCI[1], O. TÜSCHER[2], A. STROH[3];
[1]Leibniz Inst. for Resilience Res., Mainz, Germany; [2]Univ. Med. Ctr. Mainz, [3]Johannes Gutenberg-University Mainz, Univ. Med. Ctr. Mainz, Mainz, Germany

Abstract: The slow wave state is a brain state occurring in slow wave sleep and in certain anesthetic regimens, characterized by network quiescence interrupted by sudden bursts of activity or so-called slow wave events (SWEs). SWEs propagate as traveling waves of activity stereotypically along the anterior-to-posterior axis usually crossing mesial aspects of the cortex. SWE occurrence and propagation are highly susceptible to excitability changes and states of the neuronal network. Early stages of neurodegenerative and neuroimmunological disorders are marked by ensembles of hyperactive neurons and seem to alter the propagation of SWEs. This susceptibility makes SWEs an ideal target for studying brain (dys-)function across species and across diseases. In rats, we have assessed the relationship between SWEs and BOLD fMRI signals and have observed a cortex-wide BOLD pattern directly related to SWEs. In healthy humans, we have analyzed simultaneous EEG-fMRI data during non-REM sleep. SWEs individually detected in the EEG data were used as predictors in event-related fMRI analyses on single subject level to examine the relationship between SWEs and fMRI signals. For all subjects we identified significant changes in BOLD activity associated with SWEs covering substantial parts of the grey matter. We now ask whether we can resolve the interindividual differences in terms of the SWE propagation patterns in EEG-informed BOLD fMRI, a critical step towards SWE-based assessments of early network dysregulations in humans. For that, we analyzed two distinct datasets comprising simultaneous EEG-fMRI data of sleeping healthy humans (N = 29). We extracted the longest propagation path for each individual SWE based on the EEG data and considered only those events whose principal propagation direction was either along the anterior-to-posterior axis or the lateral axis for subsequent event-related fMRI analyses. Throughout the individual subjects we observed very consistently, significant and strong BOLD fMRI activations in the cingulate gyrus along with activations in the thalamus, the hippocampus, the cerebellum and the brainstem. These BOLD fMRI patterns clearly reflect the long-range coupling of activity between the cortex, the thalamus and the hippocampus and represent a key target to study SWE alterations.

Title: A Novel Computational Model of Risk-Taking Behavior in Older Adults

Authors: *Z. BARAKCHIAN, M. ANTHONY, A. G. TURNBULL, F. V. LIN;
Stanford Univ., Stanford, CA

Abstract: A Novel Computational Model of Risk-Taking Behavior in Older Adults
Functioning in daily life requires the ability to make risky decisions, for example during the managing of finances, an important activity of daily living that is affected by dementia. Understanding how risk-taking behavior changes into old age may provide a basis for understanding how and why risky decision-making is affected by cognitive decline. We introduce a novel computational model to examine decision-making under risk in older adults. Using the Balloon Analogue Risk Task (BART, a task encouraging risk-seeking) and the Iowa Gambling Task (IGT, a task encouraging risk-aversion), we explored the role of prior experience of value (average of previous rewards) and risk (standard deviation of previous rewards) in older adults' decision-making. We then performed correlations with the DOSPERT scale, a well-validated trait measure of risk tasking across multiple domains, to assess relationships between task-based decision-making metrics and trait-level risk-taking behavior. Results showed that in the BART model, both the expected value and the standard deviation of rewards significantly influenced decisions. Conversely, in the IGT model, these factors were significant for fewer participants, with the probability of winning having a more substantial impact on choices. We found trends for significant correlations of task-based risk sensitivity (standard deviation of previous rewards) with the DOSPERT for both the BART and IGT models, but in opposite directions that reflect the risk-seeking (BART: r=.3, p=.056) and risk-avoiding (IGT: r=-.3, p=.064) nature of these tasks. Our findings enhance our understanding of risk-taking behavior in older adults. We observed that individuals utilize different strategies on these two tasks. The standard deviation coefficient (risk sensitivity) of both models significantly correlated with a well-validated measure of trait-level risk taking, suggesting that how older adults evaluate recent experiences of reward during risk-taking may play a role in their trait-level risk taking behavior. This mechanism may represent an important future avenue for research into risk-taking behavior in older adults at risk for dementia.

Title: Disassociation between spontaneous and visually evoked cortical microcircuit activity in a mouse model of Anti-NMDA Receptor encephalitis

Authors: *S. ALTAHINI[1,2], J. DÖRING[4], H. BACKHAUS[5], R. GUIMARAES-BACKHAUS[5], H. PRÜSS[6], A. STROH[3];

Germany; [6]Neurology, German Ctr. for Neurodegenerative Dis. (DZNE), Charite Univ. Med. Berlin, Berlin, Germany

Abstract: Anti-NMDA receptor encephalitis (NMDARE) is an autoimmune brain inflammation induced by IgG antibodies that bind to the N-methyl-D-aspartate receptors. In addition to patients with acute anti-NMDARE, human anti-NMDAR antibodies were also detected in 1% of asymptomatic controls. This suggests that a considerable subgroup of pregnant women is at risk of transferring anti-NMDAR antibodies to the fetus during early stages of pregnancy. Here, we ask whether in utero exposure to anti-NMDAR antibodies (NMDAR-Ab) affects cortical microcircuit performance in adults. For that, we used a mouse model of maternofetally transferred anti-NMDA receptor antibodies. At P51, corresponding to adolescence in humans, we recorded cortical microcircuit activity with cellular resolution in layer I/II in visual cortex by two-photon calcium imaging in awake behaving mice. We found that microcircuits in NMDAR-Ab exposed mice exhibit a lower spontaneous activity signature compared to healthy control mice. Furthermore, antibody exposure led to a bursty neuronal firing with reduced temporal stability of network states. Notably, upon visual stimulation, neurons in NMDAR-Ab exposed mice had a higher orientation selectivity. In NMDAR-AB exposed mice, a large fraction of those neurons active upon visual stimulation did not fire spontaneously, and vice versa. This dissociation between spontaneous and stimulus-evoked activity is in sharp contrast to the operational principles in healthy networks, and indeed, in control mice, the majority of all neurons were co-active in both conditions. Overall, these findings suggest that in utero exposure to NMDAR-Ab shifts cortical microcircuits to a persistent maladaptive state, characterized by a disassociation between spontaneous and visually evoked activity. Such functional disassociation has been long hypothesized to play a role in the emergence of psychotic symptoms.

Title: Modulating arousal via pupil-based neurofeedback: what we’ve learned so far

Authors: *S. MEISSNER[1], M. BÄCHINGER[1], S. KIKKERT[1], J. IMHOF[1], S. MISSURA[1], M. CARRO DOMINGUEZ[1], N. WENDEROTH[1,2];

Abstract: *Introduction:* The locus coeruleus (LC), the principal source of noradrenaline in the brain, is one of the key regulators of the brain's arousal level. Additionally, it modulates cardiovascular function via projections to the brainstem and spinal cord. Interestingly, previous research has provided ample evidence for a link between LC activity and non-luminance dependent changes in pupil size. Utilizing this link, we investigated in a series of experiments whether changes in pupil size (i) can be *volitionally* induced via pupil-based neurofeedback (pupil-NF) training, are associated with (ii) LC activity changes, and modulate (iii) electrophysiological and (iv) cardiovascular arousal markers. *Methods:* In experiment I, 54 healthy volunteers (19-47 years) received 3 days of pupil-NF training to learn to volitionally up- and downregulate pupil size. 28 control participants (19-40 years) received the same amount of training and instructions on mental strategies but no veridical pupil-NF. To explore the link between pupil size changes and LC activity, 25 pupil-NF participants were re-recruited for experiment II combining pupil-NF with 3T functional magnetic resonance imaging (fMRI) and pulse oximetry to measure BOLD responses and cardiovascular parameters. In experiment III, 23 participants (21-41 years) completed a slightly adapted pupil-NF training with simultaneous electroencephalography (EEG) and electrocardiography (ECG) recordings. *Results:* Participants of the pupil-NF group were able to successfully self-regulate their pupil size. Such self-regulation was significantly reduced in control participants (experiment I). fMRI, EEG and ECG analyses (experiment II and III) revealed that pupil self-regulation was linked to systematic activity changes in the LC and other arousal-regulating centers in the brainstem and to changes in electrophysiological and cardiovascular arousal markers: we found higher LC BOLD responses, shallower slopes of the EEG power spectrum from 30-40 Hz, higher heart rate, and lower heart rate variability during blocks of volitional pupil size *up-* than *downregulation. Conclusion:* We provide evidence that pupil-NF makes the brain's arousal system accessible to volitional control, a finding that has potential for translation to behavioral and clinical applications across various domains.

Title: Behind the mask: EEG as a gateway to distinguish induced and posed emotions

Authors: *Q. XU[1], H. MO[1], F. V. LIN[2], G. ZHAO[1];
[1]Ctr. for Machine Vision and Signal Analysis, Univ. of Oulu, Oulu, Finland; [2]Dept. of Psychiatry and Behavioral Sci., Stanford Univ., Sunnyvale, CA

Abstract: Facial expressions play a pivotal role in facilitating social interactions. However, the accuracy of facial expressions in reflecting genuine emotions is often questionable, and previous studies have predominantly relied on stereotypical posed facial expressions. This limitation hampers the true understanding of emotional expression perception. To address this challenge, our study aims to construct a comprehensive database by integrating facial expressions and corresponding physiological signals captured during both induced and posed emotional states. In the laboratory setting, participants' facial expressions were recorded along with a 32-channel electroencephalography (EEG) recording. Two distinct sessions were conducted: an emotional induction session and a posed emotion session. In the emotional induction session, participants were exposed to various film clips from standardized movie databases, aiming to elicit six types of emotional responses (i.e., happiness, sadness, fear, anger, disgust, surprise). Conversely, the posed emotion session involved the presentation of neutral movies, during which participants were instructed to display corresponding facial expressions in their own personal style. A total of 15 healthy participants (3 females, 12 males) were recruited for data collection, with a target sample size of 50 participants (the dataset will be publicly available for academic use upon completion). By analyzing the collected data, our study aims to uncover the underlying credibility of facial expressions from EEG signals for revealing true emotional states. For this purpose, we developed a deep neural network model based on one-dimensional convolutional operations to differentiate between induced and posed emotions in EEG signals. The model consists of a temporal layer that extracts multi-scale features of each EEG channel in the time dimension, and a spatial layer that further utilizes one-dimensional convolution across all EEG channels to extract global spatial information. Preliminary results from a 6-fold cross-validation experiment on the binary classification of induced and posed emotions showed a mean accuracy of 72.95% (SD: 7.4%) and a mean F1-score of 68.87% (SD: 9.07%). This result confirms our hypothesis that EEG signals can unveil emotions concealed by facial expressions, shedding light on the distinction between genuine and feigned emotional states using multimodal data. In the future, we will continue to explore the data and investigate the correlation of features from different modalities and their fusion to detect and recognize various types of emotions in both states.

Title: From the lab to everyday-life habits: the Impact of Striatal Hypoactivity on Habitual Behavior in Parkinson's Disease

Authors: *P. GUIDA[1,2], M. MICHIELS[1,2], M. H. MONJE[3], J. OBESO[1], P. REDGRAVE[4], I. OBESO[1,5];
[1]HM CINAC, Madrid, Spain; [2]PhD Program in Neurosci., Autonoma de Madrid University-Cajal Inst., Madrid, Spain; [3]Dept. of Neurol., Northwestern Univ. Feinberg Sch. of Med., Chicago, IL; [4]Univ. Sheffield, Sheffield, United Kingdom; [5]Dept. of Psychobiology, Complutense Madrid Univ., Madrid, Spain

Abstract: Habitual behavior is crucial in every-life, covering a wide range of actions performed automatically and without conscious effort. The striatum plays a central role in the habitual system. In Parkinson's disease (PD), dopamine depletion initially affects caudal sensorimotor putamen and extends subsequently to more rostral regions. Dopaminergic putamen depletion is likely responsible for habits derangement observed in everyday-life activities in PD.Traditionally, the study of habits relied on use of lab-developed tasks. While valuable for understanding habit formation, these tasks may not fully capture the complexity of real-life behavior. To bridge this gap, we aimed to compare lab-developed and everyday-life tasks by means of behavioural and neural activations (fMRI) comparing newly diagnosed PD patients and healthy controls (HC). We designed a lab-developed task (Visuo-motor Association Task) to train associations followed by reversal phase with varying response preparation times. Also, an everyday-life task (handwriting of words) which highly automatic conditions (signature) to goal-directed ones (Greek). Patients were assessed behaviorally and inside the scanner while off medication. In the lab-developed habitual task, results revealed similar responses in both groups. However, PD exhibited fewer errors (habitual and non-habitual) than HC, specifically during the short preparation time interval. On the other hand, handwriting performance in PD patients showed reduced automatism across habitual and goal-directed conditions compared to HC. Posterior putamen activity was increased in HC during habitual conditions, while the caudate was active during goal-directed conditions in the lab task. In contrast, PD patients displayed a reduced posterior putamen activity for habitual trials. In the everyday-life task, HC also revealed posterior putamen activity during habitual conditions transitioning to anterior striatum as behavior required goal-directed efforts. Interestingly, PD patients exhibited reduced posterior putamen activity and a shift towards anterior regions during habitual behavior. This decrease in activity was more prominent when the affected side of patients matched their dominant hand.Altogether, PD patients reveal an enhanced ability to override habitual responses under temporal stress in lab-developed measures, together with reduced automaticity in executing everyday-life habits. Hypoactive posterior putamen during habitual tasks in PD impairs the ability to effectively execute habitual behaviors.

Title: Job title and years of experience are uncertain predictors of perceptual expertise

Authors: *R. ALEXANDER[1], S. WAITE[2], A. VENKATAKRISHNAN[3], S. L. MACKNIK[4], S. MARTINEZ-CONDE[4];
[1]Behavioral Sci., New York Inst. of Technol., New York, NY; [2]Radiology, [4]Ophthalmology, Neurology, & Pharmacology/Physiology, [3]SUNY Downstate Hlth. Sci. Univ., Brooklyn, NY

Abstract: Professionals and trainees are often classified into broad categories of expertise that are inferred from their title, level of training (i.e., medical student, resident, attending, specialist), and/or years of experience—rather than by any objective metric of performance. These categories dramatically oversimplify reality, overlooking individual differences, exceptional skills or natural talent, and potential age-related declines in sensitivity. Rank is usually tied to years on the job, and individuals typically move up but not down the ladder, even if their skills diminish over time. A more principled measure of perceptual expertise would provide the basis to optimize training assessments by allowing education programs to directly test whether trainees are behaving like experts and—if not—what specific behaviors are not yet at a desired level of performance. We conducted a psychophysical and eye-tracking study aimed at quantifying the gaze dynamics used by professional radiologists to detect abnormalities in medical images. Naive individuals with no medical imaging experience (n=19), radiology residents (n=42), and attending radiologists (n=42) searched through chest CTs, each of which contained one abnormality (a potentially cancerous nodule). Consistent with prior work, we found that some observers performed better than expected based on rank and years of experience. In fact, some residents early in their training outperformed attending radiologists, despite an extensive experience differential. These results highlight that, at best, experience is an uncertain predictor of expertise level, and at worse, it reflects little more than seniority. We therefore propose that individuals should instead be grouped based on their objectively measured performance in specific tasks. There is a need for the study of expertise to move beyond standard rank

descriptions or years of experience, and to develop more efficient strategies and methods to quantify expertise.

Title: Investigating the impact of prolonged sleep fragmentation on neuroinflammation and microglia response to amyloid-beta in the APPxPS1 KI mice

Authors: F. DICKINSON, H. ALI, L. SANDERS, L. Z. GUO, A. SUBRAMONIAM, H. WHITLOCK, C. JOHNSON, B. O'HARA, M. P. MURPHY, M. DUNCAN, *A. BACHSTETTER;
Univ. of Kentucky, Lexington, KY

Abstract: Poor or disrupted sleep is a hallmark of multiple aging and neurodegenerative disorders, including Alzheimer’s Disease (AD). AD has been pathologically characterized by neurofibrillary tangles and amyloid-beta (Aβ) plaque deposits. Growing evidence suggests that typical glia-mediated clearance of metabolites such as Aβ, occurs during sleep. If sleep quality worsens with age, it is possible that effective glial reactivity to Aβ aggregation may be impacted. Past literature has examined the effect of acute and chronic sleep deprivation on microglia reactivity and pathology in human and animal models. We assessed the impact of sleep fragmentation (SF), a phenomenon similar to the transient arousals observed in AD patients, on inflammatory profiles in male (N=) and female (N=) WT and APP/PS1 KI mice (average age of 9 ± 1.4 months), a mouse model that mimics the human AD condition with more gradual expression of Aβ and cognitive impairment at 9 months. They were either undisturbed during sleep (US) or exposed to SF. SF consisted of four daily sessions (1 hour each) of enforced wakefulness (induced with toys and gentle paintbrush stimulation) evenly distributed across the light phase for 5 days/per week. This US and SF procedure was carried out over three weeks (Monday - Friday). SF mice slept 20% less in the light phase, and female KI mice exhibited a 70% increase in rebound sleep during the dark phase ($P<0.001$), demonstrating our SF paradigm

modified sleep patterns. Immediately after the last SF session, mice in both groups were euthanized and cortical and hippocampal tissue was dissected and frozen. At the whole tissue level, no change was found in proinflammatory cytokine protein levels following SF. The immunohistochemical analysis found a robust genotype difference in overall microglia (IBA1+) and astrocytes (GFAP+); however, SF did not modify this effect. There was also no genotype by SF interaction. Analyses using confocal microscopy and Imaris software to explore whether SF might be associated with a more specific impact on microglia and Aβ plaques are in progress. These findings indicate that a slow progressing AD-relevant mouse model can endure three weeks of sleep fragmentation without substantial neuropathological changes, implying that the negative impact of disrupted sleep on Aβ clearance may not be mediated by proinflammatory processes but other elusive factors.

Title: Anti-$\alpha_4\beta_7$ integrin therapy decreased M1-like microglia and promoted A2 phenotype astrocytes in the brains of $App^{NL\text{-}G\text{-}F}$ mice

Authors: *S. CHANDRASEKARAN, A. M. MCINTEE, S. NOOKALA, B. SAHU, A. M. FLODEN, C. K. COMBS;
Dept. of Biomed. Sci., Univ. of North Dakota Sch. of Med. and Hlth. Sci., Grand Forks, ND

Abstract: Anti-$\alpha_4\beta_7$ integrin therapy decreased M1-like microglia and promoted A2 phenotype astrocytes in the brains of $App^{NL\text{-}G\text{-}F}$ mice. Alzheimer's disease (AD) brains are often characterized by the presence of reactive microglia and astrocytes and an overall proinflammatory milieu. Increasing evidence supports the notion that peripheral immune cells may influence the overall brain environment. For example, our prior work demonstrated that intestines of the $App^{NL\text{-}G\text{-}F}$ mouse model of AD have an altered immune phenotype and a colitis-like insult alters brain changes during disease. We also observed a noticeable reduction in GFAP and Iba-1 positive reactive astrocytes and microglia, respectively, in APP/PS1 mice treated with

anti-$\alpha_4\beta_1$ integrin antibody. These results suggest an immune-based communication of intestinal and peripheral changes to the brain during disease. To further explore this mechanism, we administered an inflammatory bowel disease (IBD) therapy, anti-$\alpha_4\beta_7$ antibody, to littermate control C57BL/6J wild type and *App*$^{NL\text{-}G\text{-}F}$ AD mice at 5-7 months of age to examine consequences on glial phenotype in the brain. Mice were randomly divided into control, anti-$\alpha_4\beta_7$, or isotype negative control groups for each sex. Antibodies were injected intraperitoneally at 10 mg/kg once a week for 10 weeks. The phenotypic characteristics of brain resident microglia and astrocytes were determined by immunohistochemistry for CD16, CD45, and S100A10 proteins. Both male and female *App*$^{NL\text{-}G\text{-}F}$ mice treated with anti-$\alpha_4\beta_7$ antibody showed a decrease in CD16 and CD45 immunoreactivity in the hippocampus when compared to untreated control *App*$^{NL\text{-}G\text{-}F}$ mice, suggesting a decline in the pro-inflammatory M1-like microglia population. Antibody treatment had no effect on CD16 or CD45 immunoreactivity in wild type mice. Anti-α4β7 treatment increased S100A10 immunoreactivity in male and female *App*$^{NL\text{-}G\text{-}F}$ mice compared to their respective untreated control groups suggesting an increase in neuroprotective A2-like astrocytes. Antibody treatment did not affect wild type astrocyte S100A10 immunoreactivity. These findings suggest that neuroinflammation and glial phenotype in AD may be influenced by intestinal immune cells and interventions focused on these peripheral immune cell targets may be sufficient to provide ameliorative effects in the brain.

Title: The Effect of Mild Repetitive Traumatic Brain Injury Early in Life on the Progression of Alzheimer's Disease in 3xTgAD Mice

Authors: *C. C. H. BARKER, L. ALMUHANNA, L. A. KOZA, D. LINSEMAN;
Univ. of Denver, Denver, CO

Abstract: Repetitive traumatic brain injuries (rTBIs) have been shown to increase neuroinflammation in both mouse models and human studies and are predicted to increase risk for neurodegenerative disorders including Alzheimer’s disease (AD). Given the number of TBIs reported just in the US each year, a large part of the population could be at an increased risk of developing AD. By using a combination of behavioral tests, histopathology, and exosomal biomarker analysis, we investigated whether brain trauma accelerates cognitive dysfunction, brain pathology and appearance of exosomal biomarkers of neurodegeneration and

neuroinflammation in 3xTg-AD mice subjected early in life to repetitive mild TBI (rmTBI). Four groups of mice including naïve 3xTg-AD mice, sham 3xTg-AD mice, rmTBI 3xTg-AD mice, and naïve wild type mice, were used for this study. Mice in the rmTBI group were given 5 mTBIs, each separated by 48 hours, at 3-months old. At 11-months old, mice were assessed for cognitive function using the Barnes maze, Y-maze, and Novel Object Recognition (NOR) behavioral tests. Blood and brain tissue were taken immediately after the conclusion of the behavioral tests. Hippocampal sections of brain were stained for amyloid-beta and phosphorylated-Tau, proteins that constitute pathological hallmarks of the disease. Total exosomes were isolated from collected plasma and cell type-specific exosome subpopulations, including those from astrocytic, neuronal, and microglial origin, were isolated from brain tissue. Preliminary results from the behavioral tests indicate that there are no significant differences in cognitive function between the 3xTgAD mouse groups. However, the wild type mice do perform better across all behavioral tests than any of the 3xTg-AD mouse groups. The histopathology data shows differences in the number of amyloid-beta plaques and p-Tau staining in the hippocampus across the 3 AD mouse groups. Future biomarker analyses will examine markers of neuroinflammation (e.g., IL-6, IL-1beta, TNF-alpha) and neurodegeneration (e.g., amyloid beta, p-Tau, and TDP-43) in total plasma-derived exosomes and cell type-specific exosome subpopulations isolated from mouse brain. Our preliminary results indicate that receiving rmTBIs early in life may accelerate disease progression, indicated by histopathology, in mice which are genetically predisposed to developing AD. Biomarker analyses will reveal if the increased brain pathology correlates with an increased appearance of exosomal biomarkers of neuroinflammation and neurodegeneration in 3xTg-AD mice subjected to rmTBIs.

Abstract: Inhibition of NLRP3 leads to reduced tau pathology and improved social behavior in 3xTg mice.
Authors: ***Jakob Green**[^], Christopher Nelson[*], Yiming Yu[#], Shijun Zhang[#], Dong Sun[*];

[^]Department of Anatomy and Neurobiology, Virginia Commonwealth University; [#]Department of Medicinal Chemistry, Virginia Commonwealth University
Abstract: Alzheimer's disease (AD) is a devastating disease that affects millions of patients around the world with limited medication available to manage the disease. In AD pathological development, neuroinflammation plays a significant role. Recent studies have identified NLRP3 inflammasome as a critical multiprotein platform regulating inflammatory response, and have shown involvement in AD pathogenesis in AD patients and animal models. In this study, we studied the role of NLRP3 in tau pathology using a combination of a pharmacological approach using a novel NLRP3 inhibitor and a transgenic approach with NLRP3 gene knock down in 3xTg-AD mice, a mouse line carrying the APP695 gene with Swedish mutations (KM670/671NL/M596L), along with the PSEN1 (M146V) and tau (P301L) mutations. The 3xTg-AD mice were treated with our novel NLRP3 inhibitor or vehicle when animals were at 5 months as single daily (20mg/kg) via oral gavage for 3 months. The 3xTg/NLRP3 KO mice were not treated. After 3 months treatment, AD related behavior changes including anxiety and cognitive functions were assessed. After completion of behavior tests, animals were euthanized, brains were collected for Western blotting and immunostaining to assess tau pathology. In comparing several phospho-tau modifications by Western blot and a novel ultrasensitive electrochemiluminescence immunoassay, we found significant effect of NLRP3 on the protein expression level of pT175, cis-pT231, pS396, pS214, and pS610 tau in female mice. Among them, pT175, cis-pT231, pS396, and pS214 showed a reduction in the treated and KO groups while pS610 only showed a significant decrease in the KO group. We also found that AT180, a similar anti-pT231 antibody, was reduced in the treatment and KO groups in both males and females. In behavior tests, no difference was found in social affiliation (sociability), a test for social motivation. In a social novelty test, an assessment for social memory, animals with NLRP3 inhibition showed significant improvement in performance. We found that NLRP3 inhibition with drug treatment or gene knock down significantly reduce AD-associated tau pathology, together with reduced anxiety like symptoms. In conclusion, our study further confirms the role of NLRP3 in AD and tau phosphorylation.

Abstract: Alzheimer's disease (AD) is a neurodegenerative disease characterized by progressive dementia and brain accumulation of Aβ peptide-containing plaques, gliosis, neuroimmune changes, and neurofibrillary tangles. Recently intestinal changes, including dysbiosis, have been suggested to also be a component of the disease process. Our prior work demonstrated intestinal dysfunction and dysbiosis in the *App*$^{NL\text{-}G\text{-}F}$ mouse model of AD and exacerbation of brain changes by inducing a colitis-like condition. This study aimed to evaluate whether a dietary intervention of the wild edible mushroom, *Phallus atrovolvatus*, recently found in Thailand could alter intestinal dysfunction and dysbiosis in the *App*$^{NL\text{-}G\text{-}F}$ mice while also reducing brain presentation of disease. Male and female 6-7 month old littermate wild type control (C57BL/6) and *App*$^{NL\text{-}G\text{-}F}$ mice were randomly assigned to either control or a diet supplemented with mushroom extract containing 30% β-glucans and 13% protein for 8 weeks to quantify changes in body weight, memory, brain cytokines, immune changes, gliosis, intestinal microbiome, and brain Aβ levels. Body weights in either genotype or sex did not significantly change throughout the study and the mushroom extract did not alter serum lipopolysaccharide compared to control diet indicating that it had no adverse effects on gut leakiness. To examine effects on behavioral performance, a cross maze test was performed. Mushroom extract feeding did not alter spatial recognition memory in either sex or genotype compared to their respective control diet groups. Our findings demonstrate that dietary intervention with a previously characterized immunomodulatory mushroom extract from *Phallus atrovolvatus* had no adverse effects on gut health or memory and support further evaluation of protective immunomodulatory or anti-Aβ effects in the brain.

Title: In vivo examination of the TREM2-dependent human microglial responses to Alzheimer's disease pathology using proteomics in chimeric mice

Authors: *Y. JIAO;
Merck, Cambridge, MA

Abstract: *In vivo* examination of the TREM2-dependent human microglial responses to Alzheimer's disease pathology using proteomics in chimeric miceAuthors: Yun Jiao[1], Hayk Davtyan[2], Carlo Ramil[1], Sepideh Kiani Shabestari[2], Jonathan Hasselmann[2], Jean Paul Chaderevian[2], Xuemei Yang[1], Alex Tamburino[1], Matt Blurton-Jones[2], Rebecca Mathew[11] Merck & Co., Inc., Cambridge, MA, USA; [2] University of California, Irvine, Irvine, CA, USA
Background: Alzheimer's disease (AD) is the most common neurodegenerative disease. Recent genome-wide association studies identified many risk genes expressed in microglia, suggesting that microglia play a central role in AD. One of the strongest risk genes, TREM2, is exclusively expressed by microglia. Loss of function mutations of TREM2 was showed to increase AD risk dramatically. TREM2 knockout in mice was shown to impair the ability of microglia to respond to beta-amyloid plaques. However, it remains unclear whether human TREM2 knockout microglia exhibit similar or perhaps additional functional deficits.Methods:To further examine the impact of TREM2 deletion on human microglia, we used CRISPR to generate TREM-knockout (TREM2-KO) induced pluripotent stem cells (iPSCs). Isogenic wildtype and TREM2-KO iPSCs were differentiated into hematopoietic progenitors (HPCs) and transplanted into postnatal immunodeficient AD mice (hCSF1-5xFAD). Six months later, human microglia were isolated from chimeric mice and examined via bulk proteomic analysis. Results:Analysis of proteomic dataset revealed significant and novel impacts of TREM2 deletion on the response of human microglia to beta-amyloid pathology. The protein abundance of a set of AD risk genes showed TREM2-dependence in their response to beta-amyloid pathology. Immune-related pathways in human microglia were altered between TREM2 genotypes in AD mice. The engulfment and phagocytosis of mouse synapses by human microglia were also altered by the loss of TREM2. These data reveal important new information about changes occurring within human microglia in response to amyloid pathology and loss of TREM2 expression.

Abstract: Alzheimer's Disease (AD) is a progressive neurodegenerative disease characterized by cognitive deficits, behavioral changes, and memory loss. Prenatal alcohol exposure (PAE) is known to affect neurodevelopment, leading to behavioral and cognitive impairment throughout the lifespan. Our previous studies related to PAE and stroke, a risk factor for dementia, have shown sex-dependent differences in behavioral outcomes; PAE male rats showed impairment during the learning phase of the Barnes maze, a spatial hippocampal task, while females did not. In this project, we examined the effect of PAE on a cued fear conditioning task in an animal model of Alzheimer's disease. Wild-type (WT) Fischer F344 females were time mated with Fischer transgenic (Tg) F344-AD males harboring the human Swedish mutation amyloid precursor protein and the presenilin-1 exon 9 deletion mutant. Pregnant dams were exposed to vapor ethanol, or room air (controls), for 1 hour daily (GD 11-16). Blood ethanol concentrations averaged 132.337 mg/DL. Male and female PAE offspring at 6 months were tested on a 3-day fear conditioning paradigm to assess cognitive function. On day 1, animals were placed in the chamber and exposed to context A for baseline recording of movement with visible light and fan switched on, then subjected to four tone-shock pairings (10 second tone co-terminated with a 1 second foot shock,0.8 mA). Fear extinction took place on day 2, in which rats were exposed to a new context (B), with 30 tone trials (1 kHz, 80 dB, 10 s) without shock. Fear extinction recall took place on day 3, also using context B, paired with 15 tone trials (1 kHz, 80 dB, 10 s). Context A had visible light and fan noise whereas context B included plastic flooring covering the metal grating, ambient white noise, near infrared lighting, a black cover over the chamber, and the scent of home cage bedding. Fear learning analysis revealed that WT male PAE rats had significantly higher freezing response (Two-way ANOVA, main effect of tone-shock, $p<0.0001$) compared to Tg-PAE males, suggesting that PAE decreased fear acquisition in AD transgenic animals. Female WT and Tg PAE animals were not significantly different in their freezing responses, however, the overall freezing response in females was lower than the males, indicating a potential sex-difference in fear learning. These findings suggest that PAE exerts sex-specific effects in associative learning in AD transgenic animals.

Title: Rostrace reveals APOE4 associated-neuroinflammation in a humanized mouse model of sporadic Alzheimer's disease

Authors: *Y. ZHU[1,2], A. YOUNG[2], J. CONI[1], M. SHELDON[1], M. RAJASEKARAN[1], B. GENOVESE[1], A. C. RAIKES[3], J.-P. WIEGAND[3], R. H. MACH[2], R. D. BRINTON[3], M. J. MCMANUS[1];
[1]Children's Hosp. of Philadelphia, Philadelphia, PA; [2]Dept. of Radiology, Univ. of Pennsylvania, Philadelphia, PA; [3]Ctr. for Innovation in Brain Sci., Univ. of Arizona, Tucson, AZ

Abstract: Alzheimer's disease (AD) is a devastating neurodegenerative disease affecting 6.5 million in the U.S. alone and has no cure. Mutations in APP and tau are associated with familial AD, but over 98% of AD patients have the late-onset, sporadic form. The greatest risk factors for late-onset AD (LOAD) are age, female sex, and apolipoprotein 4 (APOE4). These 3 risk factors converge at the mitochondrial-immune axis and transform the brain into a toxic, pro-inflammatory state that initiates AD pathogenesis. One or two copies of APOE4 alleles can increase the risk for AD by approximately 4- and 15-fold, respectively, compared to the healthy population. Mounting evidence suggests that APOE4 can cause unregulated production of reactive oxygen species (ROS) by inducing mitochondrial dysfunction in the neurons, modulating microglial immunometabolism, and accelerating blood-brain barrier (BBB) breakdown via the cyclophilin A pathway in pericytes. We hypothesize that these APOE4-associated effects join to create an environment of high oxidative stress in the brain that may emerge prior to clinical diagnostic AD symptoms. In the current study, we utilize a superoxide ($O_2^{\bullet-}$) -sensitive radioactive tracer, [^{18}F]ROStrace, to track oxidative stress in the living brain in humanized mice with targeted replacement of murine APOE4 and APP genes with the human genes. This study aimed to determine whether [^{18}F]ROStrace retention is higher in the early-stage pathology of LOAD mice. Age and gender-matched hAPOE4 and hAPOE4+hAPP mice were imaged with [^{18}F]ROStrace at mid-life, alongside control animals. Our microPET/CT data demonstrated increased [^{18}F]ROStrace retention in the hAPOE4+hAPP mouse group compared to hAPOE4 and control groups, which correlated with metabolic and behavioral changes. However, there was no difference in tracer retention between the hAPOE4 and control group. Moreover, the histological analysis also confirmed an abnormally elevated neuroinflammation in the hippocampus region of the hAPOE4+hAPP mouse brain, which was absent in the other two animal groups. Therefore, [^{18}F]ROStrace is sensitive to detecting ongoing oxidative stress and neuroinflammation in humanized LOAD mice. Thus, [^{18}F]ROStrace may provide a noninvasive method to identify LOAD patients before irreparable neurodegeneration occurs and evaluate anti-inflammatory AD therapeutics. This research is supported by NINDS grant 1R01NS114656.

Title: Early-life Exposure to Heavy Metals Promotes Neuroinflammation and Cognitive Deficits in a Mouse Model of Alzheimer's Disease

Authors: *M. COOK[1], S. DIXON[1], S. CARROLL[2], G. WANG[2];
[1]Pathology and Lab. Med., [2]Med. Univ. of South Carolina, Charleston, SC

Abstract: Environmental or occupational exposure to heavy metals is a significant public health concern. Cadmium (Cd) and lead (Pb) pose a major public health challenge due to their ubiquitous presence in the environment and their established toxicological profiles even at low concentrations. Alzheimer's disease (AD) is a debilitating and progressive neurodegenerative disorder that causes dementia and death. A growing body of evidence demonstrates that genetic, environmental, and epigenetic factors all contribute to AD pathogenesis and progression. In line with this, epidemiological studies have identified an association between the exposure to neurotoxic heavy metals and an increased risk for neurodegenerative disorders. However, the molecular mechanisms by which heavy metal exposure affects the pathogenesis and progression of AD have not been completely understood. Using the 5xFAD transgenic mouse model of AD, we have demonstrated that early-life exposure to Pb or Cd markedly accelerates the decline of cognitive functions as determined by Y-maze tests in juvenile mice that typically will not display any AD symptoms at such as a young age. Open field tests have revealed that Pb or Cd exposure induces anxiety-like behavioral changes. Although both Cd and Pb can cause anxiety-like behavioral changes and cognitive deficits, Cd induces a greater level of cognitive deficits and anxiety-like behaviors at a 100-fold lower concentration, suggesting that Cd is much more potent than Pb in promoting AD development and progression. Mechanistic studies unveil that Cd is more effective than Pb at inducing the formation of amyloid beta (Aβ) plaques in the hippocampus and cortex. Our data also show that the levels of pro-inflammatory cytokines, including IL-1β, TNF-α and IL-6, were significantly higher in the hippocampus and cortex of mice treated with Cd or Pb than that in control mice. Furthermore, we found that Cd exposure stimulated TNF-α and IL-6 expression preferentially in the hippocampus over the cortex, indicating a spatial difference in Cd-induced upregulation of IL-6 and TNF-α expression in the brain. Given the important implications of Aβ deposition and neuroinflammation in AD, these results imply that exposure to heavy metals, such as Cd in particular, may accelerate AD pathogenesis via promoting Aβ accumulation and inflammatory cytokine-mediated neuroinflammation.

Title: High-fat diet impairs memory, alters phagocytic function, and activates the complement cascade in the 3xTg-Alzheimer's Disease mouse model

Authors: *S. MACKEY-ALFONSO[1], M. BUTLER[2], N. DEEMS[2], S. MUSCAT[2], B. GONZALEZ OLMO[2], R. BARRIENTOS[2];
[1]The Ohio State Univ. Neurosci. Grad. Program, Columbus, OH; [2]Inst. for Behavioral Med. Res., The Ohio State Univ., Columbus, OH

Abstract: Alzheimer's Disease (AD) is a neurodegenerative disease characterized by profound memory impairments, synaptic loss, neuroinflammation, and the hallmark pathology of amyloid beta plaques and neurofibrillary tau tangles. High fat diet (HFD) consumption has been shown to increase the risk of developing AD in humans and exacerbate neuroinflammation and memory impairment in AD mouse models. However, the underlying mechanisms linking diet to AD risk is not well characterized. Thus, this project investigated the effect of HFD consumption on 1) memory, 2) neuroinflammation, and 3) phagocytosis of synapses in the 3xTg-AD mouse model. Following the consumption of either standard chow or short-term HFD, young adult AD mice were behaviorally assessed using the novel object recognition/location memory task. In a separate cohort, AD and WT mice fed chow or HFD were transcardially saline-perfused and the hippocampus was dissected for transcript and protein analysis of pro- and anti-inflammatory markers. Protein levels of complement markers were also assessed. In another cohort, synapses were isolated from the hippocampus of AD chow and HFD-fed mice and conjugated to pH-rhodamine, which turns red when phagocytosed by cells. The amount of phagocytosis of synapses by BV2 microglial cells was tracked over 4 hours to determine any differences between groups. Only in AD mice, HFD significantly impaired hippocampal-dependent memory and increased gene and protein levels of pro- and anti-inflammatory cytokines and a marker of microglial reactivity. Complement protein expression was higher in HFD-fed AD mice. Synapses from HFD-fed AD mice were phagocytosed at a higher rate than those from chow-fed mice. These data demonstrate HFD consumption increases neuroinflammation and complement activation in 3xTg-AD mice resulting in increased phagocytosis of synapses and memory impairment. Future studies will investigate the role of complement driving these diet-induced memory and synaptic changes.

Title: Prevention of Alzheimer pathology by blocking neuregulin signaling on microglia

Authors: J. LIU, J. GERAGHTY, S. SCHRAM, J. LEI, J. A. LOEB, ***F. SONG**;
Univ. of Illinois at Chicago, Chicago, IL

Abstract: Plaque formation, microglial activation, and synaptic loss are pathological hallmarks of Alzheimer's disease, however, removing plaques have had little clinical benefit. Here, we show that neuregulin-1, a glial growth factor, induces inflammatory cytokines and promotes phagocytic activity in vitro and augments microglial activation and plaque formation in 5XFAD Alzheimer's mice. Brain-specific targeting of neuregulin-1 by intraventricular delivery of a novel neuregulin-1 fusion protein antagonist GlyB4 significantly alters microglial morphology and function to a non-pathogenic phenotype in early-stage 5XFAD mice and prevents plaques from forming. At later stages, once plaques have already formed, GlyB4 reduces new plaque formation and prevents synaptic loss. Selective, targeted disruption of neuregulin-1 signaling on brain microglia with GlyB4 could be a novel 'upstream' approach to slow or stop disease progression in Alzheimer's disease.

Abstract: Alzheimer's Disease (AD) is the most common form of dementia. It is a fatal neurodegenerative disease that leads to both cognitive decline and altered psychological states. There is currently no cure for AD. The pathology of AD includes the clustering of insoluble amyloid-β (Aβ) plaques, tau tangles, and increased neuroinflammation. The heightened neuroinflammatory state in AD is an essential point of focus in AD research. In this study, the novel oral anti-inflammatory tumor necrosis factor-α (TNF-α) inhibitor compound PD2244 was tested to observe its effects on sensorimotor gating using prepulse inhibition (PPI), spatial memory using Barnes Maze, and anxiety using an elevated-T maze in both female and male 3xTg mice. The 3xTg mice are the only triple-transgenic model of AD that has both Aβ plaques and tau tangles and is also an aging mouse model of AD pathology onset. A specialized diet containing variable doses of PD2244 was given to 3xTg mice beginning at 6 months of age. The doses given were 0, 1, 3, 10, and 30 mg/kg of PD2244. Testing was then performed at 9, 12, and 15 months, where 15 months equated to thorough AD pathology. Regarding behavioral improvement, it was observed that all doses of PD2244 were effective in alleviating deficits in PPI at 9, 12, and 15 months of age. On the Barnes Maze, at 9 months of age, the 10 mg/kg dose of PD2244 was effective at alleviating spatial memory deficits, whereas at 12 months the 3 and 30 mg/kg dose of PD2244 were effective, and finally, at 15 months the 3, 10, and 30 mg/kg doses of PD2244 demonstrated efficacy at alleviating deficits in spatial memory performance. On the elevated T-maze, there were no effects at 9 months of age, but the 3 mg/kg dose of PD2244 resulted in anxiolytic effects at 12 and 15 months of age. Nest building behavior is also being observed in 15-month-old mice to determine effects of PD2244 on apathy since it is a common neuropsychiatric symptom of AD. In addition, there is currently a project analyzing immunohistological staining of microglial cells in the hippocampus (HPC) and prefrontal cortex (PFC) in 15-month-old animals, which will be presented. These behavioral and neurobiological analyses are designed to discover a novel, effective, anti-inflammatory treatment for cognitive deficits and increases in anxiety associated with AD.

Title: Brain cellular responses to peripheral inflammation in mouse model of Alzheimer's Disease

Authors: *Y. LU, C. SAIBRO-GIRARDI, N. F. FITZ, M. A. OSTACH, I. LEFTEROV, R. KOLDAMOVA;
Envrn. and Occup. Hlth., Univ. of Pittsburgh, Pittsburgh, PA

Abstract: Background: Peripheral infection has been implicated in the development of various neurodegenerative disorders, such as Alzheimer's Disease (AD). We aimed to test the effect of peripheral inflammation on amyloid pathology and brain transcriptome.**Methods**: We used APP/PS1 mice and had the mice intranasally exposed to *Staphylococcus aureus* (Staph) or PBS as control for different time period (chronic: 16-week-treatment, Staph n=16, 8 females and 8 males, and PBS n=20, 10 females and 10 males; acute: 1-week treatment, Staph n=4 and PBS n=4, 2 males and 2 females each group). We conducted bulk-, single-cell, and spatial-transcriptomics analysis on the mouse brain tissue, as well as cytokine assays and histology for confirmation.**Results**: Chronic exposure resulted in increased accumulation of amyloid plaques and microglia associated with plaques, leading to significant alterations in the transcriptional profile of brain barrier-associated cells and subsequent barrier dysfunction. We identified cell type- and spatial-specific transcriptional changes associated with brain barrier (BBB) functions and neuroinflammation during the acute infection. We found upregulation of BBB-related endothelial genes (*Ddit4* and *Apold1*) and functions, such as apoptosis and hypoxia. *Cldn5*, encoding an important tight junction protein, was found downregulated with Staph treatment. Both acute and chronic exposure elicited responses in brain macrophages and had detrimental effects on neuronal transcriptomics. We found upregulation of IFN-induced macrophage *Bst2* gene and other genes from the IFN-induced transmembrane proteins family, like *Ifitm2*, by acute infection. Furthermore, we observed distinct transcriptional responses in the microenvironment around amyloid plaques following acute infection, characterized by increased expression of disease-associated microglia genes (such as *Tyrobp*, *Ctss*, *Ctsd*, etc.), and a more pronounced effect on astrocytic (such as *Gfap* and *Clu*) or macrophage-associated genes (*Lyz2* and *Ccl6*), potentially facilitating the development of amyloid and related pathologies.**Conclusion**: Our findings provide insights into the underlying mechanisms connecting peripheral inflammation and AD pathology.

Title: Ubiquitinated IL1B and Defective Inflammasome Formation in Alzheimer's Disease: Implications for Chronic Brain Inflammation.

Authors: *M. G. SABBIR[1], L. M. SALGUEIRO[2];
[1]Dept. of Psychology and Neurosci., Col. of Psychology, Nova Southeastern Univ., Fort Lauderdale, FL; [2]Inst. for Neuro Immune Medicine, Nova Southeastern Univ., Fort Lauderdale, FL

Abstract: Chronic brain inflammation is implicated in the development and progression of Alzheimer's disease (AD). Inflammation manifests the release of cytokines, such as interleukin-1 beta (IL1B), a pro-inflammatory cytokine involved in immune responses and inflammation. Elevated levels of IL1B have been reported in AD brains. IL1B is initially synthesized as an inactive precursor and undergoes cleavage by caspase 1 associated with the inflammasome, releasing the active form. To downregulate IL1B and prevent excessive inflammation, the body employs ubiquitination, marking IL1B for proteasomal degradation. We hypothesize that ubiquitinated IL1B is present in inflammatory brains, including AD, and any defect in it may lead to unchecked inflammation, accelerating neurodegeneration. We conducted western blotting to assess the abundance of cleaved and ubiquitinated IL1B in postmortem brain tissues and examined their correlation with inflammasome formation. We used lipopolysaccharide and phorbol ester-activated human monocytic cells (THP-1) to characterize cleaved IL1B secretion and the expression of reactive inflammasome-associated proteins, including NLRP1/3, AIM2, NLRC4, ASC/TMS1, and Caspase-1. Next, we analyzed postmortem frontal/temporal cortex and hippocampus tissues from non-demented individuals of different age groups (young: 0-16 years, older: 67-80 years) and AD patients (N=74) to investigate age/dementia-related IL1B production in the brain. Our findings reveal the presence of 25 kDa cleaved IL1B in the inflammatory brains of some of the non-demented individuals across different age groups. Conversely, we did not detect cleaved IL1B in the temporal cortices of AD patients, but we observed variable amounts of 37-50 kDa ubiquitinated IL1B in 59% of AD patients' temporal cortices. The presence of NLRP1-associated inflammasome was inconsistent in the ubiquitinated IL1B-positive temporal cortices and only noted in 15% of AD brains. Isoelectric focusing demonstrated abnormal phosphorylation (negatively charged fraction) of ubiquitinated IL1B, which correlated with an increased accumulation of 37-50 kDa IL1B in AD brains compared to non-demented inflammatory brains. Overall, these findings suggest that abnormal post-translational modification of IL1B in AD brains may contribute to the accumulation of ubiquitinated IL1B and hinder the formation of the inflammasome, potentially impeding the resolution of inflammation in AD brains. Further characterization of this defective IL1B signaling pathway will provide novel insights into the neuroinflammatory origin of AD.

Title: Resistance exercise attenuates cognitive impairment and neuroinflammation induced by surgery performed under sevofluorane anesthesia

Authors: *A. WONG[1], R. CHANG[1,2];
[1]Lab. of Neurodegenerative Diseases, LKS Fac. of Medicine, Univ. of Hong Kong, Hong Kong, China; [2]State Key Lab. of Brain and Cognitive Sciences, The Univ. of Hong Kong, Hong Kong, China

Abstract: Resistance exercise (RE) improves cognition in human and animal studies associated with Alzheimer's Disease (AD). However, the mechanisms remain poorly investigated. Previous studies have reported that pre-existing cognitive impairment imparts susceptibility to accelerated cognitive decline following an acute systemic inflammatory episode. The aim of this study was to compare cognitive impairment between sedentary and resistance-exercise-trained mice in the Alzheimer transgenic mouse model following sevoflurane anesthesia and abdominal surgery. To evaluate the role of RE in modulating pre-existing cognitive impairment, 5-month-old female *3xTg* and age-matched (C57BL/6J) controls underwent a five-week RE-training protocol. Novel-object recognition (NOR), y-maze, and fear-conditioning (FC) tests were conducted to probe for cognition and learning. The discrimination index, spontaneous alternation percentage, and freezing behavior were the major outcomes. In a second experiment, laparotomy was performed after training, and 3 days later, the same behavior tests were performed. Brain homogenates were harvested for western blot (WB) analysis, qPCR, or post-fixed in neutral-buffered formalin solution for immuno-histochemical exploration. In *3xTg* mice, RE mice exhibited improved alternation, discrimination, and freezing in NOR, y-maze, and FC test (all $P < 0.05$). qPCR revealed decreased inflammatory cytokine transcripts in the hippocampus compared to sedentary controls. No differences were observed in control mice. In post-operative *3xTg* mice, surgery induced cognitive deficits in NOR but not in FC test. RE-trained mice showed a significant increase in discrimination and freezing percentages compared to sedentary counterparts (both $P < 0.05$) and a significant reduction in inflammatory cytokines and apoptotic signaling pathways post-surgery. RE attenuated exaggerated cellular responses and improved cognitive functions in AD mice. Sevoflurane anesthesia followed by surgery induced changes in cognition and pathological changes in the hippocampus, and pre-habilitative RE prevented the acceleration of cognitive impairment triggered by the acute inflammation insult.

Title: Niacin receptor HCAR2 affects amyloid pathology at an early stage of disease

Authors: *S. GEIS[1,2], I. CORONEL[2], M. MOUTINHO[2], G. LANDRETH[2];

Abstract: NIACIN RECEPTOR HCAR2 AFFECTS AMYLOID PATHOLOGY AT AN EARLY STAGE OF DISEASE
Samantha Geis[1], Israel Coronel[1], Miguel Moutinho[1] and Gary Landreth[1]
1) *Stark Neurosciences Research Institute, Indiana University School of Medicine, Indianapolis, IN, USA*
Background: Alzheimer's disease (AD) is a progressive neurodegenerative disease and a leading cause of dementia worldwide. Mounting evidence suggests that the accumulation and aggregation of amyloid-β (Aβ) is a key initiating factor in a cascade of events that lead to AD. The AD brain is typified by a robust microglial immune response triggered by Aβ accumulation. Although microglia have emerged as an important player in AD pathogenesis and progression, the role of these cells in disease is complex and still not fully understood. We have recently described that the niacin (nicotinic acid) receptor HCAR2 is required for an efficient microglial neuroprotective response in the 5xFAD amyloid mouse model. This analysis was performed at a stage of active and widespread plaque deposition and neuropathology. However, whether HCAR2 plays a role at an early stage of the disease remains unknown. **Methods:** We analyzed the phenotype of 2-month-old 5xFAD male and female mice lacking the HCAR2 receptor which corresponds to an early stage of disease. To examine if activation of HCAR2 at an early stage of disease exerts long-lasting beneficial effects, 2-month-old 5xFAD mice were provided with high doses of nicotinic acid through food pellets for 4 months. **Results:** Our preliminary results show that the lack of HCAR2 exacerbates amyloid burden in males at the early stages of pathology. Additionally, microglia mobilization to plaque-rich areas was reduced in both males and females at this disease stage in the absence of HCAR2. Furthermore, treatment of 2-month-old 5xFAD animals with a nicotinic acid-enriched diet for 4 months attenuated amyloid pathology. **Conclusions:** These preliminary data demonstrate that HCAR2 impacts amyloid pathology at earlier stages of the disease, highlighting an important role of this receptor in disease pathogenesis and its potential as a therapeutic target. Treatment of 2-month-old 5xFAD mice for 4 months with a nicotinic acid-enriched diet reduced amyloid pathology, highlighting the therapeutic potential of nicotinic acid in AD.

Title: Investigation of infectious theory of Alzheimer's Disease using HSV-1 in the 5xFAD mouse model

Authors: *I. ABOU-SEADA, K. R. MAGNUSSON, L. JIN, M. JANSEN, T. BREHON; Oregon State Univ., Corvallis, OR

Abstract: Alzheimer's Disease (AD) is a neurodegenerative disease that causes memory loss, cognitive decline, and is the cause of about 70% of all recorded dementia cases. AD is characterized by two main pathologies: amyloid beta (A-beta) plaques, and hyperphosphorylated tau proteins. Recent research has found the presence of some pathogens (herpes simplex virus-1 (HSV-1), and human herpesvirus-6 (HHV-6) being commonly found in the brains of post-mortem AD patients. From this data the infectious hypothesis of AD was proposed and states that a pathogen (virus, bacteria, prion, etc.) is the root cause of AD. In humans HSV-1 can commonly be reactivated from latency due to stress. In this study we used a mouse latency/reactivation model to investigate the infectious hypothesis of AD using HSV-1. 5XFAD heterozygous and wildtype mice (C57BL/6 background) were infected with neurotropic green fluorescent protein (GFP)-HSV-1 Mckrae virus at 8-10 weeks of age via application to the eye. HSV-1 was allowed to enter latency and then was reactivated via heat stress at 30 and 60 days post infection (dpi). Behavioral impairments were monitored using the Morris water maze, followed by euthanization and brain dissection to observe changes in cytokine and A-beta plaque levels. Behavioral results showed that reactivation of the virus accelerated memory problems at 30 dpi and cognitive flexibility deficits at 60 dpi. At 30 dpi infected and stressed mice performed significantly worse in the memory test than infected and unstressed mice ($p = 0.0425$). At 60 dpi infected and stressed mice performed significantly worse than infected, unstressed mice ($p = 0.016$) and uninfected, unstressed mice ($p = 0.014$). The hippocampus is important for spatial memory and the retrosplenial cortex is a region of the brain associated with cognitive flexibility. Although several heat-stressed groups appeared to have increased A-beta plaques in these regions, it did not reach significance. Cytokines (TNF-alpha and IL-1-beta) did show increased transcription levels following heat stress and following acute infection indicating the virus was reactivated and inflammatory processes were triggered. This study suggests that reactivation of the virus can lead to acceleration of the behavioral impairments seen in the heterozygous mice, which provides support for the infectious hypothesis of AD.

Title: Repurposing BT-11, an immunomodulatory drug, for treatment of Alzheimer's disease

Authors: *E. BIRNBAUM[1,3,4], P. ROCKWELL[1,4], P. SERRANO[4,2], M. FIGUEIREDO-PEREIRA[1,4];
[1]Biol., Hunter Col., NY, NY; [2]Psychology, Hunter Col., Ny, NY; [3]Clin. and Translational Investigation, Weill Cornell Med., New York, NY; [4]CUNY Neurosci. Collaborative, CUNY Grad. Ctr., New York, NY

Abstract: Neuroinflammation represents a critical target for drug development in Alzheimer's disease (AD). BT-11, an orally active compound that binds to lanthionine synthetase C-like 2 (LANCL2), shows promise in AD treatment. Clinical trials conducted in Irritable Bowel Disease (IBD) have demonstrated the immunomodulatory properties of BT-11, including its ability to increase T regulatory cells in the gut. Given the characteristic imbalance in pro-inflammatory and anti-inflammatory signaling observed in AD, BT-11's capacity to modulate inflammation through its target, LANCL2, makes it a promising candidate for repurposing in AD treatment, as supported by in silico approaches.
In our research, we employed a unique transgenic rat model (TgF344-AD) exhibiting progressive age- and hippocampal-dependent spatial learning and memory deficits, as well as AD pathology resembling that observed in AD patients. For a duration of 6 months, starting at 5 months of age (pre-pathology) and continuing until 11 months of age (full AD-pathology), we administered BT-11 orally (8.5 mg/kg) to a cohort of both wild-type (WT) and Tg-AD rats. We then assessed spatial learning outcomes. Male Tg-AD rats not receiving treatment displayed significant deficits in spatial learning compared to male WT rats. Importantly, BT-11 treatment mitigated these deficits and improved learning in Tg-AD rats compared to untreated Tg-AD rats. Immunohistochemical analyses revealed a reduction in Aβ plaques in the hippocampus of treated male rats compared to untreated male controls. Intriguingly, the analysis demonstrated a decrease in microglial cells with various morphologies in female rats treated with the drug, whereas no such effect was observed in male rats.
These findings strongly support BT-11 as a potential drug candidate for AD treatment. We are currently conducting further analyses to evaluate the impact of BT-11 on tau pathology and neuronal loss. Our objective is to elucidate the mechanism(s) by which BT-11 enhances cognition and ameliorates AD pathology, exploring whether this occurs through a direct effect in the central nervous system (CNS) or a potential peripheral impact on immune cells in the gut. Recent RNAseq data indicates that BT-11's activation of LANCL2 initiates cAMP signaling, resulting in reduced expression of pro-inflammatory cytokines and increased expression of anti-inflammatory cytokines. Ongoing investigations aim to explore this effect, as well as assess the potential influence of the drug on Treg cells in the brain, similar to observations in the gut.

Title: Characterization of structurally engineered lipooligosaccharide and its potential immunomodulatory role in Alzheimer's Disease.

Authors: *M. SHAKYA, M. SHERMAN, H. YANG, R. ERNST, A. SCOTT;
Univ. of Maryland Sch. of Dent., Baltimore, MD

Abstract: Structurally engineered variants of lipopolysaccharide (LPS) are an effective tool for the manipulation of the innate immune response, allowing for the rational design of vaccine adjuvants and inflammatory modulators. Key challenges remain, though, including cumbersome extraction methods, the effective activity of the ectopically expressed lipid A modifying enzymes, and the possibility to use these live bacterial strains to therapeutically colonize the gut. Here, we developed a first-generation strain of E. coli addressing several of these key challenges. Using a lipid-A structural engineering tool called bacterial enzymatic combinatorial chemistry (BECC), we engineered an E. coli variant, D31m4 bearing the dual lipid A modifications: 3-O-deacylation and 1-dephosphorylation (Ec DUAL). The resulting product is monophosphoryl lipid A (MPLA)-like LOS with a subset of odd chain variants and 3-O-deacylation (EcDUAL LOS). Structural characterization of EcDUAL LOS was carried out using tandem mass spectrometry, gas chromatography, and KDO assays. TLR4 structure-activity property of EcDUAL LOS was tested in human TLR4-expressing HEK293-Blue cells compared to WT LOS and a synthetic, detoxified MPLA control which showed a weak, competitive agonist-like activity of EcDUAL LOS. The parenterally administered product disseminated to the brain by 2 hours, persisted for at least 12 hours, and did not induce overt tissue pathology at the projected therapeutic dose. In a mouse gut repopulation study, the Ec DUAL live strain was found to temporarily colonize the gut and could be positively selected to improve the duration of colonization. Dysregulation of the TLR4 is repeatedly implicated in propagating and sustaining inflammation in Alzheimer’s Disease (AD) and a recent study has shown that chronic stimulation of the TLR4 pathway by a partial agonist (MPLA) significantly improved AD-related pathology in APP(swe)/PS1 mice. Similarly, our preliminary data demonstrated that APP/PS1 mouse treated once per week (IP) for twelve weeks at 30 mg/kg with EcDUAL LOS showed better spatial learning capacity (100% spontaneous alternation) in T-maze, performing better than the baseline control group suggesting further behavioral validation. Further analysis of how EcDUAL LOS affects AD-related neuropathology including Aβ accumulation, neuronal and synapse-associated proteins loss, and neuroinflammation with its mechanistic study will facilitate the understanding of the therapeutic benefits that EcDUAL LOS can produce in AD and other neuroinflammation-related diseases.

Title: Deleterious immune activation is linked to impaired memory in Abca7 deficient mice

Authors: *S. REGO[1], S. P. NEVES[2], N. DELIVANOGLOU[2], Y. REN[3], M. J. BARBER[2], G. SANCHEZ[2], T. KANEKIYO[4], S. DA MESQUITA[4];

Abstract: ATP Binding Cassette Subfamily A Member 7 (ABCA7) is a lipid transporter that has been linked to increased risk for late onset Alzheimer's disease. Deletion of *Abca7* (*Abca7*$^{-/-}$) has been shown to disrupt lipid metabolism and affect microglial activation in response to proinflammatory stimuli. In murine amyloidosis models, the lack of *Abca7* was found to exacerbate amyloid beta accumulation. Herein, we aimed at investigating the effects of *Abca7* loss-of-function on meningeal immunity and its role in modulating neuroinflammation and cognitive function in aging. Experiments involving immunofluorescence imaging and flow cytometry revealed alterations in the frequencies of brain and meningeal immune cells. Transcriptomic analysis of immune cells isolated from the brain-draining cervical lymph nodes uncovered specific gene expression signatures denoting an altered adaptive immune activation in middle-aged *Abca7*$^{-/-}$ mice. The cognitive performance of middle-aged *Abca7*$^{-/-}$ mice revealed a sex-specific impairment, which could be a cumulative result of the different changes in the immune activation profiles at the meninges and cervical LNs. Interestingly, systemic expansion of regulatory T cells (Tregs) in middle-aged *Abca7*$^{-/-}$ mice alleviated the cognitive deficits. Altogether, our data suggest that ABCA7 loss-of-function skews the adaptive immune profile towards a deleterious proinflammatory state that contributes to the appearance of cognitive deficits in aging.

Title: Lc3-associated endocytosis plays a critical role in necroptotic neurodegeneration in AD

Authors: *S. AKTER;
Mol. Med., Univ. of South Florida, Tampa, FL

Abstract: Abstract Beta-amyloid (Aß) accumulation in the brain resulting from an imbalance between Aß production and clearance is the hallmarks of AD pathology. Our lab recently discovered a novel pathway 'LC3-associated endocytosis (LANDO)' that plays a protective role against abnormal Aß deposition by mediating the recycling of Aß receptors, a mechanism crucial for the clearance of Aß plaques, hence attenuates Aß-induced inflammatory signals, and safeguards against neurodegeneration and memory loss in 5xFAD AD mouse model. Conversely, a dearth of LANDO leads to impairment in recycling of Aß receptors, developed Aß deposition, neuroinflammation, tau hyperphosphorylation, active neurodegeneration, and severe memory loss by the age of 2yrs, leading to development of age-associated AD-like pathology in mice. While it is clear that LANDO has a protective role against neurodegeneration, the mechanism involved remains unknown. Recently through transcriptomic analysis of AD patients' brain mRNA, we identified significantly higher expression of necroptotic death markers like MLKL (mixed lineage kinase domain-like protein), RIPK1 (Receptor Interacting Protein Kinase 1), and RIPK3 (Receptor Interacting Protein Kinase 3) compared to that of a healthy individual. To investigate the potential regulatory role of LANDO in necroptotic cell death in AD brains we conducted a proteomic study where we observed a remarkably enhanced expression of activated MLKL in primary macrophages from LANDO-deficient mice when the cells were treated with Amyloid-Beta and Zvad (a Pan Caspase inhibitor). Furthermore, a protein-protein interaction study revealed that kinase domain of MLKL has a strong tendency to bind Rubicon protein, a critical regulator of LANDO pathway. Through an immunostaining study, a higher expression of activated microglia was observed colocalized with accumulated Aß in MLKL-sufficient mice brain compared to that of MLKL-deficient LANDO-deficient 5xFAD. These preliminary findings firmly suggest a role for LANDO in regulating MLKL signaling and overall neuroimmune function of microglia and neuron in AD and that pharmacological intervention of MLKL signaling may hold a great therapeutic promise for AD. Hence my investigation will focus on the role of LANDO-mediated MLKL signaling in causing necroptotic neurodegeneration in AD pathology.

Title: Loss of mitochondrial protein Fus1/Tusc2 causes early cognitive and molecular changes associated with Alzheimer's disease (AD)-like dementia

Authors: *T. FARRIS[1], M. MOHAMMED[1], J. TONELLO[1], T. KANAGASABAI[1], A. SHIMAMOTO[2], F. HARRISON[3], A. IVANOVA[1], A. SHANKER[1];
[1]Meharry Med. Col., Nashville, TN; [2]Meharry Med. Col., Meharry Med. Col. Neurosci. and Pharmacol., Nashville, TN; [3]Vanderbilt Univ., Nashville, TN

Abstract: Dementia is an umbrella term representing several diseases that affect cognitive health and function of the brain. The underlying mechanisms driving the development of the different forms of dementia remains elusive and yet to be precisely identified. Calcium (Ca^{2+}) regulates neuronal plasticity underlying learning, memory and neuronal survival. Chronic dysregulation of Ca^{2+} could lead to brain cell death and degeneration. Our group has found that mitochondrial protein TUSC2 (Tumor Suppressor Candidate 2), initially named Fus1, is involved in regulation of mitochondrial/cytoplasmic Ca^{2+} fluxes in cells. Fus1 protein resides on the inner membrane of the mitochondria and assists in Ca^{2+} uptake and extrusion. The deficiency of Fus1 leads to increased oxidative stress, altered mitochondrial membrane potential and energy production in immune and cancer cells. The Fus1 function in brain cells has not been addressed in detail. Here we examined the role of Fus1 in memory and neuroimmune and molecular phenotypes by using the Fus1 knockout (Fus1 KO) mouse model. We used 4-5 month old Fus1 KO and wild-type (WT) male mice. Mice underwent behavioral testing including Y-maze and Morris Water Maze. Independently, immunophenotyping (via flow cytometry) and molecular pathways analyses (via immunoblotting) were performed. Fus1 KO mice showed impaired short-term spatial memory as assessed with Y- maze test ($p<0.05$), and long-term memory as assessed with MWM ($p<0.05$). Immune analysis of Fus1 KO brain immune subsets showed changes associated with neurodegeneration, such as increased number of activated microglia expressing IFN and TNF, increased number of activated astrocytes and T-regulatory cells. Western Blot analysis of hippocampal tissue revealed increased tauopathy in Fus1 KO brain. In addition, prominent activation of mTOR pathway (higher S6 phosphorylation), as well as increased levels of Calbindin (Ca^{2+}-binding protein), an indicator of disrupted calcium homeostasis potentially leading to synapse loss, suggested active neurodegenerative processes in Fus1 KO brain. Decreased GFAP, an early predictor of Mild Cognitive Impairment (MCI), was in line with other molecular pathologies observed in Fus1 KO mice. The studies are underway to further characterize early pathologies linked to AD in Fus1 KO mice. Overall, Fus1 deficiency plays a pivotal role in the development of pathological processes leading to cognitive impairment and AD.

Title: The effect of ubiquitous BIN1 overexpression in microglia on neuroinflammation and Alzheimer's disease pathophysiology

Authors: ***M. YUKSEL**[1,2], D. MOREIRA-SILVA[1,2], M. HANSEN[1,2], M. DELOZIER[1,2], S. NIDAMANUR[1,2], V. SKOROBOVENKO[1,2], L. COLLIER[1,2], G. THINAKARAN[1,2];
[1]Mol. Med., Univ. of South Florida, Tampa, FL; [2]USF Hlth. Byrd Alzheimer's Ctr. and Res. Institute, Univ. of South Florida, Tampa, FL

Abstract: Bridging Integrator 1 (BIN1) is the second most prevalent risk factor locus for late-onset Alzheimer's Disease (LOAD). It is expressed as more than 10 isoforms with diverse tissue and cellular distribution. A reduction in neuronal BIN1 and an increase in the ubiquitous isoform (BIN1Ubi) expression have been observed in the brains of individuals with LOAD. Bin1Ubi is one of the major BIN1 isoforms expressed in oligodendrocytes and microglia. Recently, our lab observed that microglial BIN1 plays a critical role in the neuroinflammatory response. However, how BIN1Ubi expression contributes to AD pathology remains enigmatic. This study aims to investigate the role of elevated microglial BIN1Ubi expression in neuroinflammation in health and AD pathogenesis. To this end, we generated a tamoxifen-inducible BIN1Ubi microglial overexpression model (referred to as *BIN1*^{OE}) by crossing *Rosa26*-targeted human *BIN1Ubi* transgenic mice with *TMEM119-CreERT2* (referred to as Cre). To assess how elevated BIN1 expression modifies LPS-induced neuroinflammation, we administered LPS or saline to 8-month-old *BIN1*^{OE} and Cre mice. qRT-PCR analysis showed that 8-month-old male and female Cre vs. *BIN1*^{OE} showed similar expression levels of disease-associated microglial (DAM) genes under saline conditions. However, LPS stimulation caused a significant upregulation of DAM genes *Itgax, Trem2,* and *Ifitm3* in female *BIN1*^{OE} compared to controls, showing the potential involvement of BIN1Ubi in the regulation of LPS-induced inflammatory response in a sex-dependent manner. To test how elevated BIN1Ubi in microglia alters AD pathology and innate immune response, we further crossed *BIN1*^{OE} mice to 5XFAD or PS19 mice (which develop amyloidosis or tau pathology, respectively). The qRT-PCR of DAM inflammatory gene *Cst7* showed up to a 50% reduction in both male and female 5XFAD as well as male PS19 overexpression mice compared to their respective controls. *Cst7,* coding for the protein cystatin F, is an endogenous inhibitor of cysteine proteases. This decrease in *Cst7* expression suggests a

possible role of BIN1Ubi in microglial endolysosomal homeostasis during AD pathology. Thus, these results indicate a potential involvement of microglial BIN1Ubi in regulating pro-inflammatory responses and AD neuropathology.

Abstract: Androgen deprivation therapy exacerbates Alzheimer's disease-associated cognitive decline through increasing brain infiltration of immune cells in a clinically relevant mouse model Chao Zhang[1*], Mae Aida[2, 5*], Shalini Saggu[2, 5], Haiyan Yu[1], Lianna Zhou[2], Kai Jiao[1, 6], Runhua Liu [1,3], Lizhong Wang[1,3,4], and Qin Wang[2, 4, 5]**Authors' Affiliations:** Departments of [1]Genetics, [2]Cell, Molecular, & Developmental Biology, [3]Center for Clinical and Translational Science, [4]Comprehensive Neuroscience Center, University of Alabama at Birmingham, Birmingham, AL 35294; [5]Department of Neuroscience & Regenerative Medicine, Medical College of Georgia at Augusta University, Augusta, GA 30912; [6]Center for Biotechnology and Genomic Medicine, Medical College of Georgia at Augusta University, Augusta, GA 30912
Androgen deprivation therapy (ADT) is widely applied to treat prostate cancer, which is predominantly a disease of the elderly. While effective in improving life span, ADT is associated with an increased risk of dementia. Alzheimer’s disease (AD) is the most common cause of dementia in older adults. The role of ADT for prostate cancer in AD development and

progression has not been clearly defined. The high heterogeneity of prostate cancer and AD, together with the potentially complex interaction between ADT and AD, pose major barriers for clinical mechanistic studies. Here we report establishment of a clinically relevant tumor-bearing AD mouse model by engrafting PTEN-CaP8 prostate cancer cells that recapitulate prostate cancer features and responses to ADT treatment in human patients into a well-established AD model, *App*$^{NL\text{-}G\text{-}F/NL\text{-}G\text{-}F}$ knock-in (*AppKI*) mice. Using this unique model, we revealed cognitive deficits accompanied by complex changes in immune and inflammatory responses in peripheral blood and in the central nervous system following ADT. In particular, ADT induced proinflammatory cytokines (e.g., IL-6) but decreased anti-inflammatory cytokines (e.g., IL-12), leading to increased proinflammatory responses in the brain of tumor-bearing *AppKI* mice. Pathological analyses further demonstrated enhanced gliosis without significant changes in amyloid accumulations in the brain of tumor-bearing *AppKI* mice treated with ADT. Together, these data suggest that increased neuroinflammation underlies ADT-exacerbated cognitive deficits. Our study provides critical information regarding the complex interaction among prostate cancer, ADT, and AD, and paves the way for future mechanistic and translational studies to test whether ADT can be improved to alleviate its detrimental effects on AD-related deficits.

Title: Examining the impact of progressive tauopathy on hippocampal astrocyte morphology and function

Authors: *R. C. MCREYNOLDS, III, Y. KOMURO, A. GLEICHMAN, S. T. CARMICHAEL, J. HINMAN;
Neurol., UCLA, Los Angeles, CA

Abstract: The prodromal stage of Alzheimer’s disease (AD) is characterized by age-associated, region-specific changes in glial-cell gene transcription and activation. Alterations to cytoskeletal glial fibrillary acidic protein (GFAP) staining suggest that hippocampal astrocytes display disease-associated cellular atrophy. These atrophy-associated changes are well-recognized in amyloid-based models of AD, however, whether a similar phenotype occurs among astrocytes in tau-mediated neurodegeneration remains unknown. **The aim of this study is to investigate cytoskeletal, morphological, and transcriptional changes occurring in hippocampal astrocytes during progressive tauopathy as modeled by the P301S mouse model.** We hypothesize that distinct morphological changes in hippocampal astrocytes precede the

development of tauopathy and are driven by defined molecular pathways active at the transcription level. We sparsely labeled the full morphology of astrocytes using an adeno-associated virus that encodes a membrane associated and cytosolic modified GFP protein containing V5 epitope tags (smV5). Visualizing non-GFAP-filled processes enables greater insight into tau-mediated morphological changes in astrocytes. Differences in surface area and volume of cytoskeletal and morphological astrocytic features were measured by immunofluorescent co-staining of GFAP and viral smV5. We find variation in GFAP surface area and volume as well as primary process number within the hippocampus in wild-type and P301S mice. Cellular morphology is dictated by transcriptional states, so we profiled hippocampal astrocyte transcriptomes using vTRAP, which enables the identification of genes undergoing active translation that are associated with astrocyte function and morphology during tauopathy. In wild-type mice, astrocyte vTRAP labeling results in the enrichment of astrocytic marker genes (GFAP, ALDH1L1) compared to input hippocampus samples. Multiple candidate genes associated with morphologic differences in P301S mice were identified and verified using RNAscope. A selection of differentially expressed RNA transcripts were spatially analyzed in the hippocampus across disease progression. The application of comprehensive morphologic labeling of astrocytes, vTRAP, and RNAscope in P301S mice, will identify molecular pathways driving structural changes in astrocytes. Early and progression-dependent astrocytic morphological and cytoskeletal atrophy could drive AD pathology by astrocytes retracting their peri-synaptic astrocytic processes or disrupting intercellular channels implicating a new mechanism of vulnerability to AD.

Title: Exploring Astrocyte States and Altered Pathways in Alzheimer's Disease: A Transcriptomics Approach

Authors: *K. GHAFARI[1], A. K. KUNISKY[1], S. BABU[1], H. ZHAO[1,2], H. MATHYS[1]; [1]Neurobio., Univ. of Pittsburgh, Pittsburgh, PA; [2]Tsinghua Univ., Beijing, China

Abstract: Alzheimer's disease (AD) is a neurodegenerative disorder associated with aging, marked by cognitive deterioration and a complex set of molecular mechanisms that are not yet fully understood. Astrocytes play crucial roles in maintaining the normal functioning of the nervous system and are actively involved in the development of neurodegenerative disorders like Alzheimer's disease. New findings strongly support the notion that different astrocyte states are linked to particular stages of Alzheimer's disease. The emergence of transcriptomics technologies

has facilitated rapid advancements in understanding and characterizing these abnormal astrocyte states associated with the disease. In this study, we analyzed over 145,000 astrocytes from more than 400 aged post-mortem brain samples exhibiting varying levels of pathologies related to AD. Integration of this dataset identified eight transcriptomically distinct astrocyte cell states (including non-reactive, reactive, inflammatory, stressed, and ribosomal translation), and the clusters were validated across the publicly available datasets. Comparison with the datasets revealed that the inflammatory cell type shows a similar profile to that observed in Multiple Sclerosis and indicates a common response to neurodegeneration. Using a pseudobulk-based differential gene expression analysis approach, we identified genes that were differentially expressed in high-resolution cell states across various measures of AD pathology including global AD pathology, neurofibrillary tangle burden, tangle density, overall amyloid level, neuritic plaque burden, diffuse plaque burden. We also explored the associated biological and functional ontologies, revealing that genes and gene modules related to the modulation of chemical synaptic transmission, DNA damage response, RNA metabolism, Cholesterol, and Lipid metabolism are altered in AD. Furthermore, a systematic analysis of protein complexes revealed that the TRBP-containing complex and several other complexes are altered in AD. We also analyzed the sex differences across the high-resolution cell types and their association with multiple AD pathologies. In summary, our examination of a transcriptomic atlas involving over 400 postmortem human brain samples has yielded valuable insights into astrocyte cell states, pathology-associated types, gene and pathway alterations, modified protein complexes, and the impact of sexual dimorphism on brain aging.

Abstract: Astrocytes play crucial roles in β-amyloid metabolism, neurotransmitter trafficking, neuroinflammation, and synapse remodeling. However, the precise functions of different astrocyte populations during aging and neurodegeneration remain largely unknown. The characterization of reactive astrocyte states under disease conditions is challenging due to the continuous spectrum of transcriptomic states exhibited by these cells. To address this complexity, we conducted single-nucleus RNA sequencing (snRNA-seq) on human Alzheimer's disease (AD) brain tissue from 21 donors at various stages of AD progression as well age-matched healthy controls. To enrich for astrocytes, we utilized fluorescence-activated nuclear sorting (FANS) of $Pax6^{+}NeuN^{-}$ populations from neocortical gray and white matter. Our resulting dataset consists of approximately 140,000 high-quality nuclei, encompassing astrocytes (28%), oligodendrocytes (44%), excitatory neurons (14.7%), inhibitory neurons (6.9%), microglia (2.8%), endothelial cells (2.0%), and oligodendrocyte precursor cells (1.5%). Within the astrocyte population, we identified five distinct transcriptomic states. Two states are non-reactive and expressed either *WIF1* and *RERG* (cluster 1) or *SMTN* and *MMD2* (cluster 2). Additionally, we found three reactive populations that exhibited downregulated expression of the glutamate transporters *SLC1A2* and *SLC1A3,* and expressed *GRIA1* and *SEMA5A* (cluster 3), *CHI3L1* and *CA1* (cluster 4), or *WDR49, VCAN,* and *AQP1* (cluster 5). Furthermore, we integrated this dataset with previously generated snRNA-seq data from the human AD brain to examine cell-cell interactions. This analysis revealed reactive astrocyte populations with increased interactions with distinct neuronal and microglial populations at different stages of disease progression. In early AD, reactive astrocytes exhibited heightened interactions with $CUX2^{+}/RORB^{+}$ middle cortical layer excitatory neurons, while in late AD, they displayed increased interactions -with $LAMP5^{+}/KIT^{+}$ inhibitory neurons and reactive microglia. Our dataset provides a resource for understanding the dynamics and interactions of different molecular subtypes of astrocytes in AD progression.

Abstract: Effective strategies to treat or prevent Alzheimer's disease (AD) are still lacking, in part because significant pathological changes in the brain have already occurred by the time individuals are diagnosed. Therefore, earlier intervention strategies are needed. Recent insights into the initial stages of AD suggest that deficits in sleep maintenance and slow wave sleep (SWS) can impact the production and clearance of amyloid beta (Aβ), contributing to disease progression. We previously demonstrated that reduced activity of the thalamic reticular nucleus (TRN) contributes to deficits in sleep maintenance and SWS in mice that express mutant human amyloid precursor protein (APP). However, the mechanisms underlying hypofunction of the TRN are unclear. Alterations in astrocyte function may play a role in TRN hypofunction, as they undergo morphological and functional changes in AD that can disrupt neuronal function. To assess whether astrocytes in the TRN are altered early in disease progression, we characterized astrocytes in the TRN of APP mice and nontransgenic (NTG) littermate controls at 4 months of age, when sleep deficits are robust but plaque deposition has not yet begun. We found that although the overall numbers of astrocytes remained largely stable in the TRN of APP mice, the number of GFAP-expressing astrocytes increased. The increase in GFAP-expressing astrocytes was particularly robust in the somatosensory segment of the TRN, which is responsible for sleep related rhythms. We also found a number of differentially expressed genes in the TRN of APP mice that impact astrocyte morphology. To test whether the morphology of TRN astrocytes is altered, we used an AAV that drives TdTomato expression under a truncated GFAP promotor to fully reveal their highly ramified structure. We found that both astrocyte volume and surface area are markedly decreased in TRN astrocytes in APP mice compared to those in NTG mice. Our findings suggest that TRN astrocytes undergo state dependent changes early in disease progression that could impact their influence on neuronal and synaptic function. Reciprocal interactions between neurons and astrocytes may play key roles in shaping neuronal activity in the TRN, with consequences for sleep stability in AD. Therefore, astrocytes may represent promising targets for innovative therapies to improve sleep, and slow or stop the progression of AD.

Title: Targeting xCT does not improve hippocampal function in the 5XFAD mouse model

Authors: *A. MASSIE[1], J. O. ADEYEMI[2], A. VILLERS[3], C. DELEUZE[3], H. SATO[4], G. ATES[2], L. RIS[3], L. DE PAUW[1];

Abstract: Genetic deletion of the specific xCT subunit of the cystine/glutamate antiporter system x_c^- protects against age-related hippocampal dysfunction and memory decline as well as toxin-induced neurodegeneration. Oxidative stress, (neuro)inflammation and glutamate toxicity are common pathogenic mechanisms that are active in several neurodegenerative diseases, including Alzheimer's disease (AD). Given the implication of system x_c^- in these pathways and given our previous findings in aging and other disease models, we hypothesized that targeting system x_c^- would be beneficial in a model of AD. To study the effects of genetic xCT deletion in AD, we cross-bred 5XFAD mice (C57BL/6J background) with $xCT^{-/-}$ mice. Both control ($5XFAD^{0/0}$), hemizygous ($5XFAD^{+/0}$) and homozygous ($5XFAD^{+/+}$) 5XFAD mice, with and without xCT, were obtained. Female mice were behaviourally characterized at a pre- (4 months) and symptomatic age (6 months). Next, brain tissue was collected at 5 and 7 months, and evaluated for amyloid plaques load (Aβ), neuroinflammation (Iba1, GFAP) and -degeneration (NeuN) using immunohistochemistry/-fluorescence. Hippocampal neurotransmission and long-term potentiation (LTP) were analysed at 8-10 months, using slice electrophysiology. Deficient spatial memory as well as impairment of LTP were observed in symptomatic female 5XFAD mice, mostly independent of xCT. Analysis of neuroinflammation and -degeneration is ongoing. Our first (preliminary) findings do not seem to support protective effects of xCT deletion on the development of an AD phenotype in the 5XFAD model.

Abstract: The cystine/glutamate antiporter system x_c^- is mainly expressed on astrocytes in the central nervous system and on peripheral immune cells. Deletion of its functional subunit xCT, results in lifespan extension, memory preservation in aged mice, as well as alterations in the aging hippocampal metabolome. Since aging is the main risk factor for developing Alzheimer's disease (AD), and both aging and AD are characterized by metabolic dysfunction, we investigated the metabolic health of the 5XFAD mouse model for AD, in the presence and absence of xCT.Hereto, body weight and glucose tolerance were monitored in male and female $5XFAD^{0/+}xCT^{+/+}$ and $5XFAD^{0/+}xCT^{-/-}$ mice at the pre-symptomatic and symptomatic stage. Visceral fat was weighed at the time of sacrifice, blood was collected for general blood chemistry, and metabolic health and flexibility of adult astrocytes were measured using the Seahorse metabolic flux analyzer. Results show significant peripheral metabolic changes in the $5XFAD^{0/+}$ mice, compared to age-matched $5XFAD^{0/0}$ controls, with lipid/cholesterol metabolism differently affected in the absence of xCT. Moreover, the mitochondrial health of AD astrocytes is compromised, with significant decreases in basal and maximal respiration, spare respiratory capacity, and ATP-coupled respiration, especially in the astrocytes from symptomatic $5XFAD^{0/+}xCT^{+/+}$ mice. The mitochondria of $xCT^{-/-}$ astrocytes, however, maintain their flexibility and health. Targeting xCT thus seems beneficial for the metabolic health in $5XFAD^{0/+}$ mice, putting system x_c^- forward as an interesting target to prevent AD-related metabolic decline.

Title: Development of a monoclonal antibody specific for a calpain-cleaved 48 kDa calcineurin fragment, a marker of distressed astrocytes

Authors: S. PRATEEPTRANG[1], S. HONGTHONG[1], N. THONGSOPHA[1], *S. D. KRANER[2], P. SOMPOL[2], P. T. NELSON[2], C. M. NORRIS[2];

Abstract: Calcineurin (CN) is a Ca2+/calmodulin-dependent protein phosphatase expressed at high levels in brain. In healthy tissue, CN exists mainly as a full-length (~60 kDa) highly-regulated protein involved in essential cellular functions. However, in diseased or injured tissue, CN is proteolyticaly converted to a constitutively active fragment that has been causatively-linked to numerous pathophysiologic processes. These calpain-cleaved CN fragments (ΔCN) appear at high levels in human brain at early stages of cognitive decline associated with Alzheimer's disease (AD). ΔCN tends to show-up in regions of frank amyloid and cerebrovascular pathology, especially in select subsets of astrocytes, both in humans and in animal models. Our goal was to develop a monoclonal antibody to ΔCN for use in neuropathology research. Monoclonal antibodies were produced at GenScript using the immunizing peptide corresponding to the C-terminal end of the 48 kDa calpain-cleaved fragment (Wu et al., 2004, Pleiss et al., 2016). Notably, Δ48 kDa CN lacks a key autoinhibitory domain (AID) and is constitutively active. Antibodies were initially screened in ELISAs against the immunizing peptide, but ***decision-making screens*** were carried out as a Western analysis of calpain-cleaved calcineurin, to show specificity towards the Δ48 kDa CN fragment. Using the above criteria, we obtain a mouse monoclonal antibody, designated 26A6, that selectively detects the 48 kDa ΔCN in Western analysis of calpain-cleaved recombinant human CN. Using this antibody, we screened both pathological (9 cases) and normal brain (2 cases) sections provided by the human bank at the University of Kentucky's Alzheimer's Disease Research Center. 26A6 showed low reactivity towards normal brain tissue, but detected astrocytes both surrounding AD amyloid plaques and throughout AD brain tissue. In brain tissue with infarcts, there was considerable concentration of 26A6-positive astrocytes within/around infarcts, suggesting a link with anoxic/ischemia pathways. Additionally there was staining of some non-astrocytic cells. The new monoclonal 26A6 is highly selective for the 48 kDa ΔCN proteolytic fragment and labels a subset of astrocytes, and possibly other cell types, under pathological conditions apparently identifying distressed astrocyte phenotypes. The production of a constitutively active form of CN by Ca^{2+}-driven processes is consistent with the overall Ca^{2+} dysregulation theory of brain aging and cognitive decline proposed by PW Landfield and colleagues. **References: 1)** Wu *et al*., 2004 JBC 279: 4929-4940. **2)** Pleiss *et al*., 2016, Biochimica et Biophysica Acta 1862a; 1521-1532

Abstract: GABA (γ-aminobutyric acid) is the primary inhibitory neurotransmitter in the CNS. In astrocytes, GABA is synthesized by degradation of putrescine by monoamine oxidase B (MAO-B), a process which is known to mediate tonic inhibition of neuronal excitability. This astrocytic tonic GABA and related enzymes are also reported to be involved in memory impairment in Alzheimer's Disease (AD), and therefore are potential therapeutic targets to rescue memory in AD patients. However, the enzymes downstream of MAO-B in this pathway have not been elucidated yet. To fill this gap in knowledge, we performed transcriptomic and literature database analysis and identified Aldehyde dehydrogenase 1 family, member A1 (ALDH1A1) and a histone deacetylase enzyme Sirtuin2 (SIRT2) as plausible candidate enzymes in primary cultured astrocytes. Immunostaining, metabolite analyses, and 2-cell sniffer patch recordings performed in the presence or absence of suitable inhibitors, or with genetic ablation of ALDH1A1 and SIRT2 *in vitro* and *ex vivo* mouse brain slices recapitulated their participation in GABA production from putrescine. Immunohistochemistry from an animal model of AD and human AD patients reveals elevated levels of SIRT2 in hippocampal astrocytes. Genetic ablation of SIRT2 and ALDH1A1 in hippocampal astrocytes of AD mouse models rescues memory deficits and neuronal firing, further highlighting their role in pathological astrocytic GABA production. Altogether, we uncover this previously unexplored role of SIRT2 in astrocytic GABA production and propose it as a therapeutic target to ameliorate Alzheimer's Disease pathology.

Title: Cholesterol hydroxylation in astrocytes under an inflammatory context as a predisposing factor for Alzheimer's disease

Authors: *G. CATALDI, M. MARTIN;
Cell. and Mol. Neurobio. Dept., Inst. Ferreyra, INIMEC, Cordoba, Argentina

Abstract: Cholesterol 24-hydroxylase (or CYP46) carries out the hydroxylation of cholesterol to 24(S)HOC, which is the main mechanism of cholesterol elimination from the brain. CYP46 has been mainly reported in neuronal populations, however, in cases of brain damage such as traumatic brain injury or Alzheimer's disease CYP46 increases its expression in astrocytes. At the moment, the role that CYP46 would play in astrocytes in pathological conditions is unknown. We found that CYP46 levels are greatly increased in reactive astrocytes challenged with lipopolysaccharide (LPS) or the proinflammatory cytokine IL-6. In addition, our data show that IL-6 was is able to increase APP synthesis in rat primary astrocytes by a mechanism mediated by CYP46. Indeed, the IL-6 ability to trigger APP synthesis in astrocytes is impaired by CYP46 inhibition. Further providing a link between CYP46 and APP, our results show a marked increase in APP levels in 24(S)HOC-treated primary cortical astrocytes compared to control cells. Preliminary Our preliminary data indicate that 24(S)HOC would exert its function through epigenetic mechanisms associated with histone 3 remodeling and acetylation.We propose that under a proinflammatrory context, as for example a microbial infection in the brain, 24(S)HOC would mediate the production and processing of APP and Aβ in astrocytes to face the aggression but on the other side it would predispose to Alzheimer's disease.

Title: Modifications of Brain Creatine Kinase associated with dementia

Authors: *T. ZHENG[1], J. MULDER[1], N. MITSIOS[1], D. KOTOL[2], M. UHLÉN[2], F. EDFORS[2], W. ZHONG[1];
[1]Neurosci., Karolinska Inst., Stockholm, Sweden; [2]Proteomics and Nanobiotechnology, Royal Inst. of Technol., Stockholm, Sweden

Abstract: Alzheimer's disease (AD) and dementia with Lewy body (DLB) are the most common forms of dementia. Oxidative stress is a major component of dementia pathology leading to

neuronal damage and cell death. Identification of proteins that are sensitive to oxidation is acrucial step to decipher how oxidative modification alter cellular physiology in dementia. Brain Creatine Kinase (CKB) is an enzyme that is involved in storage of energy in cells and regulates available ATP. Dysfunction of CKB enzyme activity in AD is reported. However, CKB distribution in the human AD and DLB brains is not explored in detail. To identify cellular expression, changes in protein levels and distribution associated with disease, both antibody-based and targeted proteomics approaches were used. Multiplex fluorescence analysis revealed co-existance of CKB immunoreactivity with astrocyte markers in the grey matter of the human cortex. No co-existance of CKB with neuronal markers, oligodendrocyte and microglia markers could be identified. To identify CKB distribution patterns in dementia, we investigated CKB-ir in samples from the temporal cortex (TCX) of donors diagnosed with Alzheimer's disease (n=10), dementia with Lewy bodies (n=10), and non-demented age-matched controls (n=9). Reduced CKB immunoreactivity was found in dementia patients, which was confirmed by Western Blot. Especifically, cases with a high level of amyloidosis revealed decreased CKB-ir intensity. Targeted proteomics analysis of revealed no overall change in the CKB levels in dementia, in line with CKB mRNA levels reported in the Allen Aging study. However, our quantitative mass spectrometry approach revealed disease specific pattern in CKB peptide ratios that suggest variation in efficacy or proteolytic cleavage or detection of CKB peptides disease affected brain tissue. All together these finding demonstrate a clear link between CKB and pathological processes associated with dementia. The loss of immunoreactivity and altered pepetide ratios suggest oxidation or other post-translational modification of CKB that lead to loss of CKB function in dementia.

Title: Analysis for the regulation of ApoE expression and Aβ metabolismby astrocytic SphK2/S1P signaling

Authors: *M. KOMAI, T. UEHARA, N. TAKASUGI;
Dep. Medicinal Pharmacol. Grad. Sch. Medicine, Dent. and Pharmaceut. Sci., Okayama Univ., Okayama-shi/Okayama-ken, Japan

Abstract: [Background] Alzheimer's disease (AD) is a neurodegenerative disorder characterized by progressive cognitive decline. Although the current therapeutic strategy is based on the

amyloid hypothesis, which places neuronal toxicity induced by amyloid β (Aβ) at the center of pathogenesis, the therapeutic effect is not sufficient. AD is also considered a complication with several pathologies present at the time of its diagnosis, suggesting that pathologies other than neuronal-derived Aβ need to be addressed. Recently, attention has focused on the importance of chronic inflammation by activated astrocytes. Therefore, a target that could simultaneously control neuronal and astrocytic pathology would be a major advantage as a therapeutic strategy. Our laboratory has reported that sphingosine-1-phosphate (S1P), a lipid messenger, is increased in the brains of AD patients, which may promote Aβ production in neuronal cells. Interestingly, S1P is known to have epigenetic regulatory functions in the nucleus and is involved in immunoinflammatory effects. Therefore, we hypothesized that this signal is involved in astrocyte pathology and performed the following experiments. [Methods]To investigate S1P function, we established Sphingosine kinase 2 (SphK2), S1P-producing enzyme stable expression in U87 human astrocytoma cells. We evaluated the effect of S1P on astrocytic function by analyzing Apolipoprotein E (ApoE) as an astrocyte-related factor. The effect of SphK2 inhibitor was evaluated using biochemical approach.[Results] We found that ApoE induction by LXR/RXR agonists is suppressed by SphK2 overexpression, while SphK2 inhibitor enhances ApoE expression. Since SphK2 localizes predominantly to the nucleus, we next performed ChIP analysis and found that RXR binding to ApoE promoter is lowered by SphK2 activation. In addition, ApoE induced by SphK2 inhibitor binds Aβ and promotes Aβ uptake.[Conclusion] We uncovered a novel role of nuclear SphK2/S1P in ApoE expression, and suggested SphK2 inhibitor regulates astrocytic function and Aβ metabolism and will be a promising multi-target for AD therapy.

Title: Apoe polymorphism affects functional and morphological features during the inflammatory process of ipsc-derived astrocytes from alzheimer´s disease patients

Abstract: Alzheimer´s disease (AD) is the main cause of dementia in the aging population, with the presence of the ε4 allele of Apolipoprotein E (*APOE*), the major brain lipid transporter, being the strongest genetic risk factor. Astrocytes, the main producers of APOE in the brain, mediate key processes during the progression of AD, such as the clearance of amyloid-beta (Aβ) aggregates and the inflammatory response, among others. However, the impact of the different *APOE* alleles not only on astrocyte function but also on astrocyte development and maturation remains to be elucidated. To clarify these questions, we obtained induced pluripotent stem cells (iPSCs) from fibroblasts of AD patients carrying ε3 and ε4 alleles (in homozygosis) and from healthy patients. We also used gene-edited iPSC lines homozygous for the main *APOE* variants and an *APOE* knock-out line. iPSC-derived human astrocytes were generated by establishing a differentiation protocol through the consecutive addition of small molecules and growth factors. Then, the expression of typical markers (GFAP, GLT1, AQP4, and S100beta) and APOE was analyzed by RT-PCR and immunofluorescence to confirm its astrocytic phenotype. In addition, astrocytes exhibited functional features like calcium waves production and glutamate uptake capacity, confirmed by detecting the calcium indicator Fluo-4 and by ELISA, respectively. They also responded to an inflammatory stimulus (IL-1beta and TNF-alpha) or to the presence of amyloid-beta 1-42 peptide by increasing the expression levels and release of pro-inflammatory factors and cytokines (such as IL-6) and changing their morphology. Our results show that *APOE* polymorphism not only affects the basal state of astrocytes, but also their capacity to react to both stimuli by acquiring different morphologies, which could be relevant during the disease's inflammatory process. Furthermore, the presence of the ε4 allele of *APOE* could alter the uptake/degradation capacity of Aβ by astrocytes given the differences in the percentage of astrocytes capturing a fluorescence-labeled Aβ and its distinct distribution within the cell. Our findings shed light on the relevance of *APOE* polymorphism in the morphological and functional profile of astrocytes and their potential correlation with the different risks of developing AD.

Abstract: Neurogenesis relates to the brain resilience and is reduced in Alzheimer's disease (AD). Restoring healthy levels of neurogenesis could have beneficial effects for coping with neurodegenerative pathology. Yet, the molecular mechanisms with which astroglial pro-neurogenic fate can be promoted under AD pathology are unknown. Here, we used APP/PS1dE9 mouse AD model, where astroglia adopt reactive states. We induced the expression of Nerve growth factor receptor (Ngfr) through lentiviral transduction in the hippocampus. Ngfr, a neuro-regenerative inducer in zebrafish brain model of amyloidosis, stimulated proliferative and neurogenic outcome in mice. Histological analyses of the changes in proliferation and neurogenesis, single-cell transcriptomics, spatial proteomics, and functional knockdowns showed that induced expression of Ngfr reduced reactive astrocyte marker Lipocalin-2 (Lcn2), which we found was sufficient to reduce neurogenic outcome in astroglia. We determined that anti-neurogenic effect of Lcn2 is mediated by Slc22a17, blockage of which recapitulated the pro-neurogenic effects of Ngfr. Long-term Ngfr expression reduced amyloid plaques and Tau hyperphosphorylation. Analyses on postmortem human AD hippocampi and 3D human neurogenesis cultures showed elevated LCN2 levels correlate with reactive gliosis and reduced neurogenesis. By comparing transcriptional changes in mouse, zebrafish and human cohort brains with AD for cell intrinsic differential gene expression and weighted gene co-expression networks, we observed common downstream effectors of NGFR signaling, such as PFKP, which is altered in AD patients. When we blocked PFKP, proliferation and neurogenesis was enhanced. Overall, we show the reactive and non-neurogenic fate of astroglia in AD can be switched to a pro-neurogenic fate with Ngfr, which also modulates pathological hallmarks of AD. We propose that enhancing pro-neurogenic astroglial fate may have therapeutic ramifications in AD.

Abstract: Neuroinflammation is a key player in many neurodegenerative diseases, including Parkinson's, Huntington's and Alzheimer's disease (AD). In this process, astrocytes and microglia are the main cells involved, releasing cytokines, chemokines, prostaglandins, NO, and ROS. The release of these pro-inflammatory molecules has devastating consequences, as it leads to neuronal death, synaptic dysfunction, and inhibition of neurogenesis. The protein RTP801, also known as REDD1, has been recently involved in neuroinflammation. RTP801 levels are higher in the hippocampus of AD patients. Such increased levels of hippocampal RTP801 correlated with the severity of neurofibrillary tangles distribution, progressive depositions of Aβ, and astrogliosis. Moreover, silencing RTP801 in hippocampal neurons prevented cognitive impairment and neuroinflammation in the 5xFAD mouse model of AD. This study aims to assess whether astrocytic RTP801 affects memory and neuroinflammation in the 5xFAD mouse model of AD (7-month-old). RTP801 was knocked-down specifically in astrocytes injecting bilaterally adeno-associated viral particles containing AAV2/5-GFAP-miRNA-CONTROL-GFP or AAV2/5-GFAP-miRNA-RTP801-GFP. Four weeks later, we performed a battery of behavior tests including the light/dark box test and the Plus maze test to assess anxiety like behavior and Novel object location task, T-maze and Morris water maze to test spatial learning and memory. Silencing astrocytic RTP801 (miRTP801) in 5xFAD mice recovers the anxiety-like phenotype at the Plus Maze behavioral test and improved significantly the spatial learning and memory evaluated by the T-maze and Morris water maze. Mice were subjected to 1H-MRS (Magnetic resonance spectroscopy). MRI experiments were conducted on a 7.0 T BioSpec 70/30 horizontal animal scanner equipped with an actively shielded gradient system (400 mT/m, 12 cm inner diameter). Thus, brain metabolites were detected and quantified by linearly fitting each spectrum with a simulated basis set including 19 metabolites, as well as macromolecules. Silencing RTP801 in hippocampal astrocytes in the 5xFAD mice prevented the decrease of GABA/Creatin ratio observed in 5xFAD control mice. Silencing RTP801 in 5xFAD hippocampal astrocytes also reduced the levels of the inflammasome effectors NLRP3, ASC, and pro-caspase-1 compared to miCT injected 5xFAD mice, by western blot. Hence, we conclude that astrocytic RTP801 is contributing to cognitive impairment by affecting GABA and the inflammatory response in the pathogenic context of AD.

Title: Validation of astrocytic cAMP signalling to study therapeutic targets for Alzheimer's disease

Authors: *F. E. DUCOTTERD[1], L. GRANAT[1], J. BILSLAND[2], S. JOLLY[1];
[1]ARUK UCL Drug Discovery Inst., UCL, London, United Kingdom; [2]Astronautx Tx, London, United Kingdom

Abstract: Astrocytes play a fundamental role in pathological processes associated with neurodegenerative diseases, including neuroinflammation, impaired glutamate uptake, reduced neurotrophic support and defective metabolism. Activation of cAMP signalling in astrocytes elevates glycolytic rate, increases glutamate transporter and neurotrophic factor expression, and suppresses the immune response. Molecules that regulate astrocytic cAMP signalling are therefore potential therapeutic targets for neurodegenerative diseases such as Alzheimer's disease (AD).

To aid astrocyte-targeted drug discovery, we developed an astrocyte-focused *in vitro* platform to be used for target validation and drug screening. Using primary rat and human iPSC-derived healthy and familial AD astrocytes in monoculture and in co-culture with neurons, we have optimised pharmacological assays including cAMP, Ca^{2+}, RNA-seq, multi-electrode array, and seahorse assays which can quantitatively and reliably measure changes to astrocyte function and neuronal activity.

We have used the astrocyte platform to validate the potential of astrocytic cAMP signalling as a therapeutic target for AD. Activation of adenylyl cyclase using forskolin or stimulation of a Gs-coupled GPCR using a tool compound induced cAMP signalling in rat and hiPSC-derived astrocytes. Alongside increased cAMP levels, forskolin and the tool compound led to elevated glycolytic rate, increased glutamate transporter expression, and the downregulation of pro-inflammatory pathway genes in astrocytes. We observed that addition of the tool compound in rat primary astrocyte and neuron co-culture induced an acute increase in neuronal excitability. The positive effects of cAMP activation on metabolism, glutamate transporter levels and inflammatory gene expression provide evidence that activating astrocytic cAMP signalling may translate to therapeutic benefit in AD. Our astrocyte platform has validated the pleiotropic effect of astrocytic cAMP signalling and can be applied to future novel drug discovery programs targeting astrocytes.

Title: Monomeric and oligomeric amyloid-β_{42} exposure demonstrate different reactive characteristics in human primary astrocytes within glymphatics-on-chip in vitro microfluidic model

Authors: *A. R. YSLAS, R. PARK, E. LEE;
Nancy E. and Peter C. Meinig Sch. of Biomed. Engin., Cornell Univ., Ithaca, NY

Abstract: Amyloid-β_{42} (Aβ42) is one of the two proteins responsible for the chronic and fatal neurodegenerative disease Alzheimer's disease (AD), where it is a neurotoxic extracellular aggregate. AD is characterized by dysfunction in the glymphatic system, the perivascular waste removal system of the brain parenchyma that is highly reliant upon astrocytes. To better understand how Aβ42 affects astrocytes and leads to their AD pathophysiology, including glymphatic dysfunction, we developed a three-dimensional microfluidic in vitro model of the glymphatic system (glymphatics-on-chip) containing two acellular perivascular channels and an astrocyte parenchyma embedded with either monomeric Aβ42 (mAβ42), oligomeric/aggregate Aβ42 (oAβ42), or no Aβ42 (control). The glymphatics-on-chip was manufactured via soft lithography of polydimethylsiloxane and contains human primary astrocyte cells in a 3D hydrogel of collagen 1, hyaluronan, and fibronectin as an extracellular matrix with embedded mAβ42 or oAβ42 (or no Aβ42 for the control). Following culture, these devices were either treated with fluo-4 AM calcium ion (Ca^{2+}) indicator and imaged live or fixed and imaged for immunofluorescence via confocal microscopy. Using imageJ analysis tools, the size and shape parameters were measured, with the astrocytes exposed to mAβ42 exhibiting greater size and decreased circularity and solidity, indicative of hypertrophy, compared to either of the other groups. The astrocytes exposed to mAβ42 also showed a higher ratio of cytoskeletal components nestin compared to actin, which is an accepted indicator of reactive astrocyte pathology in neurodegenerative diseases including AD. However, astrocytes exposed to oAβ42 showed greater intracellular Ca^{2+} concentrations with large temporal variations via changes in mean fluo-4 signal, demonstrating the calcium dyshomeostasis seen in AD astrocytes, both the increased intracellular Ca^{2+} concentration and the increased transients. Preliminary results show that

mAβ42 and oAβ42 have different effects on interstitial fluid flow through the glymphatic system, but confirming this is future work. Altogether, this work illustrates that mAβ42 and oAβ42 have different effects on astrocytes, and this can be used to elucidate the progression of AD pathology in astrocytes via Aβ42 aggregation, with later disruption to the glymphatics system. Our current work shows that some of the accepted hallmarks of AD pathophysiology in astrocytes may not develop simultaneously but rather in separate stages depending on whether the Aβ42 is in its monomeric or oligomeric forms.

Abstract: Structural ad Functional Aspects of Meningeal Lymphatic Vasculature in Aged Human BrainM.S. Albayram[1], K. Yagmurlu[2], E. Karakaya[3], G. Smith[1], J. Edwards[3], A. Ergul[3], **O. Albayram[3, 4]**[1]Depart. of Radiology, University of Florida, College of Medicine, Gainesville, FL; [2]Depart. of Neurosurgery, University of Tennessee, Memphis, Tennessee; [3]Depart. of Path. & Lab. Med. Medical University of South Carolina (MUSC), Charleston, SC; [4]Depart. of Neuroscience, MUSC, Charleston, SC, None of the authors has disclosure.
The brain was historically considered an immune-privileged organ separated from the peripheral lymphatic system by the blood-brain barrier. Currently, meningeal lymphatics in the brain have garnered increasing attention in the scientific literature, which has left us to investigate how the lymphatic vasculature network may be positioned within the dural matters in the brain, and the novel potential role of the meningeal lymphatic system in brain aging and age-related neurodegenerative disorders. Indeed, using the term “brain lymphatics” is still unclear because a direct connection between lymphatic channels and brain parenchyma is not recognized yet. Using a novel 3D T2-Fluid Attenuated Inversion Recovery (FLAIR) Magnetic Resonance Imaging technique, we have demonstrated a progressive age-related cervical lymph node atrophy and thickening of lymphatics channels in both dorsal and ventral regions of the human brain. This non-invasive imaging technique relies on internal signals of protein-rich lymphatic fluid rather than contrast media and visualizes the major human dural lymphatic structures. Moreover, we detect direct connections between lymphatic fluid channels along the cranial nerves, vascular systems, and cervical lymph nodes. Furthermore, by using selective antibodies against lymphatic endothelium, including Podoplanin, VEGF-R3, Prox-1, and Lyve-1, we identified the lymphatic

vasculatures in the parasagittal dura of the brain along with subarachnoid space and the possible intramural lymphatic drainage pathway in the arterial wall of the brain by using high-definition microscopy in post-mortem human brain-meningeal biospecimens. Taking advantage of emerging imaging and microscopy techniques in the live human brain and human brain tissues, we investigate to develop novel strategies to detect meningeal lymphatic vasculature in humans and translational therapeutic interventions to prevent age-associated neurodegeneration by improving brain lymphatic drainage.

Abstract: Despite its massive worldwide prevalence and staggering socioeconomic burden, there are still no medicines that halt, or even slow, Alzheimer’s disease (AD). We have identified a novel therapeutic target within the blood-brain barrier (BBB) in AD, 15-hydroxyprostaglandin dehydrogenase (15-PGDH) enzyme, that degrades various eicosanoids, including prostaglandin D2 and E2 (PGD2 and PGE2). AD pathology is characterized by early and progressive BBB deterioration, and in the 5xFAD mouse model of AD we identified an abnormal and pathological

increase of 15-PGDH activity at 6 months of age. 15-PGDH activity increases further with disease progression, and 15-PGDH expression is enriched in myeloid cells intimately associated with the BBB. We also observe similar increase in 15-PGDH in human AD brain. Notably, 15-PGDH-deficient 5xFAD mice are protected from BBB deterioration, as well as neurodegeneration and cognitive impairment. This protective efficacy is independent of any changes in amyloid pathology. Thus, 15-PGDH may represent a novel and non-amyloid based therapeutic target for AD or other forms of neurodegenerative disease.

Title: Effects of voluntary physical exercise and its correlation on the neurovascular unit in the 3xTg-AD model for Alzheimer's disease

Authors: *J. ANDRADE[1], E. ORTA[2], O. SOTO[3], S. DIAZ-CINTRA[2];
[1]Neurobio. Inst., [2]Developmental Neurobio., Univ. Autonoma de Mexico (UNAM), Queretaro, Mexico; [3]Fac. of Higher Studies Iztacala, Univ. Autonoma de Mexico (UNAM), Tlalnepantla de Baz, Mexico

Abstract: Alzheimer's disease (AD) is the most common neurodegenerative disease in theworld. It is characterized by the deterioration of memory, thinking, orientation andlearning, as well as the quality of life of the people who suffer from it. The twopathognomonic hallmarks are neuritic plaques and neurofibrillary tangles. However,it has been proposed that the cerebral vascular system is also affected and evenaggravates the symptoms of the disease. One of the most widely used animalmodels to study disease mechanisms is the 3xTg-AD triple transgenic mouse thatcontains three associated with familial AD (PS1M146V, APPSWE and tauP301L). Itshould be emphasized that up to now there is no effective treatment for AD. Anadjuvant non-pharmacological therapeutic approach for AD is physical exercise,which is a variety of planned, repetitive, and dosed physical activity, however itseffect on the cerebral vascular system is unknown. The objective of this work was toanalyze the effect of physical exercise on the neurovascular unit in the 3xTg-ADmodel. A total of 40 ten-month-old female mice, 3xTg-AD (n=20) and non-Tg (n=20),divided equally into exercise and sedentary groups, were used. A

voluntary physicalexercise intervention was carried out for 3 months with a frequency of 5 times aweek. Subsequently, memory and learning were assessed using the Barnes mazetest. Vascular morpho structure was analyzed by histological assays using vascularbasement membrane markers (anti-Collagen IV), pericytes (anti-PDGFR-β) andastrocytic feet (Aquaporin 4), other amyloid beta deposits (BAM-10) hematoxylinstaining and eosin for structural evaluation. Voluntary physical exercise did notcause improvement in cognitive ability; however, it promoted the recovery of thevascular system, anatomical changes, as well as the reduction of amyloid betadeposits, both in the form of plaques and vascular. The intervention with voluntaryphysical exercise favors the stability of the vascular system, as well as the reductionof amyloid deposits in the symptomatic stages of the disease.

Title: Coexistence of Alzheimer’s disease, cerebrovascular disease, and arthritis in humans: is there a common risk factor(s)?

Authors: A. FROLOV[1], N. MAGLASANG[1], M. A. GUZMAN[1], S. ECHOLS[2], N. LAPRESTA[1], ***D. DALY**[1];

Abstract: Cerebrovascular dysfunction leading to impairment of the blood-brain barrier (BBB) has been known to play an important role in dementia development and progression, including that associated with Alzheimer’s disease (AD). Recently, an increased risk for AD was found in a large population of patients with rheumatoid arthritis (RA) (PMID: 27470609). It has been also shown that RA is a significant risk factor for cognitive impairment (PMID: 34656753; PMID: 22647255) and dementia (PMID: 26754993). Together, these findings raise a question about the existence of common risk factor linking AD, cerebrovascular disease (cVD), and RA. To address this question, we performed a postmortem neuropathological examination and genetic screen of two individuals. The first individual (donor 1, D1) was a 74-year-old male who was diagnosed with both AD and RA, and also underwent hip replacement surgery bilaterally. The cause of death (COD) in D1 was listed as AD type dementia. The second individual (donor 2, D2) was a 90-year-old male with a reported diagnosis of RA as well as two left hip replacements. The COD for D2 was community acquired pneumonia. A thorough histochemical (H&E) and immunohistochemical (β-amyloid, tau-protein, TDP43) examination of D1 and D2 brains revealed the presence of AD related pathology in both individuals, with AD stages being mild in D1 and intermediate in D2. The cVD related pathology was also microscopically evident in both cases and was characterized by several microbleeds indicative of a compromised BBB integrity.

Blood vessel wall thickening was significant in D1 but minor in D2. The whole exome sequencing of DNA procured from D1 and D2 employing the Next Generation Sequencing (Illumina platform) was followed by a very stringent bioinformatics analysis that yielded seven rare (minor allele frequency, MAF ≤ 0.01) genetic pathologic variants: *AQP7, ARSD, FAM160A1, HYDIN, IGSF3, OTOP1,* and *PRSS1*, with all but the variant of *FAM160A1* being identical in both donors. Intriguingly, subsequent analysis of the respective literature indicated that *AQP7, IGSF3,* and *PRSS1* could be linked to either AD, cVD, or RA. Analysis of less rare (MAF < 0.05) genetic pathologic variants revealed an additional common variant, *CSPG4*, which was identical in D1 and D2. *CSPG4* is a known pericyte (BBB) marker and could be also linked to either AD, cVD, or RA. Altogether, the data presented herein are consistent with the notion that AD, cVD, and RA, when they coexist in humans, could be linked to a common genetic risk factor(s).

Atherosclerosis is a major risk factor in the development of Alzheimer's disease (AD). Disruptions to the apolipoprotein E (ApoE) gene and high-fat diet (HFD) cause hyperlipidemia and increased formation of atherosclerotic plaques. The causal relationship between atherosclerosis and AD-associated cognitive deficits remains unclear. Here, we used a murine atherosclerosis model, ApoE knockout (KO) mice with HFD feeding, to investigate the

contribution of atherosclerosis on the cerebrovascular structure and its impact on memory performance. We examined cerebrovascular alterations in ApoE KO mice fed HFD for 24 weeks (32 weeks old) using tissue clearing, 3D immunolabeling, and light sheet fluorescence microscopy. We observed increased numbers of penetrating cortical arterioles and heightened vascular tortuosity in HFD ApoE KO brains compared to age-matched ApoE KO mice with control diet. We also conducted longitudinal behavioral tests with novel object recognition (NOR) task and Y-Maze to determine whether increased atherosclerotic lesions in HFD-fed ApoE KO mice induce impairment of cognitive performance. Indeed, ApoE KO males exhibited significant impairment in the NOR and Y-maze tasks by 12 weeks (20 weeks old) of HFD feeding and ApoE KO females showed delayed onset of behavioral deficit at 16 weeks (24 weeks old) of HFD. In contrast, control diet-fed ApoE KO mice had no impairment in either test up to 30 weeks old. In summary, our findings demonstrate atherosclerosis-induced cerebrovascular remodeling and the associated memory deficit, providing insights into atherosclerosis-initiated AD-related behavioral deficit.

Title: Reduced endothelial Caveolin-1 underlies deficits in brain insulin signaling in type 2 diabetes: Implications for Alzheimer's disease

Authors: *A. SHETTI[1], A. RAMAKRISHNAN[2], L. ROMANOVA[3], W. LI[4], K. VO[1], I. RATNAYAKE[1], T. STEPHEN[4], R. MINSHALL[1], S. COLOGNA[1], O. LAZAROV[5]; [1]Univ. of Illinois Chicago, Chicago, IL; [2]Northwestern Univ., Chicago, IL; [3]Rush Univ. Med. Ctr., Chicago, IL; [4]Univ. of Illinois at Chicago, Chicago, IL; [5]The Univ. of Illinois at Chicago, Chicago, IL

Abstract: Patients with type-2 diabetes exhibit severe impairments in insulin signaling in the brain and are more likely to develop Alzheimer's disease. However, what leads to these impairments is not fully understood. Here, we show reduced expression of endothelial cell caveolin-1 (Cav-1) in the *db/db* (*Lepr^{db})* mouse model of type-2 diabetes. This reduction correlated with alterations in insulin receptor expression and signaling in brain microvessels as well as brain parenchyma. These findings were recapitulated in the brains of endothelial cell-specific Cav-1 knock-out (Tie2Cre;Cav-1$^{fl/fl}$) mice. Lack of Cav-1 in endothelial cells led to reduced response to insulin as well as reduced insulin uptake. Furthermore, we observed that Cav-1 was necessary for the stabilization of insulin receptors in lipid rafts. Interactome analysis revealed that insulin receptor interacts with Cav-1 and caveolae-associated proteins, insulin degrading enzyme, and the tight junction protein Zonula Occludence-1 in brain endothelial cells. Restoration of Cav-1 in Cav-1 knockout brain endothelial cells rescued insulin receptor expression and localization. Overall, these results suggest that Cav-1 regulates insulin signaling and uptake by brain endothelial cells by regulating IR-α and IR-β localization and function in lipid rafts. Furthermore, depletion of endothelial cell specific Cav-1 and the resulting impairment in insulin transport leads to alteration in insulin signaling in the brain of type-2 diabetes.

Title: Interaction of estrogen loss and cardiovascular disease on neurovascular coupling

Authors: *C. RICHARD[1], B. VISNIAUSKAS[2], I. FERNANDEZ-UGIDOS[2], Z. DIAZ[2], A. MCNALLY[2], R. MOSTANY[2], S. H. LINDSEY[2];
[2]Tulane Brain Inst., [1]Tulane Univ., New Orleans, LA

Abstract: While animal studies show that estrogen provides protection against cognitive decline, some clinical studies fail to find cognitive benefits in response to menopausal hormone therapy. Since human studies enrolled older patients that were many years past the menopausal transition, the results may have been influenced by subclinical disease progression. Therefore, the current study was designed to test the hypothesis that cardiovascular disease inhibits the protective effects of estrogen in the brain through detrimental effects on neurovascular coupling. Female C57BL/6J mice were ovariectomized at 10.5 months of age to match menopausal age in humans and randomized to receive either vehicle or estradiol (E2) at the time of surgery. Some mice

were infused with angiotensin II infusion (Ang; 700 ng/kg/min) four weeks before ovariectomy to promote hypertension and associated cardiovascular damage. Data from this 2x2 design (±E2/±Ang, N=3-5 per group) was analyzed by two-way ANOVA with Sidak's multiple comparisons test. Blood pressure was measured via tail cuff plethysmography, arterial stiffness was measured via ultrasound, and neurovascular coupling was measured through cranial window two-photon microscopy. As expected, E2 significantly increased uterine weight (P=0.03), and this effect was maintained in the presence of Ang (P=0.003). E2 also significantly decreased body weight (P=0.02), but this effect was lost in the presence of Ang (P=0.89). Ang significantly increased blood pressure in ovariectomized mice (P=0.005), but E2 was protective against the hypertensive response (P=0.99). Arterial stiffness, measured as pulse wave velocity, followed the same pattern as blood pressure, with Ang increasing stiffness in the -E2 group (P=0.04) but not the +E2 group (P=0.98). We expect our ongoing analysis to provide evidence that neurovascular coupling is protected by E2, but this protection is lost in the presence of Ang. These studies have significance implications for understanding the interactions between estrogen and cardiovascular disease in the aging female brain.

Title: Dysregulation of the gut microbiome contributes to compromised blood-brain barrier integrity inApoE4 transgenicmice

Authors: *M. ZHANG[1], M. T. HUUSKONEN[1], A. P. SAGARE[1], A. CHAKHOYAN[1], K. KISLER[1], A. R. NELSON[2], Y. WANG[1], B. V. ZLOKOVIC[1];

Abstract: Recent studies indicate that cognitive impairment and Alzheimer's disease (AD) can be influenced by dysfunction in brain blood vessels. *APOE4*, a prominent genetic risk factor for AD, worsens the breakdown of the blood-brain barrier (BBB) and the degeneration of brain vascular pericytes. This leads to the disruption of cerebral blood flow regulation and an increase in the deposition of amyloid, which ultimately affects neuronal function. Alongside genetic risk factors, emerging evidence suggests a strong connection between the gut microbiome and age-related neurodegenerative diseases, such as AD. Here, we investigated the difference in gut bacterial taxa in *ApoE3* and *ApoE4* transgenic mice and its contribution to the BBB permeability by treating animals with a cocktail of antibiotics amoxicillin-clavulanic acid (ABX) through

drinking water for two weeks. Our findings indicate that the gut microbiome undergoes changes caused by ABX treatment, leading to the restoration of blood-brain barrier (BBB) integrity in *ApoE4* mice. We assessed this restoration through dynamic contrast-enhanced magnetic resonance imaging (DCE-MRI) and the observation of reduced accumulation of pericapillary fibrinogen deposits. By conducting shotgun metagenomics analysis on fecal pellets collected before and after ABX treatment, we identified disruptions in the balance of three major bacterial families from the dominant phyla Bacteroidetes and Firmicutes. These disruptions may contribute to the compromised integrity of the BBB in *ApoE4* transgenic mice. These preliminary findings suggest that differences in gut microbiome between *ApoE3* and *ApoE4* transgenic mice may influence BBB permeability and that ABX treatment suppressed the proinflammatory CypA-MMP9 BBB-degrading pathway in pericytes which may help restore *APOE4*-mediated BBB disruption in mice after ABX treatment.

Title: Chronic stress accelerates cerebral hypoperfusion and cognitive decline in Alzheimer’s triple transgenic mice

Authors: *S. PRABHU[1], N. EMINHIZER[2], A. HANSHEW[2], K. KARELINA[3], E. KELLEY[4], J. W. SIMPKINS[4], P. CHANTLER[2];
[1]Pharmaceut. and Pharmacol. Sci., [2]Exercise Physiol., [3]Neurosci., [4]Physiol. & Pharmacol., West Virginia Univ., Morgantown, WV

Abstract: Chronic psychosocial stress is a risk factor for cognitive decline in Alzheimer’s disease (AD). However, there is a critical need to identify the contributing molecular factors linking stress and AD. Our previous work has shown that chronic mild stress (UCMS) in C57BL/6 mice had reduced endothelial dependent dilation of the middle cerebral artery vs non-UCMS control mice. In this study, we examined the effects of early exposure to UCMS in AD mice. Male/female 3xTg-AD (APPSWE, PS1M146V, and tauP301L) and WT-AD (C57BL6/129S) mice underwent 8 weeks of UCMS starting at 4 months of age for 5 days/week and 7 Hrs/day, while control mice did not undergo stress. To determine the role of age as a confounding variable in accelerating AD progression, all mice were taken off UCMS at 6 months of age and euthanized at 12 months of age. Prior to euthanasia, cerebral blood flow (CBF) was

measured using Laser Doppler contrast imaging and mean global flux was calculated across all treatment groups. After euthansia, tissues were harvested and homogenized for protein quantification using Western blot analysis. Cognitive outcomes such as open field, Y-maze, and Novel Object recognition were examined. Our data shows that the WT UCMS mice had a 19% reduction in CBF ($p<0.05$) compared to the WT controls. The 3xTg UCMS group showed a 10% decrease in global flux levels as compared to the 3xTg controls. Male controls showed a significant reduction in global flux ($p<0.05$) compared to females in the 3xTg Controls. Female 3xTg UCMS mice showed significantly reduced CBF ($p<0.05$) compared to female 3xTg control mice indicating the effects of stress to be more prominent in females. The recognition index for the WT control mice (time investigating the novel object) was significantly higher than the 3xTg controls ($p<0.05$). The WT UCMS group showed a significant reduction in the recognition index as compared to the WT controls. Thus, the study establishes the premise that chronic stress accelerates AD progression and cognitive decline in our early-onset model with potential sex differences. The study also lays the foundation for future studies to develop effective treatment strategies to prevent early cognitive decline in AD.

Title: Investigating the role of p-glycoprotein in amyloid β-peptide clearance: implications for alzheimer's disease.

Authors: *J. ASANTE, C. L. NAGEL, M. BALASUBRAMANIAM, S. W. BARGER; Univ. of Arkansas for Med. Sci., LITTLE ROCK, AR

Abstract: Alzheimer's disease (AD) is characterized by the accumulation of amyloid β-peptide (Aβ) in the brain, with impaired clearance playing a significant role in its pathogenesis. One key player in the clearance of Aβ is the multidrug resistance protein (MDR1), also known as P-glycoprotein (P-gp), which functions as an active transporter in the plasma membrane of cerebrovascular endothelial cells. P-gp facilitates the removal of Aβ from the brain into the bloodstream. Various substrates of P-gp can act competitively or cooperatively on one another's transport rate, depending on their binding site on the enzyme. In this cohort study, we analyzed data from the PharMetrics Plus database (IQVIA) including 471,539 participants, 65 and older who were receiving various medications known to be P-gp substrates and were free of AD at the baseline. A nested case-control analysis was performed, matching each AD case with four

controls (1:4) based on age and time of study entry using density-based sampling. AD cases (1359) and matched controls (5436) were then analyzed using time-dependent Cox regression to assess the association between the use of P-gp substrate medications and the risk of AD while adjusting for confounding factors such as age, sex, and comorbidities including stroke, hypertension, diabetes, coronary artery disease, depression, and chronic kidney disease. This provided estimated odds ratios for a number of P-gp substrates regarding risk for AD-related dementia.To supplement the epidemiological approach, we employed computational modeling and molecular dynamic simulations to identify the binding sites of Aβ and other substrates on P-gp, allowing assignment into complementation groups. Our modeling results revealed that Aβ binds at the so-called “R-site” of P-gp. Furthermore, results predict that P-gp substrates, including berotralstat, remdesivir and actinomycin D, exhibited higher binding affinity to a P-gp-Aβ complex versus P-gp alone. Our long-term goal is to gain a comprehensive understanding of the impact of P-gp substrates on the clearance of Aβ from the brain. This knowledge will contribute to the development of health policies and therapeutic strategies aimed at preventing Aβ accumulation and, ultimately, Alzheimer's disease.

Title: Oligomeric Tau Alters Tight Junction Protein Expressions and Cerebral Endothelial Permeability: Role of RhoA/ROCK Signaling Pathway

Authors: *F. HOSSEN, J. C. LEE;
Univ. of Illinios, Chicago, Chicago, IL

Abstract: Oligomeric Tau Alters Tight Junction Protein Expressions and Cerebral Endothelial Permeability: Role of RhoA/ROCK Signaling Pathway Faruk Hossen[1], James C. Lee[1]
[1]Richard and Loan Hill Department of Biomedical Engineering, University of Illinois at Chicago, Chicago, IL 60607
Introduction: Tight junction (TJ) proteins in Cerebral Endothelial Cells (CECs) play an important role in maintaining the integrity of the blood-brain barrier (BBB). In Alzheimer’s disease (AD), BBB dysfunction has been associated with amyloid beta (Aβ) pathology, but how oligomeric Tau (oTau) impacts the BBB function has yet to be fully elucidated. **Materials and Methods:** Primary mouse CECs cultured in a transwell chamber was employed as our BBB

model. Cells in the chamber were treated with oTau. To examine the involvement of the RhoA/ROCK pathway, cells were pre-treated with Fasudil, a RhoA/ROCK signaling inhibitor. Permeability of the CEC layer was measured by trans-endothelial transport of FITC-dextran and electrical resistances (TEER) assays. The expressions of TJ proteins (occludin, claudin-5, ZO-1) and p-p47phox in CECs were assayed by western blot analysis. Oxidatively modified proteins levels and proteasome activity were quantified by Protein Carbonyl Assay and Proteasome Activity Assay, respectively.**Results:** Treating CECs with oTau significantly decreased TJ protein expressions and increased the permeability of the CEC layer. It also upregulated p-p47phox (subunit of NADPH oxidase) and increased oxidative damage of proteins but decreased proteasome activity in CECs. These functional alterations of our BBB model induced by oTau were significantly suppressed by the pre-treatment with RhoA/ROCK signaling inhibitor, Fasudil. **Conclusion:** Our findings suggest that the RhoA/ROCK pathway involved in oTau-induced disruption of BBB. Regulation of the RhoA/ROCK pathway can be a potential therapeutic strategy to maintain the BBB integrity in AD.**Funding:** This work was supported by National Institutes of Health R01AG044404 (JCL).

Title: Multi-omic signature of therapeutic activated protein C analog on APOE4 neurovascular dysregulation

Authors: *K. KISLER[1], G. BARISANO[1], A. P. SAGARE[1], V. CLEMENTEL[1], A. CHAKHOYAN[1], M. T. HUUSKONEN[1], J. A. FERNÁNDEZ[2], J. H. GRIFFIN[2], M. P. COBA[1], B. V. ZLOKOVIC[1];
[1]Zilkha Neurogenetic Inst., USC, Los Angeles, CA; [2]Dept. of Mol. Med., Scripps Res. Inst., La Jolla, CA

Abstract: Apolipoprotein E4 (*APOE4*), the main susceptibility gene for Alzheimer's disease (AD), leads to blood-brain barrier (BBB) breakdown in humans and mouse models. Vascular and BBB dysfunction has also been linked to AD evolution in experimental, imaging, pathological, and epidemiological studies. Importantly, BBB dysfunction can predict cognitive decline and precedes synaptic deficits in *APOE4* carriers and *APOE4* transgenic mice. We have previously shown that *APOE4* compared with *APOE3* non-risk allele leads to an early disruption of the

BBB transcriptome in 2-3-mo-old *APOE4* knock-in (KI) mice, followed by dysregulation in protein signaling networks controlling cell junctions, cytoskeleton, clathrin-mediated transport, and translation in brain endothelium. Currently, no treatment exists to restore BBB integrity and function in *APOE4* carriers.
Here, we treated *APOE4* KI mice with 3K3A-activated protein C (APC), a cell-signaling analogue of endogenous blood serine protease APC that exerts vasculoprotective, neuroprotective, and anti-inflammatory activities in a variety of rodent disease models. Using single-nucleus RNA-sequencing and phosphoproteome and proteome analysis, we show that *APOE4* KI mice treated with 3K3A-APC had restoration of their neurovascular transcriptomic and proteomic profiles towards levels comparable to age-matched *APOE3* KI control mice. Additionally, *APOE4* KI mice treated with 3K3A-APC showed improved BBB integrity in vivo by DCE-MRI. Together these data provide a multi-omic signature of the restorative therapeutic effects of 3K3A-APC. 3K3A-APC may be a promising therapeutic to counteract the effects of *APOE4* mediated transcriptomic, proteomic, and functional BBB disruption.

Abstract: Recent studies have discovered novel genes that are associated with the co-existence of vascular pathologies and Alzheimer's disease (AD). However, the biological functions and the mechanism of action by which they contribute to the disease pathology are still to be further elucidated. Therefore, animal models that allow streamlined high-throughput functional screens in a biologically relevant manner are essential. Towards this goal, we generated adult zebrafish models of amyloid toxicity to transcriptionally compare the candidate genes identified from genetic association studies in multi-ethnic AD and control cohorts as well as single nucleus transcriptome datasets from human brains. Integration of single cell/nucleus transcriptomics of human AD patients and zebrafish brains showed remarkable similarities in the transcriptional alterations of neurons in response to amyloid in zebrafish and AD patients. By performing immunohistological analyses, gene editing for generating genetic knockouts, pharmacological intervention of selected signaling pathways and comparing the findings to human AD brains, we determined the similarities in vascular pathological mechanisms contributing to AD pathology. In this presentation, we will present our findings on an evolutionarily conserved molecular regulatory pathway that controls blood-brain-barrier integrity. Our studies propose zebrafish as a useful model for transcriptional and functional investigation of vascular pathology and AD-related genes identified in clinical studies by providing in vivo biological knowledge with which novel drug development strategies can be designed.

Abstract: Accumulation of amyloid β (Aβ) in the brain is the neuropathological hallmark of Alzheimer's disease (AD). Recently approved Aβ-directed antibodies (aducanumab, lecanemab) have demonstrated modest efficacy in AD, which may potentially be explained by poor blood-brain barrier (BBB) penetration. Transferrin receptor (TfR) mediated enhanced brain delivery of monoclonal antibodies across the BBB is a promising concept in drug development for CNS disorders. Using an advanced light sheet fluorescence microscopy (LSFM) pipeline coupled with deep learning computational analysis, the present study aimed to visualize, map and quantify amyloid plaque load following long-term therapy with a BBB shuttle-enhanced Aβ-directed antibody in a mouse model of AD. 5-9 month-old APP/PS1 transgenic mice (n=8-10 per group) were treated with an aducanumab biosimilar (AduBS, 10 or 50 nmol/kg), aducanumab biosimilar fused with a mTfR binder as BBB-shuttle (AduBS-BBB, 10 nmol/kg), control hIgG (Contr, 50 nmol/kg), or saline for 12 weeks. Whole brains were stained with an antibody against Aβ, cleared and scanned on a LSFM. A deep-learning image analysis algorithm was developed and validated for automated whole-brain visualization, segmentation, anatomical mapping and quantification of Aβ plaques using a custom mouse brain atlas. Amyloid plaque deposition was detected in the brain at micrometre resolution. Regions with marked Aβ plaque load included the cortex, hippocampus, thalamus and lateral septum. Deep-learning image analysis was employed to map potential quantitative differences in the distribution and number of Aβ plaques following long-term therapy with a BBB shuttle-enhanced Aβ antibody compared to an AduBS. The LSFM pipeline enables high-throughput quantitative LSFM 3D imaging of Aβ plaque load in mouse models of AD for preclinically profiling brain-wide effects of anti-amyloid therapies.

Abstract: An insight into embryonic-heart-expressed SEMA6D in Alzheimer's disease
Saima Shakil Malik[1], Shalini Saggu[2], Mae Aida[2], Qin Wang[2], Kai Jiao[1]* *[1]Center for Biotechnology & Genomic Medicine (CBGM), Medical College of Georgia, Augusta University [2]Department of Neuroscience and Regenerative Medicine, Medical College of*

Georgia, Augusta University
Alzheimer's disease (AD) is a progressive degenerative condition that primarily affects cognitive abilities, memory, and other cognitive functions. The brain is a highly vascularized organ, receiving cardiac output and vulnerable to the impairment of cerebral perfusion, which is a frequent event of heart failure. SEMA6D is a member of the Semaphorin family of signaling molecules and our previous study suggests it is essential to sustain late fetal or early neonatal cardiomyocytes at a proliferative and less mature status. In this study, we generated a novel model, *cTnt-Cre;Sema6D$^{loxp/loxp}$;APP$^{Ki/Ki}$*, to investigate the cardiac function impairment in hearts and its effects on AD-related pathological changes. Via echocardiography, we found that embryonic deletion of *Sema6D* in cardiomyocytes caused decreased heart function, i.e., lower ejection fraction, fractional shortening and cardiac output with various other abnormalities in the heart. Histopathological examinations revealed significantly enlarged hearts associated with thinning of LV walls, which could possibly lead to heart failure. Furthermore, we examined whether cardiomyopathy caused by embryonic heart deletion of *Sema6D* could accelerate the onset and aggravates the severity of AD-related deficits. To reveal this, we are in the process of assessing the cognitive function and testing that it is significantly decreased in mice with myocardial deletion of *Sema6D*. We are also examining amyloid deposition and glial cell reactivation in the brain of these mice. Evaluating how congenital cardiomyopathies can impact AD is a new area to explore and we are the first ones to design this mouse model and investigating the comorbid effects. Successfully accomplishing our research will open the door for future studies improving the diagnostic criteria and therapeutic approaches.

Title: Presenilin 1-FAD mutants and γ-secretase inhibitor disrupt the VEGF-induced VEGFR2 endocytosis, trafficking and in vitro and in vivo brain angiogenic functions.

Authors: *A. ZARROUK, R. PANDEY, G. TZIKAS, E. LEVENDOSKY, P. DEY, A. GEORGAKOPOULOS, N. K. ROBAKIS;
Mount Sinai Sch. of Med., New York, NY

Abstract: Brain vascular alterations observed in Alzheimer’s disease (AD) such as reduction in capillary density, may be the result of decreased angiogenesis. Angiogenesis, a process by which

new blood vessels arise from pre-existing vessels is regulated by endothelial cells (EC) and angiogenic factors such as the Vascular Endothelial Growth factor (VEGF) and its receptor VEGFR2. When VEGF binds to VEGFR2, it triggers VEGFR2 activation, dissociation from VE-cadherin, endocytosis, and activation of subsequent downstream signaling events that promote angiogenesis. Here, we explore the effects of Presenilin 1 (PS1)-Familial AD (FAD) mutants and γ-secretase inhibitor on the VEGF-induced VEGFR2 internalization, trafficking, interaction with VE-Cadherin and angiogenic functions in brain ECs and brain neovascularization. *In vitro* angiogenesis assays were performed using primary cortical EC (pCEC) from brains of wild-type and knock-in mice expressing FAD mutant PS1 I213T. Surface biotinylation assay was used to assess the VEGFR2 internalization in HEK293 cells overexpressing VEGFR2 in the presence or absence of VEGF-A and γ-secretase inhibitor (RO4929097). Immunofluorescence staining was performed in Human Umbilical Vein Endothelial cells (HUVEC) to detect VEGFR2 trafficking, using the endosomal markers Rab5 and Rab7. The role of γ-secretase in VEGF-induced formation of VEGFR2/VE-cadherin complexes was examined using RO4929097, with immunoprecipitation. Brain neovascularization was measured following VEGF injection in mice with collagen IV immunostaining and confocal microscopy. Our data show that VEGF-induced sprouting and migration are decreased in PS1 FAD mutant-expressing pCEC and that the VEGF-induced neovascularization is decreased in the brains of PS1 I213T mice. Additionally, VEGF-induced endocytosis of VEGFR2 is reduced by RO4929097 in HEK293 cells. Co-localization analysis in HUVEC showed that VEGF stimulation promotes VEGFR2 internalization to Rab5-positive early endosomes, followed by trafficking to Rab7-positive late endosomes. RO4929097 increased the VEGF-stimulated localization of VEGFR2 to Rab7-positive late endosomes. Furthermore, we found that VEGF-stimulated decrease of the VE-cadherin/VEGFR2 complexes is inhibited by RO4929097 in HUVEC. Our data suggest that PS1 FAD mutants and γ-secretase inhibitors decrease brain angiogenic functions by changing of the VEGFR2/VE-cadherin complexes, decreasing the VEGFR2 endocytosis and increasing its degradation in the lysosomes. Our findings suggest a molecular mechanism through which PS1 FAD mutants impair brain angiogenesis.

Title: Endothelial senescence mediated by $p16^{INK4a}$ leads to cerebrovascular dysfunction in mouse brains

Authors: *K. KAWATANI[1], T. AIKAWA[1], Y. INOUE[1], F. SHUE[1], T. PARSONS[1], C. YUANXIN[1], B. Y. KIM[2], T. KANEKIYO[1];
[1]Mayo Clin., Jacksonville, FL; [2]Univ. of Texas MD Anderson Cancer Ctr., Houston, TX

Abstract: Vascular cognitive impairment of dementia (VCID) is observed in around 8-15 % of aged patients with cognitive dysfunctions and is the second major cause of dementia. Aging is a strong risk factor for VCID and is predicted to be caused by an accumulation of senescent cells, in which the increase of $p16^{INK4a}$ is one of the key hallmarks in cellular senescence. Thus, we investigated how the forced expression of $p16^{INK4a}$ in vascular endothelial cells impacts cerebrovascular function, using an in vivo gene delivery system through a unique recombinant adeno-associated virus 2 (rAAV2) with a modified capsid. When $p16^{INK4a}$ or EGFP was expressed in cerebrovascular endothelial cells in wild-type mice 1 month after the rAAV2 injection, results showed an increase in IgG leakage into the brain parenchyma in the $p16^{INK4a}$-expressed mice. When cerebral blood flow (CBF) was measured by in vivo 2-photon imaging 2.5 months after the injection in the mice, we found that cerebrovascular endothelial $p16^{INK4a}$ overexpression substantially reduced CBF in arterioles and capillaries in the cortex. Furthermore, we assessed neurovascular coupling (NVC) with whisker stimulation by measuring CBF using laser speckle contrast analysis (LASCA) to analyze the function of the cerebrovascular system. NVC was disrupted in the $p16^{INK4a}$-expressed mice 6 months after the injection. RNA-sequencing in the cortex found that most top-ranked master regulator genes targeted *Cdkn1a* and *Hspa5*. In weighted gene co-expression network analysis, the pathways associated with endoplasmic reticulum (ER) stress/ unfolded protein response (UPR) activation and lipid metabolism were altered. These findings implied that forced expression of $p16^{INK4a}$ in cerebrovascular endothelial cells specifically influences senescence in the brain. In the Morris water maze test, $p16^{INK4a}$-overexpression impaired spatial memory and learning. Our results show that overexpression of 16^{INK4a} in cerebrovascular endothelial cells disturbs BBB integrity and neurovascular coupling, resulting in impaired cognitive function, which may contribute to the pathogenesis of VCID.

Title: Effects of locus coeruleus (LC) deafferentation and noradrenergic rescue on cognitive function and cerebrovascular markers in a transgenic rat model of Alzheimer's disease

Authors: *M. GIFANI[1,2], J. S. BECK[2], Y. CHEN[3], Z. FERNANDEZ[3], C. QIAN[3], L. CHAMBERS[4], D. C. ZHU[3], R. WISEMAN[3], A. M. DORRANCE[4], S. E. COUNTS[2]; [1]Michigan State Univ., Grand rapids, MI; [2]Translational Neurosci., Michigan State Univ., Grand Rapids, MI; [3]Dept. of Radiology, [4]Pharmacol. toxicology, Michigan State Univ., East Lansing, MI

Abstract: Degeneration of noradrenergic locus coeruleus (LC) neurons, which modulate attentional and memory function in cognitive forebrain regions such as prefrontal cortex (PFC), is an early feature of Alzheimer's disease (AD). Recently, we demonstrated that experimental LC degeneration results in elevated amyloid plaque pathology, cerebral amyloid angiopathy (CAA), astrogliosis, and cerebrovascular leakage in the Tg344-19-AD rat model of AD. To explore additional pathology associated with LC loss in this model and to test whether these perturbations could be ameliorated by norepinephrine (NE)-based therapies, 6-month-old Tg344-19 AD rats were stereotactically lesioned by administering the noradrenergic immunotoxin, dopamine-β-hydroxylase IgG-saporin (DBH-sap), or control IgG-sap (n = 16/group) into PFC. The rats were then randomized to receive the NE pro-drug L-DOPS + the NE reuptake inhibitor atomoxetine (ATM) or solvent placebo weekly. Rats were tested behaviorally 8 weeks later on Open Field, Novel Object, Elevated Plus Maze and Barnes Maze. After 4 weeks, cerebral perfusion was assessed in the PFC of a subset of rats by MRI using a pulsed Arterial Spin Labeling (ASL) technique called FAIR (Flow Sensitive Alternating Inversion Recovery) and echo planar imaging, followed by pressure myography studies of parenchymal arterioles and processing for pathological analysis. Based on our published data, we expect DBH-sap-lesioned rats to exhibit significant deficits in spatial and working memory compared to IgG-sap rats in addition to increased plaque, CAA, vascular leakage, and astroglial pathology. We also expect that LC lesions will reduce perfusion, alter arteriole vasoreactivity, and exacerbate additional markers of forebrain pathology including microglial activation and vascular cell senescence. Finally, we anticipate that L-DOPS/ATM treatments will rescue these behavioral and pathological deficits since L-DOPS will provide NE replacement and there are noradrenergic terminals remaining for ATM to be efficacious. If so, this would provide critical preclinical evidence that cerebrovascular pathology induced by LC projection system loss can be mitigated by different pathways promoting endogenous NE bioavailability. Thus, understanding the potential impact of LC degeneration on cerebrovascular dysfunction and vascular risk factors in AD may open up new therapeutic avenues.

Abstract: Deposition of amyloid beta (Aβ) within the walls of small blood vessels, known as cerebral amyloid angiopathy (CAA), is commonly observed in the brains of Alzheimer's disease (AD) patients alongside parenchymal Aβ plaques. The presence of CAA increases the risk of hemorrhage and independently contributes to cognitive impairment. Although anti-Aβ immunotherapy may seem like a logical treatment for CAA, safety concerns involving bleeding and edema, known collectively as amyloid-related imaging abnormalities (ARIA), have led to caution against its use in this patient group (PMID: 34237272). Recently, a promising alternative has been suggested, where targeting non-lipidated ApoE4 that co-deposits with Aβ resulted in a reduction in CAA without bleeding (PMID**: 33597265).** Despite this promise, several questions remain. Firstly, can CAA that has already been deposited be removed by anti-ApoE immunotherapy and secondly, what is the impact of removal on vascular function? We explore these questions in this study by using multiphoton microscopy to longitudinally image the vasculature of mice administered anti-ApoE immunotherapy. Nineteen mice (9 females and 10 males) expressing human APOE4 and five AD-linked mutations (APOE4 5xFAD) had a cranial window surgically implanted over the right visual cortex and underwent repeated unanesthetized imaging following a post-surgical recovery period. After an initial imaging session at 10 months of age, mice received weekly intraperitoneal (IP) injections of control IgG or anti-human ApoE antibody (50mg/kg). Throughout the treatment period, mice were imaged monthly for a further three months. CAA and Aβ plaque burden were visualized with methoxy-X04 and vascular function, including resting-state vasomotion and evoked vascular reactivity, were also recorded. After the final imaging session brains were extracted for post-mortem examination. Tissue sections were processed for immunohistochemistry to assess Aβ, Iron (for bleeds) and smooth muscle actin. After 3 months of treatment, CAA burden did not differ between mice that received anti-ApoE immunotherapy compared to those who received control IgG ($p = 0.54$). Evoked vascular activity also didn't differ between treatment groups ($p = 0.36$). Analyses conducted on in vivo data suggest that anti-ApoE immunotherapy does not actively remove CAA that is already deposited, but it may instead work to inhibit further accumulation of Aβ. This hypothesis will be explored in ongoing post-mortem studies. It is the hope that this study will add to the growing body of evidence that will help to determine the feasibility of anti-ApoE immunotherapy as a therapeutic agent in CAA patients.

Title: Effects of Aducanumab on brain pericytes in two mouse models of Alzheimer's Disease

Authors: Y. WU, N. BHAT, *M. LIU;
Med. Univ. of SC, Charleston, SC

Abstract: Aducanumab, an FDA-approved medication for treating Alzheimer's disease (AD), is a monoclonal antibody targeting amyloid-beta (Aβ). Besides its role in clearing brain parenchymal Aβ plaques, how Aducanumab affects the brain-blood barrier (BBB) and neurovascular unit (NVU) is still unknown. Brain capillary pericytes, a primary component of BBB and NVU, maintain BBB integrity and regulate cerebral blood flow. Damage and compromised pericytes are involved in AD pathogenesis. The present study examined the effects of Aducanumab on brain pericytes in two distinct AD/amyloidosis mice models: APP/PS1 mice (parenchymal dense-core amyloid plaque dominant) and Tg-SwDI mice (vascular diffuse amyloid deposition). All mice received Aducanumab (0.1 mg/kg) or vehicle via weekly intracerebroventricular (ICV) injections for three weeks. Then we measured the level of cerebrospinal fluid (CSF) soluble platelet-derived growth factor receptor beta (sPDGFRβ) with *ELISA* assay. Multiple studies have found that injured brain pericytes shed sPDGFRβ into CSF. Therefore, an elevated CSF sPDGFRβ level has become a sensitive marker for detecting pericyte injury. Our results demonstrated that Aducanumab treatment in APP/PS1 mice dramatically decreased CSF sPDGFRβ level, which was nearly 5-fold lower when compared to the vehicle control. In contrast, Aducanumab treatment caused a 2-fold increase in CSF sPDGFRβ level in the Tg-SwDI control mice compared to the vehicle control. Furthermore, we identified that Aducanumab triggered cerebral microhemorrhage (microbleeds) in Tg-SwDI mice rather than APP/PS1 mice. These results indicate that Aducanumab may alleviate pericyte damage in mice with dominant parenchymal Aβ while exacerbating pericyte damage in mice with dominant vascular amyloid deposition. The intensified damage to capillary pericytes may be associated with increased cerebral microhemorrhage, a common side effect observed in patients receiving anti-Aβ treatment.

Abstract: Alzheimer's disease (AD) is late-onset even when patients carry lifelong genetic susceptibility, suggesting the brain defends itself for decades before succumbing to AD. The underlying basis for this loss of resilience, however, is unknown. Here, we report impaired brain metabolism as diminished NAD^+/NADH in human AD and two AD mouse models: amyloid-driven 5xFAD mice and tau-driven PS19 mice. P7C3-A20-mediated pharmacologic normalization, but not elevation above normal, of brain NAD^+/NADH in 5xFAD mice from the 2-month-old presymptomatic stage until 6 months of age prevents acquisition of blood-brain barrier deterioration, neurodegeneration, neuroinflammation, impaired hippocampal neurotransmission, aberrant neuropsychiatric behavior, and cognitive impairment. Furthermore, normalization of brain NAD^+/NADH from the 6-month-old symptomatic stage to 12 months of

age reverses these features. AD-like cognitive impairment was also reversed in 12-month-old severely symptomatic PS19 mice after one month of P7C3-A20-mediated brain NAD^+/NADH normalization. Thus, normalizing brain NAD^+/NADH confers brain resilience that prevents and reverses AD. These results illustrate the potential for not only preventing or slowing AD, but also for disease reversal through restoring brain resilience.

Title: Hormesis-like interactions between amyloidβ and environmental stressors in C. elegans, mediated by key stress response pathways

Authors: ***J. LICHTY**, A. SAN MIGUEL;
Chem. and Biomolecular Engin., North Carolina State Univ., Raleigh, NC

Abstract: Alzheimer’s Disease (AD) is a neurodegenerative disorder which presents as a progressive loss of mental and physical function in those afflicted with it. AD is characterized by many abnormalities in the brain, such as widespread oxidative stress, immunity activation, neurodegeneration, inflammation, and protein aggregation. Amyloid β (Aβ) accumulation and aggregation has been associated with several AD traits, implicating it in the disease. To study this peptide’s role in AD, several models using the organism *C. elegans* have been engineered to express Aβ pan-neuronally. Previous work has shown Aβ’s ability to aggregate and induce oxidative stress, neurodegeneration, and reduced lifespan in *C. elegans,* but there are several other ways in which Aβ may influence the organism’s health. To fully capture Aβ’s impact on the organism and accurately translate it into a physiologically relevant result for humans, we need understand exactly what and how Aβ is interacting with the worm’s own physiology. Environmental stressors, including heat stress, oxidative stress, starvation, and hypoxia, are known to significantly impact worm health, but their interactions with Aβ have been largely unexplored. This work focuses on elucidating how Aβ influences worm health and survival in response to several different stressors. We initially hypothesized that environmental stressors and

Aβ would act synergistically to the detriment of worm health and survival. By exposing Aβ-expressing *C. elegans* to different stressors and scoring for survival, we show Aβ induces lowered oxidative stress resistance. Contrary to expectations though, Aβ expression increases resistance to several other stressors, indicating a possible hormesis-like effect. Additionally, we show, with a temperature inducible Aβ, a correlation between Aβ levels and heat stress resistance. By expressing Aβ in different tissues, we show that this a neuron-specific effect. Using gene-expression analysis techniques, we identified the daf-16 pathway as a possible route for this interaction. Targeted gene suppression indicated the possibility of a generalized daf-16 activation in response to Aβ expression. We also explore contributions from other stress response pathways. This work aims to improve our understanding of how Aβ affects *C. elegans* to better design AD experiments and interpret the results in this model organism.

Title: Soluble amyloid-beta impairs place cell network and circuit function in the APP/PS1 mouse model of Alzheimer’s disease

Authors: *H. LI, Z. ZHAO, R. J. F. GREEN, S. N. GOMPERTS;
Massachusetts Gen. Hosp., Boston, MA

Abstract: Early in the course of Alzheimer’s disease, soluble amyloid-beta (Aβ) deposits to form Aβ plaques in a cascade that causes progressive hippocampal failure. Prior work has shown that Aβ plaques are associated with impaired hippocampal activity and place cell representations, but the effects of soluble Aβ on neural systems function, before plaque deposition, are less well understood. We acquired chronic electrophysiological recordings together with simultaneous dynamic calcium imaging with GCaMP6f in hippocampal CA1 of young APP/PS1 mice expressing soluble Aβ to investigate the impact of soluble Aβ on hippocampal place cell network and circuit function linked to memory encoding and consolidation. Although hippocampal place cell spatial information was comparable in young (5.2 ± 0.2 months) APP/PS1 mice compared to age-matched (4.7 ± 0.2 months) littermate controls, young APP/PS1 mice showed delayed place field formation and diminished hippocampal theta-gamma phase-amplitude coupling. While coordination of hippocampal sharp wave ripples and cortical spindles in slow wave sleep (SWS) remained intact in young APP/PS1 mice, place cell pairwise reactivation was reduced. Compared to control mice, young APP/PS1 mice showed elevated synchronization in the theta and delta range between CA1 neuronal somatic calcium fluctuations and the local field potential in both

exploratory behavior and SWS. Together, these results suggest that soluble Aβ is sufficient to impair hippocampal function both online and offline, identifying early manifestations of Aβ-associated hippocampal dysfunction in Alzheimer's disease.

Title: PrP^C expression affects APP processing and Aβ secretion

Authors: *N. MEHTA[1], L. GREGORY[2], A. SOLANKI[2], J. MASTRIANNI[1];
[1]Neurol. Dept. and Committee on Neurobio., The Univ. of Chicago, Chicago, IL; [2]Neurol. Dept., Univ. of Chicago, Chicago, IL

Abstract: The cellular isoform of prion protein (PrP^C) is a GPI-anchored membrane protein that is highly expressed in neurons. Although central to the development of prion disease, evidence suggests that PrP^C interacts with amyloid-β (Aβ), a 38 to 42 amino acid peptide released from amyloid precursor protein (APP) through sequential enzymatic cleavage, and deposited extracellularly as amyloid plaques, a hallmark of Alzheimer's Disease (AD). We previously established a direct relationship between PrP^C expression and $Aβ_{42}$ secretion in mouse neuroblastoma (N2a) cells stably expressing human APP carrying the Swedish mutation linked to familial AD (N2a-APPswe), although the mechanism by which this occurs is unclear. We questioned whether PrP^C exerts its effect on Aβ secretion by modulating APP processing. To do this, we employed MSD electrochemiluminescence, qRT-PCR, and ELISA to quantify changes in Aβ secretion and the balance between the non-amyloidogenic (α-secretase-generated) and amyloidogenic (β-secretase-generated) processing pathways of APP, before and after siRNA-induced knockdown of PrP^C in N2a-APPswe and N2a-APPwt cells. We show that a ~70% PrP^C knockdown significantly reduced all major species of Aβ ($Aβ_{38}$, $Aβ_{40}$ and $Aβ_{42}$) in both cell lines. Using qRT-PCR, APP mRNA levels were unchanged, arguing against reduced APP expression as the cause. To determine whether PrP^C affects the processing of APP by α or β-secretase, we measured the changes in soluble(s) APPα and APPβ, the secretion products of α-secretase and β-secretase cleavage, respectively. We show that PrP^C knockdown significantly reduced sAPPβ levels in the media of both N2a-APPswe (2148 $\pm$ 43 vs 1833 $\pm$ 69 ng/mL, n=12 samples, $p<0.0059$) and N2a-APPwt (28996 $\pm$ 499 vs 24370 $\pm$ 611 pg/mL, n=6 samples, $p<0.0048$) cells. Although not yet tested in N2a-APPswe cells, PrP^C knockdown produced a striking increase in sAPPα in N2a-APPwt cells (19459 $\pm$ 278 vs 29221 $\pm$ 1241 pg/mL, n=6 samples, $p<0.0001$). Overall, the unaltered APP mRNA levels, substantial increase in sAPPα,

and moderate reduction in sAPPβ following PrP^C knockdown all suggest that PrP^C may normally suppress α-secretase activity and its loss shifts APP processing to the non-amyloidogenic pathway, reducing Aβ levels. Other effects are still possible, such as enhanced β-secretase activity or changes in APP trafficking. Additional studies are planned in cells and mouse models of AD with normal or absent PrP^C expression, to further clarify this relationship. In conclusion, our results provide insight into a possible role for PrP^C in modulating APP processing by promoting cleavage in the amyloidogenic pathway, leading to increased Aβ secretion at baseline.

Title: Defective lysosomal acidification contributes to TNF-TNFR1 mediated neuronal cell death

Authors: *C. H. LO[1], G. W. Z. LOI[1], E. N. SAIPULJUMRI[1], L. M. O'CONNOR[2], R. REYNOLDS[3], A. M. BARRON[1], J. ZENG[1];
[1]Lee Kong Chian Sch. of Med., Nanyang Technological University, Singapore, Singapore, Singapore; [2]Col. of Biol. Sci., Univ. of Minnesota, Minneapolis, MN; [3]Dept. of Brain Sci., Imperial Col. London, London, United Kingdom

Abstract: Tumor necrosis factor receptor 1 (TNFR1) signaling contributes to the pathogenesis of neurodegenerative diseases including Alzheimer's disease (AD). Recently, it has been shown that TNF induced TNFR1 activation leads to autophagic dysfunction and subsequently results in neuronal cell death. Autophagy is a homeostatic mechanism involved in the disposal of damaged organelles and toxic protein aggregates. However, the exact mechanism of how TNFR1 induced autophagic dysfunction leads to neuronal death remains unclear. In this study, we reveal that TNFR1 activation results in a downregulation of genes associated with lysosomal, autophagic, and mitochondrial functions and an upregulation of genes in cell death pathways in TNF treated SH-SY5Y neuronal cells and human iPSC derived primary neurons. Functionally, we show for the first time that lysosomal acidification is impaired only in neurons treated with TNF but not with other cytokines, contributing to inhibition of autophagic flux. Furthermore, we illustrate that there is defective mitophagy in neurons with TNFR1 activation, together with a decrease in mitochondrial membrane potential and an increase in reactive oxygen species. Importantly, we demonstrate that a novel type of lysosome-targeting acidic nanoparticles restores lysosomal acidification, autophagic activity, and mitochondrial function, as well as rescues neuronal cell

death in both cellular models and APP knock-in mouse model of AD. This opens avenues for new therapeutic directions to target lysosomal dysfunction, in addition to the existing efforts in developing receptor-specific inhibitors that target TNFR1 signaling.

Title: Cell-based small molecule screening for γ-secretase inhibitors and modulators

Authors: *J. KIM, S. PARK, D.-G. JO;
Sch. of Pharm., Sungkyunkwan Univ., Suwon, Korea, Republic of

Abstract: The accumulation of amyloid-beta (Aβ) plaques in the brain is a critical factor in the development of Alzheimer's disease (AD). Aβ is generated through the processing of amyloid precursor protein (APP) by β and γ-secretase. Although numerous attempts have been made to regulate Aβ generation by inhibiting γ-secretase, most clinical trials have failed due to the side effects caused by the inhibition of notch, a substrate of γ-secretase. Accordingly, modulating γ-secreatse activity has become a potent therapeutic strategy in treating AD pathology. In this study, we developed a fluorescence-based γ-secretase reporter system to assess γ-secretase activity in neuronal cell line. Using this reporter system, we screened FDA-approved drugs and identified several compounds as potential γ-secretase inhibitors or modulators. In addition, one of these compounds has shown improvements in cognitive function in the 5XFAD mouse model. To confirm the regulation of γ-secretase activity by this compound, we measure Aβ plaque and APP C-terminal fragment protein levels in the brain. Our findings highlight the therapeutic potential of this compound as a γ-secretase modulator for treating Alzheimer's disease.

Title: Aβ42 induces neuronal process degeneration and mitochondrial dsDNA release in an inducible human cortical organoid model of Alzheimer's disease

Authors: *M. HEBISCH, J. PARK, S. KWAK, T. KALATTURU, B. TAILOR, K. WASHICOSKY, R. E. TANZI, D. KIM;
Genet. and Aging Res. Unit, Inst. for Neurodegenerative Dis., Massachusetts Gen. Hosp., Charlestown, MA

Abstract: Alzheimer's disease (AD) is the most common cause of dementia, currently affecting 55 million patients. The amyloid-β (Aβ) hypothesis posits that accumulation of pathogenic Aβ42, but not the Aβ40 isoform, triggers a pathogenic cascade leading to neurodegeneration. However, there is no human AD model clearly recapitulating Aβ42-induced neurodegeneration. Previously, our lab has developed Aβ-driven 3D AD cellular models that demonstrate the functional link between amyloid generation and phospho-tau pathology in a 3D gel matrix. Here, we created a human cortical organoid (CO) model of Aβ-driven AD pathology using a doxycycline-inducible transgene in the AAVS1 locus. This novel model generates large quantities of Aβ species with either pathogenic (Aβ42-CO) or non-pathogenic (Aβ40-CO) isoform ratios and enables the isoform-specific interrogation of Aβ effects without confounding effects from altered development or other amyloid precursor protein (APP) fragments such as sAPPα/β or C99. Both Aβ conditions, as well as non-transgenic controls, initially develop cortical plate structures, neurons, and astrocytes. However, upon transgene induction, Aβ42-COs deposit Congo red-positive Aβ aggregates and accumulate oligomeric tau protein. Importantly, we found 60% less neuronal immunoreactivity after 8 weeks in Aβ42-COs, whereas Aβ40-COs closely resembled non-transgenic controls, clearly demonstrating Aβ42-driven neurodegeneration. Single-cell RNAseq analysis confirmed dysregulation of neuronal development, synapse maintenance, mitochondrial dynamics, and axon outgrowth (including Stathmin 2 depletion) in Aβ42-COs. Furthermore, Aβ42-COs contained approx. 50-70% less mitochondrial mass as indicated by TOMM20, and mitochondria in Aβ42-COs showed reduced DNA content in immunocytochemical analyses. Interestingly, we also detected cytoplasmic double-stranded (ds) DNA-positive specks in Aβ42-COs, likely representing released dsDNA from mitochondria. Previous studies showed that cytosolic release of mitochondrial dsDNA triggers innate cellular immune responses, including the cGAS-STING pathway. Indeed, another study from our lab found that Aβ42 accumulation activates the cGAS-STING pathway and accelerates the AD pathogenic cascade in human neurons cultured in a 3D gel matrix. Thus, Aβ42-mediated mitochondrial impairment and innate immune responses may explain the robust neurodegeneration in our human cortical organoid model of Alzheimer's disease. We are currently exploring underlying molecular mechanisms of Aβ42-induced mitochondrial damage and neuronal process degeneration.

Title: Understanding the effect of Abeta pathology on astroglial oxidative stress by using in vivo multiphoton microscopy

Authors: *M. SANCHEZ-MICO, E. KIRONDE, S. HOU, M. ALGAMAL, M. CALVO-RODRIGUEZ, M. ARBEL-ORNATH, B. BACSKAI;
Dept. of Neurol., Massachusetts Gen. Hosp., Boston, MA

Abstract: Amyloid beta (Aβ) plaques are one of the key hallmarks of Alzheimer's disease (AD) that can lead to astroglial dysfunction resulting in reduced metabolic support for neurons. This pathological cascade has been linked to disease progression. Using a genetically encoded calcium sensor targeted to astrocytes and multiphoton microscopy, we recently reported evidence of calcium dysregulation in astrocytes *in vivo* from an Aβ plaque-depositing AD transgenic mouse model (APPswe/PS1dE9; PMID: 19251629), and after direct application of naturally secreted soluble Aβ oligomers (Aβo) to the healthy brain (PMID: 37236808). Calcium dyshomeostasis is closely associated with the increase of reactive oxygen species (ROS) in AD and other neurodegenerative diseases. Increased ROS is responsible for promoting oxidative damage to DNA, RNA, proteins and lipids, triggering cell death, a key hallmark of AD pathology. While most studies in AD have focused on neurodegeneration or neuroinflammation, the extent and the mechanism of astroglial dysfunction in AD remains poorly understood. For that reason, we aimed to specifically investigate how Aβ plaques and soluble Aβo contribute to the ROS insult in astrocytes *in vivo*. We leveraged intravital microscopy to characterize *in vivo* the intracellular oxidative stress of astrocytes, by using a genetically encoded indicator (*roGFP*) that selectively reports the reduced/oxidized glutathione (GSH/GSSG) ratio specifically targeted to astrocytes (GFA2.roGFP). We evaluated astroglial oxidative stress after the deposition of Aβ plaques in APPswe/PS1dE9 mice compared to aged-matched non-transgenic mice, as well as after acute application of naturally secreted soluble Aβo (conditioned medium from cultured transgenic primary neurons) onto the living brain of 4-6-mo-old non-transgenic mice. Our preliminary data show an increase in astroglial oxidative stress in APPswe/PS1dE9 mice compared to non-transgenic mice, as well as upon topical soluble Aβo application, in the astroglial cytosol. Aβ-immunodepleted transgenic conditioned media and wild-type conditioned media did not alter astrocyte cytosolic oxidative stress, supporting the specificity of the observed effects. These results together support a detrimental role of Aβ which leads to astrocyte oxidative stress *in vivo*, implying that Aβ accumulation is involved in the astrocytic dysfunction observed in AD. Future studies will address whether this oxidative stress is cause or consequence of the pathology, the specific pathways affected, and the implications for neuronal activity, survival and synaptic functionality.

Title: Role of soluble amyloid β in increased ER calcium levels in a mouse model of Alzheimer's disease in vivo

Authors: ***M. ALGAMAL**[1], M. CALVO RODRIGUEZ[2], S. S. HOU[2], B. J. BACSKAI[2]; [1]Massachusetts Gen. Hosp., Boston, MA; [2]Neurol., Massachusetts Gen. Hospital-Harvard Med. Sch., Charlestown, MA

Abstract: The hallmarks of Alzheimer's disease (AD) include the deposition of Aβ plaques and neurofibrillary tangles, synapse loss, and neuronal cell death. Calcium (Ca^{2+}) dyshomeostasis is a neurodegenerative mechanism that impacts neuronal function and survival in AD. The endoplasmic reticulum (ER), mitochondria, and their contacts are crucial for regulating Ca^{2+} signaling. We have recently shown that mitochondrial Ca^{2+} overload plays a pivotal role in neuronal death in AD mouse models. However, the reason behind increased Ca^{2+} levels in neuronal mitochondria and the contribution of ER to mitochondrial Ca^{2+} dyshomeostasis remain unexplored in vivo. To address this, we employed viral delivery of a Ca^{2+} reporter targeted to ER (D1ER) and longitudinal in vivo multiphoton microscopy to assess ER Ca^{2+} levels in the cortex of an APP/PS1 mouse model of cerebral β-amyloidosis. We also test the effect of acute exposure to soluble Aβ on neuronal ER calcium using canula-mediated intracortical injections. Our results show increased ER Ca^{2+} levels in 4-10 months-old APP/PS1 mice compared to non-transgenic controls. Longitudinal imaging of ER calcium levels in APP/PS1 mice over several months indicated that the onset of plaque deposition does not impact ER Ca^{2+} levels, suggesting a role for soluble Aβ. In support of this hypothesis, acute exposure to a transgenic culture media containing soluble Aβ increased ER calcium levels in non-transgenic mice replicating the phenotype observed in APP/PS1 mice. In contrast, the exposure to non-transgenic control media did not result in significant ER calcium elevations. These findings highlight the pivotal role of soluble Aβ in mediating calcium dyshomeostasis and cellular toxicity in AD.

Title: Amyloid-β Precursor Protein facilitates tau spreading in Alzheimers Disease models

Authors: ***M. PRZYBYLA**[1], J. VAN EERSEL[1], M. CHU[1], G. CHAN[1], M. SABALE[1], A. VAN HUMMEL[1], L. HOU[1], J. VAN DER HOVEN[1], A. F. FEITEN[1], T. FATH[1], A. ITTNER[1], J. KRIL[2], G. SUTHERLAND[2], Y. D. KE[1], L. ITTNER[1];
[1]Macquarie Univ., Macquarie Park, Australia; [2]Discipline of Pathology, Sydney Med. Sch., The Univ. of Sydney, Sydney, Australia

Abstract: Tau spreading within the brain correlates with disease progression and leads to distinct neuropathological changes in Alzheimer's disease (AD). In AD, abnormal cleavage of the amyloid-β (Aβ) precursor protein (APP) results in Aβ formation, which is a disease initiating step upstream of tau pathology. Here, we show that APP facilitates neuronal release and spreading of tau, highlighting a novel role of APP in disease progression towards dementia. We further demonstrate that this process is amplified by pathogenic APP mutations and increased

APP levels. In summary, our data shows that APP is an integral part of tau pathology spreading and further delineates a novel role for pathogenic APP mutations in AD.

Title: Calcineurin inhibition counteracts hippocampal synaptic plasticity impairment induced by brain-derived tau oligomer

Authors: *P. SCADUTO, R. KAYED, G. TAGLIALATELA;
Neurol., UTMB, Galveston, TX

Abstract: Background: Cognitive decline in Alzheimer’s disease (AD) is closely linked with tau protein build-up, with the most toxic species being in form of oligomers. Given the polymorphic nature of tau oligomers, isolating and testing brain-derived tau oligomers (BDTO) directly from AD patients could provide new insights into tau toxicity. BDTO are potent inhibitors of long-term potentiation (LTP) in hippocampal brain slices, but the implicated mechanism is yet to be fully elucidated. We previously reported significantly reduced incidence of AD in aging humans chronically treated with an FDA-approved calcineurin inhibitor, FK506, used as immunosuppressant after solid organ transplant. Here, we found that synaptic function deterioration provoked by BDTO is rectified by calcineurin inhibition using FK506, via selective transcriptomic changes. **Methods:** Combination of electrophysiological and RNA-seq techniques were used. *Ex-vivo* slices from 8-12 weeks old C67BL/6J mice were treated with aCSF (Ctrl), BDTO (100nM) or BDTO+FK506. Field excitatory post-synaptic potentials (fEPSPs) recordings were performed by stimulating the Schaffer collateral pathway, and recording electrode was located at the junction of the alveus and cornu ammonius 1 (CA1). After electrophysiological recordings, the hippocampus was isolated from the brain slice, snap frozen and processed for RNA-seq. **Results:** FK506 treatment significantly ameliorated the BDTO-induced attenuation of fEPSP. One-way ANOVA followed by Tukey’s test, showed that BDTO caused reduction of fEPSP compared to Ctrl ($p=0.068$). fEPSP was re-established at physiological levels in the group BDTO+FK506 (vs Ctrl $p=0.603$; vs BDTO $p=0.0163$). A similar trend was observed when we analyzed the paired-pulse ratio. We performed a Gene Ontology enrichment analysis on the differentially expressed genes to hierarchically cluster the experimental groups. This revealed

two distinct clusters: 1) BDTO cluster, characterized by enhanced mRNAs associated with the regulation of protein catabolic processes and transcriptional regulation, and 2) CTRL and BDTO+FK506 cluster, characterized by upregulation of genes related with energy and metabolic processes. **Conclusion:** Our study provides evidence that FK506 has the potential to block the BDTO toxic effect on synaptic plasticity. These results suggest that FK506 may represent a promising therapeutic strategy for the treatment of AD. Further research is needed to elucidate the precise molecular mechanisms underlying FK506-mediated neuroprotection and to explore its potential in *in-vivo* models of AD.

Title: The role of WAVE1 in the regulation of tau phosphorylation

Authors: *C. BERDASCO[1,3], B. CARABELLI[3], Y. KIM[3,2];
[2]Brain Hlth. Inst., [1]Rutgers Univ., Piscataway, NJ; [3]Dept. of Neurosurg., Robert Wood Johnson Med. School, Rutgers Univ., Piscataway, NJ

Abstract: Alzheimer’s disease (AD) is the most common cause of dementia and a progressive neurodegenerative disorder. Wiskott-Aldrich syndrome protein (WASP) and WASP-family verprolin-homologous protein 1 (WAVE1) is a major regulator of Arp2/3 complex-mediated actin polymerization in the brain. Previously, we found a significant downregulation of WAVE1 gene (*WASF1*) expression in AD brains. We also observed the role of WAVE1 in the trafficking of amyloid precursor protein (APP)-containing vesicles and thereby Aβ production. Because experimentally reducing WAVE1 gene expression dramatically reduced Aβ levels and restored memory deficits in APP/PS1 mice harboring APPs and PS1ΔE9, WAVE1 reduction found in AD brains might be a cellular compensatory mechanism to control Aβ production. However, the role of WAVE1 in the regulation of tau hyperphosphorylation has not been studied. To examine the potential effect of WAVE1 reduction on tau hyperphosphorylation, we crossed P301S tau PS19 mice with WAVE1 KO mice. P301S tau mice carrying WAVE1 wild type (WT), heterozygous or homozygous alleles were sacrificed, and the hippocampi were lysed to perform Western blotting. We found that the protein level of WAVE1, but not Cdk5 or p35, is significantly reduced in the hippocampus of P301S tau mice harboring WAVE1 WT alleles compared to non-transgenic control mice. We also found that tau hyperphosphorylation at S202/T205 (detected by AT-8 antibody) and T231 (AT-180) sites were significantly reduced in P301S mice harboring either heterozygous or homozygous WAVE1 deletion compared to the levels in the P301S mice

expressing WT WAVE1. However, phosphorylation at S199 was not significantly altered by WAVE1 deletion, indicating that the effect of WAVE1 KO on tau hyperphosphorylation is site-specific. These results suggest that WAVE1-mediated actin polymerization is a potential therapeutic target for amyloid as well as tau pathology in AD.

Title: Pathological Tau Mediates Dysfunction of the Nuclear Lamina in Alzheimer's Diseased Brains

Authors: *Z. WALTON[1], M. MONTALBANO[2], R. KAYED[3];
[1]John Sealy Sch. of Med., [2]Neurol., [3]Univ. of Texas Med. Br., Galveston, TX

Abstract: Background: Tau is a microtubule stabilizing protein belonging to the microtubule-associated protein (MAP) family. Tau aggregation is associated with neurodegenerative disorders, such as Alzheimer's Disease (AD). Recent findings from our group suggest a connection between oligomeric forms of tau and nuclear dysfunction, including alterations in the nuclear lamina (NL). The NL is a meshwork formed from various combinations of four intermediate filament lamin proteins (lamins A, B1, B2, and C) located along the nuclear perimeter. The NL provides a structure for attachment and organization of heterochromatin and is a vital connection between the nucleoskeleton and cytoskeleton. We hypothesized that Tau aggregates modify the NL structure, thus altering nuclear structure and morphology. **Methods:** We performed immunofluorescence (IF) imaging of lamin proteins in cortical human brain tissue samples from age-matched patients with AD and non-demented controls. Alterations in lamin expression and structure between control and AD nuclei were quantified and analyzed using Imaris Explore 10.0 software. To corroborate our observations, we performed western blot (WB) of subcellular fractionations from human brain tissue samples. To determine tau's impact on the NL, we treated inducible cells with tetracycline (Tet) to induce tau expression and further examined NL dysfunction via immunocytochemistry.**Results:** IF imaging revealed changes in nuclear morphology, structure, and lamin expression in AD brains. Large amounts of lamin proteins were mislocalized throughout the nucleoplasm and cytoplasm from the nuclear margin. WB confirmed abnormal localization of lamin proteins in the cytoplasmatic and cytoskeletal fractions of AD brains. Confocal Imaging revealed that AD brains contain less nuclei positive to lamin A but more nuclei positive to lamin C. We also observed invaginations and ruptures of the nuclear envelope. Additionally, lamin A and B1 components of the NL are significantly thicker

in AD nuclei compared to control nuclei. In our in vitro model, cells treated with Tet disclosed a thicker NL with a higher number of cells containing invaginations comparable to our observations in human samples.**Conclusions:** In AD brains, the NL is morphologically and structurally altered as characterized by defective lamin expression and cellular localization. Furthermore, our in vitro experiments highlight tau's role in NL dysfunction. Our data contributes to additional molecular insights of tau-induced toxicity in cell nuclei.

Abstract: Synaptic and axonal degeneration are early hallmarks of Alzheimer's disease and related disorders (ADRD) that are also characterized by pathological aggregation of the tau protein. Normal microtubule-based fast axonal transport (FAT) is disrupted in ADRD and many other neurodegenerative diseases and represents a potential mechanism of tau-induced degeneration. FAT involves the bidirectional movement of cargo carried out in the anterograde direction by kinesin motor proteins and in the retrograde direction by cytoplasmic dynein motor protein complex. Pathological forms of tau, including tau aggregates and tau monomers with disease-associated pseudophosphorylation or frontotemporal lobar degeneration (FTLD) tau mutations, disrupt FAT in squid axoplasm and/or mammalian primary neuron models. We previously found that pathological tau aberrantly activates a phosphorylation-based signaling pathway involving protein phosphatase 1 and glycogen synthase kinase 3β resulting in changes to kinesin function. However, a subset of these pathological tau forms also disrupt dynein-based

retrograde FAT but the mechanisms mediating tau's effects on transport in this direction are not yet known. Here, we sought to determine how expression of pathogenic FTLD-tau mutants (R5L, A152T, P301L, and R406W) affect FAT compared to wild-type (WT) tau expression. We co-transfected mixed-sex primary hippocampal neurons from tau knockout (TKO) mice with WT or one of the FTLD-tau mutants and a fluorescent-tagged cargo protein (synaptophysin or Rab6) then generated live cell movies of cargo transport on a confocal microscope at ~28 frames/second. Expressing pathogenic tau increases pause frequency of both cargo proteins compared to WT tau or GFP-expressing cells, indicating a disruption of normal FAT. To identify potential mechanisms of the effect on retrograde FAT we expressed WT or mutant tau in primary TKO hippocampal neurons using lentiviruses. We measured active and total levels of several kinases known to modulate retrograde FAT to determine how tau expression affected their activity. Multiple pathogenic tau mutants induced a significant increase in levels of active p38 (MAPK14) compared to WT tau or GFP-expressing neurons while the activities of other kinases were unaffected. The p38 kinase is linked to disease-associated FAT disruptions in amyotrophic lateral sclerosis (ALS) but a role in ADRD is not yet identified. Using p38 inhibitors we are determining how its activation is linked to pathogenic tau-induced disruption of retrograde FAT in our primary neuron model. This represents a potential mechanism for tau-induced disruptions to retrograde FAT.

Title: Nicotinic acid modulates microglia phenotypes and tau phosphorylation in the PS19 tauopathy model

Authors: *I. CORONEL[1,2], R. DELVECCHIO[3,2], D. SONI[2], H. PATEL[2], S. PUNTAMBEKAR[2,4], P. MARTINEZ[2], A. OBLAK[2], C. LASAGNA-REEVES[2], G. LANDRETH[2], M. MOUTINHO[2];

Abstract: Alzheimer's disease (AD) is the most common type of dementia, for which there is no effective treatment. AD is characterized by a robust immune response, the presence of extracellular amyloid-β (Aβ) plaques, and intraneuronal neurofibrillary tangles (NFTs) composed of hyperphosphorylated tau. Dietary intake of nicotinic acid has been correlated with

decreased risk of AD and age-related cognitive decline. Our recent evidence showed that nicotinic acid activates the microglial receptor HCAR2 to induce a protective phenotype in an amyloid mouse model of AD, attenuating disease severity. We hypothesized that the beneficial effects of nicotinic acid extend to tau pathology as well. To investigate the role of HCAR2 in tau pathology we used the tauopathy mouse model PS19. We treated a cohort of 6-month-old female PS19 mice with the FDA-approved formulation of nicotinic acid (Niaspan®) or vehicle by daily oral *gavage* for 30 days, and evaluated microglia phenotype, synaptic markers, and tau species expression. Although 6-month-old PS19 mice exhibit a mild disease phenotype, we can already observe a significant increase in microgliosis within the hippocampus of PS19 compared to *wild-type* control mice (B6). Interestingly, oral Niaspan® treatment decreased hippocampal microglial Iba-1 staining and mRNA expression with respect to vehicle control mice. Niaspan® treatment also reduced expression of high-molecular-weight phosphorylated tau determined in soluble and insoluble fractions, but not the expression of synaptic proteins such as PSD95 and synaptophysin. Our results indicate that oral Niaspan® treatment reduces microglial activation and ameliorates the expression of phosphorylated tau aggregates in PS19 mice. Recent studies have shown that microglia contribute to the progression of tau pathology through the spreading of tau seeds. Nonetheless, the activation of HCAR2 did not elicit changes in tau seeding, thus, it is possible that activation of microglial HCAR2 with niacin, and the subsequent mitigation of microgliosis, lead to increased clearance of tau aggregation and phosphorylated tau. Pharmacological evaluation of the effect of Niaspan® on the PS19 tauopathy model at multiple ages will further our understanding of the potential use of this FDA-approved drug to be repurposed for AD at different stages of the disease.

Abstract: Alzheimer disease (AD) is the most common neurodegenerative disorder, which is characterized by two types of pathological amyloid deposition, amyloid β peptide (Aβ) and tau. Extracellular Aβ deposition has already appeared 15-20 years before the onset of cognitive decline in the brains of patients with AD and is known as an initiator for intracellular tau deposition and spreading throughout the brain. However, the detailed mechanism by which Aβ induces and spreads the tau pathology is still unknown. Several studies have reported that the intracellular tau is physiologically and pathologically released into the extracellular milieu, and that tau secretion mediates the spread of tau pathology. We, therefore, examined the relationship between tau secretion and Aβ deposition. As candidates, we selected several molecules whose expression is increased along with Aβ deposition in the human AD brain and investigated the effect of them on tau secretion from tau overexpressing mouse neuroblastoma Neuro2a (N2a) cells. In the result, we identified amyloid precursor protein, APP, and its soluble N-terminal fragment, sAPPβ, as a positive regulator. APP is accumulated in neuronal cells around Aβ plaques, and the production of sAPPβ is also increased by APP cleavage via BACE1. We revealed that overexpression of APP increased tau secretion from the tau stable overexpressing N2a cell line. On the other hand, knockout of APP dramatically decreased tau secretion, indicating APP-dependent tau secretion. In addition, tau secretion was also enhanced by overexpression of sAPPβ, but not by other cleavage fragments from APP. These results suggest a new tau secretion pathway induced by APP, especially sAPPβ. We will further investigate the detailed molecular mechanism and its relationship with AD pathogenesis. In addition, we will elucidate the effect of other candidates to identify other regulators on tau secretion.

Title: G protein coupled receptor kinase 2 modulates tau pathogenesis in human neurons

Authors: *T. RAFAEL GUIMARAES[1], M. MACDONALD[2], A. THATHIAH[3];
[2]Psychiatry, [3]Neurobio., [1]Univ. of Pittsburgh, Pittsburgh, PA

Abstract: Aggregation of the hyperphosphorylated tau protein in neurofibrillary tangles (NFTs) is a pathological hallmark of Alzheimer's Disease (AD) brains. Several kinases contribute to the pathological phosphorylation of tau; however, kinase targeted therapies for AD have failed in clinical trials due to low efficacy and severe side effects. G protein coupled receptor (GPCR)

kinases (GRKs) have been implicated in neurological disorders, such as Parkinson's Disease, via phosphorylation of non-GPCR substrates, e.g., a-synuclein. Previously, we showed that GRK2 is abundantly expressed in neurons, positively correlated with soluble tau levels, and associated with NFTs in the human AD brain. Therefore, we hypothesized that GRK2 can directly modify tau phosphorylation and aggregation. To test this hypothesis, we first showed that genetic deletion of *Grk2* induces global changes in the tau phosphoproteomic profile, while GRK2 overexpression increases tau phosphorylation (pTau) at a disease-relevant site (PHF1). Furthermore, we used an inducible optogenetic system (optoTAU), which allows for control of the expression and temporal aggregation of tau, to show that optoTAU aggregation, and specifically soluble tau, is reduced in *Grk2*-deficient cells. We show that GRK2 directly interacts with tau and pathogenic species *in vitro*, which is in accordance with our previous human brain observations. Moreover, we find that GRK2 modulates pTau in a kinase activity-independent manner, via other major tau kinases (e.g., ERK, GSK3B). Specifically, ERK-mediated phosphorylation of GRK2 species at residue 670 is protective against pTau formation and is this found downregulated in AD brains. Interestingly, pharmacological inhibition of GRK2 in human directly converted induced neurons (iNs) increases both ERK activation and GRK2 s670 levels, while decreasing pTau and reactive oxygen stress in AD-derived iNs. Lastly, *Grk2* genetic deletion enhances tau ubiquitination and interaction with HSP90, which further increases tau degradation, protecting the cells from aggresome formation upon proteasome inhibition. Collectively, these studies causally implicate GRK2 as a multifactorial modulator of tau pathology through changes in phosphorylation, aggregation, and degradation of tau and support further investigation of therapeutic interventions against GRKs in AD.

Abstract: The stereotypical propagation of tau protein aggregates in the brain drives the progression of Alzheimer's disease. This process is involved in the cell-to-cell transmission of

pathological tau proteins between anatomically connected regions. The majority of tau proteins released from neurons into the extracellular space are membrane-free form. Recently, exosomes, a class of extracellular vesicles, were shown to contribute to the delivery of pathological tau proteins in the brain. However, reassessment of exosomal composition has revealed exosomes are heterogeneous. To elucidate the roles of exosome-dependent tau protein propagation in the disease progression, here, we developed a method for the isolation of tau-containing exosomes secreted from mouse neuroblastoma Neuro2a cell line stably expressing full-length tau with the P301S mutation. We isolated exosomes from the culture medium of these cells using differential centrifugation followed by 6%-30% iodixanol density gradient fractionation. We then analyzed distributions of tau proteins and exosomal markers in each fraction. Iodixanol density gradient fractionation separated exosomal fractions into two subpopulations. We found that a novel subpopulation of exosomes contained a substantial amount of tau proteins together with the calcium-regulated plasma membrane-binding protein Annexin A2. Annexin A2 was known to be a potential interaction partner of tau proteins in neurons. The tau-containing exosomes were distributed in distinct fractions from those with exosomal tetraspanin markers such as CD9, CD63, and CD81. Thereafter, the membranes of the isolated tau-containing exosomes were labeled by DiI, a lipophilic carbocyanine fluorescent dye. Time-lapse live cell imaging demonstrated that a large amount of the DiI-labeled, tau-containing exosomes were taken up by Neuro2a cells within twelve hours after addition to the cell culture medium. In conclusion, we established a high-resolution density gradient fractionation method to identify a novel subpopulation of exosomes containing tau proteins. These tau-containing exosomes are distinct from those expressing classical exosomal markers. Moreover, they are internalized to neuronal cells, suggesting that they might contribute to the transcellular transmission of tau proteins.

Title: Cholesterol transporter GRAMD1B expression correlates with lipid droplet formation and tau pathology.

Authors: *T. KIM[1,2], D. ACOSTA[1], N. SWEENEY[1], S. CHEN[1,2], G. E. SERRANO[3], E. BELL[4], L. S. HONIG[5], J. G. VONSATTEL[5], D. SCHARRE[4], T. G. BEACH[3], H. FU[1]; [1]Neurosci., [2]Biomed. Abstract: Tau protein hyperphosphorylation and aggregation are pathological hallmarks of tauopathies such as Alzheimer's disease (AD) and Frontotemporal lobar degeneration (FTLD). Lipid dyshomeostasis is thought to play an important role in early AD and other tauopathies. Previous studies suggest that increased cholesterol levels were associated with tau pathology and neuronal dysfunction in AD. Recently, we identified a cholesterol transporter, GRAM domain containing 1B (GRAMD1B), was significantly increased in neural organoids derived from induced pluripotent stem cells (iPSCs) from an FTLD patient with *MAPT* R406W mutation compared to isogenic control organoids. GRAMD1B protein mediates the transport of cholesterol from the plasma membrane to the endoplasmic reticulum, contributing to cholesterol homeostasis. However, little is known about GRAMD1B levels in the brain of tauopathies, or its role in disease progression. We hypothesized that GRAMD1B may contribute to lipid droplet formation and tau pathology in the early stages of AD and other tauopathies. We performed immunofluorescence staining on the entorhinal cortex of human post-mortem brain tissues and tau mouse models to evaluate the immunoreactivity of GRAMD1B and its relationship with lipid droplets and tau pathology. Lipid droplet formation was assessed using Oil red O or LipidSpot 610 stain which measures neutral lipid stores. Interestingly, we found that lipid droplets were colocalized with increased hyperphosphorylated-tau (PHF1+, pS396/S404 tau) and GRAMD1B in early AD and FTLD, and in tau mouse models. We also found that PHF1-positive cells had a lower level of GRAMD1B than neighboring PHF1-negative cells, but GRAMD1B expression was significantly increased in PHF1-negative cells in human AD and FTLD as well as tau mouse models compared to control samples without tau pathology. In conclusion, our data suggest that there is a positive correlation between neuronal GRAMD1B, lipid droplets, and tau pathology in the early stages of tauopathies. We will further investigate the molecular mechanisms underlying GRAMD1B expression on lipid dyshomeostasis, tau pathology, and neurodegeneration.

Title: Suppression of nutrient sensing receptor GPRC6a modifies lysosomal function and improves tau clearance in PS19 tauopathy mice

Authors: *K. CAMPBELL, H. LIANG, C. MA, J. HUNT, M. KILLION, D. LEE;
Univ. of Kentucky, Lexington, KY

Abstract: Arginine increases during the course of neurodegenerative diseases, such as Alzheimer's disease (AD) in both humans and animal models of tauopathies. The kinase complex mechanistic target of rapamycin (mTORC1) senses nutrients in eukaryotes. mTORC1 is recruited to the lysosomal surface to increase protein synthesis and cell growth during nutrient abundance. When nutrients are scarce mTORC1 fails to translocate to the lysosome and autophagy is uninhibited. During neurodegenerative disease mTORC1 signaling can become uncoupled and precipitate proteinopathies. Arginine is a potent activator of mTORC1 and signals through various protein sensors and lysosomal transporters. GPRC6a is an amino acid sensor that binds arginine with high affinity, signals to mTORC1, and increases in AD brains and tauopathy models. We hypothesize that tau pathology promotes nutrient sensing dysfunction leading to hyper mTORC1 activation. We posit that GPRC6a suppression increases activates autophagy, which rebalances proteostasis and hallmarks of tau pathology. Tau transgenic mice (*PS19*) and non-transgenic littermates were bred to mice with GPRC6a hemizygous deletion to generate four genotypes: (*nTg, GPRC6a* $^{+/-}$*, PS19, PS19/GPRC6a* $^{+/-}$). Mice were aged to 7-9 months before brains were harvested for western blot and bulk RNA-seq. Tau biochemistry was measured in detergent soluble and urea soluble fractions from the anterior and posterior cortex. Markers for mTOR activation, lysosomal function, and autophagy were also measured. Hippocampal tissue was used for bulk RNA seq Nanostring for transcriptome pathway analysis. Hemizygous deletion of GPRC6a (*PS19/GPRC6a* $^{+/-}$) decreased total tau (HT7) and various forms of phospho-tau (Ser199/202, PHF1, AT8) in soluble and insoluble fractions compared to *PS19* mice. GPRC6a suppression in PS19 mice significantly decreased phospho mTOR2448/ total mTOR ratio suggesting decreased mTORC1 activation compared to PS19 mice. Autophagy and autophagosome formation significantly increased in PS19/GPRC6a $^{+/-}$ mice, as shown by an increase in active ULK1. Both LC3-I and LC3-II increased in PS19/GPRC6a$^{+/-}$ mice compared to PS19 mice suggesting increased lysosomal biogenesis. PS19 mice showed increased transcripts associated with autophagy, neurogenesis, and proteotoxic stress compared to *nTg* littermates, and hemizygous deletion of GPRC6a (*PS19/GPRC6a*$^{+/-}$*)* normalized these signatures to that of control levels. These data indicate that GPRC6a expression regulates proteostasis of tau and could serve as a therapeutic target in tauopathies. Additionally, our data suggests that GPRC6a impacts lysosomal function and mTORC1 activation state.

Title: Investigation of the role of complement receptors in extracellular tau clearance

Authors: *C. YOO[1,2], E. BOK[1], J. KIM[1];
[1]Korea Brain Res. Inst. (KBRI), Daegu, Korea, Republic of; [2]DGIST, Daegu, Korea, Republic of

Abstract: Abnormal accumulation of misfolded tau aggregates is a key pathological hallmark of various tauopathies including Alzheimer's disease. Pathological tau spreads along anatomically connected areas in the brain through intercellular transmission and templated misfolding. The spatiotemporal spreading of tau pathology is closely correlated with cognitive decline and behavioral deficits in patients of tauopathies. Therefore, identifying the molecular mechanisms underlying the release and uptake of tau is critical to understand the pathological mechanisms of many tauopathies. The various innate immune receptors have been reported to play a role in recognition, internalization, and clearance of various toxic proteins. In particular, CR3 and CR4, two major phagocytic receptors in microglia, are known to mediate phagocytosis of fibrillar Aβ and α-synuclein, respectively. In this study, we investigated the role of CR3 and CR4 in regulating clearance of extracellular tau. In this study, we identified that CR4 selectively binds to tau fibrils but not to tau monomers using dot-blot- and immunoprecipitation assay. We further demonstrated that silencing of CR4 dramatically reduce the uptake and clearance of tau fibrils. However, silencing of CR4 does not affect the degradation of extracellular tau in the culture media. Moreover, conditioned media form CR4-silenced BV2 culture treated with tau fibrils are more potent in inducting tau aggregation in Tau RD cells compared to the controls. Taken together, our data suggest that CR4 is a novel receptor for tau fibril clearance and may play a critical role in tau spreading.

Title: Tau interactome identifies interactions associated with various cellular compartments and reveals interactions with specific tau domains

Authors: *A. ATWA[1,2], B. COMBS[1], M. M. ALHADIDY[1,2], J. LAMP[1,3], I. E. VEGA[1,2,3], N. M. KANAAN[1,2,4];
[1]Michigan State Univ., Grand Rapids, MI; [2]Neurosci. Program, Michigan State Univ., East Lansing, MI; [3]Integrated Mass Spectrometry Unit, Michigan State Univ., Grand Rapids, MI; [4]Hauenstein Neurosci. Ctr., Mercy Hlth. St. Mary's, Grand rapids, MI

Abstract: Tau protein aggregation is central to neuropathological alterations in Alzheimer's Disease (AD) and other neurodegenerative diseases collectively known as tauopathies. Tau was initially reported as a microtubule-associated protein involved in regulating microtubule dynamics. Multiple lines of evidence suggest that Tau plays diverse microtubule-independent functional roles regulated, in part, by direct and/or transient protein interactions. Deciphering the Tau interactome is a critical step toward better understating the physiological and pathological Tau-mediated cellular processes. In this work, we sought to map potential members of the Tau interactome using the BioID2 approach that allows for *in situ* protein labeling in living neurons. Biotin-labeled proteins are identified by biotin-targeted pulldown and mass spectrometry. We generated lentiviruses expressing fusion proteins between full-length human Tau (2N4R isoform) with BioID2 on either the N-terminus (BioID2-Tau) or C-terminus (Tau-BioID2). Tau can be subdivided into three domains: the N-terminus domain (Nterm), the microtubule binding region (MTBR), and the C-terminus domain (Cterm). To further dissect the Tau interactome, we created fusion proteins between Tau domains and BioID2 (Nterm-BioID2, MTBR-BioID2 and Cterm-BioID2). A control lentiviral construct was created to express only the BioID2 protein. Embryonic day 18 Tau knockout (TKO) primary cortical neurons were transduced on the 4th day in vitro (DIV4), and lysates were collected on DIV12 for biotin-targeted pulldown and mass spectrometry identification (n=3 biological replicates). Utilizing this approach, we identified 391 proteins as candidates of the Tau interactome among which 189 proteins interacted with the Nterm, 196 proteins with the MTBR, and 237 proteins with the Cterm. Protein interactions were further validated by either co-immunoprecipitation from adult human Tau knockin (hTKI) mouse cortical tissue (n=3) or proximity ligation assay in hTKI cortical neurons (n=3). Gene Ontology enrichment analysis mapped protein interactors associated with the somatodendritic compartment, mitochondria, cytoskeleton, synapses, ribosomes, ubiquitin-proteasome system, and the ribonucleoprotein complex. While KEGG pathways identified proteins associated with neurodegenerative diseases, including AD, Parkinson's disease, and Huntington's disease. Thus, this approach can identify potential members of the Tau interactome via *in situ* labeling. This work helps expand the growing list of Tau's potential functional roles and may advance our understanding of its biological and neurodegenerative functions.

Title: Tau Citrullination Elicits Confirmer Diversity in Various Tauopathies.

Authors: H. LIANG[1], M. SERRANO[1], M. NELSON[1], D. CRASTA[1], J. B. HUNT, Jr.[1], C. SAUNDERS[1], K. CAMPBELL[1], P. NELSON[2], M.-L. SELENICA[3], ***D. LEE**[1];
[1]Sanders-Brown Ctr. on Aging/ Neurosci., [2]Sanders-Brown Ctr. on Aging, [3]Sanders-Brown Ctr. on Aging/ Mol. Cell. Biochem., Univ. of Kentucky, Lexington, KY

Abstract: Tau deposition causes different clinical phenotypes and pathological outcomes depending on the tau strain and brain region. The pathological sequalae can stem from posttranslational modifications (PTMs) that alter structure, function, and regional susceptibility. To that end, we discovered a new modification on tau named citrullination (citR) which changes the amino acid arginine to a citrulline via the enzyme peptidyl arginine deiminases (PADs). PAD4 is primarily restricted to neurons and activated by calcium, but also harbors SNPs that increase AD (*rs16824888*) and ALS (*rs2240335*) risk. Structurally, this conversion permanently alters the target by producing loss of positive charges, changes in protein stability, and inter/ intramolecular interactions. We uncovered citR tau at 14 arginine sites via mass spec using recombinant protein and created 11-highly citR tau antibodies to the various domains. We found that citR impacts tau phosphorylation, degradation, and fibrillization. Interestingly, tau citR decreased fibrillization at the expense of accumulating oligomers, suggesting that citR promotes soluble tau aggregates. We also found increased citR tau in three different models of tauopathy mice. PAD4 overexpression increased citR tau in cellular and animal models of tau deposition. Importantly, citR tau increased in AD and tauopathies including PSP, CTE, Pick's disease, ARTAG, PART, FTLD, AGD, but not in TBI, dementia with DLB compared to control brains. Despite PAD4/ 2 being the only PADs recognized in the CNS, various tauopathies showed selective epitope specificity and regional expression of citR tau. This suggests that PAD4 may elicit 3R- versus 4R- bias for disease-related tau confirmers and regional vulnerability to coordinated calcium activation. We aim to discriminate differences in citR tau signatures that impact clinical aggressiveness of tauopathies. Collectively, we identified a common yet unknown PTM for human tauopathies that has broad implications, new biology, and provides novel therapeutic targets for the tauopathy field.

Title: Sucrose gradient-derived Alzheimer's disease tau oligomers impair synaptic functioning and plasticity

Authors: *N. MORENO, L. FUNG, N. BHATT, A. HAQUE, C. JEREZ, A. LIMON, R. KAYED;
Neurol., Univ. of Texas Med. Br., Galveston, TX

Abstract: Alzheimer's disease (AD) is histopathologically characterized by amyloid β (Aβ) and tau accumulation as amyloid plaques and neurofibrillary tangles, respectively. Tau oligomers are thought to be the major neurotoxic species in AD, but there is currently a gap in knowledge concerning standardized methods for isolating and characterizing tau oligomers. Here, we used sucrose density gradient ultracentrifugation to isolate BDTOs from Alzheimer's disease brain tissue and performed electrophysiological recordings on oligomers from fractions 4 and 5 of the sucrose gradient to investigate the effect of these BDTOs on neuronal transmission and synaptic plasticity Our results demonstrate that fraction 4 and fraction 5 BDTOs substantially impair neuronal transmission and synaptic plasticity. Interestingly, the fraction 4 and fraction 5 sucrose density oligomers, as well as recombinant tau oligomers, appear to have dose-dependent mechanisms underlying the observed disruption of basal neuronal transmission. Ultimately, our results demonstrate that sucrose gradient ultracentrifugation can be used to isolate toxic tau oligomers from human tissue, and, while there is some variability in oligomer size and behavior between fractions, synaptic toxicity is preserved.

Title: Human tauopathy strains defined by phosphorylation in repeat domains of tau

Authors: *E. D. SMITH[1,2], Q. VO[1,2], B. I. GIASSON[2,1,3,4], D. R. BORCHELT[1,2,4], S. PROKOP[5,2,3], P. CHAKRABARTY[2,1,4];

Abstract: Recent proteomic studies have identified a set of post-translational modifications (PTM) on tau protein located in the Proline-Rich Region (PRR), Microtubule Binding Region (MTBR), and C-terminal region that are found specifically in fibrillized tau isolated from Alzheimer's disease (AD) patients. In this study, our overarching aim was to determine whether

selective phosphorylation on these PTM sites will impact tau seed-induced misfolding and aggregation of tau protein. Using host tau protein that is modified on these select phosphorylation residues, we show that presence of phosphorylation mimicking substitutions in the repeat domains (S262/T263/S289/S305) substantially reduce seeding efficiency of insoluble AD-tau seeds derived from Alzheimer's disease (AD). The resultant detergent-insoluble seeded tau shows deficient phosphorylation on AT8, AT270, AT100, AT180 and PHF1 epitopes compared to parent tau carrying no phospho-mutations indicating cooperativity between phosphorylation sites located across the different structural domains of tau during the seeding process. On the other hand, PSP-tau (derived from Progressive supranuclear palsy donors) seeding efficiency is not modulated by these phospho-mimicking mutations in the repeat domains, suggesting strain-specific differences between AD-tau and PSP-tau seeds. Phospho-deficient substitutions in these selective sites do not alter seeding activity of either AD-tau or PSP-tau in our cellular assay. Finally, we identify S305 as a major determinant of the seeding efficiency of AD-tau, which suggests that modification(s) at this site could serve as a protective mechanism against templated seeding in the context of AD-tau seeds. Collectively, our data confirms the functional role of specific tau phosphorylation epitopes in determining the prion-like templated seeding properties of tau in AD and PSP.

Title: Tau pathology kinetics and features depend on the nature of the tau seed

Authors: *A. O. MATE DE GERANDO, A. KHASNAVIS, R. PERBET, L. WELIKOVITCH, B. T. HYMAN;
Massachusetts Gen. Hosp., Charlestown, MA

Abstract: Aim: Alzheimer's disease (AD) progression has been associated with the propagation of both oligomeric and fibrillar tau species, yet their respective contribution to the pathology's dynamics is poorly understood. We now directly compare *in vivo* the spatiotemporal bioactivity of PBS soluble tau oligomers (hereby referred to as high molecular weight tau or HMW) and sarkosyl insoluble tau fibrils (SARK) derived from the same AD brain. **Methods:** HMW and SARK tau were both extracted from the parietal cortex of a Braak V AD subject. Their bioactivity was monitored in hTau mice expressing non-mutant human tau on a mouse tau null background. Mice were bilaterally injected into the dorsal hippocampus and sacrificed 1 day, 3

days, 1 week, 2.5 weeks, 1 month or 3 months after injection. The hippocampus and projection sites, e.g. entorhinal cortex, were analyzed by histology as well as by biochemistry and FRET-based *in vitro* seeding assays and data corrected to PBS-injected littermates. **Results**: *In vitro* seeding data on hippocampal homogenates show the progressive disappearance of seed-competent tau by 1 week and its return starting from 1 month after injection in parallel to the appearance of AT8-positive pyramidal neurons in both injection groups. In the entorhinal cortex, only HMW tau-injected animals start presenting seed-competency together with AT8-positive cells as early as 1 month after injection suggesting faster spreading of oligomeric than fibrillar tau species. Interestingly, newly formed tau seeds seem to replicate initial seeds as soluble seed-competent tau species are present in both HMW and SARK-injected mice but only SARK-injection triggers seed-competent sarkosyl-insoluble tau formation. **Conclusions:** Our data confirm that both HMW and SARK tau fractions contain analogous conformations to promote seeding yet reveal differential kinetics implying different contributions of these tau species to AD pathology. In addition, we show, *in vivo*, the replication of injected tau seeds characteristics, in favor of the prion-like hypothesis.

Abstract: *Background:* Spouses of Alzheimer's disease (AD) patients are at a higher risk of developing incidental dementia. However, the causes and underlying mechanism of this clinical observation remain largely unknown. One possible explanation is linked to microbiota dysbiosis, a condition that has been associated with AD. However, it remains unclear whether gut microbiota dysbiosis can be transmitted from AD individuals to non-AD individuals and contribute to the development of AD pathogenesis and cognitive impairment. *Method:* We, therefore, set out to perform both animal studies and clinical investigation by co-housing wild-type mice and AD transgenic mice, analyzing microbiota via 16S rRNA gene sequencing, measuring short chain fatty acid amounts, and employing behavioral test, mass spectrometry, site-mutations and other methods. *Result:* The present study revealed that co-housing between wild-type mice and AD transgenic mice or administrating feces of AD transgenic mice to wild-type mice resulted in AD-associated gut microbiota dysbiosis, Tau phosphorylation, and cognitive impairment in the wild-type mice. Gavage with Lactobacillus and Bifidobacterium restored these changes in the wild-type mice. The oral and gut microbiota of AD patient partners resembled that of AD patients but differed from healthy controls, indicating the transmission of microbiota. The underlying mechanism of these findings includes that the butyric acid-mediated acetylation of GSK3β at lysine 15 regulated its phosphorylation at serine 9, consequently impacting Tau phosphorylation. *Conclusion:* Pending confirmative studies, these results provide insight into a potential link between the transmission of AD-associated microbiota dysbiosis and development of cognitive impairment, which underscore the need for further research in this area.

Title: Single-molecule protein analysis to explore Tau proteoform heterogeneity

Authors: S. GUHA[1], S. TAN[1], J. JOLY[1], R. WANG[1], B. NORTMAN[1], T. GILLIES[1], V. BUDAMAGUNTA[1], J. ROBINSON[1], T. RINKER[1], J. SHERMAN[1], A. ELLAHI[1], T. WEIDERHOLD[2], D. S. KIRKPATRICK[3], J. LIPKA[4], T. WENDORFF[4], N. J. PANDYA[4], A. ROHOU[4], ***G. KAPP**[1], P. MALLICK[1];

Abstract: Tau protein is modified by both mRNA transcript splicing and post-translational modification with a range of modifications (phosphorylation, acetylation, ubiquitination, and many others). The populations of specific Tau splicing variants and specific post-translational modifications have been linked to Alzheimer's disease and disease progression. However, the diversity of different Tau isoforms (proteoforms) that exists in a human sample, resulting from splicing and modification, is underexplored due to the difficulty of linking multiple modifications to a single protein molecule. It is possible to address this difficulty with analytical techniques that operate at the single-molecule level, without digesting the protein into peptide fragments. We describe a new analytical platform that leverages a set of splicing-specific and modification-specific affinity reagents to probe Tau proteins at the single-molecule level. With this single-molecule resolution, the landscape of Tau proteoforms can be investigated and specific patterns of modifications can be identified in Alzheimer's samples. The same single-molecule platform can also be used to analyze the entire set of proteins (the full proteome) in a sample using Protein Identification by Short-epitope Mapping (PrISM), which leverages proprietary multi-affinity probes designed to recognize short epitopes and a machine learning algorithm that decodes binding of hundreds of multi-affinity probes into protein quantifications. We used this new single-molecule analysis platform that combines Tau antibodies with novel instrumentation, single-molecule biochemistry, and machine learning bioinformatics to enable deep proteoform analysis. We first demonstrated that a small set of antibodies can define the combinations of modifications that are seen in both normal, healthy samples and those linked with Alzheimer's disease. Initial validation was performed with defined mixtures of recombinant proteins. Then the platform was used to analyze the Tau proteoform landscape in Tau protein enriched from induced pluripotent stem cell (iPSC)-derived neurons. Finally, the diverse

proteoform landscape of Tau in human samples, healthy and diseased, was analyzed. We focused this initial work on splice isoforms and phosphorylation, but there are many additional modifications of the Tau protein. As additional modification-specific antibodies are added to increase the analytical set, the number of identifiable proteoforms grows exponentially, enabling greater resolution into single-molecule proteoforms, any one of which may be a more precise biomarker or better therapeutic target.

Title: Dnajb6 as a regulator of tau

Authors: *A. ESQUIVEL[1,2], S. HILL[1,2], L. BLAIR[1,2];
[1]Mol. Med., Univ. of South Florida, Tampa, FL; [2]USF Hlth. Byrd Alzheimer's Inst., Tampa, FL

Abstract: Tauopathies, such as Alzheimer’s Disease (AD), are a group of progressive neurodegenerative diseases marked by pathological tau. Disease severity and progression of these diseases can be linked to the pathological accumulation of tau. Recent evidence has demonstrated the prion-like properties of tau, where pathological tau templates the misfolding of native tau and propagates through synaptically connected regions of the brain. Molecular chaperones, a diverse set of proteins responsible for proteostasis, become dysregulated in AD and other tauopathies and are involved in normal and pathological tau processing. Initially, we performed an unbiased screen on approximately 60 molecular chaperones (n=2 biological replicates), across 6 different major chaperone families that identified the Hsp40s, or DnaJs, as a family enriched in regulators of tau. DnaJA2, DnaJB1, and DnaJB6 were found to significantly decrease tau seeding and their overexpression in cellular models of tau reduced intracellular tau levels. Follow up knockdown assays indicate that levels of DnaJB1 and DnaJB6 inversely correlate with tau levels. DnaJB6 was particularly potent in a more aggressive cellular model of tauopathy and was found to coimmunoprecipitate with tau. Additionally, DnaJB6 levels are decreased in PS19 mice. Additional studies are underway to identify the impact of DnaJB6 on tau *in vivo*. Overall, our data identify a role for DnaJB6 in regulating tau and support a number of studies that provide evidence for DnaJB6 as a powerful antagonist of amyloidogenic proteins.

Title: Igf1r interacts with β arrestins and translocates into nucleus in Alzheimer's disease

Authors: *P. SENGUPTA, D. MUKHOPADHYAY;
Biophysics & Structural Genomics, Saha Inst. of Nuclear Physics, KOLKATA, India

Abstract: The IGF1R signaling cascade forms the crux of this study due to its importance in Alzheimer's Disease (AD), crosstalk possibilities and regulatory mechanisms. IGF1R expression significantly increases in AD and several studies have shown its ablation reverses cognitive impairment. We begin our exploration by monitoring β-arrestins due to IGF1R's cytoplasmic βarr1/2 binding domain which has not been investigated in neurodegenerative scenarios before. We observed a significant upregulation in β-arr1 and downregulation in β-arr2 in SHSY5Y cells in AD like conditions (AICD is overexpressed along with extracellular introduction of Aβ) (n=4). An increase in interaction between IGF1R and β-arr1 leads to sustained MAPK signaling which is co-related with prior studies. We further probed the cAMP production (due to IGF1R's hybrid GPCR nature) through cAMP Glo assay (n=8) using various combinations of overexpression and silencing of related genes, and observed a marked reduction in cAMP in IGF1R overexpression experiments concurrent with AD like conditions. Incidentally, IGF1R-deficient cells showed relative increase in cAMP production, which further indicates that in AD, cAMP regulation is impacted by IGF1R. Furthermore, treatment with sumoylation inhibitors and phosphorylation inhibitors which potentially blocks IGF1R translocation into the nucleus, leads to increase in cAMP levels. We performed live imaging to visualize the trafficking of GFP tagged IGF1R when treated with Aβ and found that it eventually translocated to the nucleus. To ascertain that this enhanced nuclear shuttling was not an artefact of neuroblastoma, a differentiated neuronal model was generated and the cholinergic neuronal lineage was validated through an Acetylcholine assay. In the differentiated model, we further observed nuclear IGF1R in a greater number of cells treated with Aβ as compared to control sets, which was validated with fractionation studies. The study was also performed on B6C3-Tg(/APPswe,PSEN1dE9/)85Dbo/J mice brains against control brain tissue and more nuclear specs were found there as well. For the first time an altered distribution of IGF1R in AD was quantified and is gradually being understood. Thus, to conclude IGF1R interacts with β arrestin1, hyperactivates MAPK pathways at the membrane after vescicle formation, upon sumoylation travels into the nucleus in AD to regulate key pathways involved in cognition.

Title: Rumex japonicus Houtt. alleviates Parkinson's disease by inhibiting mitochondrial disfunction and colonic damage in 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP)-induced C57BL/6N mice

Authors: *H.-Y. KIM;
Pusan Natl. Univ., Yangsan-si, Korea, Republic of

Abstract: Parkinson's disease (PD) is common neurodegenerative disease in elderly people in the world. *Rumex japonicus* Houtt. (RJ) has been used to treat several gastrointestinal and inflammatory diseases in Korea. We recently confirmed the protective effect of RJ in colitis and colorectal cancer in mice and the neuroprotective effect of RJ in an in vitro PD model. In this study, we investigated the effects of RJ in the mitochondria of brain and the colon in MPTP-induced PD mice. C57BL/6N male mice (10-week old) were injected with MPTP (30 mg/kg, i. p.) for 5 days and treated with low or high dose of RJ (p. o.) for 14 days. RJ inhibited decrease of loss of tyrosine hydroxylase-positive cells and the mitochondrial protein expressions such as PINK1, Parkin and DJ-1 in the substantia nigra (SN). In addition, RJ reduced mitochondria-dependent apoptosis, increase of α-synuclein and inflammatory factors such as LPS, IL-1β and TNF-α in both the SN and the colon. Moreover, RJ suppressed collapse of tight junction (TJ) barrier in the colon and blood-brain barrier in the SN by regulating the expression of TJs (ZO-1, occluding and claudin-5) and/or adherens junction protein (VE-cadherin). Therefore, RJ alleviates MPTP-induced PD by protecting normal function of mitochondria and TJs in the brain and the colon.

Title: Parkinson's disease relevant pathological features are manifested in male Pink1/Parkin deficient rats.

Authors: B. LAMBERTY, L. ESTRELLA, J. MATTINGLY, K. EMANUEL, A. TREASE, S. TOTUSEK, L. SHELDON, J. GEORGE, M. ALMIKHLAFI, T. FARMER, ***K. STAUCH**; Univ. of Nebraska Med. Ctr., Omaha, NE

Abstract: Animal disease models are important for neuroscience experimentation and in the study of neurodegenerative disorders. The major neurodegenerative disorder leading to motor impairments is Parkinson’s disease (PD). The identification of hereditary forms of PD uncovered gene mutations and variants, such as loss-of-function mutations in PTEN-induced putative kinase 1 (Pink1) and the E3 ubiquitin ligase Parkin, two proteins involved in mitochondrial quality control, that could be harnessed to create animal models. However, to date, such models have not reproducibly recapitulated major aspects of the disease. Here, we describe the generation and phenotypic characterization of a combined Pink1/Parkin double knockout (dKO) rat, which reproducibly exhibits PD-relevant abnormalities, particularly in male animals. Motor dysfunction in Pink1/Parkin dKO rats was characterized by gait abnormalities and decreased rearing frequency, the latter of which was responsive to levodopa treatment. Pink1/Parkin dKO rats exhibited elevated plasma levels of neurofilament light chain and significant loss of tyrosine hydroxylase expression in the substantia nigra pars compacta (SNpc). Glial cell activation was also observed in the SNpc. Pink1/Parkin dKO rats showed elevated plasma and reduced cerebrospinal levels of alpha-synuclein as well as the presence of alpha-synuclein aggregates in the striatum. Further, the profile of circulating lymphocytes was altered, as elevated CD3+CD4+ T cells and reduced CD3+CD8+ T cells in Pink1/Parkin dKO rats were found. This coincided with mitochondrial dysfunction and infiltration of CD3+ T cells in the striatum. Altogether, the Pink1/Parkin dKO rats exhibited phenotypes similar to what is seen with PD patients, thus highlighting the suitability of this model for mechanistic studies of the role of Pink1 and Parkin in PD pathogenesis and as therapeutic targets.

Title: Assessing anxiety and depression comorbidities in a primate model of Parkinson's Disease

Authors: A. SADOUN[1], Q. LI[2], E. BEZARD[3], ***E. PIOLI**[4];
[1]Motac, Bordeaux, France; [2]Motac Neurosci., Motac Neurosci., Beijing, China; [3]Inst. of Neurodegenerative Dis., Bordeaux, France; [4]MOTAC, Bordeaux, France

Abstract: Parkinson's disease (PD), in which there is widespread degeneration of the catecholamine system, is characterised by both motor and non-motor symptoms, such as impairment in cognitive performance. Anxiety and depression are also known comorbidities associated with Parkinson's disease. The study aimed to examine the anxiety/depression-like phenotype in the gold standard primate model of motor symptoms in PD, the so-called 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP) macaque model. The cognitive performance was also evaluated. The anxiety / depression-like phenotype was evaluated in 11 MPTP and 6 normal macaques (*Macaca mulatta*) by ethological scan in the Human Intruder Test. The cognitive performances were assessed by the delayed matching to sample (DMTS) and the Variable Delayed Response (VDR) tasks from the Monkey CANTAB battery.The MPTP monkeys presented a passive reaction toward challenging stimuli during the intruder test, which is a sign of depressive-like individuals compared to normal animals. The MPTP monkeys showed longer learning latencies and decreased performance in the long delays in DMTS and VDR tasks. The rich behavioural repertoire of non-human primates makes them ideal translational models in which neuropsychiatric conditions can be studied. The present results that the MPTP-treated macaque replicates some depressive-like behaviour associated with PD.

Abstract: Parkinson's disease (PD) is now understood to be a multifactorial disorder involving genetic and environmental risk factors. Increasing research efforts have been made to understand how genetic and environmental factors may act in concert to impair homeostasis and elevate risk. Inflammation could be one unifying biological factor that could weaken homeostasis affecting neurodegenerative disease risk, onset, and progression. In this study, we created a double-hit animal model of PD to investigate whether overexpression of α-synuclein and inflammation accelerate the progression of PD neurodegeneration. Two months old rats overexpressing human α-synuclein (Snca) and *wild-type* littermates were intraperitoneally injected with a single dose of lipopolysaccharide (LPS, 5mg/kg) or with saline (SAL). Three months after injection, we evaluated nigrostriatal dopaminergic neurodegeneration, α-synuclein pathology, and neuroinflammation by immunohistochemistry, immunofluorescence, constant potential amperometry, and high dimensional flow cytometry analyses. We also investigated associated general locomotor and depressive-like behavior dysfunctions. The acute injection of LPS in rats caused long-lasting neuroinflammation in the *substantia nigra* (SN) and the striatum (STR). Microglia showed morphological changes, with less complex and shorter branching and increased expression of M1 activation markers. In LPS-Snca rats, macrophage and T-lymphocytes infiltration was increased into the SN and the STR. Phospho-S129 α-synuclein appeared qualitatively more inside microglial cell somas in the SN and the STR of LPS-Snca rats than in the control groups. In this context, more than 40% of nigral TH+ neurons were lost in LPS Snca rats, and these cells showed altered dendritic arborization that branches from the SN *pars compacta* (SNpc) towards *pars reticulata*. The dopaminergic neuronal loss was associated with a slight reduction in the STR-evoked dopamine release in LPS-Snca rats. However, no significant decrease in the TH+ fibers was observed in LPS-treated compared to saline-treated rats, nor behavioral changes in general locomotor activity, motor balance, and coordination. Interestingly, LPS-Snca rats preferred the 1% sucrose solution, with higher sucrose intake than the control groups. Our two-hit animal model involving a genetic mutation and an inflammatory factor reproduced some key pathogenic PD features and, most notably, accelerated the progression of PD neurodegeneration in the SNpc. Thus, it could be a valid animal model to study the mechanisms whereby α-synuclein and inflammation interactions mediate neurodegeneration in PD.

Title: Nigral cell loss and neuroinflammation following a lesion to the locus coerulean noradrenergic system

Authors: *F. SHIMSHEK SHENER[1], E. HENRIKSSON[2], R. EL-HABTA[2], M. BLYBERG[2], D. PAPOVA[2], A. VIREL[2], S. AF BJERKEN[2];

Abstract: Parkinson's disease is characterized by loss of dopaminergic cells in the substantia nigra, as well as loss of noradrenergic neurons in the locus coeruleus. Neuroinflammation and microglia are thought to contribute to the progression of Parkinson's disease. Noradrenaline, aside from its neurotransmissive role, exerts anti-inflammatory effects and is hypothesized to act as a protector for dopaminergic cells in the substantia nigra.
We have recently using the N-(2-chloroethyl)-N-ethyl-2-bromobenzylamine (DSP4) toxin-based rat model of noradrenergic denervation demonstrated a direct link between locus coerulean denervation and long-term loss of dopaminergic cells in the substantia nigra. In addition, we observed increased neuroinflammation, characterized by microglial activation, over the substantia nigra. To investigate the immunosuppressive and protective effects of noradrenaline further, we have now administered lipopolysaccharide (LPS) to DSP4-treated rats and evaluated the neuroinflammatory and degenerative process using cytokine arrays, ELISA, and stereological cell counting.
Post-mortem cell counting showed a significant reduction in tyrosine hydroxylase (TH)-positive cells in the substantia nigra of subjects treated with DSP4 or LPS compared to controls at the 6-month time point. In addition, additional dopaminergic degeneration was seen in the double treated subjects, DSP4+LPS compared to LPS only. Analysis of brain tissue revealed alterations in pro-inflammatory and anti-inflammatory cytokines, emphasizing the importance of the noradrenergic system as a modulator. Motor function and coordination assessment using the RotaRod test demonstrated a significant decrease in subjects treated with DSP4 or LPS compared to controls at both the 3-month and 6-month time points.
Our findings suggest that the substantia nigra is more susceptible to LPS-induced neuroinflammation in the absence of protection from an intact noradrenergic system.

Title: Alterations in mitochondrial bioenergetics and increased phosphorylated alpha-synuclein in older mice lacking ATP13A2

Authors: *K. M. CROUCHER[1,2], J. K. LEPP[1], S. M. FLEMING[1];
[1]Pharmaceut. Sci., Northeast Ohio Med. Univ., Rootstown, OH; [2]Biomed. Sci. Grad. Program, Kent State Univ., Kent, OH

Abstract: ATP13A2 is a lysosomal protein involved in polyamine transport. Loss of function mutations in ATP13A2 have been linked to the neurodegenerative disorders Parkinson's disease (PD), Kufor-Rakeb Syndrome, Neuronal Ceroid Lipofuscinosis, and Hereditary Spastic Paraplegia. In vitro studies show loss of ATP13A2 impairs mitochondrial function and may contribute to the neurodegeneration found in these disorders. The present study sought to investigate the effect of loss of ATP13A2 function on mitochondrial function during aging in mice. In addition, given the link with PD, pathological phosphorylated alpha-synuclein was measured within the mitochondrial fraction. Male and female wildtype (WT), heterozygous (Het), and *Atp13a2* knockout (KO) mice at 3, 12, and 18 months of age were included in the study. Mitochondrial bioenergetics was measured in the prefrontal cortex, striatum, ventral midbrain, and cerebellum. Fresh mitochondrial fractions from each region were isolated and the oxygen consumption rate (OCR) of mitochondria (5ug/well) was measured in triplicate using the Seahorse XFp Flux Analyzer. OCR was measured in response to sequential injections of the substrates ADP, Oligomycin, FCCP, and Rotenone/Antimycin A in the presence of energetic substrates (glutamate, succinate, and malate). Mitochondrial bioenergetics analysis revealed a significant decrease in basal respiration in the striatum in 12 and 18 month KO mice compared to Het mice at the same age. At 12 months of age striatal OCR in KO mice was significantly reduced in response to oligomycin, FCCP, and Rotenone/Antimycin A. Further, phosphorylated alpha-synuclein in striatal mitochondria was significantly increased in 18 month KO mice. Overall, these data indicate loss of ATP13A2 in vivo disrupts mitochondrial function and promotes pathological alpha-synuclein within the striatum during aging.

Title: Characterization of a novel mouse model hLRRK2-G2019S for Parkinson's disease

Authors: *B. HUANG[1], X. LI[2], Z. YUE[3];
[1]Icahn Sch. Of Med. at Mount Sinai, New York, NY; [2]Icahn Sch. of Med. at Mount Sinai, New York, NY; [3]1470 Madison Ave, Mount Sinai Sch. of Med. Dept. of Neurol., New York, NY

Abstract: Background: Leucine-rich repeat kinase 2 (LRRK2) variant G2019S is found in both familial and sporadic Parkinson's disease (PD). Many LRRK2 G2019S mouse models have been created to investigate pathogenic mechanism of PD but have yet to show a robust Parkinson's disease phenotype. While the sequence difference between human and mouse LRRK2 (~83% homologous) may contribute to the lack of PD related symptoms, the manifestation of neuropathologies even with the expression of human LRRK2 variant could be tempered by the endogenous rodent Lrrk2. Furthermore, recent evidence from multiple reports (including ours) have shown a significant enrichment of LRRK2 expression in microglia from human tissues, yet mouse models were not able to capture that. Thus, distinct cell type expression patterns of LRRK2 between mouse and human could also underlie the difference. Therefore, we propose to establish a new mouse model of humanized LRRK2-G2019S (*h*LRRK2^{G2019S}), which may allow for better PD modeling while limiting the competing effects between human and endogenous LRRK2.Methods: We established a novel model by replacing mouse *lrrk2* with the human genomic sequence of LRRK2-G2019S. We confirmed the expression of human LRRK2 variant and lack of mouse LRRK2 in this model. Early characterizations of this model focused on male mice because of the increased severity of PD in males. We performed immunohistochemistry analysis of the kidney and brain slices obtained from *h*LRRK2^{G2019S}, Lrrk2 G2019S Knock-In (KI), LRRK2 KO, and WT mice and compared the pathologies among the mice with different genotypes. Results: In contrast to control and Lrrk2-G2019S KI mice, *h*LRRK2^{G2019S} mice show remarkable renal pathology associated with autophagy defects and an increase of pS129 α-synuclein levels. We also detected an increase of phosphorylation of rab10 and rab12 in *h*LRRK2^{G2019S} brains, compared to the control mice. Conclusions: Our ongoing study shows that the humanized LRRK2 G2019S model shows distinct pathology in peripheral tissues from the previously reported mouse KI LRRK2 G2019S and transgenic mice expressing human LRRK2 variants. We are currently investigating the humanized LRRK2 PD model in the brain and multiple peripheral tissues. Our study is expected to show better tools to understand PD and investigate peripheral molecular biomarkers due to G2019S dependent kidney dysfunction.

Title: Effect of Combinations of Commonly-Used Pesticides on Organismal Toxicity in Drosophila

Authors: *A. ATHEBY, F. ABDUL-RAHMAN, H. LAWAL;
Delaware State Univ., Dover, DE

Abstract: Parkinson's Disease (PD) is a debilitating, progressive neurodegenerative disease characterized in part by the loss of dopaminergic neurons in the substantia nigra pars compacta. Epidemiological studies have established that exposure to certain pesticides and herbicides increase an individual's likelihood of developing PD. Although the full catalog of pesticides that pose risks for PD is not currently known, some potentially toxic compounds are commonly used for agricultural or gardening purposes, and may be purchased at local stores. The objective of this study therefore, was to determine whether different combinations of commercially-available pesticides and herbicides have either a synergistic or additive effect on toxicity in *Drosophila*. We first established a dose response curve in the following pesticides: acephate, atrazine, and diuron. We then exposed *Drosophila* to different combinations of the compounds at a concentration at which each alone was minimally toxic. We performed survival and locomotion ability analyses on each experimental group. We demonstrate that combinations involving atrazine and diuron show strong decreases in survival that were greater than each single pesticide alone. Moreover, we find that atrazine, which has been implicated in Parkinson's disease etiology in work by others, shows elevated toxicity. We also present data on our analysis of the effects of these compounds on reactive oxygen species generation and measures of neurotoxicity. Together, our data suggest that exposure to combinations of commonly-used pesticides such as atrazine and diuron may elevate susceptibility to environment toxins, including those that are implicated in PD.

Title: Sex differences in novel transgenic mice with constitutively upregulated nicotinic acetylcholine receptors: implications for parkinson's disease

Authors: *G. PANDEY[1], R. SRINIVASAN[2];
[1]Texas A&M Univ. Neurosci. Inst. For Neurosci., Bryan, TX; [2]Texas A&M Univ., College Station, TX

Abstract: Sex Differences in Novel Transgenic Mice with Constitutively Upregulated Nicotinic Acetylcholine Receptors: Implications for Parkinson's Disease
Gauri Pandey[1,2*], Sara M. Zarate[1], and Rahul Srinivasan[1,21]Department of Neuroscience and Experimental Therapeutics, Texas A&M School of Medicine, Bryan, TX, USA[2]Texas A&M Institute for Neuroscience, Texas A&M University, College Station, TX, USA
Parkinson's disease (PD) incidence rates predict a worldwide pandemic that will affect over 12 million people by 2040, underscoring the urgent need for neuroprotective drugs. Unfortunately, no neuroprotective drugs are currently available, and most proposed neuroprotective drugs failed clinical trials because PD is produced by a range of insults not replicated in any one animal model. For this reason, we focus on hyperactivated endoplasmic reticulum (ER) stress, a convergent apoptotic mechanism for multiple PD-related toxicities. Nicotine reduces PD risk; however, nicotine concentrations in tobacco users cannot activate neuronal nicotinic acetylcholine receptors (nAChRs), making this an unlikely mechanism for neuroprotection of dopaminergic (DA) neurons. We have previously shown that nanomolar concentrations of the nicotinic ligand cytisine rapidly chaperone β2-subunit-containing (β2*) nAChRs out of the ER. This directly reduces the ER stress response, which is critical for neuroprotection. To test this hypothesis, we created a novel transgenic mouse line named β2-mutant, with enhanced ER export of β2* nAChRs. Surprisingly, β2-mutant mice demonstrate significant increases in Sec24D ER exit sites (ERES) within substantia nigra pars compacta (SNc) DA neurons in only female but not male mice. We also induced parkinsonism in mice by unilateral injection of 6-OHDA in the dorsolateral striatum. Interestingly, the β2-mutations reduced apomorphine rotations only in female mice. This reduction corresponds with a decrease in the loss of TH+ neurons. Our data suggests the β2-mutations exert neuroprotection only in female mice. We are also testing the consequences of upregulating β2* nAChRs on striatal dopamine release using the optogenetic sensor GRABDA.

Title: Exercise boosts dopamine release in the new parkinR275W mouse model of autosomal recessive juvenile parkinsonism

Authors: *L. ZANETTI[1], G. BASTIOLI[1], J. C. PATEL[2], M. REGONI[1], F. VALTORTA[1], J. SASSONE[1], M. E. RICE[2];
[1]Vita-Salute San Raffaele Univ., Milano, Italy; [2]NYU Grossman Sch. of Med., New York, NY

Abstract: Mutations in PARK2 gene cause Autosomal recessive juvenile parkinsonism (ARJP), an early onset familial form of Parkinson's disease characterized by early and severe dopamine (DA) neurons loss in substantia nigra pars compacta (SNc). At the moment, no neuroprotective approach exists, and a symptomatic therapy only is available. Complementing drug treatments, physical exercise has been shown to improve motor performance in individuals living with PD. However, underlying mechanisms are not yet understood. Our previous study showed that voluntary exercise for 30 days leads to an increase in evoked DA release throughout the striatum in WT mice. Based on this observation, we wanted to test the effects of exercise on DA release in pathological conditions. To fulfill this aim, we used our new, innovative mechanistic mouse model of *PARK2*-related ARJP. This model was created by taking advantage of CRISPR/Cas9 genome editing to insert the PARKIN R275W missense mutation, found with highest allelic frequency in *PARK2* patients. Characterization of this model showed it recapitulates major Parkinson's disease hallmarks, such as age-dependent loss of DA neurons in the SNc, progressive motor impairment, and decrease of DA content. Using the method of fast-scan cyclic voltammetry (FSCV), we further characterized the mouse model assessing the electrically-evoked DA release in striata slices before and after an exercise protocol. Data suggested a DA release impairment in non-runner, 6-months-old R275W mice, which worsened in aged (12-months-old) mice. Subsequently, we analyzed the effect of 30-days voluntary running protocol in 12-months old mice: we observed an increase in stimulus-evoked DA release in the striatum as well as an amelioration of motor phenotype. These findings highlight a pivotal role of exercise in treatment of PD by boosting DA release in the brain and shed light on the importance for research to learn underlying mechanistic insights.

Abstract: The connection between neurons and T lymphocytes, particularly the role of T helper 17 (Th17) CD4 lymphocytes, has garnered attention in the study of Parkinson's disease (PD) and potential therapeutic strategies for neurodegenerative diseases. It has been reported that Th17 lymphocytes can mediate neuronal cell death in in vitro models. However, the mechanism underlying the progression and persistence of Th17 lymphocyte infiltration into the brain following the injection of 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP) in a non-human primate (NHP) model of PD remains unknown. This study aimed to investigate the long-term infiltration of Th1, Th2, and Th17 cells into the substantia nigra (SN) during the progression of PD in an NHP model after MPTP administration. The study examined the acute, sub-acute, and chronic phases of PD to understand the progression and persistence of Th1, Th2, and Th17 cell infiltration. The acute phase infiltration of Th17 cell coincides with the concurrent death of dopaminergic neurons, in contrast to the delayed infiltration of Th1 and Th2 cells. The findings of this study shed light on the infiltration progression of T lymphocytes in the NHP model of PD and provide novel insights into the pathogenesis of PD. Understanding the role of Th17 cells and their infiltration patterns in PD may contribute to the development of new therapeutic approaches for the treatment of this neurodegenerative disease.

Title: An Expression based approach to assessing a Parkinson’s Disease-like state in 6-OHDA exposed Zebrafish larvae.

Authors: *A. ROMERO, M. S. EL-HALAWANY, A. K. HAMOUDA, B. R. BILL;
Univ. of Texas, Tyler, Tyler, TX

Abstract: Parkinson’s disease (PD) is a neurodegenerative disorder characterized by the loss of A-9 midbrain dopaminergic neurons in the substantia nigra pars compacta. The disorder is clinically characterized by motor symptoms including but not limited to tremor at rest, rigidity,

akinesia , and postural instability affecting the quality of life for over 10 million people worldwide. The neurotoxin 6-hydroxydopamine (6-OHDA) is a well-established methodology to chemically induce a PD-like state in animal models by damaging dopaminergic neurons. In our effort to optimize a 6-OHDA-based PD-like model in zebrafish for drug screening, we used an RNA expression-based assessment to determine optimal 6-OHDA-exposure conditions (zebrafish age at time of exposure, 6-OHDA concentration, duration of exposure). We used dopaminergic neuronal markers (e.g., *th*), PD-related genes (e.g., *pink1*), reactive oxygen species pathway genes (e.g., *sod2*) as quantitative molecular endpoints. Our preliminary results established a workflow that consists of 24 hours of 6-OHDA exposure (10-30 µM) during 3-4 day post fertilization in the presence of 0.2% ascorbic acid, 0.23 ppm methylene blue, and buffered with 40 mM HEPES (pH 7.4). RT-qPCR confirmed a statistically significant reduction in *th* and *pink1* genes expression and statistically significant upregulation of *sod2* gene expression without apparent changes in the expression of control housekeeping genes *hprt1* in zebrafish larvae treated with 30 µM 6-OHDA using the above workflow. Exposure to 30 µM 6-OHDA using this workflow resulted in no morphological or developmental differences in surviving fish as compared to control, however, 30 µM 6-OHDA exposure was associated with ~50% lethality. Further work is ongoing to improve the workflow to reduce lethality while keeping the desired quantitative molecular endpoints of selective damage in dopaminergic neuron.

Abstract: Throughout the past few years, the field of CNS gene therapy has witnessed a continuous race for the development of novel AAV capsid variants that can bypass the BBB upon systemic delivery. Several different options fulfilling this unmet need have been made available recently, these options opening a broad range of applications for both disease-modeling purposes as well as for therapeutic uses. Among existing possibilities, Voyager Therapeutics (Cambridge, MA) recently developed several AAV9 capsid variants by taking advantage of a RNA-driven screen platform known as TRACER (Tropism Redirection of AAV by Cell-type-specific Expression of RNA; see PMID: 33553485). This approach resulted in the characterization of ten individual variants showing up to 400-fold higher brain transduction over AAV9 following systemic administration. Here we took advantage of the AAV9-P31 capsid variant for modeling Parkinson’s disease in naïve, non-transgenic mice. To this aim, AAV9-P31 encoding the human tyrosinase gene (the enzymatic precursor of neuromelanin), was delivered in the retro-ocular plexus of C57BL/6 mice. One cohort of animals was euthanized four weeks post-AAV delivery, whereas another cohort was sacrificed with a follow-up time of 16 weeks. In all animals injected with AAV9-P31-hTyr, the conducted histological processing revealed an specific, time-dependent pigmentation of dopaminergic neurons located in the substantia nigra pars compacta and the ventral tegmental area, together with a somehow weaker pigmentation of noradrenergic neurons in the locus coeruleus. Moreover, preliminary results suggested the presence of intracytoplasmic inclusions positive for traditional markers of Lewy body pathology such as P62 and alpha-synuclein in pigmented neurons. Bearing in mind the well-known reciprocal association between the incidence of melanoma and Parkinson’s disease, the conducted approach enabled the development of a novel pre-clinical mice model of Parkinson’s disease mimicking the known neuropathological hallmarks of this disorder with unprecedented accuracy. By going this way, it is also worth noting that intraparenchymal delivery of AAVs will no longer be required, an issue obviously broadening the gene therapy field by allowing the implementation of a whole range of novel therapeutic strategies.

Title: Znf746 undergoes liquid-liquid phase separation and poly(adp-ribose) mediated solidification

Authors: *S. PARK;
Sungkyunkwan Univ., Suwon-si, Korea, Republic of

Abstract: ZNF746 was identified as a parkin-interacting substrate (PARIS). To understand the pathophysiological properties of PARIS, we examined PARIS’s biophysical properties, showing that PARIS undergoes liquid-liquid phase separation (LLPS) and amorphous solid formation. LLPS of PARIS required the N-terminal low complexity domain 1 (LCD1), whereas the prion-like domain (PrLD, GGGGSGSGGGGGGS) at C-terminus was critical for the liquid to solid phase transition. In addition, we observed that poly (ADP-ribose) (PAR) strongly binds to the C-terminus of PARIS near the PrLD, accelerating its LLPS and solidification. MNNG-induced PAR formation led to PARIS oligomerization in human iPSC-derived dopaminergic neurons that was prevented by the PARP inhibitor, ABT-888. Furthermore, SDS-resistant PARIS species were observed in the substantia nigra (SN) of aged mice overexpressing wild-type PARIS, but not with a PAR binding-deficient PARIS mutant. PARIS solidification was also found in the SN of α-synuclein preformed fibril (α-syn PFF) injected mice and adult conditional knockout (KO) of parkin, but not in that of PARP1 KO mice injected with α-syn PFF. Herein, we demonstrate that PARIS undergoes LLPS and PAR-mediated solidification in PD models.

Title: SARS-CoV-2 infection enhances susceptibility in oxidative stress-induced and genetic models of Parkinson's Disease

Authors: *D. CHATTERJEE, T. RODRIGUEZ, K. CROWTHER, R. J. SMEYNE;
Farber Inst. of Neurosci. Thomas Jefferson Univ., Philadelphia, PA

Abstract: Parkinson’s disease (PD) is a neurodegenerative disease characterized by the loss of dopaminergic (DA) neurons in the SNpc of the midbrain, inflammation, and the formation of insoluble aggregates of phosphorylated alpha-synuclein. Although its causes are multifactorial, viral infections, including influenza, have been associated with the development of parkinsonism

(e.g encephalitis lethargica associated with the 1918 Spanish flu pandemic). Given the similarities in systemic responses after infection with SARS-CoV-2 (COVID-19) to those reported after the 1918 Spanish flu pandemic, we investigated, using mouse models of viral infection, whether SARS-CoV-2 infection would have the potential to elicit a similar neurological syndrome. In this study we examined if prior infection with SARS-CoV-2 increased midbrain pathology in two models of experimental parkinsonism: 1) administration of a subacute level of 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP), and 2) mice carrying a G2019S mutation in the LRRK2 gene. Two strains of SARS-CoV-2 (WA-1 and omicron) were used. For MPTP experiments, C57BL/6J mice expressing the human ACE2 receptor (k18-hACE2) were infected with SARS-CoV-2 to induce moderate disease. After 38 days of recovery, mice were administered a subtoxic dose of MPTP and euthanized 7 days later. To examine effects in a familial mode, k18-hACE2 mice crossed with G2019S LRRK2 KI mice and were infected with the same titer of virus and euthanized 30 days later. Subsequent neuroinflammation and SNpc DA neuron loss were determined using stereology. Mice infected with SARS-CoV-2 or MPTP alone showed no significant SNpc DA neuron loss. However, in mice infected with SARS-CoV-2 (WA-1), MPTP induced a 23% or 19% greater loss of SNpc DA neurons than WA-1 alone or MPTP alone respectively ($p < 0.05$). Examination of microglial activation showed a significant increase in the number of activated microglia in the SNpc of the WA-1 + MPTP group compared with WA-1 or MPTP alone ($p < 0.01$). In k18-hACE2 X G2019S mice, WA-1 induced a 19% loss of SNpc DA neurons ($p < 0.01$), and a significant increase in the number of activated microglia ($p < 0.05$) compared to uninfected mice. Preliminary data shows that infection with the omicron variant similarly induces a 20% loss of SNpc neurons when exposed to MPTP, compared to omicron alone ($p<0.01$). Our observations have important implications for long-term public health, given the number of people who have survived a SARS-CoV-2 infection, as well as for future public policy regarding infection mitigation. Further, it will be critical to determine whether these observed effects are abrogated by vaccination or antiviral treatment.

Title: Abnormalities in Y-Maze Test in P+L Treated Parkinsonian Rats and its Protection with Oral Squalamine Treatment

Authors: *T. WHITE, V. PESHATTIWAR, C. SWAIN, K. LE, D. POKHAREL, T. SUBRAMANIAN;
Neurol., The Univ. of Toledo Col. of Med. and Life Sci., Toledo, OH

Abstract: Parkinson'sDisease (PD) is a chronic neurodegenerative condition with motor and non-motorclinical manifestations. One of the non-motor features that is under intenseinvestigation is cognitive decline. We previously reported a novel rat model ofPD that uses subthreshold doses of Paraquat (P) and Lectins (L) administeredorally to cause parkinsonism that simulates the environmental gut brainpathogenesis of PD with associated nigral synucleinopathy, levodopa responsiveparkinsonism and protection against PD via subdiaphragmatic vagotomy performedprior to P+L exposure. We have also reported in the past that squalamine, anatural bile salt derived from the dog fish shark when administered orallyprovides protection against parkinsonism. The Y-maze has been used extensivelyin animal models of PD to assess short-term memory. We hypothesized that animals with moresevere parkinsonian motor symptoms will exhibit a worse performance in theY-maze task as defined by spontaneous alternation. We tested this using threetreatment groups: no treatment (Normal), paraquat + lectin via oral gavage(P+L), paraquat + lectin and squalamine solution (P+L+S). Within the P+L group,animals exhibited varying degree of motor deficits as confirmed by our battery ofbehavioral tests. Twenty-fiveSprague Dawley rats were placed in a Y-Maze apparatus with an overheadautomated movement tracking system (AnyMaze). For five minutes, each rat'smovement was tracked and scored for their independent spontaneous alternation patternwith minimal distractions. The validity of the software's output was confirmedby manual scoring. Each spontaneous alternation was reported as a raw scorebased on the total of triads completed in each trial. One-way ANOVA confirmed asignificant difference ($p=0.02$) in spontaneous alternation and a valueapproaching significance ($p=0.090$) for the percent spontaneous alternationbetween treatment groups. Post-hoc analysis using student t-tests shows asignificant difference when comparing all three P+L subcategories to normalanimals. No significant difference was noted between P+L+S and normal animals.These preliminary results suggest that although motor deficits differed betweenanimals treated with P+L, the short-term memories of these animals were equallyaffected regardless of the extend of the motor deficits. When animals weretreated with oral squalamine, these cognitive deficits were not observed,suggesting that the observed phenomenon is linked to synucleinpathy.

Title: Cellular localization of Neurotrophin-3 in adult zebrafish brain and its role in Parkinson's Disease

Authors: *N. OMAR[1,2], J. MURTHY[2], S. TEOH[2];
[1]Universiti Sains Islam Malaysia, Nilai, Malaysia; [2]Universiti Kebangsaan Malaysia, Kuala Lumpur, Malaysia

Abstract: Background Neurotrophin-3 (NT3) is a class of neuroprotective growth factors that are secreted in the nervous system that induces the development, maintenance, and survival of a specific neuronal population. NT3 has been sparsely studied in a zebrafish model. This study aims to present the cellular localization of NT3 in adult zebrafish brains and investigate the role of NT3 in a Parkinson's Disease (PD) model. **Methodology** Localization of NT3 expression was conducted in zebrafish brains using *in situ* hybridization to identify the neurotrophin-3 (*ntf3)* mRNA followed by fluorescence immunohistochemistry (FIHC) to visualize the co-expression of *ntf3* mRNA in neuronal and glial markers. Following that, an assessment of NT3 expression was conducted in the zebrafish PD model using the quantitative polymerase chain reaction (qPCR) method, Enzyme-Linked Immunosorbent Assay (ELISA), and NT3 IHC to investigate the alteration in NT3 expression following the induction of PD in zebrafish. **Results and Discussion** The *ntf3* mRNA-expressing cells (hereafter refers to as NT3 cells) were identified over the olfactory bulb, telencephalon, diencephalon, mesencephalon, and in rhombencephalon of the zebrafish brains. This opens the emphasis on the role of NT3 in the central nervous system apart from the previously established role in the peripheral nerve. Double labeling with the glial (GFAP) and neuronal (HuC/D) markers showed 100% overlap with the neuronal marker however with less than 20% overlap with the glial marker. This is slightly different from other neurotrophins such as the brain-derived neurotrophic marker (BDNF) where glial cells were more pronounced in expressing the proteins. Double labeling using the FIHC method was conducted for the dopaminergic marker (tyrosine hydroxylase) as well which showed 80% overlap in the region of the posterior tuberculum of the diencephalon, which is the pathognomonic location of PD in zebrafish. The *ntf3* gene expression was significantly downregulated 20 times in the PD model (0.05±0.04) compared to the control group (p=0.003). ELISA assessment of zebrafish brain was coherently dropped in NT3 protein level in the PD model (3295.32±186.11; p=0.04). The NT3 IHC assessment showed a global reduction in the intensity of the NT3 staining in the tissue section of the PD model's brain compared to the control. **Conclusion** The NT3 is actively expressed in adult zebrafish brains and showed its potential role in the pathogenesis of PD. This could offer a possibility of NT3 as part of the potential treatment of PD.

Title: Increased Anxiety-Related Behaviors Following Dopamine Loss Alters Glutamate Synapses in the Medial Prefrontal Cortex in an Animal Model of Parkinson's Disease

Authors: C. MOORE[1], M. HELMS[1], M. A. NIPPER[2], L. WINFREY[1], D. FINN[1,3], ***C. K. MESHUL**[4,3];
[1]VA Med. Center/Portland, Portland, OR; [2]Behavioral Neurosci., Oregon Hlth. & Sci. Univ., Portland, OR; [3]Behavioral Neurosci., OHSU, Portland, OR; [4]VA Med. Ctr., Tigard, OR

Abstract: Anxiety is a prominent non-motor symptom of Parkinson's disease (PD). Changes in the B-spectrum recordings in PD patients of the pre-frontal cortex correlate with increased anxiety (de Hemptinne *et al.*, 2021). Loss of nigrostriatal dopamine (DA) has been resulted in a decrease in spine density in the medial prefrontal cortex (mPFC; Solis *et al.*, 2007), but no behavioral testing was carried out. We reported changes in glutamate synapses in the striatum and substantia nigra following DA loss (Meshul *et al.*, 1999; Moore *et al.*, 2020). We hypothesize that loss of DA will result in increased anxiety-related behaviors, and this will be associated with alteration in glutamate synapses. In the current study, male C57BL/6J mice (12-16 wks old) were tested for anxiety-related behavior using the elevated plus maze (Finn et al., 1997) following 4 weeks of vehicle (VEH) or treatment MPTP treatment (Moore *et al*., 2020), resulting in a 65% loss of striatal tyrosine hydroxylase and a 37% loss of DA neurons. The mice were then euthanized for histological evaluation for Golgi spine density, glutamate immunogold labeling within Layers II/III using electron microscopy, and for western blotting of various glutamate markers of the mPFC. There was an increase in anxiety-related behaviors (80% increase in closed arm entries; 100% increase in closed arm distance; 43% decrease in % open arm entries; 70% decrease in % distance in open arms) and a 78% decrease in plasma corticosterone levels in the MPTP vs VEH groups. This was associated with a 30% decrease in the density of dendritic spines in Layers II/III, and a 53% decrease in the density of glutamate immunogold density within vesicular glutamate transporter 1 (Vglut1; cortico-cortical connections) labeled nerve terminals and their associated spines, with no change within vesicular glutamate transporter 2 (Vglut2; thalamo-cortical connections) positive terminals/spines in the MPTP vs VEH groups. This decrease in glutamate terminal density suggests an increase in glutamate release (Meshul *et al*., 1999). There was a 15% decrease in the width of the synaptic cleft and a 23% increase in the length of the contact between the pre- and postsynaptic membranes in the MPTP vs VEH groups. There was an increase in protein expression of Vglut1 (40%) and Vglut2 (37%), a decrease in GLT-1 (50%) and EAAC1 (51%), and an increase in GLAST (225%) in the MPTP vs VEH groups within the mPFC. These data suggest that nigrostriatal DA loss results in a decrease in dendritic spines within the mPFC, which may be due to increased glutamate release/extracellular glutamate levels (decrease in glutamate transporters) and an associated change in anxiety-related behavior.

Abstract: BACKGROUND: Neuromelanin (NM) is a catecholamine-based polymer pigment derived from dopamine (DA) and DA precursors. During the lifespan NM is synthetized and then accumulated in a large part of DA neurons, particularly in the substantia Nigra pars compacta (SNpc) and in noradrenergic neurons of locus coeruleus. Over the years, several studies tried to shed light on the exact mechanism underlying NM synthesis and accumulation. Still, only a few works investigated if the selective accumulation of NM could induce behavioral and/or cellular dysfunctions. Notably, some of these works suggested that the accumulation of oxidized DA and NM could cause mitochondrial dysfunction in Parkinson's disease (PD) patient-derived neurons.Epidemiological observations, functional magnetic resonance study, and postmortem brain analysis have supported the central role of neuromelanin in PD pathogenesis.METHODS: In the present work, to selectively induce accumulation of NM, we injected into SN of male and female rats an Adeno-Associated Virus able to over-express human tyrosinase AAV9-CMV-htyr-GFP (AAV-htyr) or AAV9-CMV-null-GFP (AAV-null). Two months-old rats were injected, and after 4 weeks, they were behaviorally tested (motor, anxiety, and compulsive domain). The mitochondrial metabolic activity was directly assessed on SNpc punches through Seahorse XF96. Data were analyzed, keeping gender separate, to evidence sex differences.RESULTS: Animals tested in grip strength show a hypertonic response independently from sex, but when the same animals undergo anxiety characterization, AAV-htyr

males are more anxious than AAV-null. This difference was not found in females. Moreover, to verify sensitivity to psychostimulants, we administered 2.5 mg of amphetamine i.p., and we measured locomotion pre and post-injection; our results suggest that AAV-htyr males are more vulnerable to amphetamine effects on locomotion compared to AAV-null. No marked difference was found in females. Regarding mitochondrial activity, our data show that both sexes are affected. Taken together, our results suggest that in the initial stages of neuromelanin formation both sexes are affected with slight differences. Future studies should investigate if this trend remains the same after more time from the injection of AAV-htyr.

Title: Neurodegeneration in the systemic rotenone model of Parkinson’s disease is associated with neuroinflammation, oxidative stress and gliosis

Authors: *J. PRENDERVILLE[1], R. WINTERS[1], W. LAU[2], D. FENG[2], J. KAHN[3], E. MCECHERN[3], T. ROSAHL[3], D. ZWILLING[3], J. BROWNLEES[4], G. HIGGINS[2]; [1]Transpharmation Ltd., Dublin, Ireland; [2]Transpharmation Ltd., Fergus, ON, Canada; [3]MRL Neuroscience, Merck & Co., Inc., West Point, PA; [4]MSD Neurosci. MSD (UK) Limited, London, United Kingdom

Abstract: Parkinson’s disease (PD) is the most common movement disorder, estimated to affect more than 8.5 million individuals globally. Motor symptoms of PD include bradykinesia, tremor and postural instability, and non-motor symptoms include cognitive impairment. The primary pathophysiological feature of PD is degeneration of dopaminergic neurons in the substantia nigra (SN). This neurodegenerative process is associated with phosphorylation of alpha-synuclein and accumulation of protein aggregates, neuroinflammation, oxidative stress and gliosis. This study characterised the systemic rotenone rat model of PD based on Cannon et al 2009, investigating the temporal progression of motor symptoms and neuropathology.
Male Lewis rats (n=8/group) received daily administration of rotenone by intraperitoneal injection (3.25mg/kg) for 1, 5 or 10 days. Behavioural assessments (locomotor activity, postural instability and beam walk tests) were performed at baseline and on the final day of treatment (day 1, 5 or 10) prior to tissue collection. Tyrosine hydroxylase (TH) positive cells were

quantified in the SN by immunohistochemistry. Immunofluorescence quantification of phosphorylated (P129) alpha-synuclein and microglia (Iba1 positive cells) was performed. Neuroinflammatory markers (TNF-alpha, IL-6, IL-1beta) in brain homogenate were analysed. Both 5- and 10-days rotenone treatment resulted in motor deficits, including reduced rearing counts (Day 10: Veh: 144$\pm$23; Rot: 13$\pm$10; $p<0.05$) and postural instability (Day 10: Veh: 4.2$\pm$0.1; Rot: 7.3$\pm$0.5; $p<0.05$). A 50% reduction in TH positive cells in the dorsolateral SN was observed following 10-day rotenone treatment ($p=0.057$). The number of microglia in the dorsolateral SN was increased with 10-day treatment ($p<0.05$) and evidence of alpha-synuclein accumulation was also observed. TNF-alpha and IL-6 were increased in whole brain homogenate at 10 days ($p<0.05$). Dopamine levels were reduced in 1-, 5- and 10-days treatment by 44%, 50% and 62%, respectively, compared to vehicle treated control.
There is an unmet clinical need for new PD therapeutics with improved efficacy. The establishment of robust preclinical models effectively modelling the behavioural and pathophysiological features of PD is required to advance drug discovery. This study reports that the systemic rotenone rat model of PD is associated with disease relevant motor symptoms and dopaminergic neurodegeneration in the SN. Furthermore, neurodegeneration in this model is associated with temporal changes in markers of oxidative stress, neuroinflammation and gliosis, and a useful approach to studying treatments that may modify these processes.

Title: Nigrovagal chemogenetic inhibition effects on paraquat+lectin model and electrophysiology of the hemiparkinsonian substania nigra

Authors: *J. A. KALBUS, C. SWAIN, K. LE, T. SUBRAMANIAN, K. VENKITESWARAN; Univ. of Toledo Col. of Med., Toledo, OH

Abstract: We tested the hypothesis that unilateral chemogenetic inhibition of the nigrovagal pathway will provide contralateral protection and cause ipsilateral hemiparkinsonism. Adult Sprague Dawley (SD) rats were stereotactically injected with AAV2- Ef1a-eYFP-IRES-WGA-Cre into the DMV and AAV8-hSyn-DIO-hM4Di-mCherry into the SNpc on the left side. This allowed chemogenetic inhibition of the left nigrovagal pathway when P+L was given with chemogenetic activator JHU in the water supply. Control animals received inactive vectors. In a second experiment DAT-Cre transgenic rats received AAV8-hSyn-DIO-hM4Di-mCherry into the SNpc on the left side followed by P+L oral gavage for a week while on JHU. All test animals developed stable left hemiparkinsonism and control animals developed bilateral parkinsonism as per Vibrissae and stepping tests. Histology showed unilateral expression of hM4Di and mCherry exclusively in the left nigrovagal pathway in the wild type SD rats and ipsilateral SNpc neuronal preservation with all its projections expressing hM4Di and mCherry in the transgenic rats. Contralateral SNpc demonstrated >50% neuronal degeneration. We show that maladaptive nigrovagal neuronal hyperactivity plays a critical role in accelerating synucleinopathy and SNpc degeneration. In our experiments, we observed that after 7 days of P+L exposure some adult Sprague Dawley rats naturally became hemiparkinsonian even without nigrovagal inhibition. Previous experiments have demonstrated that neuronal firing in the subthalamic nucleus (STN) increases with PD progression (Remple et al., Mov Disord., 2011). We wanted to see if significant differences in neuronal firing and burst between the pathologic and nonpathologic Substancia Nigra pars compacta (SNpc) and reticulata (SNr) are present. In vivo electrophysiology was done and showed significant difference between the affected side and unaffected side in various region of the basal ganglia, with the unaffected side being similar to normal animals. Recordings in the affected STN of hemiparkinsonian animals showed significantly higher firing rates (40-60 Hz) compared to normal animals (8-20 Hz), while the unaffected side did not have such difference. The SNpc firing rate was decreased in the affected side and the SNr had an abnormal firing pattern. While these results are from naturally hemiparkinsonian rats, we expect that further investigation will show that chemogenetically protected hemiparkinsonisn rats will have similar electrophysiological findings.

Title: Effects of 17-β-estradiol depletion in cytisine treated female mice using a 6-OHDA mouse model of Parkinson's disease

Authors: *R. C. GARCIA[1], G. PANDEY[2], S. ZARATE[1], R. SRINIVASAN[1];
[1]Texas A&M Univ. Sch. of Med., Bryan, TX; [2]Texas A&M Univ. Inst. For Neurosci., Bryan, TX

Abstract: Parkinson's disease (PD) is characterized by the progressive loss of dopaminergic neurons in the substantia nigra and the two greatest risk factors for PD are advanced age and male sex. While there is a nearly two-fold higher prevalence of PD in men than women, currently there are no neuroprotective treatments for either sex, underscoring an unmet need for the development of neuroprotective treatments. Interestingly, chronic tobacco use has been shown to reduce the risk of PD by 50% and our studies have shown that low doses of nicotine (100 nM) attenuate apoptotic endoplasmic reticulum (ER) stress in DA neurons. Thus, we rationalized that nicotine and nicotinic agonists could reduce ER stress. Using a 6-OHDA model of PD we found that alternate day i.p. injections of 0.2 mg/kg cytisine, a partial nicotinic acetylcholine receptor agonist, was sufficient to reduce parkinsonian motor deficits and decrease 6-OHDA induced neurodegeneration of DA neurons only in female mice. In contrast, cytisine treated male mice showed no change in motor deficits or DA neuron loss but rather showed a pathological increase in nuclear expression of the apoptotic ER stress protein CHOP. To test whether cytisine and estrogen could work in combination to exert neuroprotection in female mice, we exposed primary DA cultures to 10 nM 17-β-estradiol, 200 nM cytisine, or 17-β-estradiol and 200 nM cytisine. We found that 17-β-estradiol alone reduced expression of CHOP and that 200 nM cytisine reduced two additional ER stress proteins, ATF6 and XBP1. To characterize the combined effects of cytisine and 17-β-estradiol in vivo, we are testing three methods of estrogen depletion in female mice (1) surgical depletion of 17-β-estradiol via ovariectomy (OVX) (2) chemical inhibition of aromatase activity, and (3) depletion of 17-β-estradiol in reproductively senescent female mice. In the model of OVX we have found that intact cytisine treated females had significantly less apomorphine induced rotations than intact saline treated females; however, there was no difference in the average number of rotations between intact cytisine females and OVX cytisine female mice. Additionally, we found no differences in SNc TH intensity or GFAP reactivity after 6-OHDA lesion for either the intact cytisine or OVX cytisine groups but found decreased TH intensity and increased GFAP reactivity in the intact saline group. These data suggest sex specific mechanisms in cytisine pharmacology and distinct roles for cytisine and 17-β-estradiol in the neuroprotective effect of cytisine in female mice.

Abstract: Parkinson's disease (PD), a progressive neurodegenerative disorder, is caused by dopaminergic neuronal cell death in substantia nigra region of the brain. To explain this site specific neuronal loss, several studies suggest that dopamine (DA) itself can induce cytotoxicity. The current available therapy for PD is L-DOPA (LD), a precursor for DA synthesis. Whether L-DOPA therapy can accelerate neurodegeneration in PD patients or not is still inconclusive. However, lessening the detrimental effects induced by DA is anticipated to prolong the efficacy of the therapy. Our study determines the role of (i) Monoamine oxidase mediated DA degradation and (ii) dopamine-quinones, the two major governing factors of DA toxicity, on cell survival and mitochondrial homeostasis. Methods including neuronal cytotoxicity assays, confocal imaging and immunoblotting were employed to explore the shared druggable pathways. Our *in vitro* data demonstrate that both these factors enhance Calcineurin (CaN) activity, thereby resulting in mitochondrial translocation of DRP1 which leads to apoptotic mitochondrial fragmentation. Inhibition of CaN-DRP1 axis can prevent DA toxicity as a whole. Further, evaluation of the impact of DA exposure on PD progression in MPTP-induced C57BL/6 mice model (male, 8-10 weeks) of sporadic PD reveal that LD mediated behavioral improvement diminishes with time, mostly because of continued DAergic neuronal death and dendritic spine loss at striatum. CaN inhibition alone, or in combination with LD, can provide prolonged behavioral protection. This protective effect is observed when specifically CaN-DRP1 axis is hindered, whereas inhibiting interaction between CaN and other substrates, including proteins involved in neuro-inflammation(e.g. NFAT), remained ineffective when LD is co-administered. In this study, we conclude that CaN inhibition can mitigate DA toxicity and can rescue PD related behavioral abnormalities by preserving neuronal architecture at striatum. We propose that CaN inhibitors might extend the therapeutic window of LD therapy.

Title: Dopaminergic specific accumulation of neuromelanin in mice promotes neuronal damage and leads to parkinsonian-like motor impairment

Authors: *A. DRUMOND-BOCK[1], K. CARTER[1], H. E. BLANKENSHIP[1,2], E. TROYANO-RODRIGUEZ[1], D. WEINSHENKER[3], M. J. BECKSTEAD[1,4];

Abstract: Intracellular accumulation of the pigment neuromelanin (NM) in dopaminergic neurons of the substantia nigra pars compacta (SNc) is a natural process occurring in the human brain. Although NM could potentially have a protective function neutralizing excessive dopamine (DA), metals and other protein aggregates into lipid rich organelles, its buildup in catecholaminergic areas in aging individuals correlates with neurodegeneration associated with Parkinson's disease (PD). While NM synthesis is well documented in humans and other species, there are no reports of visible aggregation of the pigment in the brains of rats or mice, making it challenging to study this process in a laboratory animal context. To overcome this issue, a recent study promoted age-dependent accumulation of NM in neurons of the SNc through adenoviral-induced expression of human tyrosinase (hTyr), the rate-limiting enzyme for melanin synthesis in peripheral tissues. The consequent increase of NM in the SNc promoted PD tissue phenotype similar to the observed in patients, including nigrostriatal degeneration. We are adapting this technique, inducing dopaminergic-specific expression of hTyr by performing injections of adenovirus containing a floxed *hTyr* gene into the SNc of $DAT^{IREScre}$ mice (transgenic mice expressing *Cre recombinase* gene under the dopamine transporter (*Dat*) gene promoter). Immunofluorescence images revealed large expression of hTyr exclusively in the DA neurons of the SNc 7 days after adenoviral injection and a posterior loss of hTyr and tyrosine hydroxylase (TH) starting at 14 days, culminating with the complete absence of TH-positive cells by 35 days. The progressive loss of TH-positive dopaminergic neurons occurred in parallel with formation of NM granules, observed in unstained brain sections and after Fontana-Masson stain. Patch-clamp recordings of these neurons detected disruption of pacemaker firing as early as 14 days after *hTyr* induced-expression. Finally, behavioral studies confirmed locomotor impairment in these mice, which lost the ability to maintain rotarod balance, spent less time exhibiting ambulatory and exploratory behavior, and spent more time resting. Overall, our results suggest that dopaminergic-specific aggregation of NM in the SNc affects neuronal function and electrophysiological properties and promotes parkinsonian locomotor phenotypes. This tool will enable a further investigation into the interaction between NM accumulation and the progression of PD.

Title: Determining the Efficacy of a Novel Daglb-knockout mouse Model for Parkinson's Disease

Authors: D. BASU, *L. WANG, H. CAI;
Natl. Inst. on Aging, Bethesda, MD

Abstract: Our lab previously found that a rare genetic missense mutation of the 2-arachidonoyl-glycerol (2-AG) synthase diacylglycerol lipase β (DAGLB), which is enriched in nigral dopaminergic neurons (DANs), contributes to early onset of Parkinson's Disease (PD). Viral knockdown of *Daglb* in nigral DANs of mice induced a reduction of substantia nigra (SN) 2-AG levels and impaired locomotor skill learning. To further model DAGLB-deficiency in PD, the present study generated a conditional knockout (cKO) model of the same *Daglb* enzyme in mice by crossing a dopamine transport (DAT)-Cre strain with a novel *Daglb* flox/flox strain. The *Daglb* cKO model was evaluated through a series of behavior tests which assessed locomotion, motor skill learning, and non-motor behaviors. Additionally, fiber photometry was used to measure the release of 2-AG in the nigrostriatal pathway. In our results, we were able to verify that the *Daglb* cKO mice had a decreased level of *Daglb* in nigral DANs compared to littermate controls via RNA Scope. However, this reduction did not translate into any further differences between groups. Both *Daglb* cKO and controls performed similarly in open field tests (which measured locomotion) and the rotarod task (which measured motor skill learning). Both groups also performed similarly in non-motor behavioral assays which measured anxiety levels. Furthermore, fiber photometry revealed that *Daglb* cKO mice and control mice had an equivalent level of 2-AG production in SN, meaning the decrease of *Daglb* levels in the cKO did not induce a decrease in nigral 2-AG. Overall, we did not observe any behavioral or physiological phenotypes in this new line of *Daglb* cKO mice. We suspect that the discrepancy of results between *Daglb* cKO mice and our previous viral knockdown approach might be due to a compensatory mechanism through the other diacylglycerol lipase, *Dagla*. Presence of *Dagla* in the mouse nigral DANs was verified in our RNA scope data. Future experiments will use AAV vectors to deliver Cre selectively in the nigral DANs of adult *Daglb* floxed mice and *Dagla* floxed mice. The resulting mouse models may better capture the disease phenotypes.

Title: Maresin 1 changes reactive microglia from pro-inflammatory to pro-survival states in 6HODA model of Parkinson’s Disease

Authors: *T. E. MPOFU, T. CHANEY, J. M. CALANDRIA, S. KALA BHATTACHARJEE; Neurosci. Ctr. of Excellence, LSUHSC New Orleans, New Orleans, LA

Abstract: Parkinson's disease (PD) is a progressive neurodegenerative disorder that affects the dopaminergic neurons in the substantia nigra. Microglia, the resident macrophage-like cells located in the central nervous system, mediates synaptic pruning, perform phagocytosis of cellular depositions and waste, and release pro and anti-inflammatory responses contributing to neurodegeneration or neuroprotection. Microglia become reactive upon stimulus from neurons or astrocytes determining the type of phenotype these cells acquire. These phenotypes modulate defensive or neuroprotective efforts to modulate neuroinflammation. The pro-inflammatory phenotypes exhibit cytokine responses, while the pro-survival ones are accompanied by high LC3-associated phagocytosis (LAP) that scavenges debris and unfolded fibrillar subproducts like alpha-synuclein fibrils. These two phenotypes corelates with morphological changes. Here we propose that DHA derivative Maresin 1 (Mar1) induce the second step in the polarization to enhance the activation of the LAP phagocytic state, leading to a decrease in the inflammatory signals and a change in the morphology of the microglia in the Sustantia nigra. This hypothesis was tested “in vivo” in a 6- hydroxydopamine (6-HODA) toxicity rat model and “in vitro”, in adult rat brain cultures of microglial cells treated with Tumor necrosis factor (TNF) and interferon alpha (IFNα) or alpha-synuclein (α-syn) fibrils to induce classical activation. In rat culture microglial cells, we used immunocytochemistry to detect p65 nuclear translocation and LC3 vesicles. Mar1 induced a decrease in p65 translocation, elicited LC3-phagocytosis as it was observed by the increase in the LC3-positive vesicles. To confirm these findings, we recorded the changes in phagocytic activity of α-synuclein fibrils tagged with pHRodo, a molecule that changes fluorescent wavelength emission when it reaches the lysosomal lower pH, using Incucyte real-time imaging system. In the 6HODA toxicity model, immunohistochemistry using IBA1 to detect microglial cells in different areas of the rat brain showed that microglia were more abundant, and the shape resembles more to pro-inflammatory when rats treated with saline than when treated intranasally with Mar1.Altogether these data points to a pro-survival role of Mar1 in the polarization of microglia that lay to road to future therapeutical developments for PD.

Abstract: Parkinson's disease (PD) is a progressive neurodegenerative disease that affects over 10 million people worldwide. Currently, it is estimated that 80-90% of all PD cases manifest with no identifiable cause. Recent research efforts have worked to pinpoint risk genes and environmental factors that increase risk of PD development. Single-nucleotide polymorphisms in the cluster of differentiation 38 (CD38) gene locus have been associated with increased risk of PD in multiple GWAS studies. CD38 is an ectoenzyme that converts NAD+ to NAM and contributes to maintaining cellular bioenergetics. In the CNS, CD38 is highly expressed in motor regions affected by PD pathology (midbrain). Our own studies further determined that CD38 enrichment is highest in astrocytes and microglia. In the work presented herein, we describe how CD38 influences astrocytic gene expression and mitochondrial function. We further describe how CD38 expression regulates NAD+ and NAM levels in the midbrain. Astrocyte samples for RNA-sequencing were prepared from midbrains of one-year old male C57BL/6J CD38 wild-type (WT), heterozygous (HET), and knockout (KO) mice using our magnetic-activated cell sorting (MACS) method to acquire astrocyte isolates. RNA-sequencing revealed numerous DEGs in pairwise comparisons of CD38 KO to WT mice, with moderate differences between CD38 HET and WT mice. Interestingly, mitochondrial DEG and GO analysis data suggested mitochondrial dysfunction in both CD38 HET and KO mouse astrocytes. In a subsequent set of experiments, mitochondrial function was evaluated in primary astrocyte cultures from CD38 WT, HET, and KO mice utilizing the Seahorse XF platform. CD38 HET and KO astrocytes displayed altered mitochondrial function compared to WTs. In addition to astrocyte-specific evaluations, midbrain tissues from one-year old CD38 WT, HET, and KO were measured for NAD+ and NAM content. Relative to WTs, CD38 KO samples had increased NAD+ and decreased NAM, further suggesting bioenergetic dysfunction. These findings serve to provide direction for future studies

to evaluate the relationship between CD38 function, aging, and vulnerability of neuronal populations compromised in Parkinson's disease.

Title: Long-term alterations in mitochondrial function in the alpha-synuclein preformed fibril rat model of Parkinson's disease

Authors: ***J. K. LEPP**[1], K. M. CROUCHER[1], A. C. STOLL[2], C. J. KEMP[2], J. R. PATTERSON[2], K. C. LUK[3], C. E. SORTWELL[2], S. M. FLEMING[1];

Abstract: The alpha-synuclein (aSyn) preformed fibril (PFF) model of Parkinson's disease (PD) is widely used to understand the mechanisms that contribute to progressive neurodegeneration in the PD. Mitochondrial dysfunction is well established in the brain and periphery in PD and is known to interact with aSyn. When aSyn PFFs are injected into the striatum, aSyn pathology is found in the cortex and amygdala in addition to the nigrostriatal pathway. However, how aSyn PFFs impact mitochondrial bioenergetics in these regions is not clear. In the present study, the effect of intrastriatal aSyn PFFs on mitochondrial bioenergetics in multiple brain regions was investigated in rats receiving unilateral injections of PBS (n=10) or aSyn PFFs (16 μg; n=10). At approximately 18 months post injection, brains were removed, and mitochondria were isolated from the ipsilateral and contralateral prefrontal cortex (n=5), striatum (n=5), amygdala (n=5), and ventral midbrain (n=5). Oxygen consumption rate (OCR) was measured in the presence of the substrates ADP, Oligomycin, FCCP, and Rotenone/Antimycin A for each sample in triplicate (5ug/well of mitochondria). In the PFF rats there was a significant decrease in basal OCR (pmoles O_2/minute/ug protein) in the ipsilateral striatum and ventral midbrain compared to the contralateral side. In the ipsilateral striatum OCR was significantly lower in response to Rotenone/Antimycin A compared to the contralateral side. In the ipsilateral ventral midbrain OCR was significantly lower compared to contralateral ventral midbrain. There was no difference in OCR between ipsilateral and contralateral sides in the PBS-treated rats. There was

also no effect of PFFs in the prefrontal cortex or amygdala. Protein analysis measuring aSyn, phosphorylated aSyn, and mitochondrial proteins is ongoing. These data indicate that intrastriatal aSyn PFFs alter mitochondrial bioenergetics specifically within the nigrostriatal system despite aSyn pathology in extranigral regions.

Abstract: Parkinson's disease (PD) is a relentlessly progressive neurodegenerative disorder characterized by debilitating motor deficits and neurocognitive decline over the course of aging. Although symptomatic therapies are available, a major issue faced by PD patients is the lack of treatments that can deter the progression of the disease. Mitochondrial abnormalities are a known feature of PD and many studies indicate an early role for mitochondrial dysfunction in the disease. In this context, we have previously identified 5 hydroxytryptamine 1F (5-HT1F) receptors as novel mediators of mitochondrial biogenesis (MB). We have also demonstrated, in an acute 6-hydroxydopamine (6-OHDA) mouse model, that the administration of a specific 5-HT1F receptor agonist LY344864 enhanced MB and improved locomotor activity. Based on these data, we are currently assessing the therapeutic potential of the FDA-approved 5-HT1F receptor agonist, Lasmiditan, in a more chronic and progressive mouse model of PD (lin61 Thy1-ASyn mice). Firstly, we studied the pharmacokinetic (PK) and pharmacodynamic (PD) properties of Lasmiditan in wild-type and PD mice. Robust levels of both total and unbound Lasmiditan were seen in both plasma and brain, with a Tmax was around 0.5 hours in plasma and just over 1 hour in the brain. Additionally, total brain to plasma ratios were generally >2 and unbound brain to plasma ratios were >1, indicating good brain penetration of Lasmiditan. Examination of protein markers of MB (such as TFAM, NDUFS1, NDUFB8) via western blot, indicated that Lasmiditan was able to significantly induce MB in PD-relevant brain regions such as the striatum and substantia nigra. It was found that 0.3 mg/kg and 1 mg/kg doses were most

efficient at MB induction, with effect saturation usually occurring at the 1mg/kg dose. Given this, we treated 4 mos old WT and Thy1-ASyn mice with Lasmiditan (1mg/kg, IP, alternate dats for 1.5 mos) and are assessing several motor and cognitive behaviors in the mice, as well as analyzing the mouse brains at cellular and molecular levels. Ongoing experiments will also additionally examine 10-month-old aged mice to evaluate the efficacy of Lasmiditan as the first molecular pathogenesis-based therapy for PD.

Title: Muscarinic M5 Receptor as a Therapeutic Target to Decrease Motor Symptoms in Mouse Models of Parkinson's Disease

Authors: *D. HALL[1], N. E. CHAMBERS[2], D. NABERT[2], P. WAGNER[1], M. MILLETT[3], M. S. MOEHLE[2];
[2]Pharmacol. & Therapeut., [3]Pharmacol., [1]Univ. of Florida, Gainesville, FL

Abstract: Parkinson's disease (PD) is a neurodegenerative movement disorder associated with debilitating motor deficits such as bradykinesia and akinesia. Loss of nigral dopamine neurons and the development of Lewy bodies in the brain precedes these motor symptoms. Past research has investigated the importance of acetylcholine receptors as modulators of Parkinsonian motor symptoms; however the contributions of the M5 muscarinic acetylcholine receptor (M5) has not been investigated for therapeutic efficacy. M5 has unique expression profile largely rectricted to dopaminergic cells, and are present on nigrostriatal DA terminals the striatum and cell bodies in the substantia nigra. Data from drug dependency studies suggest that the net activity of M5 is pro-dopaminergic and suggests that M5 positive allosteric modulators (PAM) may be beneficial in Parkinson's disease.. To test this hypothesis we used two Parkinsonian mouse models. In the first set of experiments we used mice with a unilateral medial forebrain bundle 6-OHDA lesion to model severe Parkinson's disease with over 95% loss of unilateral DA neurons. Three weeks after lesion surgery we performed a motor battery consisting of Erasmus ladder, cylinder test, and forehand adjusting steps test. Consistent with our expectations, 6-OHDA lesioned mice showed deficits in the use of the lesioned forehand and show bradykinesia in the Erasmus ladder compared to normal age-matched controls. Using a within-subjects design, mice received M5 PAM or NAM, both with and without L-DOPA. There were no effects of M5 PAM and NAM on Parkinsonian motor deficits, likely due to the large extent of DA lesion. Additionally, we tested

the effects of M5 PAM on L-DOPA-induced dyskinesia. In the second set of experiments we used the preformed fibril model (PFF) of Parkinson's disease, in which 50-70% of DA neurons remain, and monomer controls. To investigate how the progression of DA loss may play a role in M5's ability to modulate motor symptoms, we tested PFF animals at 3 and 6 months post-injection. Following recovery from surgery, animals were tested for their baseline motor phenotype in the Erasmus ladder. Excitingly, PFF animals showed deficits vs. monomer controls at both 3 and 6 months. These deficits were modified by treatment with M5 PAM, suggesting that increasing striatal DA release with M5 PAM may be a viable treatment strategy in early and mid-stage Parkinson's disease.

Title: Positive allosteric modulation of $mGlu_2$receptors with AZD8529 alleviates L-DOPA-induced dyskinesia and psychosis-like behaviours in the MPTP-lesioned marmoset

Authors: *J. SHAQFAH[1], I. FROUNI[1,2], C. KWAN[1], D. BÉDARD[1], S. G. NUARA[3], J. C. GOURDON[3], A. HAMADJIDA[1], P. HUOT[1,2,4,5];
[1]Montreal Neurolog. Inst., Montreal, QC, Canada; [2]Dept. de Pharmacologie et Physiologie, Faculté de Médecine, Univ. de Montréal, Montreal, QC, Canada; [3]Comparative Med. and Animal Resource Ctr., [4]Dept. of Neurol. and Neurosurg., McGill Univ., Montreal, QC, Canada; [5]Div. of Neurology, Dept. of Neurosciences, McGill Univ. Hlth. Ctr., Montreal, QC, Canada

Abstract: AZD8529 is a highly selective metabotropic glutamate 2 ($mGlu_2$) receptor positive allosteric modulator (PAM) that has undergone clinical trials for schizophrenia and smoking cessation. In previous studies, we demonstrated that the selective $mGlu_2$ PAMs LY-487,379 and CBiPES alleviated L-3,4-dihydroxyphenylalanine (L-DOPA)-induced dyskinesia and psychosis-like behaviours (PLBs) in the 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP)-lesioned marmoset model of Parkinson's disease (PD). However, neither drug has clinically relevant pharmacological properties, contrary to AZD8529, which could be repurposed for PD if efficacious in pre-clinical studies. To assess the effect of AZD8529 on L-DOPA-induced dyskinesia and PLBs in the MPTP-lesioned marmoset, marmosets (n=6) were rendered parkinsonian by repeated MPTP injections followed by a recovery period to ensure development of a stable phenotype. Dyskinesia and PLBs were elicited by daily oral administration of L-DOPA/benserazide (L-DOPA/vehicle) for a minimum of 30 days. On experimental days,

marmosets were injected with L-DOPA (15/3.75 mg/kg subcutaneously [s.c.]) along with vehicle or varying concentrations of AZD8529 (0.1, 0.3, 1, and 10 mg/kg s.c.). These doses were selected based on the pharmacokinetic profile of AZD8529 in the marmoset, which will be reported separately. After treatment, marmosets were individually recorded in observation cages for 6h, and this footage was analysed for dyskinesia, PLBs, and parkinsonism by an experienced, blinded, rater. The results showed a significant reduction in global dyskinesia severity (by 45%, 46%, 61%, 70%, respectively; $P<0.001$ for all doses), and on-time with disabling dyskinesia (by 83%, 86%, 99%, and 97%, respectively; $P<0.001$ for all doses) when compared to L-DOPA/vehicle. Similarly, there was a significant reduction in global PLB severity (by 44%, 45%, 58%, and 64%, respectively; $P<0.001$ for all doses), and on-time with disabling PLBs (by 82%, 83%, 97%, 94%, respectively; $P<0.001$ for all doses) when compared to L-DOPA/vehicle. Additionally, AZD8529 significantly increased the duration of the anti-parkinsonian action of L-DOPA at doses of 0.3 mg/kg and above (by 29%, 21%, and 26%, respectively; $P<0.05$ for all doses). Our results demonstrate the potential of AZD8529 and $mGlu_2$ positive allosteric modulation for alleviating L-DOPA-induced dyskinesia and PLBs and amplifying L-DOPA anti-parkinsonian effects.

Abstract: Alpha-synucleinopathies such as dementia with Lewy bodies (DLB) are characterized by pathologically phosphorylated, insoluble alpha-synuclein as well as microglia/macrophage reactivity. We have modeled the limbic Lewy-related pathologies of DLB with injections of preformed alpha-synuclein fibrils (PFFs) in the bulbar anterior olfactory nucleus (OB/AON) of 18-month-old, nontransgenic mice. These mice develop impairments in spatial reference memory in the Y-maze and Lewy-like pathology across the limbic rhinencephalon. In patients with DLB, microglia/macrophages display dystrophic and gnarled morphologies associated with cellular senescence. Therefore, we tested the hypothesis that depleting and repopulating microglia/macrophages with transient dietary delivery of PLX5622, an inhibitor of the colony-stimulating factor receptor 1 (CSF1R), may hold therapeutic potential in our experimental model. We infused mice with PFFs at 18 months of age, and one week later, we administered 1200 mg PLX5622 per kg chow for 14 days. After an additional seven weeks, we noted more entries in the novel arm of the Y maze in the microglia/macrophage-repopulated group, suggesting superior spatial reference memory, particularly in female mice. Male mice treated with PLX5622 became slightly hyperactive, suggesting that caution must be exercised with use of CSF1R inhibitors. When we counted $Iba1^+$ and $pSer129^+$ objects with AI/Deep Learning, we found that $pSer129^+$ inclusion counts were only lowered by PLX5622 withdrawal in male mice. In OB/AON tissue extracts subjected to ultracentrifugation of the Triton X-insoluble fraction, levels of nonionic detergent-insoluble alpha-synuclein were also lowered by transient PLX5622 in males. Unexpectedly, the average sizes of the $pSer129^+$ inclusions were increased by microglia/macrophage repopulation in both males and females. Spatial reference memory was negatively correlated with $pSer129^+$ inclusion counts and with $Iba1^+$ hydraulic radii (a measure of microglia/macrophage reactivity), but positively correlated with average inclusion size. We therefore conclude that depletion and repopulation of microglia/macrophages modifies limbic alpha-synucleinopathy by lowering inclusion counts and detergent-insoluble alpha-synucleinopathy but also raising inclusion sizes, albeit in sex-biased manners. Further studies are warranted to identify how repopulated microglia/macrophages increase inclusion sizes while lowering inclusion counts, and to test if fewer but larger inclusions are less toxic than smaller, more abundant inclusions.

Title: Exploratory omics study reveals potential roles of sigma-2 receptor modulators in AAV1/2A53T-aSyn rat model of Parkinson's disease

Authors: *A. REAVER[1], B. N. LIZAMA[1], K. PANDEY[2], D. M. DUONG[3], N. SEYFRIED[3], A. O. CAGGIANO[1], M. E. HAMBY[1];

Abstract: Synucleinopathies, including Lewy body dementia (DLB) and Parkinson's disease (PD) comprise the second most common neurodegenerative disease worldwide. In synucleinopathies, alpha-synuclein (αSyn) oligomers cause neuronal dysfunction. The sigma-2 receptor (S2R) is involved in pathways associated with age-related disease including autophagy, oxidative stress and intracellular trafficking. We have shown that S2R modulation *in vitro* reverses αSyn oligomer-induced deficits in neuronal vesicle trafficking. Given this data and S2R's functional overlap with pathways affected in PD, we hypothesized that S2R modulation would alter PD-related transcripts and pathways *in vivo*. Mutations in the αSyn gene, such as A53T, cause familial PD. Ectopic expression of human A53T αSyn *in vivo* causes production of toxic αSyn oligomers, resulting in neuroinflammation and loss of dopaminergic neurons. Using this model, we assessed the impact of two chemically distinct S2R modulators, CT1812, an investigational therapeutic currently in Phase 2 clinical trials for DLB and AD, and CT2168 for their ability to modify disease-relevant pathways at the transcriptional and protein level. Human A53T-αSyn (AAV1/2-hA53T-aSyn) or AAV1/2 empty vector was administered unilaterally into the right substantia nigra of female Sprague Dawley rats. hA53T-αSyn AAV-injected animals were dosed with vehicle, CT1812, or CT2168 (3mg/kg) and empty vector-injected animals dosed with vehicle (N=14 per group) for ~45 days. Ipsilateral striatal tissue was harvested for proteomics and RNAseq. Differential expression and pathway analyses identified transcripts, proteins, and pathways significantly altered by mutant αSyn as compared to control. Significant changes included increases in inflammatory pathway-related genes and proteins ($p \leq 0.05$) and decreases in dopamine pathway-related proteins ($p \leq 0.01$), demonstrating that the A53T αSyn *in vivo* model recapitulates key features of synucleinopathies. To investigate the role of S2R, we next analyzed the effect of CT1812 and CT2168 on the striatal transcriptome and proteome in the disease model. Both compounds altered transcripts and proteins involved in signal transduction and the glutamatergic pathway, and downregulated inflammation-related proteins and transcripts that were upregulated in the disease model ($p \leq 0.05$). In sum, these omics analyses suggest that S2R modulators may impact key pathways disrupted in synucleinopathies, including neuroinflammation and stress response. These findings support further development of S2R modulators for synucleinopathies. This research was supported by the Michael J. Fox Foundation.

Title: Potent Antioxidant and Mitochondrial-protect Effects of ATH434, a Novel Inhibitor of α-Synuclein Aggregation with Moderate Iron-binding Affinity

Authors: *D. BAILEY[1], R. NIHLAWI[1], M. J. BRADBURY[2], D. J. KOSMAN[1];
[1]Biochem., State Univ. of New York, Univ. at Buffalo, Buffalo, NY; [2]Alterity Therapeut., Newark, CA

Abstract: Iron is essential for supporting energy metabolism, mitochondrial function, and maintaining cellular redox potential. Excess labile iron can generate reactive oxygen species in mitochondria which, if unchecked, can lead to sustained oxidative stress and eventual cell death. Parkinson's disease (PD) and Multiple System Atrophy (MSA) are neurodegenerative conditions characterized by regional excess brain iron and resultant oxidative stress in areas of pathology, leading to clinical trials of iron binding small molecules for their treatment. ATH434, a small molecule drug candidate with moderate ferric iron affinity (K_d 10^{-10}, Finkelstein 2017), promotes cellular iron efflux, reduces excess brain iron and aggregated α-synuclein, improves neuronal survival, and restores motor performance in murine PD and MSA models. ATH434 is currently in phase 2 MSA trials. Deferiprone (DFP) is a high ferric iron affinity drug (K_d 10^{-21}, Hider 2014) approved for treating systemic iron-overload disorders. Because DFP is designed to reduce cellular iron stores, it has potential for maladaptive pharmacological effects in healthy cells. DFP has also demonstrated efficacy in preclinical PD models. The required doses, however, are higher than expected given its ready brain access and high ferric iron affinity, suggesting that ATH434 may possess unique beneficial properties.In this study, we investigated the efficacy of ATH434 and DFP as potential antioxidants and mitochondrial protectants using a menadione-induced model of oxidative stress in the glutamatergic neuronal HT22 cell line. ATH434 restored the reduced mitochondrial membrane potential after menadione-stressed neurons, demonstrating an ability to preserve mitochondrial function. ATH434 also demonstrated in-solution antioxidant capacity in an ABTS radical scavenging assay. DFP was ineffective in both of these assays. The chemical antioxidant effect and cellular effects with an ATH434 analog possessing dramatically reduced iron binding affinity suggests a direct interaction between ATH434 and free radicals. Superoxide production in menadione-stressed neurons, as determined by changes in the indicator MitoSOX, was not reduced by ATH434 or iron chelators such as DFP, suggesting that superoxide is not the interactant. Reductions in peroxide and hydroxyl radicals may therefore underlie the direct antioxidant potential of ATH434. Together, these results suggest that antioxidant activity may be an important contributor to the efficacy of ATH434 in neurodegenerative disorders characterized by excess labile central iron, thus enhancing the efficacy of its moderate iron binding.

Title: Inhibition of the Y-chromosome gene, SRY, attenuates neuroinflammation and disease progression in acute and progressive rat models of Parkinson's disease.

Authors: *D. KIM[1,3], P. PINARES-GARCIA[3,2], E. JACKSON[1], M. MICHALAS[1], J. THOMPSON[1], T. SIMPKINS[1], J. LEE[1,3,2];

Abstract: Parkinson's disease (PD) is characterized by loss of dopamine (DA) neuron in the substantia nigra pars compacta (SNc). Whilst the cause(s) of PD is unknown, increasing evidence points to the male-sex as a strong risk factor. Men are twice as likely to be diagnosed with PD than women with an earlier age of onset and faster disease progression. We previously showed that aberrant upregulation of the Y-chromosome gene, *SRY*, mediates a novel male-specific mechanism of DA cell loss (Lee et al., 2019, PNAS). Here, we assessed the i) cellular relationship between SRY expression and disease progression and ii) consequence of SRY suppression on neuroinflammation and mitochondrial function in pre-clinical rat and cellular models of PD. Time-course studies in the acute 6-OHDA and progressive rotenone rat PD models revealed progressive losses in nigral TH neurons, which was paralleled by increase in activated OX42+ microglia with disease progression in both models. SRY and OX42 co-immunofluorescence revealed an increase in SRY-positive, but not SRY-negative, activated microglia with disease progression in both PD models. In contrast, SRY-positive TH neurons were not affected by disease progression in both PD models, suggesting DA neurons that expressed SRY are more resilient. Remarkably, suppressing SRY expression in male rats, via nigral SRY antisense oligonucleotide (ASO) infusions, at 4 weeks post rotenone treatment reversed the progression of motor deficits and nigral degeneration, and attenuated microglial activation ($P<0.001$ vs sense control, two-way ANOVA). Moreover, qRT-PCR analysis revealed

that rotenone induced up-regulation of pro-inflammatory cytokine or anti-oxidant genes in male rat SNc were all diminished by ASO infusion. SRY siRNA pre-treatment in the human male neuronal cell line, M17, diminished rotenone-induced upregulation of SRY, SOD2 and BAX protein, without altering oxygen rate consumption or TOM20 expression and content, suggesting that SRY regulates antioxidant capacity but not mitochondrial function in rotenone-injured neurons. Collectively, these results demonstrate a positive relationship between SRY and neuroinflammation and suggest that microglial SRY inhibition may present a novel disease-modifying strategy for male PD patients.

Title: In a hemi-lesioned model of L-DOPA-induced dyskinesia neuronal firing was reduced in the un-lesioned striatum and ketamine reduced burst-like firing in striatal neurons bilaterally

Authors: *A. VISHWANATH[1,2], M. J. BARTLETT[3,4], A. KEENER[2], T. FALK[3,5], S. L. COWEN[2];
[2]Psychology, [3]Neurol., [4]Surgery, [5]Pharmacol., [1]The Univ. of Arizona, Tucson, AZ

Abstract: Parkinson's Disease (PD) is a neurodegenerative disorder associated with the loss of dopamine producing neurons in the substantia nigra pars compacta. While levodopa (L-DOPA) is the gold standard treatment for PD, long-term use often results in L-DOPA Induced Dyskinesia (LID), a debilitating condition associated with aberrant facial and limb movement and dystonia. LID symptoms are also correlated with a fine-tuned 80 Hz oscillation in the primary motor cortex (M1) and sub-regions of the basal ganglia. LID and PD have been shown to increase firing rates and burst firing in cortical and striatal neurons. Sub-anesthetic doses of ketamine, a N-methyl-D-aspartate receptor antagonist, have been shown to reduce LID symptoms in preclinical models and reduce burst firing in cortical neurons. This study sought to identify changes in neural activity associated with LID and the treatment of LID with ketamine. **We hypothesized that burst firing of M1 and striatal neurons would be associated with LID and that ketamine would reduce burst activity along with behavioral measures of dyskinesia.** Methods: An animal model of LID was produced using the 6-hydroxydopamine hemi-lesioned rat model of PD. PD animals were administered L-DOPA (12 mg/kg >10

consecutive days) to establish stable LID. Dyskinetic and sham-lesioned rats were implanted bilaterally with 16-tetrode hyperdrives (M1: AP: 1.5, ML: ±2.2, DV: <2mm, striatum: AP: 1.5, ML: ±2.2, DV: >3mm). The LID (n = 5) and sham-lesioned (n = 5) rats were administered L-DOPA (12 mg/kg, *i.p.*) or saline followed by ketamine (20 mg/kg, *i.p.*). Local-field potentials and single-unit activity (M1: n >1000; striatum: n = 198 neurons) were recorded. Contrary to our predictions, the data indicated that LID did not change the firing rates of medium spiny neurons (MSNs) in the lesioned hemisphere, but reduced MSN firing in the un-lesioned hemisphere. This suggests a mechanism whereby neural activity in the dopamine-intact hemisphere compensates for persistent dopamine depletion in the lesioned hemisphere. We also observed that ketamine reduced striatal and M1 burst firing in the lesioned and un-lesioned hemispheres. Future analyses will investigate interactions between M1 and striatum by measuring cross-correlations between regions and spike-field coupling with LID-associated oscillatory activity.

Title: Neuroprotective effects of caffeine, camellia sinensis and telfairia occidentalis in MPTP-induced PD in female Swiss mice

Authors: *A. O. IMAM-FULANI, A. O. SHUAIB, J. INYANG, H. AFOLABI, H. OLORUNOJE, O. ALIMI, O. BABATUNDE, O. ADEKUNLE, O. ONOSHI, E. A. MAKANJUOLA, T. E. ESO, T. T. OGUNSESAN;
Physiol., Univ. of Ilorin, Ilorin, Nigeria

Abstract: L-dopa is the most commonly used drug for managing Parkinson's Disease (PD). However, most L-dopa-treated patients develop complicated motor fluctuations and dyskinesia. Also, Adenosine slows movement and becomes more active as Parkinson's progresses, so targeting A_2A receptor may help improve movement when combined with dopamine-replacement therapy such as L-dopa. Caffeine has been linked to dopamine pathways, although there are still controversies on this. Epigallocatechin gallate (EGCG) in Camellia Sinensis (CS) have also been implicated in neuroprotection especially in AD. However, Telfeiria Occidentalis (TO), despite its widely explored systemic functions, there is still sparsity of information on the neuroprotective effect. Research on natural dopamine supplements is not as comprehensive considering the global significance. We therefore studied the effects of caffeine, CS and TO

saponins on antioxidant, inflammatory parameters and motor activity in MPTP-induced PD in female Swiss mice. 40 mice (20-30g) were used for the study, 35 were injected MPTP (ip) to induce PD. Mice were grouped into 8 (n=5); Control, were healthy mice administered 0.2ml of vehicle, Groups 2-8 were MPTP-induced PD administered; 0.2ml vehicle; 10mg/kg L-Dopa; 10mg/kg caffeine; 5mg/kg caffeine; 400mg/kg CS; 200mg/kg CS and 25mg/kg TO respectively for 3 weeks. Behavioral tests were performed using pole test, beam test and open field maze for motor activity and anxiety. Brain, liver and heart tissues were collected for antioxidant (SOD, CAT, GSH), inflammatory (TNFα, IL1-α), oxidative stress (MDA) markers, and serum lipid profile (TC, TG, HDL) assays. Brain tissues were also collected for IHC. TH and α-synuclein (α-syn) were assessed to account for dopamine loss. Results on brain showed CAT and GSH loss in PD mice, and was restored by caffeine, CS and TO administration. No change occurs for SOD across all groups. MDA was elevated in PD but was significantly reduced with the treatments. TNFα and IL1-α elevated in PD mice was also reduced close to normal in treated groups. Motor activity in the PD was impaired compared to control and treated groups with enhanced activity. Biochemical analysis showed that caffeine, CS, TO showed anti-inflammatory and antioxidant properties in the brain and other tissues. All treated groups showed enhanced serum lipid profile compared to PD model. More importantly, the IHC showed that TH was significantly increased in the treated groups and α-syn expression showed significant reduction in treated groups. Collectively, this study revealed that there was enhance motor activity and neuroprotection with caffeine, CS and TO treatment in MPTP-induced PD.

Title: Unbiased proteomic and transcriptomic analysis of sigma 2 receptor modulation in an in vivo model of synucleinopathy

Authors: *B. N. LIZAMA[1], A. REAVER[1], K. PANDEY[3], D. M. DUONG[4], N. T. SEYFRIED[4], A. O. CAGGIANO[2], M. E. HAMBY[1];
[1]Cognition Therapeutics, Inc., Pittsburgh, PA; [2]Cognition Therapeutics, Inc., Purchase, NY; [3]Emtherapro, Atlanta, GA; [4]Emory Univ. Sch. of Med., Atlanta, GA

Abstract: Synucleinopathies, which include Parkinson’s disease and dementia with Lewy bodies (DLB), comprise the second most prevalent neurodegenerative disease worldwide. Alpha

synuclein (αSyn) oligomers are the toxic form of αSyn protein contributing to neurodegeneration. αSyn oligomers can bind to synapses and spread trans-synaptically to anatomically connected regions. Small molecule modulators of the sigma 2 receptor (S2R) block αSyn oligomers from binding to neurons and reverse oligomer-mediated trafficking deficits *in vitro*. To elucidate the mechanisms by which the S2R impacts aspects of synucleinopathies, S2R modulators CT1812 and CT2168 were tested in an *in vivo* preformed fibril (PFF) model of pathological αSyn spreading. Using proteomics and transcriptomics, we assessed proteins, transcripts, and pathways in the PFF model that were altered by S2R modulators.
aSyn PFF or monomer was injected into the striatum of female Sprague Dawley rats. PFF-treated rats were dosed once daily *p.o.* (3mg/kg) with vehicle, CT1812, or CT2168, and monomer-treated rats dosed with vehicle, for ~60 days. Striatal tissue was harvested for proteomics (TMT mass spectrometry), and substantia nigra was harvested for RNAseq (N=10 per group), followed by differential expression and pathway analyses (Metacore, STRING).
Compared to monomer, αSyn PFF significantly decreased tyrosine hydroxylase (TH) and dopamine-related signaling proteins and transcripts ($p \leq 0.05$). αSyn PFF increased proteins and transcripts related to the immune response and significantly enriched pathways related to synapses and vesicle cycling ($p \leq 0.05$). We next analyzed the effects of CT1812 and CT2168 in the disease model. While a subset of significant proteins/transcript changes were unique to each compound, we observed overlapping changes related to cholesterol transport, metabolism, and cell survival ($p \leq 0.05$). All significantly differentially expressed proteins (47) and transcripts (74) in common between the two compound treatments exhibited the same directionality of change, including an increase ($p \leq 0.05$) in mRNA expression of cerebral dopamine neurotrophic factor (*Cdnf*), a neuroprotective protein. Given that each compound is chemically distinct, these data suggest that these common changes are driven by S2R.
Ongoing work includes mechanistic studies to further elucidate the mechanism of action of S2R modulation. These findings demonstrate that S2R ligands can modulate pathways associated with synucleinopathy and support further clinical development with CT1812, currently in Phase 2 clinical trials for DLB (NCT05225415). This work was supported by the Michael J. Fox Foundation.

Title: Pravastatin sensitizes parkinsonian rats to L-DOPA and blocks the long-term anti-dyskinetic activity of sub-anesthetic ketamine

Authors: *C. J. STOPERA[1], M. J. BARTLETT[5], S. L. COWEN[2], S. J. SHERMAN[3], T. FALK[4];
[1]Neurosci. GIDP, [2]Dept. of Psychology, [3]Dept. of Neurol., [4]Dept. Of Neurol., The Univ. of Arizona, Tucson, AZ; [5]Dept. of Neurol., Col. of Med., Tucson, AZ

Abstract: Our lab has shown that sub-anesthetic ketamine-treatment (10-hrs; 5 x 20 mg/kg *i.p.*; 2-hrs apart) both attenuates and provides long-term reduction of L-DOPA-induced dyskinesia in a rat 6-hydroxydopamine (6-OHDA) Parkinson's disease (PD) model. Additionally, our group also found that the long-term anti-dyskinetic effects of ketamine were brain-derived neurotrophic factor (BDNF)-dependent. HMG-CoA reductase inhibitor Pravastatin, a polar compound, has been shown by other groups to block the long-term anti-depressive activity of ketamine by interfering with the direct binding of ketamine to the receptor for BDNF, the TrkB receptor. Therefore, we tested if two types of statins, Pravastatin and Lovastatin that differ in polarity, also interfere with the anti-dyskinetic activity of ketamine. Unilateral 6-OHDA lesioned male Sprague-Dawley rats (n=12-17 per group) were pre-treated for 14 days with either vehicle, pravastatin (10 mg/kg; *s.c.*), or lovastatin (10 mg/kg; *i.p.*), and then maintained with daily injections of the treatment for an additional 14 days. During the treatment phase, rats were also simultaneously primed with daily L-DOPA injections (6 mg/kg; *i.p.*). The rats were treated with either vehicle or ketamine (20 mg/kg; *i.p.*) via the 10-hr treatment protocol on days 0 and 7 of the study, with no additional treatment on day 14. Limb, axial, and orolingual abnormal involuntary movements (AIMs) were scored every 3-4 days by a blinded investigator. On Days 0, 7, and 14, ketamine by itself and ketamine combined with lovastatin (the non-polar statin) significantly attenuated AIMs ($p<0.05$) compared to the vehicle treated group. These scores were not significantly different when comparing ketamine by itself to ketamine combined with lovastatin. Additionally, lovastatin by itself provided temporary reduction of AIMs score compared to vehicle ($p<0.01$) that did not persist long-term on Day 14. In contrast, on Day 0, pravastatin by itself significantly increased AIMs score compared to the vehicle treated group ($p<0.05$). When ketamine was combined with pravastatin (the polar statin) on Day 14, pravastatin blocked the long-term effects of ketamine, causing a significant increase in the AIMs score. This data suggests that the polar statin drug pravastatin sensitized the parkinsonian rats upon first exposure of L-DOPA and further interferes with the long-term anti-dyskinetic effects of ketamine, whereas the non-polar statin drug lovastatin does not interfere, and actually provides some anti-dyskinetic effects on its own. This data provides further support for the use of non-polar statin drugs when required by a patient with Parkinson's disease taking L-DOPA.

Abstract: Mitochondrial dysfunction underlies deficits in bioenergetics and degeneration of neurons in several neurodegenerative diseases. The Polg mutator ($Polg^{D257A}$ knock-in mutant) mouse model and cultured mouse embryonic fibroblasts (MEFs) from this model recapitulate the pathological elements of age-related somatic mitochondrial dysfunction observed in neurodegenerative and metabolic muscle diseases; and therefore could prove to be a valuable model in which to test drug efficacy and establish quantifiable biomarkers of mitochondrial dysfunction. $Polg^{D257A}$ mice demonstrate increasing locomotive deficits with age compared to littermate controls in open field locomotion and accelerating rotarod measures. In 8-10 month old $Polg^{D257A}$ mice, there was significant elevation of plasma lactate, 3-hydroxybutyrate, TCA metabolites (e.g. fumarate, malate, succinate and 2-ketoglutarte) and amino acids such as alanine, threonine, and isoleucine. In CSF, there were decreases in ascorbate, myo-inositol, amino acids, and TCA metabolites. Concurrent with elevated plasma alanine, we observed elevated levels of downstream 1-deoxysphingolipids in brain extracts from $Polg^{D257A}$ mice by LC-MS/MS quantification. Specifically, alanine-derived deoxydihydroceramides (doxDHCers) and deoxyceramides (doxCers) were elevated in Polg brain extracts and exhibited marked age-dependent increases compared to age-matched wild type controls. Furthermore, $Polg^{D257A}$ mutant MEFs show reduced oxidative consumption rate and increased glycolytic respiration when compared to wild type controls as measured by Seahorse mitochondrial stress test. High-passage $Polg^{D257A}$ MEFs (passage 16+) exhibit increased lactate production, decreased mitochondrial membrane potential and increased mtDNA copy number, suggestive of deficits in mitochondrial quality control. Further omics evaluation of the model is planned to enable an unbiased approach towards identifying a deficit signature for the mouse. Establishing quantifiable biochemical endpoints in both *in vitro* and *in vivo* systems against a common genotype and mitochondrial

deficit, enabled identification and validation of early and sensitive biomarkers for testing the efficacy of novel mitochondrial-targeted therapeutics.

Title: Naloxone partially blocks the anti-dyskinetic and enhances the antiparkinsonian effects of sub-anesthetic ketamine

Authors: *R. PARMAR[1], C. STOPERA[3], M. J. BARTLETT[4], A. ESQUEDA[5], S. J. SHERMAN[6], T. FALK[2];
[2]Dept. Of Neurol., [1]Univ. of Arizona, Tucson, AZ; [3]The Univ. of Arizona, Tucson, AZ; [4]Univ. Of Arizona, Tucson, AZ; [5]Yale Univ., New Haven, CT; [6]Dept. of Neurol., Univ. of Arizona Col. of Med., Tucson, AZ

Abstract: We have previously demonstrated that treatment with sub-anesthetic ketamine can reduce L-DOPA-induced dyskinesia (LID) in 6-hydroxydopamine (6-OHDA)-lesioned male rats and is acutely antiparkinsonian. Other studies have shown that ketamine is a multifunctional ligand with similar binding affinity to both *N*-methyl-D-aspartate (NMDA) and opioid receptors. Through NMDA receptor antagonism ketamine modulates neuroplasticity. Ketamine has agonist activity on μ- and κ-opioid receptors. In addition, the striatum is rich in both μ- and δ-opioid receptors and long-term L-DOPA therapy changes the levels of opioid peptides, and recent data indicates that opioid agonism is required for the anti-depressive activity of ketamine. We hypothesize that ketamine may also activate opioid receptors in the basal ganglia, contributing to either anti-dyskinetic or antiparkinsonian action. In a 1st study, we used the pan-opioid receptor antagonist naloxone to investigate if opioid receptor activation is necessary for reducing LID. Unilateral 6-OHDA lesioned male Sprague-Dawley rats were treated with 6 mg/kg of L-DOPA for 21 days to establish a pre-clinical model of LID. Once abnormal involuntary movements (AIMs) were stable over three testing days, the rats (n = 10-11/group) were treated on Day 0 with either vehicle, ketamine (20 mg/kg), or ketamine (20 mg/kg) + naloxone (3 mg/kg or 5 mg/kg) using a 10-hour treatment protocol where all animals received 5 treatments (i.p.) 2 hours apart.

Finally, L-DOPA was administered immediately following the 10-hour protocol and AIMs were assessed. All animals received L-DOPA (6 mg/kg) every 3-4 days to maintain the LID and AIMs were scored once a week. Similar to our published data, ketamine alone significantly reduced AIMs following the treatment ($p < 0.05$ vs. vehicle). Naloxone at the 3 mg/kg dose did not prevent the effect of ketamine ($p < 0.05$ vs. vehicle) to reduce LID. However, the addition of naloxone at the 5 mg/kg dose had a partial antagonistic effect and the anti-dyskinetic effect of ketamine was reduced by ~50%. This data suggests that opioid receptor activation may be contributing to the anti-dyskinetic effects of ketamine. In a 2nd study, we investigated if the antiparkinsonian activity of ketamine is dependent on opioid receptor activation in unilateral 6-OHDA-lesioned rats, using the forelimb adjusting steps (FAS) test in groups treated with ketamine or ketamine + naloxone (3 mg/kg or 5 mg/kg; n = 10/group). At the 3 mg/kg dose, naloxone did not change the efficacy of the antiparkinsonian activity of ketamine, whereas at 5 mg/kg dose, naloxone enhanced the antiparkinsonian effect of ketamine ($p< 0.05$ vs. ketamine alone).

Title: A structural perspective on the interaction between glucocerebrosidase and the positive allosteric modulator BIA 28-6156

Authors: J. M. DANTAS, N. M. F. S. CERQUEIRA, ***V. L. BATALHA**, L. KISS, T. KAROLI, J. HOLENZ;
BIAL - Portela & Cª. S.A., Trofa, Portugal

Abstract: BIA 28-6156 is a Phase II clinical candidate for the treatment of patients with Parkinson`s Disease (PD) who have a mutation in the Glucocerobrosidase (GBA1) gene (GBA-PD). Heterozygous GBA1 pathogenic variants are the most common genetic risk factor for PD, accounting for 5-15% of PD patients. Usually, GBA-PD patients present an earlier age of onset, may progress more rapidly, and may experience earlier and more significant cognitive impairment as compared with idiopathic PD patients. Here we describe the proposed structural

interaction of BIA 28-6156 with human recombinant glucocerebrosidase protein (hrGCase) and the impact of this interaction in presence of saposin C (Sap C), a key activator protein for glucocerebrosidase (GCase) in the lysosome. BIA 28-6156 increases *in vitro* wt hrGCase activity as determined using the 4-methylumbelliferyl-β-D-glucopyranoside (4-MUG) assay. Key structural interactions between BIA 28-6156 and an allosteric binding pocket of hrGCase were investigated using ligand- and protein-based NMR experiments. The binding site and binding pose of BIA 28-6156 at hrGCase were identified and characterized by molecular docking using glide and molecular dynamic simulations using the Desmond force field. The interaction between GCase with BIA 28-6156 and Sap C was modelled using HADDOCK. NMR experiments mapped the epitopes of BIA 28-6156 interacting with hrGCase and showed that this molecule influences the interaction between hrGCase and Sap C. Molecular modelling studies indicate that BIA 28-6156 binds to GCase in a shallow binding pocket, near the long α-helix of domain III and close to TRP312. This residue is located in an unfolded loop of GCase structure that undergoes a conformational change and is stabilized by BIA 28-6156. A model for GCase with BIA 28-6156 in complex with Sap C is reported suggesting a role played by BIA 28-6156 in the interaction between both proteins and provides insights on the mechanism underling the observed positive allosteric modulation of GCase.

Title: Investigating the impact of gut bacterial levodopa metabolism on Parkinson's disease outcomes

Authors: *C. OLSON, J. STANSIL, M. SANDY, K. SPITLER, E. BROWN, C. TANNER, A. NELSON, S. GOLDMAN, P. TURNBAUGH;
UCSF, San Francisco, CA

Abstract: Several studies report that the gut microbiota affects pathogenesis in Parkinson’s disease (PD) murine models. However, precise mechanisms are difficult to identify, and whether microbiome-based findings in PD models are clinically relevant is unclear. Our laboratory’s

prior collaborative work demonstrates that a common gut bacterium *Enterococcus faecalis* catabolizes levodopa through tyrosine decarboxylase. In preliminary findings in mice, antagonizing *E. faecalis* worsened whole blood levodopa pharmacokinetics. Through transcriptomic, sequencing, and pharmacokinetic approaches, we are evaluating which host and/or bacterial pathways are responsible for suppressed levodopa absorption. In a paired double-blind clinical trial of PD patients taking levodopa while consuming a mild antibiotic, we are evaluating whether particular gut bacterial composition, metabolism, or metabolites correspond with patient behavioral outcomes and responsiveness to levodopa. Combining a sequencing and targeted metabolomic approach may help identify gut bacterial pathways contributing to levodopa drug response and broader patient outcomes impacting quality of life.

Title: Investigating the role of free radicals and inflammation on the spread of pathological factors in Parkinson's disease

Authors: *P. XIAO[1], J. Y.-S. HO[2], R. CHANG[3];
[1]The Univ. of Hong Kong, Hong Kong, China; [2]The Hong Kong Polytechnic Univ., The Hong Kong Polytechnic Univ., Hong Kong, China; [3]Lab. of Neurodegenerative Diseases, LKS Fac. of Medicine, Univ. of Hong Kong, Lab. of Neurodegenerative Diseases, LKS Fac. of Medicine, Univ. of Hong Kong, Hong Kong, China

Abstract: Parkinson's disease (PD) is the second most common neurodegenerative disease worldwide. Loss of dopaminergic neurons within the Substantia nigra pars compacta (SNpc) and levy body deposits within cells are two major pathological characters of the PD. It has been shown that the spread of α-synuclein and tau protein, from the brainstem to limbic and neocortical structures, is one of the most important pathological factures of the PD dementia. Free radicals and inflammation play an important role in the development of PD, while their exact effect on the spread of pathological factors and mechanisms remains unclear. This study aims to investigate the effect of free radicals on the spread of pathological factors in PD mice model and evaluate their potential mechanisms. 6-OHDA is stereotactic injected into the median brain bundle of C57BL/6N mice to construct PD model. Our results show that at 3 weeks after the injection, there was significant motor function impairment and TH^+ cell loss (80.34 ± 2.48%) in the ipsilateral side of SNpc in 6-OHDA groups, compared with control group. At 7 weeks

after the injection, there was no significant cognitive impairment, neuronal loss, increased expression of mRNA for cytokines, and oxidative stress in the ipsilateral hippocampus in 6-OHDA groups by behavioral tests, qPCR and immunohistochemical analysis. In addition, no significant change of phosphorylate α-synuclein and tau was found in the ipsilateral hippocampus in 6-OHDA groups. These results may help us to understand whether oxidative stress is a key factor promoting spreading of pathological factors in PD pathogenesis.

Abstract: Accumulation of aggregated alpha-Synuclein (α-Syn) fibrils in Lewy bodies and Lewy neurites is a characteristic feature of Parkinson's disease (PD) and Dementia with Lewy Bodies (DLB). Phosphorylation of α-Syn at Ser129 is considered a marker of pathological α-Syn in synucleinopathies. Characterizing the factors that regulate this phosphorylation state can elucidate the molecular pathogenesis of these disorders and potentially identify new therapeutic strategies. We previously found that the B55α containing protein phosphatase 2A (PP2A) isoform is the main enzyme that dephosphorylates α-Syn at Ser129. The assembly and activity of this trimeric holoenzyme are regulated by reversible carboxyl methylation of the catalytic C subunit, a process governed by the opposing activities of a PP2A-specific leucine carboxyl methyltransferase (LCMT-1) and a PP2A-specific methylesterase (PME-1). Notably, our postmortem studies have shown that LCMT-1 expression is decreased while PME-1 expression is increased in PD and DLB affected brains. In this study, we aimed to determine if over-expressing LCMT-1 can mitigate α-Syn mediated pathology in a mouse model. Preformed fibrils (PFF) of α-Syn or PBS were injected in the right striatum of mice that overexpress LCMT-1 in forebrain neurons under the control of the calcium calmodulin kinase IIα (*CaMKIIα*) gene promoter as well as in control mice. At six months post-PFF injections, LCMT-1 over-

expressing mice exhibited better performance on the rotarod and nesting behavior compared with PFF injected control mice. Immunohistochemical stains showed that the ipsilateral striatum in LCMT-1 over-expressing mice had a smaller decrease in tyrosine hydroxylase (TH) levels and a smaller increase in the microglial marker Iba1 compared to PFF injected control mice. Additionally, LCMT-1 over-expressing mice exhibited less abundant phospho-S129-α-Syn labeled cells in the ipsilateral striatum and substantia nigra pars compacta compared to PFF injected control mice. These findings demonstrate that LCMT-1 over-expression mitigates the pathogenicity of α-Syn and its tendency to propagate in the brain. They also suggest that the reduced levels of LCMT-1 in human synucleinopathy brains contribute to the pathogenicity of these diseases through reduced phosphatase activity leading to increased α-Syn phosphorylation state. Thus, efforts to enhance PP2A activity have the potential for disease modification in synucleinopathies. Funding support: NINDS grant NS101134t

Department, Georgetown Univ. Sch. of Medicine, Biol. Department, Georgetown Univ. Col. of Arts and Sciences., Georgetown, DC

Abstract: In studying, age-related neurodegenerative proteinopathies, how microglia detect and react to disease-relevant proteins is not fully understood. We hypothesize that Toll-Like Receptors (TLRs), a subtype of pattern recognition receptors found on many types of innate immune cells including microglia, preferentially recognize and respond to pathogenic proteins like α-synuclein preformed fibrils (PFFs) and the HIV-1 protein Tat. Ligand binding to TLRs promotes the nuclear translocation of NF-κB, a transcriptional regulator of proinflammatory molecules. In this study we exposed HEK-TLR5 reporter cells to PFFs, Tat, or negative &

positive controls. The reporter, secreted alkaline phosphatase (SEAP) is under the control of NF-κB and SEAP activity, a surrogate for TLR activation, was measured in the cell culture supernatant. When compared to vehicle, both PFF- and Tat-exposed cells resulted in significant activation of TLR5 signaling (p<0.0001). Furthermore, inhibition of NF-kB signaling broadly via bindarit and of TLR5 more specifically using the novel antagonist (TH1020) caused significant reduction of SEAP activity. Next, we exposed primary microglia cultures to PFFs and showed an increase in TLR5 RNA expression (p<0.0009) and an increase in expression of the proinflammatory cytokines IL-1ß (p<0.0001) and IL-6 (p<0.0001). The gene expression of additional inflammatory modulators, matrix metalloprotease-9 (MMP; p< 0.0001), MMP-3 (p=0.0004); MMP-13 (p<0.0001) was also increased. Using ELISA and zymography, we confirmed significant increases in TNF-α (p=0.0002), IL-1ß (p=0.001), and MMP-9. However, when TLR5 antagonists or NF-kB inhibitors were applied to primary culture there were no significant changes to these proinflammatory molecules. Taken together, these data support the hypothesis that PFFs and TAT activate TLR5 promoting an inflammatory profile and suggest that attenuation of this signaling pathway may decrease NF-κB signaling. Future studies will test combinatorial drug approaches.

Title: Exogenous alpha-synuclein fibrils cause postsynaptic deficits in Lewy body dementia

Authors: *S. C. VERMILYEA[1], C. PEREZ DE NANCLARES[1], R. SCHLICHTE[1], J. MEINTS[1], H. CLARK[1], D. LIAO[1], A. ARAQUE[1], M. K. LEE[1,2];
[1]Univ. of Minnesota - Twin Cities, Minneapolis, MN; [2]Inst. for Translational Neurosci., Minneapolis, MN

Abstract: Alpha-synuclein (αS) is currently the primary pathological protein implicated in Parkinson's disease dementia (PDD) and dementia with Lewy bodies (DLB). Previously we have shown that mutant A53T αS transgenic mice (TgA53T) have tau-dependent age-related cognitive deficits. Further, A53T expressing neurons have GSK3β-dependent tau mislocalization to

dendritic spines leading to synaptic dysfunction. However, in PDD/DLB, most cases are linked to a known genetic mutation. Because dementia in PDD/DLB is associated with high neuritic αS pathology in CA2, likely from afferents of the entorhinal cortex (EC), without overt neurodegeneration, we hypothesize that in sporadic DLB, the neurites from EC neurons are releasing toxic αS, impacting hippocampal dendrites, leading to tau mislocalization and synaptic deficits that leads to cognitive deficits. Analysis of hippocampal sections from sporadic PD cases confirm neuritic αS pathology within the CA regions of the hippocampus. Significantly, while PD cases were devoid of pathological tau (e.g. AT8), hippocampal neurons exhibit tau mislocalization to the somatodendritic compartment in sporadic PD cases compared to controls. To directly test our hypothesis, we exposed primary cultures of hippocampal neurons to αS preformed fibrils (PFF). The neurons were transfected to express DsRed and Tau-eGFP to monitor the neurites/spines and tau, respectively. Live cell imaging at 24 hours post-PFF treatment shows that αS PFF, even at very low doses (0.05-4.0 υg/mL; 3.5-280 nM), causes tau mislocalization. Treatment of αS monomer (4.0 υg/mL) had no effect. We also show that αS PFF dependent mislocalization of tau occurs independent of endogenous αS but requires GSK3β activity. Longer term analysis shows that αS PFF does not impact the integrity of the spines within 72 hours. However, αS PFF causes significant loss of spines by 14 days post-PFF treatment, and both pre- and post-synaptic markers synapsin and PSD95 respectively, are significantly reduced. Finally, to define the in vivo significance of our hypothesis, we show that WT mice stereotactically injected with αS PFF to the CA1 region of the hippocampus have mEPSC frequency and amplitude deficits 48 hours after injection, as well as a lack of LTP following high frequency stimulation. We conclude that in PDD/DLB, Lewy neuritic pathology may be releasing toxic αS species leading to tau mislocalization and synaptic deficits that leads to circuit dysfunction and cognitive deficits.

Title: Blocking the aerobic/energy source in neurons via SGLTs inhibits/delays α synuclein transmission/propagation

Authors: *A. TANVIR, H. NOH, J.-B. KIM, S. PARK;
Dept. of Pharmacol., Ajou University, Sch. of Med., Suwon, Korea, Republic of

Abstract: Progressive loss of dopaminergic neurons in the substantia nigra (SN) pars compacta (SNpc) and the formation of cytoplasmic inclusions containing misfolded α-synuclein (α-syn), Lewy bodies (LBs), are two major neuropathological hallmarks of Parkinson Disease (PD),

which is the second most common neurodegenerative disease. PD and Diabetic mellitus (DM) share potential contributing factors and have overlapping pathology. Studies have unveiled a crucial connection between PD and DM. DM is characterized by impaired glucose metabolism and subsequent hyperglycemia. The elevated risk of developing cognitive abnormalities in individuals with impaired glucose metabolism has been well-documented. Hyperglycemia, a common pathogenesis in T2DM, has been shown to contribute to the onset of α-syn pathology in neurons and oligodendrocytes. Phosphorylated α-syn inclusions have been found in pancreatic β cells of T2DM subjects, indicating the existence of PD-related peripheral pathology in DM. But the complicated effect of glucose transporter on PD induced dopaminergic degeneration is still not well understood. Here, we demonstrate that α-syn fibrils induce active glucose energy transporter SGLTs activation in A53T alpha-synuclein overexpressing cells, which increase the uptake of α-syn into neurons. Furthermore, the inhibition of SGLTs inhibits the α-syn uptake and the formation of Lewy body-like inclusions. These results demonstrated a new therapeutic approach for PD.

Dis. Research, Dept. of Physiol. and Pharmacol., Univ. of Georgia, Georgia, GA; [6]The Univ. of Queensland, Brisbane, Australia

Abstract: Gut microbiome dysbiosis is closely associated with neurodegenerative diseases and the changes in the concentration of gut microbial metabolites act as a proof of concept for gut microbiome dysbiosis and potential prognostic biomarker in PD. Recent research has shown gut microbiome dysbiosis in PD patients that can lead to increased gut permeability and systemic inflammation. Recent studies have shown the circulating trimethylamine-n-oxide (TMAO) can cross the blood brain barrier (BBB) and associated with the progression of neurological diseases. Furthermore, emerging evidence suggests that gut microbial metabolites such as trimethylamine

(TMA) are elevated in PD patient bloods and associated with faster disease progression. In this study, we aimed to measure and compare the circulating levels of TMAO in healthy (n= 44) and PD (n= 46) patients. We also performed high resolution metagenomic shotgun analyses on healthy (n= 60) and PD (n= 17) patients to link the metabolites to altered gut microbial metabolism. Using mass spectrometry, we found levels of plasma TMAO were significantly higher in PD patients compared to controls. In consistent with this, we found an elevated levels of TMAO by- product, formaldehyde (FA) in plasma of PD patients. Interestingly, the shotgun metagenomic analysis of fecal sample showed altered diversity in the microbiota between PD and HC with an increase in the TMA-producing bacterial species and enzymatic pathways. Consistent with the published literature our data confirmed increased in the circulating levels of TMAO and metagenomics data confirmed key changes in microbiota composition such as *E. coli* and *Clostridium sp* between healthy individuals and PD patients. This suggests an increased propensity for production of pathogenic microbial metabolites such as TMA in the gut of PD patients due to gut dysbiosis causing an elevation in the levels of TMAO which can cross the blood- brain barrier (BBB), contributing to PD pathology and progression.

Abstract: Synucleinopathies, including Parkinson disease and multiple system atrophy (MSA), are a group of neurodegenerative diseases characterized by the intracellular accumulation of α-synuclein (α-syn). Recently, cryo-EM analysis demonstrated that α-syn fibrils in the brain of patients have disease-specific structures, although they shar the same cross-β-sheet structure. The structure of fibrils generated *in vitro* from recombinant α-syn (preformed fibril, PFF) also differs from that of the patient-derived fibrils. The difference in the structure of α-syn fibrils contribute to the difference in the disease-specific interactors that regulate the intracellular aggregation of α-syn. However, the exact molecules are still unknown. In this study, we aimed to identify disease-specific regulators of α-syn aggregation and performed a genome wide screening based on the CRISPR/Cas9 system. We edited the genomes of a monoclonal HEK293A cell line co-expressing Cas9 and α-syn with a genome-wide gRNA library and induced intracellular α-syn aggregation using PFF and MSA patient-derived fibrils. The intracellular α-syn fibrils were visualized by a fluorescent probe and cells were isolated based on fluorescence intensity using flow cytometry. Among 19,114 genes included in the gRNA library, 92 genes for MSA-derived fibrils were identified as disease-specific candidate genes. Gene ontology analysis of these candidates revealed disease-specific pathways related to α-syn aggregation. Our study suggests that disease-specific regulators and pathways may regulate intracellular α-syn aggregation, and that these may explain the difference in the pathogenesis of synucleinopathies.

Title: Exploring the impact of alpha synuclein on intracellular trafficking: insights into neurodegenerative disease mechanisms

Authors: *M. OVEJERO[1], M. BISBAL[1], A. CACERES[2], A. ANASTASIA[1,2];

Abstract: The regulation of intracellular trafficking in neurons is crucial since this cell type has a unique architecture, and the proper functioning of the exocytic pathway plays a fundamental role for its survival. Alpha synuclein (AS), is a widely studied protein for its involvement in various neurodegenerative diseases, including Parkinson's disease and synucleinopathies.

Despite being the focus of several studies, its normal function and its role in neuronal death remains partially understood. One intriguing hypothesis suggests that AS may be affecting intracellular trafficking, thus affecting neuronal survival. Our research focuses on unravel the effects of AS on this crucial process in mammalian neurons and how it affects their structure and function. We use an innovative exocytic pathway synchronization system which allows coordinated release of transmembrane proteins from the endoplasmic reticulum (ER) using a specific drug. This system enables us to analyze alterations in protein trafficking dynamics and vesicle flow. Through this synchronization system, we found that AS selectively affects protein trafficking from the Golgi apparatus to neuronal processes. Interestingly, AS modulates the trafficking of p75NTR and its vesicle size, while leaving the Transferrin Receptor unaffected. Furthermore, cofilin expression rescues AS-induced trafficking defects and neurodegeneration, as assessed by Sholl analysis. We propose that AS may alter the dynamics of the actin cytoskeleton, thus affecting the fission machinery of p75NTR vesicles. This result could explain the reduced p75NTR trafficking observed after the expression of AS. Our findings suggest that AS could induce neurodegeneration, at least partially, by affecting protein trafficking.

Abstract: Although dopaminergic neurons located in the ventral tier of the substantia nigra pars compacta (SNCv) are known to be more vulnerable to degenerate than those located in the dorsal

tier (SNCd), the underlying mechanisms sustaining such a differential vulnerability still are poorly understood. In this regard, the content in calbindin, a calcium-buffering protein specific for SNCd neurons and not found in SNCv neurons, has often been claimed to play a major role. Here we took advantage of a cohort of four non-human primates (NHPs) being injected with an adeno-associated viral vector encoding the human tyrosinase gene (AAV-hTyr) to further enhance pigmentation of dopaminergic neurons in both tiers of the SNC. Pigmented dopaminergic neurons exhibited Lewy body pathology made of endogenous alpha-synuclein, later on leading to a time-dependent degeneration of dopaminergic neurons, together with a pro-inflammatory scenario. Immunohistochemistry for calbindin and ALDH-1 was used to disclose between neurons in the SNCd and SNCv respectively, together with P62 as a marker for Lewy body pathology. Obtained data showed a preferential location for Lewy bodies within SNCv neurons (identified as ALDH-1+), this distribution accounting for more than 90% of P62+ intracytoplasmic inclusions observed in pigmented neurons throughout the whole rostrocaudal extent of the SNC. Lewy bodies were also found in SNCd neurons, although to a much lower extent than those observed in SNCv. In summary, here we provide evidence showing that the location of Lewy body pathology, instead of the lack of calbindin, may be taken as the driving force sustaining the susceptibility of dopaminergic SNCv neurons to neurodegeneration.

Abstract: α-Synuclein (αSyn), one of major components of Lewy bodies (LBs) and Lewy neurites (LNs), is physiologically expressed in presynapses and is involved in synaptic function. Abnormal intracellular aggregation of αSyn is observed as LBs and LNs in neurodegenerative disorders such as Parkinson’s disease or dementia with Lewy bodies. Accumulated evidence suggests that abundant expression of αSyn is one of the risk factors for neurodegeneration. Therefore, it is important to know the endogenous expression profiles of αSyn. Our previous

studies demonstrated brain region-dependent differential expression patterns of αSyn using wild-type mice. Synaptic expression of αSyn is mostly accompanied by the expression of vesicular glutamate transporter-1 (vGluT-1), an excitatory presynaptic marker protein. In contrast, expression of αSyn in GABAergic inhibitory synapses is different among brain regions. For examples, in the cerebral cortex and hippocampus, αSyn is not observed in inhibitory synapses. On the other hand, αSyn is clearly expressed in inhibitory synapses of the globus pallidus and substantia nigra pars reticulata. These results indicate that expression of αSyn is regulated in cell-type or brain-region dependent manner. Here, we studied expression profiles of αSyn in human and common marmoset brain. In the cerebral cortex of the primate brain, αSyn was mainly expressed in the excitatory synapses expressing vGluT-1, as happens in mouse brain. Interestingly, there were some αSyn-positive synapses co-expressing glutamic acid decarboxylase in those brains. These results suggested that expression profile of αSyn in inhibitory synapses was different between rodents and primates. Precise characterization of these αSyn-positive inhibitory neurons is under progress. Further studies of the differential expression of αSyn among different species will provide new insights for understanding physiological function of αSyn.

Title: Phosphoproteomic changes as an early stage predictive indicator of cortical synaptic dysfunction in synucleinopathies

Authors: *A. SCOTT[1], S. DUTTA[2], H. KHAN[1], R. FERREIRA[1], L.-A. ROSSITTO[3], U. ARAYAL[1], K. JAYANT[1], X. CHEN[3], J.-C. ROCHET[1];

Abstract: Cortical dysfunction plays a critical role in non-motor symptoms associated with Parkinson's disease (PD) and other synucleinopathies. Recent studies have reported functional changes in cortical circuitry in pre-clinical models of PD, but with limited mechanistic insight. Therefore, in search of causative or predictive factors, we hypothesized that aSyn aggregation leads to alterations of the cellular phosphoproteome. To address this hypothesis, we utilized an *in vivo* model of aSyn aggregation involving the injection of aSyn preformed fibrils (PFFs) in the mouse cortex and striatum to study the downstream effects of aggregation. We analyzed phosphoproteomic profiles of the cortical homogenates of the PFF injected vs monomer injected mice. In this model, we showed that PFF injection leads to the presence of aSyn aggregates that

stain positive for the phosphorylated form of serine residue 129 (pSer129) in the sensorimotor cortex, SNpc, and other anatomically connected brain regions. Phosphoproteomic analysis of the sensorimotor cortex revealed significant differences between the PFF and monomer groups 3 months post-injection. Gene ontology analysis of the phosphoproteomic changes suggested that aSyn PFF administration led to perturbations in modulation of chemical synaptic transmission and synaptic signaling. Moreover, we identified phosphosites that were previously not reported and distinct from sites reported for acute synaptic excitation. Further, motif enrichment analysis and kinase prediction show that the majority of differentially abundant motifs are predicted to be phosphorylated by cyclin dependent kinase 5 (CDK5) or casein kinase II (CKII). The phosphoproteomic changes suggest a possible mechanism of synaptic dysfunction in the sensorimotor cortex of PFF-injected mice. Collectively, these findings deepen our understanding of the molecular underpinnings of synucleinopathy disorders, particularly the prodromal phase, laying the groundwork for developing well-tailored intervention strategies.

Title: Partial Demyelination Worsens a-Synucleinopathy in the Preformed Fibril Model

Authors: *R. N. CLARK[1], R. E. LANDES[1], M. ABBAS[1], A. JAMENIS[1], K. MINER[1], K. C. LUK[2], X. HU[3], R. LEAK[1];

Abstract: Lewy body disorders are characterized by deposition of aggregated alpha-synuclein protein into insoluble inclusions. In Parkinson's disease, long and unmyelinated axons (*e.g.*, nigrostriatal fibers) are more likely to harbor alpha-synuclein^{+} inclusions, compared to sturdier, myelinated fibers (*e.g.*, cerebellar tracts), but it is not known if this relationship is causal. To address this problem in an experimental model of Lewy body disease, we infused preformed fibrils into the anterior olfactory nucleus of the caudal olfactory bulb (OB/AON) in 9 to 11-month-old mice of both sexes. Partial demyelination was elicited by dietary administration of cuprizone (0.3%), an established oligodendrocyte-targeting, copper chelating agent, for 8 weeks.

Compared to control diet mice, cuprizone-fed animals of both sexes displayed the expected decrease in two major protein constituents of the myelin sheath, myelin basic protein (MBP) and proteolipid protein (PLP) in the OB/AON. However, no additional loss of MBP and PLP was observed in fibril-treated mice, suggesting that cuprizone and fibril exposure act neither additively nor synergistically on myelin-associated proteins, perhaps because they impinge on the same physiological processes in white matter. However, cuprizone exposure increased the fraction of Triton-insoluble alpha-synuclein that was phosphorylated at Serine 129 (pSer129) in the amygdala and piriform cortex, revealing an exacerbation of insoluble Lewy-like pathology with forced demyelination. Insoluble pSer129 levels were negatively correlated with PLP levels in fibril-infused mice under control diet conditions (r=-0.7026; two-tailed p=0.0187), and this negative correlation was abolished by cuprizone exposure (r=-0.1067; two-tailed p=0.7692). Thus, higher levels of myelin-related protein PLP are associated with lower Lewy-like pathology as expected, but forced demyelination uncouples this link. Similarly, we discovered a negative correlation between PLP and Triton-insoluble pSer129 alpha-synuclein levels in amygdala tissues from men (but not women) with Lewy body disease (Pearson r=-0.9026, two-tailed p=0.0054), and a trend towards a negative correlation between MBP and insoluble pSer129 in the human amygdala samples (Pearson r=-0.7233, two-tailed p=0.0662). Finally, we noted that Lewy body disease was associated with lower MBP levels in the olfactory bulbs of men compared to women. Further investigations into oligodendrocyte precursor cells and pre- and post-myelinating oligodendrocytes are now warranted, to understand the impact of myelination status on Lewy body disease.

Title: Synucleinopathy decreases the expression and membrane localization of the complement regulator CD55 prior to neurodegeneration.

Authors: N. C. KUHN[1], J. R. PATTERSON[1], C. J. KEMP[1], A. C. STOLL[1], K. STEECE-COLLIER[1], K. C. LUK[2], C. E. SORTWELL[1], ***M. J. BENSKEY**[1];

Abstract: Parkinson's disease (PD) is characterized by loss of midbrain dopamine neurons, accumulation of fibrillar alpha synuclein (a-syn) in Lewy bodies, and neuroinflammation.

Neuroinflammation occurs in early-stage PD patients, suggesting it may contribute to neurodegeneration. The complement system is a division of the innate immune system that coordinates the clearance of debris, synapses, and cells in the central nervous system. Activated complement proteins label Lewy body containing neurons in the PD brain, indicating complement may mediate phagocytic removal of synucleinopathy affected neurons. However, activation of complement in PD and associated models has only been documented after neurodegeneration has occurred, making it impossible to determine if complement activation occurs in response to cell death or prior to cell death, where it may drive to neurodegeneration. We aimed to determine if complement activation occurs in the substantia nigra pars compacta (SNc) prior to neurodegeneration in a model of synucleinopathy. Intra-striatal injection of recombinant a-syn pre-formed fibrils (PFFs) in rats results in aggregation of endogenous a-syn and gliosis that peaks 2 months post injection, followed by nigral degeneration at 6 months post injection. To determine if synucleinopathy causes complement activation prior to neurodegeneration we used ddPCR to quantify transcripts representing different parts of the complement cascade. We observed significant increases in transcripts from the classical (C1qa, C4b) and alternative activating pathways (CFd, Cfb), anaphylatoxin receptors (C3aR, C5aR), phagocytic receptor CD11b (ITGAM) and the complement regulator, C1 Inhibitor (Serping1). We observed significant decreases in transcripts for the complement regulators CD55 and CD59. We performed immunofluorescence (IF) in the SNc at the same time point to determine if the decrease in CD55 occurred in nigral neurons. CD55 immunoreactivity was decreased in nigral neurons of PFF injected rats, where neurons containing serine 129 phosphorylated a-syn (pSyn) were almost devoid of CD55 immunoreactivity. Using the proximity ligation assay we observed interaction between a-syn and CD55 in the rat SNc, and this interaction was increased between CD55 and pSyn. We performed similar analyses in postmortem human PD tissue and observed decreased CD55 in nigral neurons, interaction between pSyn and CD55 in the SNc, as well as CD55 in the core of Lewy bodies. Taken together, these data demonstrate synucleinopathy causes a robust activation of the complement system and a decrease in the expression of membrane bound complement regulators in nigral neurons.

Abstract: Neuroinflammation has been implemented as a confounding variable in the pathology and progression of neurodegenerative diseases such as Alzheimer's (AD) and Parkinson's (PD). However, methods in capturing and concurrently measuring these pathological markers (such as alpha-synuclein) and their affected systems (cytokine readouts) in a singular animal are limited by collection methods and analytical viability. The benefits of simultaneous profiling for immune-markers and disease biomarkers may elucidate pathways and therapeutic windows that can alter and/or ameliorate disease progression. To address this limit, we set out to test the concurrent sampling methods of large molecule microdialysis, push-pull (semi-porous membrane with 1-3 MDa cutoff) versus open flow (unfiltered, theoretically no limit). We acquired a cohort of 22-month aged PD transgenic (TG) mice that overexpressed human wild-type alpha-synuclein (JAX# 017682), their age-matched non-carrier (WT) littermates, and stereotaxically implanted a bilateral guide in the hippocampus (A/P -3.1mm to bregma, M/L +/- 2.8mm to midline). After a two-week recovery period, a push-pull probe (PP PE 6/3, CRL-GRO, the Netherlands) was inserted in the left hippocampus (D/V -4.1mm to dura), and an open flow sampling stylet (cOM-8, BASi, USA) in the right hippocampus (D/V -3.6mm to dura). A dynamic-no-net-flux (DNNF) microdialysis was performed in awake, freely behaving animals at four varying flow rates from 0.5 µl/min to 1.25 µl/min. Probes and stylets were perfused with aCSF (147 mM NaCl, 3.0 mM KCl, 1.2 mM CaCl2 and 1.2 mM MgCl2) containing 1% BSA and 2mM glucose. Samples were collected and aliquoted for alpha-synuclein protein analysis and a proinflammatory panel assay from Meso Scale Discovery (MSD# K15048). All samples were measured via ELISA/EIA kits acquired from MSD®. As expected, probe recoveries for absolute concentrations of the various analytes were higher from the open flow conditions when compared to the push-pull method. Surprisingly, the flow rate affected the recovery of analytes in the "unfiltered" open flow stylet, like the push-pull condition where higher flow rate samples measured lower analyte concentrations. Furthermore, BSA additives for non-specific binding during collection and analysis also showed differing analyte concentrations (*in vitro* results). Therefore, generating accurate biomarker profiles in disease pathology from large molecule dialysis must be sensitive to technical conditions and analytes of interest in neuropathology.

Title: Impact of post-translational modifications on membrane-induced alpha-synuclein aggregation in synucleinopathy disorders

Authors: *M. GUZMAN SOSA[1], O. ALI[1], S. DONZELLI[3], S. DUTTA[1], A. SADEK[3], P.-M. E. IVEY[1], K. J. WEBB[1], H. A. LASHUEL[4], J.-C. ROCHET[2];

Abstract: Alpha-synuclein (aSYN) is a presynaptic protein that forms aggregates in the brains of individuals with Parkinson's disease (PD) and other synucleinopathy disorders. aSYN is a natively unfolded protein in solution but can adopt an alpha-helical structure upon binding to phospholipid membranes, and this interaction is thought to play a role in vesicle trafficking and the release of neurotransmitters. Data from our group and others suggest that the aggregation of membrane-bound aSYN plays a central role in the protein's neurotoxicity in PD via a mechanism involving vesicle disruption. Furthermore, increasing evidence suggests that the mechanism of membrane-induced aggregation is distinct from the more extensively studied process of aSYN aggregation in the absence of membranes. Although various post-translational modifications (PTMs) of aSYN identified in cell culture, animal models, or human brain have been shown to modulate aSYN aggregation in the absence of lipids, little is known about the effects of PTMs on membrane-induced aSYN self-assembly. We hypothesize that certain PTMs promote the protein's aggregation at the surface of phospholipid membranes, resulting in enhanced aSYN neurotoxicity, based on evidence that some PTMs alter the conformation of membrane-bound aSYN and/or perturb aSYN-membrane interactions. To address this hypothesis, aSYN variants with N- and C-terminal truncations previously identified in the human brain were characterized in terms of their relative propensities to undergo membrane-induced self-assembly and elicit vesicle disruption. We found that aSYN variants with C-terminal truncations underwent more extensive oligomerization and accelerated fibrillization compared to WT aSYN when incubated with phospholipid vesicles at a low pH mimicking the acidic conditions of endocytic compartments. Moreover, the rate of aSYN-mediated vesicle disruption at pH 7 (relevant to cytosolic conditions) increased with the extent of the C-terminal truncation. In general, N-terminal aSYN truncation mutants formed oligomers or fibrils more rapidly than WT aSYN in the presence of vesicles at low pH but had a reduced ability to elicit membrane permeabilization at pH 7. Current efforts are focused on characterizing our panel of aSYN truncation variants in terms of aggregation propensity in neuronal cell culture models using fluorescence lifetime imaging microscopy (FLIM) analysis. The results of these studies will provide new insights into the role of aSYN PTMs and membrane-induced aggregation in the pathology of synucleinopathy disorders, setting the stage for developing therapies targeting aSYN in the brains of patients.

Abstract: The defining feature of Parkinson disease (PD) and Lewy body dementia (LBD) is the accumulation of alpha-synuclein (Asyn) fibrils in Lewy bodies and Lewy neurites. We developed and validated a novel method to amplify Asyn fibrils extracted from LBD postmortem tissue samples and used solid state nuclear magnetic resonance (SSNMR) studies to determine atomic resolution structure. Amplified LBD Asyn fibrils comprise two protofilaments with pseudo-2_1 helical screw symmetry, very low twist and an interface formed by antiparallel beta strands of residues 85-93. The fold is highly similar to the fold determined by a recent cryo-electron microscopy study for a minority population of twisted single protofilament fibrils extracted from LBD tissue. These results expand the structural landscape of LBD Asyn fibrils and inform further studies of disease mechanisms, imaging agents and therapeutics targeting Asyn.

Title: Caffeic Acid Inhibits α-Synuclein Seeding Activity in Real-time Quaking-Induced Conversion (RT-QuIC) Seed Amplification Assay: Relevance to Translational Research in Synucleinopathies

Authors: *A. GEORGE[1,2], C. JANARTHANAM[2], P. PADHI[2], J. THOMAS[2], H. JIN[2], V. ANANTHARAM[2], A. KANTHASAMY[2], G. PHILLIPS[3], A. KANTHASAMY[2];

Abstract: Parkinson's Disease (PD) and other synucleinopathies, including Dementia with Lewy Bodies (DLB) and Multiple System Atrophy (DLB), are characterized by the accumulation of proteinaceous amyloid fibrils primarily composed of α-synuclein (αSyn) in the brain. The currently available treatment options for PD mainly target its symptoms but do not alter αSyn seeding activity and disease progression. Recently, we and others have developed an ultra-sensitive αSyn real-time quaking-induced conversion (RT-QuIC) seed amplification assay termed αSyn SAA for detecting αSyn seeding activity in multiple biomatrices including brain, CSF, submandibular gland and skin. To extend this versatile αSyn SAA platform for translational drug discovery, we tested whether it can be adapted to identify compounds intervening in the seeding activity. As proof of principle, we tested caffeic acid (CA), which is a well-known phytochemical enriched in many foods and drinks including coffee. CA has been shown to possess diverse biological functions, such as anti-inflammatory and antioxidant properties. Our initial experiments tested various CA concentrations ranging from 50nM to 100μM range in αSyn SAA. The addition of CA to the RT-QuIC reaction mixture containing human αSyn synthetic fibers exhibited a dose-dependent inhibition on the formation of αSyn fibrillar seeds, with complete suppression observed at low μM concentrations. Next, we prepared human brain homogenates obtained from autopsy-confirmed PD cases to test in the αSyn SAA in the presence and absence of different concentrations of CA. We observed a consistent dose-dependent inhibition of αSyn seeding activities upon the addition of CA, with complete suppression at low μM concentrations. In line with the RT-QuIC findings, dot blot analysis of the RT-QuIC end-products obtained from PD brain homogenates using an αSyn filament-specific antibody also demonstrated a dose-dependent inhibitory effect of CA against αSyn seeding *in vitro*. Collectively, these findings indicate that CA exerts an inhibitory effect on the aggregation of αSyn and suggest that CA and its related analogs should be further explored for the development of anti-αSyn pharmacotherapy for treating synucleinopathies. Our data also demonstrate that the RT-QuIC-based αSyn SAA could be exploited as an *in vitro* drug discovery platform for screening anti-synucleinopathy agents.

Title: Altered cortical cellular and network dynamics in a PFF-based model of Parkinson's Disease

Authors: *P. A. PATEL, K. A. FERGUSON, J. A. CARDIN, M. J. HIGLEY;
Neurosci., Yale Univ., New Haven, CT

Abstract: Parkinson's disease (PD) is characterized by progressive decline of motor function and tremor primarily resulting from loss of dopaminergic cells in the substantia nigra. However, prodromic and progressive cognitive symptoms also suggest neocortical dysfunction, a structure for which relatively little is known about PD-associated cellular- or circuit-level changes. To explore this question, we adopted a pre-formed α-synuclein fibrillar (PFF) seeding model to drive pathogenesis in cortical projection neurons. We found that injection of PFFs into the dorsal striatum robustly drives intracellular accumulation of α-synuclein phosphorylated at serine 129 (pS129) in pyramidal neurons (PNs) of the ipsilateral somatosensory and motor cortices. To monitor neural activity, we carried out 2-photon calcium imaging of GCaMP6s-expressing PNs in these cortical areas of awake, head-fixed mice placed on a freely-moving running wheel. We used animals of both sexes over the course of pathological progression. Control experiments included imaging the cortex contralateral to the injection site as well as imaging mice injected with a non-pathogenic α-synuclein monomer. Individual neurons were tracked across multiple imaging sessions spanning several weeks. At the conclusion of the final imaging session, brains were collected for pS129 immunostaining to identify cells with pathological aggregates. These images were then aligned post-hoc with *in vivo* imaging data to determine the single-neuron relationship between dysfunction and the presence of inclusions. Our initial results suggest pathological cells exhibit elevated levels of resting cytosolic calcium. Furthermore, there were significantly reduced amounts of spontaneous activity and blunted modulation in response to fluctuations in behavioral state, measured via variation in pupil diameter, whisking, and locomotion. Finally, using immunohistochemistry to probe activated microglia via increased IBA1 and CD68 immunoreactivity as well as astrocyte activation by elevated GFAP, we found evidence of non-cell autonomous glial inflammatory activity surrounding the areas of altered neuronal activity. Together, these results provide novel insight into cellular and circuit mechanisms underlying the progression of neocortical α-synuclein pathology.

Title: Regulation of L-type Ca^{2+} channels by alpha-synuclein

Authors: *S. CHOI[1,2], M. BEN-JOHNY[3], M. SOMAYAJI[4], E. KANTER[4,2], D. SULZER[4,2], E. V. MOSHAROV[4,2];

Abstract: α-Synuclein (α-Syn) plays a central role in sporadic and familial Parkinson's Disease (PD) via a toxic gain-of-function mechanism, and a variety of experimental strategies are under development to decrease α-Syn levels in PD patients. α-Syn deficiency has been shown to alter the kinetics of dopamine release, but there has been relatively little analysis of changes in endogenous physiological responses in neurons expressing normal levels of the protein. We studied the effects of α-Syn deficiency on intrinsic electrophysiological properties in mouse mesencephalic neuron in culture and acute midbrain slices. Although substantia nigra (SN) dopaminergic neurons from α-Syn deficient cells showed overall normal electrophysiological properties, they had significantly lower L-type Ca^{2+} channels (LTCC) activity than cells from wild-type animals. This effect was likely related to a decrease in surface expression of LTCCs with no alteration in mRNA or single channel open probability and conductance. The decreased activity-dependent Ca^{2+} flux resulted in deficient pCREB/cFos induction - a central step in the regulation of immediate early genes expression required for synaptic plasticity. We conclude that strategies for α-Syn reduction should examine possible changes in LTCC activity and downstream second messenger systems that regulate synaptic plasticity and learning.

Title: Role of Norepinephrine in the spread and aggregation of Lewy pathology in an α-synuclein PFF mouse model.

Authors: *R. MIRABEL;
Univ. of Florida, Gainesville, FL

Abstract: Specific Aims
Role of Norepinephrine in the spread and aggregation of Lewy pathology in an α-synuclein PFF mouse model.
Background: Parkinson's disease (PD) is a neurodegenerative disorder prevalent in ~1% of the population above 60 years, and is characterized by severe motor deficits as well as non-motor symptoms such as loss of smell, constipation and cognitive disability. Sporadic PD is characterized by widespread alpha-synuclein (α-syn) positive inclusions called Lewy bodies and neurites in the brain, along with loss of dopamine neurons of the S*ubstantia nigra pars compacta* (SNpc). However, the underlying mechanisms of α-syn mediated pathogenesis, progression, and neurodegeneration are still not clear. Consequentially, strategies for treating pathogenesis and progression of sporadic PD have not been well developed. Previous studies and our preliminary data suggest that the norepinephrine transporter (NET) is a potential therapeutic target for α-syn pathology in PD. Our overall **hypothesis** is that genetic deletion or pharmacological inhibition of NET will reduce α-syn propagation, neurodegeneration, neuroinflammation and behavioral deficits. We will test our hypothesis by injecting pre-formed fibrils (PFFs) of α-syn in a genetic or pharmacological mouse model of NET inhibition.**Method**: 5 μg of α-syn PFFs or 0.8 μl of PBS (control) were injected unilaterally into the dorsal striatum of WT and NET KO mice. 3- or 6- months after injection, brains from WT and NET KO mice were isolated, sectioned, and stained for phosphorylated serine 129 (pSer129) of α-syn, tyrosine hydroxylase (TH) and NET. A separate cohort of WT mice seeded with PFFs were also administered desipramine (30mg/kg/day) in their drinking water after PFF injections. All mice also underwent behavioral analyses for motor function prior to immunostaining.**Results**: pSer129 α-syn aggregates and neurites were observed throughout the cortex, basal ganglia and midbrain in WT mice at 3- and 6-months post-injection. In the midbrain, pSer129 α-syn labeling was partially colocalized with TH labeling. pSer129 α-syn labeling was reduced in NET KO mice compared to WT mice in all brain regions at 3 and 6-month timepoints.**Conclusion**: Genetic or pharmacological inhibition of NET reduces the spread and aggregation of α-syn in a PFF seeding mouse model, and has a reduced propensity to cause motor dysfunction.

Title: Serine-129 phosphorylation of α-synuclein is an activity-dependent trigger for physiologic protein-protein interactions and synaptic function

Abstract: Phosphorylation of α-synuclein at the Serine-129 site (α-syn Ser129P) is an established pathologic hallmark of synucleinopathies, and also a therapeutic target. In physiologic states, only a small fraction of α-syn is phosphorylated at this site, and most studies have focused on pathologic roles of this post-translational modification. We found that unlike wild-type (WT) α-syn that is widely expressed throughout the brain, the overall pattern of α-syn Ser129P is restricted, suggesting intrinsic regulation. Surprisingly, preventing Ser129P blocked activity-dependent synaptic attenuation by α-syn - thought to reflect its normal function. Exploring mechanisms, we found that neuronal activity augments Ser129P, which is a trigger for protein-protein interactions that are necessary for mediating α-syn function at the synapse. AlphaFold2-driven modeling and membrane-binding simulations suggest a scenario where Ser129P induces conformational changes that facilitates interactions with binding partners. Our experiments offer a new conceptual platform for investigating the role of Ser129 in synucleinopathies, with implications for drug-development.

Title: Age-dependent motor and cognitive decline following neurotoxic α-synuclein exposure in new Parkinson's disease models

Authors: M. CHEN[1], K. SZELONG[1], J. VINCENT[1], A. EZEANII[1], S. WAKADE[2], S. YERIGENAHALLY[1], **D. E. MOR**[1];
[1]Augusta Univ., Augusta, GA; [2]Georgia Inst. of Technol., Atlanta, GA

Abstract: Parkinson's disease (PD) is a debilitating neurodegenerative disorder characterized by both motor and cognitive symptoms and the formation of pathological inclusions containing aggregated α-synuclein protein. The gut-to-brain hypothesis of PD suggests that α-synuclein aggregation may originate in the gastrointestinal tract, potentially due to environmental toxin exposures, and thereafter spread to the central nervous system in a prion-like fashion. While rodent models have demonstrated that gut-to-brain α-synuclein spreading can occur, the precise mechanisms of α-synuclein transmission and resulting neurotoxicity remain largely unknown. Animal models that are amenable to rapid, high-throughput investigation are needed in order to facilitate the discovery of disease mechanisms and potential therapeutic targets. To this end, we have developed new 'gut-to-brain' PD models using the small model organism, *C. elegans. C. elegans* have a well-defined nervous system with highly conserved neurotransmitter signaling, a diverse set of motor and cognitive behaviors, and high genetic tractability. To initiate α-synuclein spreading from the gut, worms are exposed to an exogenous source of wild-type human α-synuclein pre-formed fibrils (PFFs). We have shown that PFFs are ingested, spread to body tissues, and induce age-dependent motor dysfunction that is dependent on host expression of human α-synuclein in neurons or muscle, consistent with prion-like mechanisms. PFF feeding also promotes dopamine neuron degeneration and the aggregation of host α-synuclein, recapitulating key features of PD. Furthermore, PFF exposure causes age-dependent loss of learning and memory function, offering new models of cognitive decline in PD. To identify mechanisms by which gut-derived α-synuclein may enter neurons and cause toxicity, we conducted a targeted RNAi screen and showed, for the first time *in vivo*, that heparan sulfate proteoglycans regulate disease phenotypes caused by α-synuclein PFFs. The results of this study offer new tools and potential targets for PD therapeutics aimed at halting the neurotoxic spread of α-synuclein from the gut to the brain.

Title: Reactive astrocyte-derived neurotoxins are responsible for the neurodegeneration in a model of Parkinson's disease

Authors: J.-J. SONG, H. PARK, Y. CHOI, J. WANG, J. SHIN, S.-C. CHOU, A. JHALDIYAL, V. DAWSON, T. DAWSON, ***T.-I. KAM**;
Dept. of Neurol., Johns Hopkins Univ. Sch. of Med., Baltimore, MD

Abstract: Activation of microglia can lead to the conversion of astrocytes to neurotoxic species of reactive astrocyte that are observed in post-mortem tissues of various neurodegenerative diseases including Parkinson's disease (PD) and Alzheimer's disease (AD). However, it is not clear whether and how reactive astrocytes contribute to neurodegeneration of PD. We have recently developed a mouse model of sporadic α-synucleinopathy in which α-synuclein (α-syn) preformed fibrils (PFFs) were injected into the duodenum and the pylorus muscularis layer in the stomach that are innervated by the vagal nerve. In this gut-brain α-syn model, the α-syn pathology spreads in the brains and the mice exhibit a non-motor behavior including cognitive deficits as well as motor deficits. Here, we showed genetic depletion of neurotoxic reactive astrocytes in the gut-brain α-syn mouse prevented the loss of neurons and behavioral deficits, suggesting that neurotoxic reactive astrocytes play an important role in neurodegeneration induced by pathologic α-syn. Using secretome analysis, we isolated the neurotoxins that are secreted from the α-syn-induced reactive astrocytes and induce the neurotoxicity. Inhibition of secretion of neurotoxins in astrocytes or its receptor in neurons suppressed the reactive astrocyte-mediated neurotoxicity in cultures. Moreover, pharmacological inhibition or genetic depletion of neurotoxin receptor prevented pathologic α-syn-induced neurodegeneration and movement and cognitive deficits in the gut-brain α-syn mouse. Thus, strategies aimed at inhibiting reactive astrocyte-derived neurotoxins and its neuronal receptor could hold promise as a disease-modifying therapy to prevent the loss of neurons in α-synucleinopathies.

Title: Alpha-synuclein-induced cognitive impairment and disruption of glutamate and complement systems in the hippocampus and striatum of mice

Authors: *Y.-T. HUANG[1], Y.-Y. LEE[1], H.-Y. LI[3], J.-C. CHEN[2];
[1]Chang Gung Univ., Tauyuan, Taiwan; [2]Chang-Gung Univ., Chang Gung Univ., Tao-Yuan, Taiwan; [3]Oregon Inst. Technol., Oregon Inst. Technol., Klamath Falls, OR

Abstract: Parkinson's disease (PD) belongs to a neurodegenerative disease with characteristic phenotype of movement disorder, while some patients show non-motor symptoms of anxiety, depression and dementia (so called PDD). Clinically, abnormal aggregation of α-synuclein (α-Syn) was found in patient's brain, whereas α-Syn-enriched Lewy bodies signal a neuronal death. So far, the cause of PDD is rarely explored and molecular alterations linking hippocampal synucleinopathy to dementia requires further investigation. To mimic the symptoms the PDD, mice were injected with AAV-α-Syn bilaterally into the substantia nigra (SN). Mice exhibited motor dysfunction after 6 months viral injection, along with anxiety, depression-like behavior and cognitive-related deficits. Biochemical analyses revealed decreased gene expression of glutamatergic receptors (NR2A, NR2B, mGluR5, AMPA1) in the SN, striatum (STR) and hippocampus (HIP). The microglia markers, Iba1 and complement C3 were also decreased in the STR and HIP. At the protein level, Syn211 expression increased in the SN, STR, and HIP, and phosphorylated Ser129 of α-Syn was observed in the SNc, along with activated GFAP and Iba1. To understand synucleinopathy-induced dementia, mice were injected α-Syn preformed fibrils (PFFs) into the hippocampus bilaterally. After 8 months of PFF injection, there was a significant increase in amount of α-Syn/pSer129. The mice displayed cognitive deficits in recognition memory, social memory, working memory, and long-term memory. In addition, RNA-sequencing analysis revealed pathway of transforming growth factor beta (TGFβ) were enriched in the PFF-injected mice. The TGFβ-related genes were increased in the HIP during the progress of synucleinopathy, i.e. BMPR2, BMP2, BMP5, TGFβ1 and the downstream signals of Smad1/5/8 and Smad2. Additionally, there is a time-dependent change in the expression of GFAP, Iba1, inflammasome and the complement system, with most gene expression decreased at 8 months, while increased at 12-13 months after PFF injection. Moreover, amount of AMPA1/pSer845 of glutamate receptor increased after post-PFF injection at both time intervals. Collectively, our findings present a model of Parkinson's disease dementia (PDD) in which α-Syn aggregation begins in the substantia nigra (SN) and subsequently leads to changes in the glutamatergic system, potentially contributing to the development of dementia. Consistently, hippocampal synucleinopathy successfully replicates the cognitive impairments associated with dementia, with notable change observed in the BMP/TGFβ pathways, immune complement and glutamate systems.

Title: The expression of E50K optineurin affects the lysosome-related organelles in murine retinal cells

Authors: *W. OTSU[1], M. OBAYASHI[1], H. TSUSAKI[1], M. SHIMAZAWA[1,2];
[1]Biomed. Res. Laboratory, Gifu Pharmaceut. University, Gifu, Japan, Gifu, Japan; [2]Mol. Pharmacology, Dept. of Biofunctional Evaluation, Gifu Pharmaceut. Univ., Gifu, Japan

Abstract: Glaucoma is a group of eye disorders characterized by the progressive degeneration of retinal ganglion cells and their axons, leading to permanent vision loss or blindness. One of the genes linked to familial normal-tension glaucoma (NTG) is *OPTN*, which encodes optineurin (OPTN), a multifunctional adaptor protein involved in various intracellular vesicular trafficking pathways. The E50K mutation in the *OPTN* gene is the most prevalent one in patients with NTG. It has been reported that OPTN has an important role in selective autophagy, especially mitophagy, and E50K/OPTN impacts Rab8-mediated vesicular transport and autophagy-mediated degradation. However, the molecular mechanisms underlying the retinal cell death induced by glaucoma-associated *OPTN* mutations are not fully understood. Here we investigated the effect of the E50K/OPTN expression on the endolysosomal system in a murine immortalized retinal cell line, 661W, and in the mouse retina. To monitor the intracellular distribution of OPTN, we generated the construct expressing tandem fluorescent-tagged OPTN (OPTN-pHluorin-mCherry). Expressed wild-type OPTN was predominantly seen as both pHluorin- and mCherry-positive (yellow) puncta throughout the cell, indicating their distributions at the neutral environment of the cytosol. Wild-type OPTN with only mCherry fluorescence (red) was also found in some vesicular structures, suggesting it can exist in acidic compartments such as lysosomes or autolysosomes. On the other hand, E50K/OPTN was localized in red or yellow granular structures rather than the cytosolic pattern. The expression of E50K/OPTN also altered the morphology of Rab8-positive organelles to swollen vacuoles, which tend to form clustering at the perinuclear region. Immunoblotting revealed that lysosome-related proteins such as Transcription Factor EB and Lamp1 decreased in the presence of E50K/OPTN expression but not of wild-type. For *in vivo* experiments, embryonic retinal transfection was performed in Slc:ICR mice (Japan SLC, Hamamatsu) at gestational day 14.5 as reported previously (Otsu *et al.*, 2019, *J. Neurosci.*). Transfected eyes were harvested at postnatal 21 days, and subjected to immunostaining. Wild-type OPTN appeared as small puncta at both cell body and axon in retinal ganglion cells, whereas E50K/OPTN were detected as enlarged granules. These abnormal structures containing E50K/OPTN were frequently found at the axon in the prelaminar region of the optic nerve head. In conclusion, the exogenous expression of E50K/OPTN results in the suppression of the lysosomal gene expression and the morphological changes of the endolysosomal organelles in retinal cells.

Laboratories, Ltd., Kagoshima, Japan

Abstract: In recent years, with remarkable advances in science and technology, we have been surrounded by many electronic devices in our daily lives, such as smartphones and tablets equipped with light-emitting diode (LED) displays. Although the widespread use of electronic devices has made it easy for us to access information worldwide, light emitted by these devices is a concern for vision health because too much exposure to light is known as a risk factor leading to retinal disorders, including age-related macular degeneration. It has been reported that endoplasmic reticulum (ER) stress in light-exposed retinas is linked to photoreceptor cell death. However, it has yet to fully understand the mechanism underlying the stress response to light and its link to the pathophysiology of retinal diseases. We have reported that exposure to blue LED light induces excessive production of reactive oxygen species (Kuse *et al*., 2014. *Scientific Reports*) and unfolded protein response, significantly the increase of Activating transcription factor 4 (ATF4) expression (Ooe *et al*., 2017. *Molecular Vision*). This study aims to search for compounds that exhibit protective effects against photodamage. Here, we examine the effect of PENTADECYL, a bioactive product obtained from *Aurantiochytrium limacinum*, on either chemical-induced or blue LED light-induced ER stress. PENTADECYL is a triglyceride mixture composed of odd-chain saturated fatty acids, including pentadecanoic acid. We used a murine photoreceptor cell line, 661W, as an *in-vitro* model. PENTADECYL at the concentration of 0.1-10 µg/mL suppressed either thapsigargin- or tunicamycin-induced cell death in a concentration-dependent manner. PENTADECYL showed a protective effect against blue LED light-induced cell death at the concentration of 10 µg/mL. In contrast, PENTADECYL did not inhibit cell death caused by hydrogen peroxide treatment. Quantitative RT-PCR analysis revealed that the treatment of PENTADECYL at 10 µg/mL significantly attenuated the thapsigargin-induced gene expression of unfolded protein response target genes, including *Atf4* and *Bip*. Consistently, immunoblotting showed that PENTADECYL suppressed the increased ATF4 protein level induced by either thapsigargin or blue LED light exposure. In conclusion, PENTADECYL is a novel compound having a protective effect against light-induced ER stress in photoreceptors.

Title: Recombinant progranulin protects dopaminergic neurons in vivo and decreases alpha-synuclein via promoting autolysosome degradation in vitro.

Authors: *H. FUJIMORI[1], T. OHBA[1], S. NAKAMURA[1], M. SHIMAZAWA[1,2], H. HARA[1,2]; [1]Mol. Pharmachology, Dept. of Biofunctional Evaluation, [2]Lab. of Collaborative Res. for Innovative Drug Discovery, Gifu Pharmaceut. Univ., Gifu, Japan

Abstract: [Purpose] Progranulin (PGRN) is a secreted protein that is linked to inflammation and lysosomal function. PGRN haploinsufficiency inhibits proteolysis and causes frontotemporal dementia through the accumulation of a denatured protein, TAR DNA-binding Protein of 43kDa. Parkinson's disease (PD) is a progressive neurodegenerative disorder characterized by the loss of nigrostriatal dopaminergic neurons due to the accumulation of alpha-synuclein (α-Syn), an also denatured protein, and subsequent motor dysfunction. α-Syn is degraded by the autophagy lysosomal Pathway, but the relationship between PGRN and PD pathogenesis is unknown. Therefore, we evaluated the effects of recombinant PGRN on dopaminergic neurons *in vivo* and on α-Syn degradation, including the autophagy-lysosome pathway, *in vitro*.
[Methods and Results] PGRN protein expression in the striatum was increase in 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP)-induced PD model mice both after 1 and 3 days. Intracerebroventricular (i.c.v.) administration of PGRN ameliorated the decrease in expression of tyrosine hydroxylase, a dopaminergic neuron marker, in MPTP-treated mice. In addition, PGRN tended to improve the MPTP-induced decrease of TH-positive cells by immunofluorescence in substantia nigra. Furthermore, i.c.v. administration of PGRN ameliorated 6-hydroxydopamine-increased rotation locomotor by rotation test. In SH-SY5Y human neuroblastoma cells, 1-methyl-4-phenylpyridinium ion (MPP^+), an active metabolite of MPTP, increased α-Syn expression. In contrast, PGRN ameliorated MPP^+-induced increase in α-Syn expression. Although PGRN suppressed the increase of the levels of autophagy-related proteins sequestosome-1 (p62) and MAP1LC3 (LC3)-II by MPP^+ treatment, PGRN did not influence the phosphorylation of 5' adenosine monophosphate-activated protein kinase and mechanistic target of rapamycin, which are also proteins that regulate autophagy. Immunostaining analysis showed that PGRN ameliorated MPP^+-induced increase of LC3 puncta, an indicator of autophagosome, and co-localization of LC3 and α-Syn. The DALGreen assay showed that PGRN ameliorated the

MPP^+-induced decreasing trend of autolysosomes.
[Conclusion] These results suggest that PGRN has a protective effect against dopaminergic neuron injury, and decreases α-Syn expression via activation of lysosome function in autophagy degradation. Further studies on the functions of PGRN may lead to a definitive treatment for PD that targets α-Syn.

Abstract: Multiple System Atrophy (MSA) is a unique subtype of Parkinson's Disease (PD), characterized by distinct biochemical indicators and medication responses compared to typical PD. To facilitate a differential diagnosis and promote targeted treatments, it is crucial to identify reliable biomarkers for MSA. In this study, we sourced blood plasma from MSA patients, contrasting miRNA and extracellular vesicle (EV) protein profiles with various Parkinsonian patient groups and healthy controls (HC). Using the Biomedical Oriented Logistic Dantzig (BOLD) selector, we narrowed down to 1-5 key markers from approximately 2700 microRNAs

and 4700 potential EV proteins. The identities of EV protein candidates revealed important insights into cholesterol homeostasis. Notably, the EV protein candidate Lecithin-Cholesterol Acyltransferase (LCAT) is necessary for converting the neurotoxic cholesterol metabolite, 24-hydroxylcholesterol (24OH-C), into 24-hydroxylcholesterol esters (24OH-CE). We discovered significantly lower quantities of plasma EV-derived LCAT in MSA patients than HCs or other PD patients, indicating aberrant accumulation of toxic cholesterol metabolite. On top of that, we found that the inflammation and oxidative stress pathways linked to MSA-related EV protein candidate Kallistatin (SERPINA4), which acts as an anti-inflammatory protein. MSA patients exhibited less Kallistatin in their plasma EV compared to HCs or PD patients, potentially leading to increased inflammation. Furthermore, analysis of MSA-associated plasma miRNAs from an independent patient cohort highlighted a significant correlation between fatty acid biosynthesis and the abovementioned pathways. Integrating putative targets from 22 MSA-associated miRNAs highlighted fatty acid biosynthesis, which may be involved in cholesterol homeostasis, inflammation, and oxidative stress. We propose an integrated regulatory network on cholesterol homeostasis, comprising miRNA target genes and EV proteins, potentially providing new diagnostic and therapeutic targets. Furthermore, the level of 24OH-CE in plasma may serve as another layer of novel biomarkers of MSA progression and contribute to the understanding of the systemic pathophysiology of MSA.

Abstract: Parkinson’s disease (PD), Dementia with Lewy Bodies (DLB), and Multiple System Atrophy (MSA), all gathered in the synucleinopathies family disease, share the aggregation of α-synuclein (α-syn) in intracellular inclusions in neurons and/or glial cells as a pathological hallmark. Aggregated forms of α-syn accumulated in neurons are called Lewy Bodies (LB). They are found in PD and DLB and are associated with a dopaminergic neuronal loss in the substantia nigra. We have previously shown that injection of patient-derived LB and noLB fractions in the striatum of non-human primates (NHP) induces nigral and striatal degeneration of dopaminergic neurons as well as α-synuclein pathology two years after administration.This study examines the effect of PD-patients derived fraction containing LB or noLB following striatal injections in baboon monkeys from different ages over time, including various pre-determined time points (6, 12, or 24 months after injection) (n=37). One hundred eighty variables were examined, covering behavioural, histological, western blot, scan sampling, or dot blot results. Extensive analysis showed increased significantly different variables between experimental and control groups over time. To understand pathogenic alterations mechanisms, we performed a proteomic analysis of the putamen and the entorhinal cortex, two brain regions strongly impacted at 24 months of this large cohort of NHP.Overall, we observed that experimental groups injected with LB- and noLB-enriched fractions followed different neuropathological pathways over time in response to the injection and that a significant level of shared variables between LB and noLB experimental groups diverged from the control group.

Title: Harnessing chaperone-mediated autophagy through viral- based LAMP2A overexpression in non-human primates as a Treatment of Parkinson's Disease

Authors: M.-L. AROTCARENA[1], M. FOUKA[2], L. STEFANIS[2], E. BEZARD[1], M. XILOURI[2], ***B. DEHAY**[1];
[1]Inst. of Neurodegenerative Dis., Bordeaux Cedex, France; [2]Biomed. Res. Fndn. of the Acad. of Athens, Biomed. Res. Fndn. of the Acad. of Athens, Athens, Greece

Abstract: Lysosomal impairment is strongly implicated in Parkinson’s disease (PD). Chaperone-Mediated Autophagy (CMA) is a major lysosomal pathway responsible for alpha-synuclein

(aSyn) clearance but, at the same time, can be a direct target of aSyn-related neurotoxic effects. The rate of CMA depends mainly on the levels of LAMP2A (lysosomal transmembrane protein 2A) and the presence within the lysosomal lumen of the lys-HSC70 chaperone. This project aimed to investigate whether the CMA lysosomal pathway induction may benefit the highest-order mammalian synucleinopathy model, the non-human primate, by targeting CMA's rate-limiting step, the LAMP2A receptor. To this end, we performed bilateral injections of the AAV2/9-LAMP2A-HA vector (or the control Stuffer vector) in the SNpc of 14 male rhesus macaque monkeys (*Macaca mulatta*) together with unilateral intrastriatal injections of low doses of aSyn-containing Lewy body (LB) extracts purified from the SNpc of PD brains (or extracts from non-PD brains as control). Animals were terminated 15 months later, and brains were harvested. Extensive histochemical and biochemical analyses were performed to evaluate cerebral pathological markers known to be affected in PD. We characterized the pattern of dopaminergic loss in the striatum and the substantia nigra, the regional distribution of aSyn immunoreactivity in several brain structures, as well as its pathological status (i.e., S129 phosphorylation) and the occurrence of lysosomal dysfunction. Overall, our data so far show that viral-mediated LAMP2A overexpression protects dopaminergic neurons from the cell loss induced by the injection of PD brain extracts. Interestingly, LAMP2A-injected animals displayed significantly improved performance in the behavioral tests related to pre-frontal cortex-dependent cognitive function, suggesting that our gene therapy approach induces a beneficial cognitive effect. Lastly, LAMP2A overexpression decreases extracellular aSyn levels in the monkey biological fluids.In conclusion, this study demonstrates that viral-based overexpression of LAMP2A attenuates the dopaminergic neurodegeneration in a non-human primate model of PD. These results support the idea that enhancement of CMA through LAMP2A overexpression or other means, possibly pharmacological, might open new therapeutic opportunities for slowing down the degenerative process in patients with PD and related synucleinopathies.

Title: A partial Drp1 knockout improves autophagy flux independent of mitochondrial function

Authors: *R. Z. FAN[1], C. SPORTELLI[2], Y. LAI[2], S. S. SALEHE[2], J. R. PINNELL[2], J. R. RICHARDSON[2], S. LUO[3], K. TIEU[2];

Abstract: Dynamin-related protein 1 (Drp1) is a member of the dynamin GTPase superfamily typically known for its role in mitochondrial fission. A partial inhibition of this protein has been reported to be protective in experimental models of neurodegenerative diseases. The protective mechanism has been attributed primarily to improved mitochondrial function. Drp1 inhibition has also been demonstrated to reduce protein aggregation in experimental models of Parkinson's disease, Alzheimer's disease, and Hungtington's disease, indicating the potential involvement of protein removal pathways such as autophagy. However, it is not feasible to untangle with certainty whether Drp1 inhibition reduces protein aggregation via mitochondria, autophagy, or a combination of both in those models since these two pathways bidirectionally regulate each other Herein, we provide evidence showing that a partial Drp1-knockout improves autophagy flux independent of mitochondria using low doses of manganese (Mn) as a model. Mn causes parkinsonian-like symptoms in humans and it has been proposed as a risk factor for PD.. In this study, first, we characterized in cell models that at low non-toxic concentrations (up to 125μM in both N27 rat dopaminergic neuronal cells and Hela autophagy reporter cells), Mn impaired autophagy flux but not mitochondrial function or morphology. Furthermore, chronic low dose of Mn treatment in mice through drinking water impaired autophagy pathways but not OXPHOS in the ventral mid brain based on RNAseq and KEGG pathway analysis. Imaging using autophagy reporter mice as well as Laser-capture microdissection-assisted cell-type specific immunoblotting revealed nigral dopaminergic neurons were more sensitive than their neighbouring GABAergic counterparts. Second, in cells with a partial Drp1-knockdown and $Drp1^{+/-}$ mice, autophagy impairment induced by Mn was significantly attenuated. This study demonstrates that autophagy is a more vulnerable target than mitochondria to Mn toxicity. Furthermore, improving autophagy flux is a separate mechanism conferred by Drp1 inhibition independent of mitochondrial fission. In summary, the present study provides two major novel mechanisms relevant to neurological disorders. The combined protective mechanisms of improving autophagy flux and mitochondrial function conferred by Drp1 inhibition make this protein an even more attractive therapeutic target.

Title: Drp1 inhibition reduces neuroinflammation in vivo

Authors: R. Z. FAN, ***Y. LAI**, S. S. SALEHE, H. BROWN, A. D. RAYMOND, J. R. RICHARDSON, K. TIEU;
Florida Intl. Univ., Miami, FL

Abstract: Dynamin related protein 1 (Drp1) is a “master regulator” of mitochondrial fission. We previously reported that Drp1 inhibition attenuated mitochondrial dysfunction, oxidative stress, impaired autophagy flux, and release of exosomes that contain neurotoxic α-synuclein. Given the important role of neuroinflammation in Parkinson's disease (PD), herein we investigated the impact of Drp1 inhibition on neuroinflammation. First, as a model of neuroinflammation, we injected $Drp1^{+/-}$ mice and their wild-type (WT) littermates with lipopolysaccharides (LPS), collecting the ventral midbrains (VMB) 6h later. Nanostring neuroinflammation analysis showed that LPS increased levels of many pro-inflammatory genes in WT mice; however, significant protection was observed in $Drp1^{+/-}$ littermates. The most dramatic change was lipocalin 2 (*Lcn2)* gene, whose gene product activates NLRP3 inflammasome. These results were validated through qPCR and Meso Scale Discovery cytokine assay. Sholl analysis confirmed morphologically less microglial activation in $Drp1^{+/-}$ mice. To further investigate the role of Drp1 in microglia, we treated LPS in mice with inducible microglia-specific Drp1 deletion by crossing Drp1-LoxP with $Cx3Cr1\text{-}Cre^{ERT}$ mice, then captured individual microglia in the substantia nigra using laser microdissection, followed by qPCR analysis. Results revealed that microglia with $Drp1^{+/-}$ expressed less pro-inflammatory genes. Lastly, we also detected increased levels of *Lcn2* and other pro-inflammatory genes in transgenic α-synuclein mice but attenuated in those crossed with $Drp1^{+/-}$ mice. Together, our data indicate that a partial Drp1 knockout is sufficient to reduce neuroinflammation in multiple animal models, suggesting Drp1 is a promising therapeutic target for PD. The mechanism underlying the anti-inflammatory effects conferred by Drp1 inhibition is being investigated.

Title: Intracerebrally-delivered AAV-synuclein (with or without fibroin) leaks to the mouse peripheral organs: in vivo and ex vivo monitoring by bioluminescence imaging

Authors: C. MAZZOCCO[1], C. GENEVOIS[2], E. DOUDNIKOFF[3], ***M. LANDRY**[4], N. DUTHEIL[1], T. LESTE-LASSERRE[6], E. BEZARD[5];

France; [3]Univ. De Bordeaux, Bordeaux, France; [4]Inst. of Neurodegenerative Dis., BORDEAUX, France; [5]Inst. of Neurodegenerative Dis., Bordeaux, France; [6]Neurocentre Magendie, Bordeaux, France

Abstract: The popular viral vector-mediated delivery of wild-type or mutated (A53T) α-synuclein requires improving its induced lesion in mice as well as following up *in vivo* its expression. With these objectives in mind, we tested a bioluminescent expression reporter of α-synuclein embedded or not in a fibroin solution, the main protein of the silkworm's silk, classically used in optogenetic studies for increasing viral vector-mediated transfection.We developed an in vivo bioluminescent expression reporter of α-σψνυχλειν under the control of the synapsin promoter engineered into an AAV2/9. We used the bioluminescence enzyme Nanoluc, which is more efficient for deep-tissue imaging. We first verified the expression of the fused protein in vitro by bioluminescence imaging, then established the acquisition time for the most intense bioluminescence imaging signal and evaluated substrate concentrations to optimise the signal. Next, two groups of 15 male C57Bl6Jr mice were unilaterally injected with the fused protein Nanoluc_humanA53Tα-synuclein above the substantia nigra (SN) combined (or not) with fibroin, a silkworm protein, as a vehicle to stabilise its expression in space and time. We first validated the expression of the Nanoluc-humanA53Tα-synuclein fusion protein *in vitro* by optical imaging on transfected HEK293T cells and Western blotting using anti-Nanoluc and anti-human α-synuclein antibodies. The *in vivo* cerebral bioluminescence signal was more intense in the presence of fibroin. Using immunohistochemistry, we found that the humanA53Tα-synuclein staining was more restricted to the striatum and the SN with fibroin. Counting of tyrosine hydroxylase-labelled neurons revealed a greater induced-lesion when injected with fibroin. We, however, detected a bioluminescence signal in peripheral organs such as the prostate, the intestine and the liver, all more intense in the absence of fibroin. We suspected expression leakage and therefore verified by RT-qPCR the presence of viral RNA corresponding to the injected AAV in the positive organs, confirming this leakage despite using a specific neuronal promoter. Our data have two main consequences: (i) Mixing AAV with fibroin ensures accurate control of transgene expression while diminishing the peripheral leakage. (ii) In vivo Nanoluc_humanA53Tα-synuclein protein expression tracking by bioluminescence imaging would enable proper animal selection in preclinical testing of therapeutic strategies, first by allowing post-surgery animal selection and (ii) by possibly providing an in vivo monitored end-point of success (or failure) of the tested therapy.

Title: Disentangling the respective role of aggregopathy versus neurodegeneration on extracellular space nanometric diffusional parameters in synucleinopathy

Authors: J. ESTAUN-PANZANO[1], S. NANDI[2], Q. GRESIL[2], E. DOUDNIKOFF[3], C. MAZZOCCO[4], ***W. MEISSNER**[5], B. DEHAY[6], M.-H. CANRON[4], M.-L. AROTCARENA[7], L. COGNET[2], E. BEZARD[6];

Des Maladies Neurodégénératives, Bordeaux, France; [6]Inst. of Neurodegenerative Dis., Bordeaux, France; [7]Neurodegeneratives Dis. Inst., Bordeaux, France

Abstract: Synucleinopathies represent a group of neurodegenerative disorders characterised by the accumulation of aggregated α-synuclein inside cells. The pathogenic mechanisms underlying synucleinopathies are believed toinvolve the spread and propagation of α-synuclein aggregates throughout the central nervous system and at least partially through the extracellular space (ECS). The ECS and its proteic scaffold, the extracellular matrix, are emerging as a critical component for communication and regulation in health and disease. Single particle tracking of near-infrared emitting Single Wall Carbon Nanotubes (SWCNTs) has become a powerful tool to characterise some of the fundamental ECS properties at the nanoscale. The recording of long trajectories in the so-called transparency window of tissue permits the reconstruction of ECS maps with nanometric resolution and extracts instantaneous diffusion coefficients and estimation of channel width. Using SWCNTs single-particle tracking, we previously unravelled a significant increase in Substantia Nigra pars compacta extracellular diffusion values in the context of α-synuclein pathology accompanied by nigral neuron degeneration. To disentangle the respective roles of neurodegeneration and aggregopathy in leading these dramatic changes, we here investigated ECS instantaneous diffusion coefficients and estimation of channel width in the substantia nigra and the striatum of mice featuring neurodegeneration (our classic PD patient-derived Lewy bodies extract) versus ones exhibit a synuclein aggregopathy without degeneration (strain 1B of synuclein pre-formed fibrils (PFF)). Our results show that: (i) SN and striatum present different diffusional regimes; (ii) neurodegeneration models present increased diffusion regimes in the SN but also in the striatum, (iii) the sole presence of secondary aggregates (without neurodegeneration) in the striatum in an aggregopathy model also causes an increased diffusion regime in the striatum. The spread of the synucleinopathy can therefore affect ECS diffusional parameters, thereby likely further contributing to its propagation. We hypothesise that these aggregates can affect the surrounding microenvironment, triggering inflammatory responses, which would widen the ECS. Understanding the distinct effects of these synucleinopathy models on the ECS is crucial for unravelling the mechanisms underlying synuclein propagation, neurodegeneration, and associated clinical manifestations. Elucidating the interplay between aggregated α-synuclein and the ECS may unveil potential therapeutic targets to modulate synucleinopathy progression.

Title: Human TFEB overexpression prevents mutant human A53T-α-synuclein toxicity in a prevention design applied to a rat model of Parkinson's disease

Authors: M.-L. AROTCARENA[1], **R. KINET**[2], G. DABEE[3], *E. BEZARD[3], B. DEHAY[3]; [1]Neurodegeneratives Dis. Inst., Bordeaux Cedex, France; [2]Inst. of Neurodegenerative diseases, Bordeaux, France; [3]Inst. of Neurodegenerative Dis., Bordeaux, France

Abstract: The synucleinopathies Parkinson's disease (PD) and Multiple system atrophy (MSA) — characterised by neurodegeneration and α-synuclein intracytoplasmic inclusions into, respectively, neurons and oligodendrocytes — are associated with impairment of the autophagy-lysosomal pathways (ALP). Increased expression of the master regulator of ALP, transcription factor EB (TFEB), is hypothesised to promote the clearance of WT α-synuclein and survival of dopaminergic neurons.Here, we explore the efficacy of targeted human TFEB overexpression in substantia nigra neurons to reduce the pathological burden of α-synuclein in a viral-based rat model of nigral human A53T α-synuclein overexpression. To assess whether the timing of therapeutic intervention application vis-à-vis the pathological trigger matters, we evaluated the effects of AAV-hTFEB in three experimental designs: (i) in a therapeutic setting (i.e., striatal AAV-hTFEB injection at one mo p.i. after nigral AAV-Synuclein injection) and two prevention settings (ii) concomitant injections of nigral AAV-hTFEB and AAV-Synuclein; and (iii) concomitant injections of nigral AAV-Synuclein and intrastriatal AAV-hTFEB. All groups were followed behaviourally. The brains were harvested four months after AAV-Synuclein injection. Extensive histochemical analyses were performed to evaluate cerebral pathological markers known to be affected in PD. We characterised the human TFEB expression, the pattern of dopaminergic loss in the striatum and the substantia nigra, the regional distribution of α-synuclein immunoreactivity in several brain structures, as well as its pathological status (i.e., S129 phosphorylation). We observed that human TFEB was correctly expressed in the rat substantia nigra and the striatum. Human TFEB nigral expression was sufficient to prevent nigrostriatal neurodegeneration in this PD rat model both at the cell body (substantia nigra) and terminal (striatum) levels when injected only at the nigra level. This beneficial effect was associated with a decreased accumulation of α-synuclein into the substantia nigra and a strong clearance of phosphorylated (S129) α-synuclein.Our study confirms the disease-modifying potential of human TFEB by extending the demonstration to an AAV-A53T synuclein rat model and, for the first time, validating the human version of TFEB transgene, paving the way for gene therapy of PD.

Abstract: The nuclear receptor, Nurr1, is critical for both the development and maintenance of midbrain dopamine neurons (mDANs), representing a promising molecular target for Parkinson's disease (PD). We previously identified three Nurr1 agonists (amodiaquine, chloroquine and glafenine) that share an identical chemical scaffold, 4-amino-7-chloroquinoline (4A7C), suggesting a structure-activity relationship. Herein we report a systematic medicinal chemistry search in which over 570 4A7C-derivatives were generated and characterized. Multiple compounds enhance Nurr1's transcriptional activity, leading to identification of an optimized, brain-penetrant agonist, 4A7C-301, that exhibits robust neuroprotective effects in vitro. In addition, 4A7C-301 protects mDANs in the MPTP-induced male mouse model of PD and improves both motor and non-motor olfactory deficits without dyskinesia-like behaviors. Furthermore, 4A7C-301 significantly ameliorates neuropathological abnormalities and improves motor and olfactory dysfunctions in AAV2-mediated α-synuclein-overexpressing male mouse models. These disease-modifying properties of 4A7C-301 may warrant clinical evaluation of this or analogous compounds for the treatment of patients with PD.

Title: High metabolic rate reveals selective vulnerability of SNc dopamine neurons in Parkinson's Disease

Authors: *C. MENG[1], S. ELIASEN[2], A. PAPANERI[2], G. CUI[2];
[1]NIH/NIEHS, Rtp, NC; [2]NIH/NIEHS, Research Triangle Park, NC

Abstract: Parkinson's disease (PD) is the second most common neurodegenerative disease featuring progressive loss of dopamine (DA) neurons in substantia nigra pars compacta (SNc). However, the mechanism underlying the selective vulnerability of SNc-DA neuron in PD is still unknown. Computational studies proposed that SNc-DA neurons are more vulnerable than other neurons during aging because of their high bioenergetic demand due to the longer and more branched axons paired with non-stopped pacemaker firing. Here, we explored whether SNc-DA neurons have higher basal metabolic rate than other neuronal types, including glutamatergic-, GABAergic-, cholinergic- and norepinephrinergic neurons, and DA neurons in the ventrotegmental area using genetically encoded fluorescent ATP/ADP ratiometric sensor percevalHR in freely moving mice. We show that SNc-DA neuron has the lowest ATP/ADP ratio, indicating the highest ATP utilization and metabolic rate in the brain. We further confirm that the axonal terminals of SNc-DA neurons show higher ATP demands on energy supplies than somata, which may trigger the early axonal degeneration when energy demand exceeds the supply in the early stages of PD. These findings provide definitive evidence that SNc-DA neurons are more metabolically demanding than other neuronal types, which may contribute to the their selective vulnerability in PD.

Abstract: Parkinson's disease (PD) is a neurodegenerative movement disorder characterized by the loss of nigral dopaminergic neurons and the presence of alpha-synuclein positive fibrillar cytoplasmic inclusions known as Lewy bodies. Oxidative stress is a prominent etiological feature in the loss of dopaminergic neurons in PD, although the pathways that govern defense against reactive oxygen species in neurodegeneration remain unclear. Oxidation resistance 1 (*OXR1*) was first identified in a screen for human genes that could rescue the DNA oxidation repair-defective phenotype of a spontaneous *E. coli* mutant. Increasing evidence suggests that OXR1 has a regulatory role in controlling several stress response genes associated with survival during oxidative stress. Here we show the upregulation of OXR1 in cellular and mouse models of PD and suggest that OXR1 is a novel early marker of stress in neurons and potentially a new neuroprotective factor. Oxr1 overexpression in the mouse prion promoter-driven (PRP)-OXR1 transgenic mice attenuated 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP) as well as mouse alpha-synuclein preformed fibril-mediated loss of nigrostriatal dopaminergic neurons and reduced expression of markers for oxidative stress and neuroinflammation. Co-immunoprecipitation studies show that OXR1 interacts with the vacuolar-type H+-ATPase (v-ATPase), a proton pump critical for lysosomal acidification. Neuronal cells lacking OXR1 exhibited an increase in lysosomal pH, reduced lysosomal proteolytic activity, and exacerbated neurodegeneration in preclinical models of PD. We employed innovative systems biology approaches to compare similarities in affected pathways between single-nuclei transcriptomic data from human PD patients and proteomic data from preclinical models of alpha-synucleinopathy overexpressing OXR1. Our analysis revealed that lysosomal pathways are involved in neuronal survival due to the overexpression of OXR1 in PD preclinical models. These results suggest that OXR1 plays an integral role in lysosomal mechanisms of neuroprotection and that upregulation of OXR1 is a promising therapeutic approach for PD and synucleinopathies.

Title: Optogenetic stimulation of astroglia prevents dopamine neuron degeneration

Authors: *J. L. MCNEILL[1], I. TRUJILLO-PISANTY[2], S. SIMARD[1], C. A. RUDYK[1], C. GROULX[1], K. FARMER[1], S. P. HAYLEY[1], G. COPPOLA[3], N. SALMASO[1,4];
[1]Neurosci., Carleton Univ., Ottawa, ON, Canada; [2]Ctr. for Studies in Behavioral Neurobio., Concordia Univ., Montreal, QC, Canada; [3]Dept. of Pathology, [4]Child Study Ctr., Yale Univ., New Haven, CT

Abstract: Astrocytes are an abundant and heterogenous glial cell type that are intimately involved in several critical functions including the modulation of ion and neurotransmitter homeostasis, the regulation of oxidative stress and the production of key energy substrates for neurons. They are also essential in injury and disease response through morphological, physiological and functional changes, in a process known as reactive astrogliosis. Given this, it is unsurprising that astrocyte dysfunction is observed in Parkinson's disease (PD). For example, mutations in genes associated with PD have been linked to impaired mitochondrial function in astrocytes[1], and the overexpression of α-synuclein specifically in astrocytes is sufficient to produce earlier and more severe motor deficits.[2] Furthermore, the selective targeting and stimulation of astroglia using optogenetics has been shown to stimulate the release of FGF2 and increase functional repair in vitro and in vivo following administration of MPTP and 6-hydroxydopamine (6-OHDA)[3].This suggests a neuroprotective effect of astrocytes in PD. In this study, we further investigate the therapeutic potential of astroglia using optogenetics to stimulate astroglial cells in the substantia nigra (SNc) of rats injected with 6-OHDA. Briefly, rats were injected unilaterally with 6-OHDA into the dorsal striatum followed the next day by optogenetic stimulation of astroglia within the SNc. The rats were then tested on a battery of behavioral tests either 8- or 21-days post 6-OHDA administration. While there was no significant effect of the lesion 8 days post 6-OHDA administration, there were, as expected, significant motor deficits on the rotarod and apomorphine-induced rotations test 21 days post lesion. Interestingly, these deficits were attenuated with stimulation of SNc astroglia. In addition, a significant decrease in tyrosine hydroxylase (TH) positive neurons was noted in lesioned animals that was also attenuated with optogenetic stimulation of SNc astroglia. Taken together, this suggests an astroglial-induced neuroprotective effect at both the cellular and behavioral level. RNA-sequencing analysis of the SNc revealed differentially expressed genes that are implicated in microglial activation, immune pathways, and cytokine signaling. Altogether, results from this sequencing analysis further supports the notion that multi-cellular cross-talk is integral to neurodegeneration and neuroprotective processes.

Title: Exercise-induced angiogenesis and midbrain neuroprotection in a mouse model of experimental Parkinson's Disease.

Authors: *T. N. RODRIGUEZ, R. J. SMEYNE, M. SMEYNE;
Dept. of Neurosci., Farber Inst. of Neurosci. Thomas Jefferson Univ., Philadelphia, PA

Abstract: Parkinson's disease (PD) is a debilitating neurological disorder that affects 2% of the population aged 50 and older. Characteristic PD pathology includes loss of dopaminergic (DA) neurons in the Substantia Nigra pars compacta (SNpc). Loss of 60-70% of these neurons in the SNpc manifests in motor symptoms: tremor, bradykinesia, and gait disturbances. Currently, PD symptomology can be addressed with drugs/surgery, but these treatments fail to slow the progression of the disease. Epidemiological studies offer an intervention that appears to slow physical motor symptom progression, may protect DA neurons from further degeneration and lowers the risk of developing the disease: exercise. Aerobic exercise has been shown to stop progression of motor symptoms in humans, as well as protect against neuronal pathology in mice. However, the mechanisms underlying exercise-induced neuroprotection from PD symptoms remain largely unknown. Previous work in our lab has shown that administration of the neurotoxin 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP) causes a 40% loss of DA neurons in the SNpc of standard-house mice, compared to a 5% loss in exercised mice. We demonstrated that one mechanism underlying this neuroprotection is exercise's ability to cause cellular hypoxia in the SNpc. Cellular hypoxia induces transcription of target genes that include those that increase angiogenesis. Early studies demonstrated that DA neurons in the SNpc have intimate spatial relationships with capillaries. In PD patients, normal contacts between nigral neurons and capillaries are lost at early disease stages, accompanied by abnormal capillary morphology. Exercise has profound angiogenic capabilities in the muscular and cardiovascular systems, but exercise-induced microvascular changes have yet to be characterized in the SNpc in the context of neuroprotection. In this study, we perfused mice with a tomato lectin conjugate and co-labeled DA neurons to model microvasculature in the SNpc. Using Imaris Filament Tracer, we are able to reconstruct a model of the microvasculature and characterize angiogenesis in the SNpc in response to exercise. The goal of this study is to assess the correlation between exercise-induced angiogenesis and SNpc DA neuron survival when MPTP is administered. Future studies to determine biochemical and epigenetic changes to the NVU architecture in response to neuroprotective amounts of exercise and blockade of those pathways to assess exercise-induced neuroprotection are planned.

Title: Differential Effective of Exercise on Young and Old Rats in Protecting Against 6OHDA Toxicity

Authors: *M. HANNA[1], V. FERNANDEZ[2], A. TALAUGON[1];
[2]Biol., [1]Vanguard Univ., Costa Mesa, CA

Abstract: Parkinson's disease (PD) is a neurodegenerative movement disorder characterized by the degeneration of the dopaminergic neurons of the nigrostriatal pathway. Patients with PD typically experience motor symptoms, including tremors, rigidity, slow movement, and postural instability. Lewy Body pathology from misfolded α-synuclein aggregates is another major hallmark of the disease. In animal models of PD, increased oxidative stress, reactive oxygen species, inflammatory cytokines, and microglial activation have been reported to play a significant role in mediating PD pathology. Previous studies mostly look at young rats in examining whether exercise can act as a protective factor against 6-OHDA toxicity. This study examined the effects of four weeks of spaced, high-intensity exercise in protecting against the dopaminergic neurotoxin 6-hydroxydopamine in 2-month and 12-month-old rats. After a unilateral injection of 6-OHDA, behavioral tests were assessed within one week by examining apomorphine-induced rotation, asymmetric paw use, and stride length. Apomorphine-induced rotation is used to evaluate the extent of impairment caused by 6-OHDA and directly correlates to the degree of dopaminergic loss. Results showed that in 6-OHDA injected rats, exercise training reduced apomorphine-induced contralateral rotation compared to the non-exercised 6-OHDA group. Young, exercised rats showed less apomorphine-induced rotation compared to old rats. Exercised rats also showed less asymmetric paw use compared to non-exercised rats. Old, exercised rats had higher asymmetric paw use than young, exercised rats. The data suggest that high-intensity, short-term exercise can act as a neuroprotectant factor by reducing the extent of dopaminergic neurodegeneration. The data also indicate that old rats are less susceptible to the protective effects of exercise.

Title: Optimizing levodopa-treatment through treadmill controlled exercise in a hemiparkinsonian rat model

Authors: *S. VENKATESH[1], H. HOLDEN[2], N. KINZONZI[3], A. CENTNER[4], C. R. BISHOP[4]; [2]Binghamton Univ., [1]Binghamton Univ., Vestal, NY; [4]Binghamton Univ., [3]Binghamton Univ., Binghamton, NY

Abstract: Parkinson's disease (PD) is a progressive neurodegenerative motor disorder characterized by a degeneration of dopamine (DA) neurons within the substantia nigra pars compacta (SNpc). DA replacement therapy using levodopa (L-DOPA)improves motor symptoms, however chronic use results in L-DOPA-induced dyskinesia (LID) characterized by abnormal involuntary movements (AIMs). In recent clinical and experimental studies, exercise has demonstrated potential disease-modifying effects within PD while also reducing LID liability. To better characterize the benefits of exercise, the aim of this study was to evaluate the effect of treadmill exercise on motor performance, L-DOPA's pro-motor efficacy and the development of LID.To do this, male and female Sprague-Dawley rats were rendered hemiparkinsonian by a unilateral injection of 6-hydroxydopamine (6-OHDA) into the left medial forebrain bundle. Following lesion, animals were counterbalanced into equally lesioned sedentary and exercise groups using the forepaw adjusting steps (FAS) test and amphetamine-induced rotations. Thereafter, a 4-week testing period was implemented, where exercised animals underwent 35 mins of treadmill-controlled exercise every weekday and received a performance score between 1-4. One hour post exercise, all animals were administered 4 mg/kg of L-DOPA. To observe LID development across both treatment groups, AIMs were observed on days 1, 7, 14, and 21, rated on a scale of 1-4 based on their presence of axial, limb and orolingual (ALO) dyskinesia behaviors. Additionally, rotarod testing was conducted a day prior to or following AIMs testing to evaluate latency to fall as an additional measure of motor performance. After the 4-week testing period, FAS and rotarod were conducted 60 min after L-DOPA administration to assess differences in L-DOPA efficacy between sedentary and exercise groups. Results demonstrated that all lesioned rats displayed a clear reduction in motor performance on FAS, however no exercise-related improvements were observed. Interestingly, consistent treadmill exercise appeared to attenuate and delay the onset of LID development. These findings suggest chronic exercise can maintain the efficacy of L-DOPA while reducing side effects like LIDin PD.

Title: A Non-Invasive Method for Quantitative Tremor Assay in Mice Using Piezoelectric Sensors

Authors: *D. HUFFMAN[1], R. BERNAT[1], S. SUNDERAM[2], K. DONOHUE[1], B. F. O'HARA[3,1];
[1]Signal Solutions, LLC, Lexington, KY; [2]F Joseph Halcomb III MD Dept of Biomed. Engin., [3]Dept of Biol., Univ. of Kentucky, Lexington, KY

Abstract: Essential Tremor (ET) is the most prevalent movement disorder, affecting an estimated 25 million individuals worldwide. Involuntary shaking (tremor) of the body is a hallmark symptom of ET, and significantly impacts quality of life. Thus, assessing and quantifying tremor and its response to therapeutic intervention is a key component of ET research. However, while means of reliably inducing tremor in preclinical models are well established, existing methods for assessing tremor and its response to intervention are limited in either their throughput or specificity, and better research tools are needed. Previously, we have shown that the *PiezoSleep* system can resolve various rodent behaviors, such as sleep and wake, breathing, and seizures. Here, we investigate the application of the system in resolving movements specific to tremor to serve as the basis for a high-throughput tremor assay in mice. Nine female C57BL/6 mice (3 months aged) were transferred to *PiezoSleep* cages where motion data was continuously recorded throughout two experiments: one in which animals received saline and one in which animals received harmaline (15 mg/kg) (both subcutaneously administered). During experiments, animals were visually monitored to confirm presence of tremor, and a continuous video record was collected. Following experiments, motion signals (sampled at 120 Hz) corresponding to the 30-minute pre- and 240-minute post-injection periods were loaded into MATLAB™, and processed to visualize signals and quantify the relative contribution of tremor-band frequencies (11-15 Hz) to total signal power (Tremor Band Contribution; TBC). Of the nine mice treated with harmaline, eight developed visible motor tremors that resulted in clear tremor-band motion signals. Tremor signals were successfully resolved by the TBC measure both in terms of tracking discrete tremor events as well as the course of tremor progression throughout the experiment. Following harmaline, TBC significantly deviated from levels observed following saline, with no significant difference observed during the pre-treatment period. This rise and fall of TBC throughout the recording also followed observed tremor dynamics. These results suggest the *PiezoSleep* system shows promise in its utility as a non-invasive, high-throughput alternative for tremor research.

Title: Biochemical and cellular effects of atp13a2 mutations linked to hereditary spastic paraplegia

Authors: *C. MASSARI, D. MOORE;
Van Andel Res. Inst., Grand rapids, MI

Abstract: ATP13A2 is a transmembrane P5-type ATPase that can function to export polyamines from the lysosomal lumen to the cytosol. Mutations in the *ATP13A2* gene have been reported to cause a range of autosomal recessive, familial neurodegenerative diseases, such as Kufor-Rakeb syndrome, juvenile-onset Parkinson's disease, neuronal ceroid lipofuscinosis, and hereditary spastic paraplegia (HSP). HSP comprises a range of heterogeneous inherited neurodegenerative and neurodevelopmental disorders characterized by weakening of the lower limbs. However, familial HSP-linked mutations in ATP13A2 have not yet been biologically characterized, and there is a lack of knowledge regarding their pathogenic effects. Here, we developed a series of expression plasmids that comprise full-length human ATP13A2, either wild-type (WT) or 9 familial mutations linked to HSP (Q122*, R444*, Q486RFS*26, T512I, R704T, R740*, L820NFS*30, P851RFS*26 and Q1135*), in order to evaluate how these mutations might lead to phenotypes in HSP. We initially find that a number of HSP-linked mutations reduce the steady-state levels of ATP13A2 protein in human cell lines, suggesting that they may impair protein stability. Pulse-chase assays using the protein synthesis inhibitor, cycloheximide, confirm that most HSP mutations accelerate the turnover of ATP13A2 protein compared to the WT protein. Consistent with this effect, HSP-linked ATP13A2 mutants exhibit enhanced degradation by the proteasome and lysosome compared to WT protein. We also find that HSP-linked mutations can induce the mislocalization of ATP13A2 away from LAMP1-positive lysosomes and towards the protein disulfide isomerase-positive endoplasmic reticulum in human cells, consistent with a loss of proper protein folding and stability. In primary cortical neurons we find that HSP-linked mutations also disrupt the normal lysosomal localization of ATP13A2. We have recently developed new plasmids expressing ATP13A2 fused to APEX2 for proximity-based

labeling to allow the identification of novel ATP13A2-interacting proteins in live cells, where we will further compare the effects of WT and HSP-linked mutations. Our data support the idea that HSP-linked mutations in *ATP13A2* exert their pathogenic effects through a loss-of-function mechanism. The study of HSP-linked *ATP13A2* mutations will enable a better understanding of HSP pathobiology and related neurodegenerative diseases.

Title: A conditional mouse model of GEMIN5 neurodevelopmental disorder with motor dysfunction and cerebellar atrophy

Authors: *C. H. NELSON, IV, S. KOUR, T. R. FORTUNA, S. AGNIHOTRI, U. B. PANDEY;
Univ. of Pittsburgh, Pittsburgh, PA

Abstract: GEMIN5 is a multidomain RNA binding protein with varying functions. As a member of the SMN complex GEMIN5 is involved in snRNP biogenesis while also has RNA regulatory functions as an independent protein. Recent studies have identified GEMIN5 as the cause of a novel neurodevelopmental disorder characterized by cerebellar atrophy, global developmental delay, and motor dysfunction (NEDCAM). Patients display low levels of GEMIN5 protein expression and possess variants in a homozygous or compound heterozygous manner, suggesting a LOF modality. Previous model organisms have included *Drosophila*, Zebrafish, and KO mice; however, larval/embryonic lethality has been observed in all models, hindering investigation. The cre-loxP system is a well characterized framework for the creation of conditional mouse models with temporospatial control. Here, we report the creation of a conditional mouse model for the study of *Gemin5* using Cre-ERT2 linked to a human ubiquitin C promoter and a uniquely engineered floxed *Gemin5* transgene. Animals homozygous for this transgene, both with (hom-cre) and without UBC-Cre-ERT2 (hom-ctrl) expression were used for experimentalpurposes.3.5-week-old hom-cre animals (n=7) injected with a high dose of tamoxifen showed rapid deterioration, significant short-term differences in mass, and some alterations in gait when compared to hom-ctrl mice (n=7). To increase survival time in the hopes of observing a phenotype closer to NEDCAM, tamoxifen dosage and injection timepoint were lowered. 3-week-old hom-cre animals (n=6) injected with 50 mg/kg bodyweight of tamoxifen showed slower deterioration while still showing bodyweight differences when compared to control (n=14). Significant alterations in Hom-cre (n=12) gait and movement were also observed in gait analysis and open field testing when compared with control (n=12). Importantly, hom-cre mice (n=3) also showed significant differences in cerebellar volume based on MRI when compared with

control(n=3), a hallmark of NEDCAM. Together, we report a conditional mouse model displaying motor dysfunction as well as cerebellar atrophy for the study of NEDCAM. While further testing and characterization is required to maximize utility, the temporospatial control offered by the cre-loxP system allows fora wide range of future studies, including GEMIN5 mutant expression *in utero*. Further, the model will allow for testing of genetic influencers as well as potential treatment options.

Abstract: Mutations in LIS1 (lissencephaly-1) cause lissencephaly, a severe neurodevelopmental disorder. These genetic mutations disrupt neuronal migration and cortical organization during embryonic development, leading to significant neurological impairments. However, our understanding of LIS1's functions after brain development is limited. LIS1 regulates cytoplasmic dynein, an essential motor protein involved in cellular transport, cell division, and organelle positioning. Current models indicate that LIS1 directly interacts with dynein to enhance motor activity. Our study focused on Lis1's post-developmental role due to its elevated levels in the adult mouse nervous system. Severe phenotypes were documented using a tamoxifen-inducible LIS1 knockout mouse model, where CreER expression was controlled by an actin promoter (Act-LIS1iKO). Homozygous iKO mice displayed early-onset neurological phenotypes and death shortly after tamoxifen administration. These findings strongly support LIS1's role in adult mice, but the underlying cellular defects causing the severe phenotypes remain unknown. During the occurrence of severe phenotypes, the Cre reporter exhibited mosaic recombination, primarily in subcortical and peripheral regions. Furthermore, recombination was observed in various cell types, including glial and neuronal cells. Considering the important role of LIS1 in regulating dynein-dependent axonal transport, we hypothesized that LIS1 depletion in neurons was the primary underlying cause of the observed Act-LIS1iKO phenotypes. We have

now selectively depleted LIS1 exclusively in projection neurons of adult mice using the Thy1 promoter to drive the expression of a $CreER^{T2}$ fusion protein. Projection neurons are distinguished by their long axons, which place significant demands on microtubule-based intracellular transport. The Thy1 promoter also drives YFP expression in these mice, enabling visualization of the specific cells expressing the recombinase. Adult Thy1-LIS1iKO mice received a tamoxifen treatment regimen of 0.05 mg/g body weight per day for five consecutive days. Homozygous iKO mice exhibited neurological phenotypes, including severe shivering and leg clasping behaviors, followed by seizures that ultimately resulted in their death within 10 days after the initial injection. A reduced tamoxifen dosage led to a moderate phenotype suggesting that the lower dose targets fewer neurons. Control mice had no observable phenotypes. Lis1 expression notably decreased in YFP-positive cells, highlighting its crucial role in adult projection neurons. Future studies will investigate the mechanisms behind these phenotypes.

Title: Behavioral and electrophysiological deficits in corticostriatal pathways of mice lacking junctophilin-3, the gene mutated in Huntington’s Disease-like 2

Authors: *H. JAARO-PELED[1], X. ZHAN[2,1], R. L. MARGOLIS[1];
[1]Johns Hopkins Univ., Baltimore, MD; [2]Physiol. and Biophysics, Howard Univ., Washington, DC

Abstract: Huntington’s Disease like 2 (HDL2), a neurodegenerative disorder clinically and pathologically nearly indistinguishable from Huntington’s disease, is caused by expansion of a CTG/CAG repeat on chromosome 16q24. In the sense strand, the repeat falls in a variably spliced exon of *junctophilin3 (JPH3)*. JPH3 contributes to the formation of the Cav1-RyR2-KCa3 complex between the plasma membrane and the endoplasmic reticulum in neurons, critical for slow afterhyperpolarization and hence neuronal excitability. JPH3 is lower in HDL2 postmortem brains, and mice lacking JPH3 develop motor abnormalities, suggesting that JPH3 loss-of-function contributes to HDL2 pathogenesis. Here we aimed to examine the role of JPH3 in corticostriatal pathways by testing the effect of loss of *JPH3* expression on relevant mouse behaviors and on electrophysiological properties of striatal medium spiny neurons (MSNs) in

brain slices.
The development and initial motor analysis of *JPH3* KO mice (on C57BL/6J background) have been previously described (Nishi et al, 2002; Seixas et al, 2012). We tested young adult *JPH3* KO mice (wildtype, heterozygous and homozygous littermates, N>=9) of both sexes in 3 behavioral paradigms representing 3 different aspects of corticostriatal circuitry: novel object recognition - recognition memory; prepulse inhibition (PPI) - sensorimotor gating; sucrose preference - responsiveness to a natural reward. *JPH3* KO mice were not impaired in novel object recognition or sucrose preference, but did show a lower startle response and a lower PPI. Slices were prepared from adult KO mice and controls using standard procedures. MSNs were identified, and examined using current or voltage clamps. In homozygous or heterozygous *JPH3* KO mice, rheobase currents were smaller than in wildtypes, whereas there was no significant difference in depolarization-induced spiking rates. Ca-dependent afterhyperpolarization currents were significantly reduced in *JPH3* KO mice.
Taken together, the attenuated startle response and PPI in *JPH*3 KO mice provide evidence that JPH3 leads to abnormal sensorimotor gaiting in addition to previously detected motor deficits, consistent with the sensorimotor deficits detected in many neuropsychiatric disorders, including HD. Even heterozygous loss of *JPH3* expression appears to have prominent effects on afterhyperpolarization in MSNs, suggesting a potential contributing factor to deficits in corticostriatal circuitry. Our data support the hypothesis that loss of *JPH3* expression leads to abnormal MSN function and contributes to HDL2 pathogenesis via disruptions of corticostriatal circuity.

Title: Significantly less somatic expansion in HDL2 than in HD human blood and brain revealed by DNA fragment analysis and Nanopore sequencing

Authors: *Z. ZHA[1], H. FENG[1], S. ABDOLLAHI[1], V. C. WHEELER[2], C. ROSS[1], P. LI[1], S. DOLL[1], D. MOHR[1], A. SCOTT[1], H. JAARO-PELED[1], R. L. MARGOLIS[1];

Abstract: Huntington’s Disease Like-2 (HDL2) is an autosomal dominant, late-onset neurodegenerative disease that is clinically and pathologically nearly indistinguishable from Huntington’s Disease (HD). HDL2 is caused by an expanded CTG/CAG repeat (> 40 triplets) on

chr:16q24; the repeat falls in exon 2A of the variably-spliced junctophilin-3 (JPH3) gene on the sense strand, and in a cryptic transcript on the antisense strand. Given the accumulated evidence that somatic expansion (i.e., the progressive increase in triplet count with age in somatic tissue) is a key feature of HD pathogenesis, we explored whether somatic expansion is similarly present in HDL2.
We extracted genomic DNA from HD and HDL2 blood and brain samples from age and repeat length-matched patients. DNA was amplified using FAM-labelled HD and HDL2 primers. After fragment measurement and visualization by GeneMapper, the expansion index (EI; Lee JM et al, 2010) was calculated to quantify the degree of expansion, normalizing by the initial repeat length and controlling for background signal. In HD (N = 5), EI = ~1.0 in cerebellum and = ~ 3 in frontal cortex, consistent with previous findings. In HDL2 (N =4), cerebellum EI = ~1.0. However, EI in frontal cortex was < 1.0. Replication, starting with new DNA extraction from the same brains and followed by amplification using two HDL2 PCR primer pairs, yielded the same finding.
In parallel, DNA was amplified using nested PCR and sequenced (Nanopore). We developed an "Island-Building" algorithm to analyze error/mutation-adjusted repeat length counts from each tissue sample, and again found lower EI in HDL2 than in HD in most brain regions. EI ranged from ~3.0 to 6.0 in amygdala, caudate, superior frontal gyrus, and thalamus from HD brains, but was ~< 2.0 in these regions from HDL2 brains (N = 2-3). Additionally, analysis of DNA-derived from blood (N: HD = 19, HDL2 = 21) using the same approach yielded a strong correlation between EI and initial repeat length in both HD and HDL2 (R_0=0.80, 0.56), but a 3.5x steeper slope in HD, indicating substantially faster growth of EI per increment in baseline repeat length in HD than in HDL2.
In summary, using both DNA fragment analysis and Nanopore sequencing, we found that somatic expansion is markedly less prominent in HDL2 than in HD, despite the remarkably similar phenotypes of the two disorders, including age of onset for a given repeat length. This suggests that somatic expansion may not be strictly necessary for the pathogenesis of CAG/CTG repeat expansion disorders. Determining the difference in DNA-repair pathway response to the HD and the HDL2 repeat expansion may shed light on the mechanism of somatic expansion of both disorders.

Genomic medicine provides potential for novel diagnostic targets and therapeutic solutions. As mutations in human genes are identified and associated with Neurodevelopmental disease, transgenic animal models offer an opportunity to invasively study the mutant gene and its role in the pathophysiology of the disease. We have previously reported the first mutation in type 2 vesicular monoamine transporter (VMAT2), causing an infantile Parkinsonism phenotype Parkinsonism-dystonia-2 (PKDYS2) (OMIM 618049)[1]. Over the past decade, several additional mutations have been identified in VMAT2, giving rise to a broad phenotype spectrum and variable responses to treatment. Here, we characterize the disease's first viable transgenic mouse model and also analyze the molecular impact of the VMAT2 mutations in silico to understand the pathophysiology better and potentially improve treatment approaches. We based our analysis on the high-confidence three-dimensional structure of the VMAT2 protein produced by the AI-based Alphafold2 algorithm. The model was manually inspected, and mutations were evaluated using the Pymol program.Additionally, residue conservation was assessed with Consurf, and pathogenicity was predicted with Polyphen-2, Mutpred2, and Snpeff. We correlated the VMAT2 structural changes due to mutations with phenotypes. We found that there is a clear genotype-phenotype correlation, and this aids in guiding clinical decisions, enhancing patient outcomes, gaining an understanding of pathophysiology, and developing personalized treatment protocols. This work that includes animal model generation, behavioral characterization, and protein structure-phenotype analysis, advances our understanding of the disease and provides insights for creating personalized management protocols for this, and possibly other, neurodevelopmental disorders affecting neurotransmission.

Title: Self-limiting gene addition in a mouse model of hereditary spastic paraplegia due to a defect in the small subunit of serine palmitoyl transferase complex

Authors: *Y. GONG[1], A. QIAN[1], G. KENNETH[2], M. SELIG[1], C. MAGUIRE[1], T. DUNN[2], F. EICHLER[1];

Abstract: Sphingolipids (SLs) are lipid molecules that play essential structural and signaling functions in eukaryotes and have been linked to many neurological diseases. Serine palmitoyl transferase complex (SPT) mediates the first and rate-limiting step in the de novo sphingolipid biosynthetic pathway. The larger subunits SPTLC1 and SPTLC2/SPTLC3 together form the catalytic core with a smaller third subunit either SSSPTA or SSSPTB propelling the catalytic efficiency and providing substrate specificity for the fatty acyl-CoA substrates. Recently, the SPTSSA^{T51I} mutation was discovered in two girls with stagnant neurodevelopment, and both showed substantially elevated levels of several SLs. To further investigate the pathophysiology of this disease-causing mutation and explore therapeutic approaches, we developed a mouse model T51I knock-in mouse using targeted introduction of the T51I allele into exon 2 of the *SPTSSA* gene by CRISPR technology in fertilized eggs and further assessed the sphingolipid biochemistry and behavior in these mice. Surprisingly, supplementation with 10% L-serine for 2-3 months increased SL levels, caused significant myelin deficits and worsened the hind limb clasping behavior. This suggests a critical threshold in lipid chemistry impacting myelin organization and functionality and thereby affecting motor behavior. *In vitro* data in patient fibroblasts demonstrated successful transduction with adeno-associated virus (AAV) vector encoding wildtype SPTSSA (AAV-SPTSSA) and improvement in lipid chemistry. This has provided the justification for ongoing *in vivo* studies of AAV-SPTSSA gene therapy in Sptssa^{T51I} heterozygous mice. In conclusion, our preliminary studies in mouse suggest the functional importance of the small subunit variant in Sptssa^{T51I} heterozygous mice by demonstrating the association of hind limb clasping with SL elevations. Our studies demonstrate the feasibility of adding a single unit of a multisubunit enzyme complex to confer functional benefit. AAV-mediated delivery in human fibroblasts suggests that addition of SPTSSA can combine with other native subunits and impart self-limiting specific catalytic efficiency and restore the normal homeostasis of SPT.

Title: Mechanisms underlying the role of the deubiquitinase USP7 in the CAG triplet repeat disorder spinal and bulbar muscular atrophy

Authors: *M. SENGUPTA[1], E. H. NOLEN[1], A. DIBSIE[1], Y. LIU[1], S. M. SHEKARABI[1], A. PLUCIENNIK[1], S. V. TODI[2,3], D. E. MERRY[1];

Abstract: Spinal and bulbar muscular atrophy (SBMA) is a progressive neurodegenerative disease affecting males with ≥38 glutamine-encoding CAG repeats in androgen receptor (AR) gene. Androgen-bound polyglutamine-expanded AR (**AR^{exp}**) misfolds, aggregates, causes lower motor neuron (MN) and muscle dysfunction, and, ultimately, cell death. Patients experience MN loss from brainstem and spinal cord, muscle weakness and atrophy, resulting in impaired mobility, dysphagia, and dysarthria. There is no effective treatment. E3 ubiquitin ligases add ubiquitin to proteins, tagging them for degradation, while deubiquitinases like **USP7** remove ubiquitin, altering the proteins' cellular fates. We previously showed that USP7 plays a role in SBMA as its knockdown reduced AR^{exp} aggregation and toxicity in PC12 cell, MN, *Drosophila*, and mouse models. USP7 deubiquitinates AR^{exp} at 8 lysine (8K) residues, and a lysine-to-arginine (KR) mutation blocking ubiquitination at one lysine site (K17) increased AR^{exp} aggregation. This suggests that USP7-mediated deubiquitination at K17 may prevent AR^{exp} degradation and contribute to its aggregation and associated cell death. This raises two research questions:**(1) Does USP7 contribute to AR aggregation and cell death by deubiquitinating AR^{exp} at K17 alone, or at 8K, or by acting on (an)other substrate?** We created PC12 AR^{exp} cell lines with ubiquitination blocked at either K17 (AR^{exp} K17R) with or without USP7 knockdown, or at 8K (AR^{exp} 8KR), and *Drosophila* AR^{exp} K17R or 8KR strains. Preliminary experiments indicate that USP7 knockdown in PC12 AR^{exp} K17R cells does not reduce AR^{exp} aggregation, suggesting that USP7-mediated deubiquitination at K17 is sufficient to promote AR^{exp} aggregation. We will quantify AR^{exp} ubiquitination, turnover, aggregation, and cell death with and without USP7 knockdown or inhibition in these SBMA mutant lines.
(2) Which E3 ligase ubiquitinates AR^{exp} at USP7-regulated sites? A differential ubiquitinome study found that 4 of the 8K (including K17) are less ubiquitinated in PC12 AR^{exp} S16A (phosphorylation blocked at S16) cells, suggesting that S16 phosphorylation may regulate ubiquitination at these sites. A peptide-pulldown assay identified several E3 ligases differentially interacting with pS16 over S16A. This list was further narrowed down based on USP7 interaction. We will knock down each E3 ligase in PC12 cells to understand its role in AR^{exp} ubiquitination, aggregation, and turnover. In summary, the insights revealed by our studies will help us understand the role of USP7 in SBMA.

Title: Chronic at-home thalamocortical recordings during sleep in patients with Essential Tremor

Authors: *N. GEIGEL[1], J. WONG[2], K. D. FOOTE[3], J. HILLIARD[3], A. GUNDUZ[4]; [2]Neurol., [3]Neurosurg., [4]J. Crayton Pruitt Family Dept. of Biomed. Engin., [1]Univ. of Florida, Gainesville, FL

Abstract: Essential Tremor (ET) is one of the most common movement disorders in the world. It afflicts over 7 million people in the US (2.2% of the population). It is a progressive neurodegenerative disease characterized by a 4-12Hz shaking of the upper extremities. Deep brain stimulation (DBS) has emerged as an effective therapy for people suffering from medication refractory ET. Significant tremor suppression for patients can be achieved by targeting and stimulating the thalamic ventral intermediate nucleus (VIM). In clinical practice, DBS is delivered continuously, resulting in stimulation when not needed, particularly during sleep when tremor disappears. Although the feasibility of intention-based closed-loop algorithms for ET has been demonstrated, there has been a lack of research on their behavior during sleep. To this end, we are investigating the modulations in the thalamocortical network during sleep. We captured at home-recordings from depth electrodes in the VIM and from a cortical strip over the primary motor cortex. The subjects were instructed to record 30 minutes of awake data, keep recording through the night, and indicate when they woke up. We recorded local field potentials overnight with interchanging stimulation at 0mA and at the clinical amplitude. Multi-taper spectral analyses are used to extract spectral information across sleep and awake states. We aim to uncover how intention-based closed-loop algorithms respond to changes from wakefulness to sleep. Furthermore, we aim to develop closed-loop algorithms that terminate stimulation during sleep.

Title: Coupling between thalamus and cortex is spectrally and spatially organized in patients with essential tremor

Authors: *A. STEINA, S. SURE, M. BUTZ, J. VESPER, A. SCHNITZLER, J. HIRSCHMANN;
Heinrich-Heine-Universität Düsseldorf, Duesseldorf, Germany

Abstract: Essential tremor (ET) is a common movement disorder that is characterized by postural and intention tremor in the absence of other neurological signs. In severe ET the ventral intermediate nucleus of the thalamus (VIM) is an effective target for deep brain stimulation. Although the VIM is of therapeutic importance, its functional connectivity has rarely been investigated in humans. In this study, our goal was to identify the cortical areas coupled to the VIM in patients with ET, while the patients were at rest. We combined magnetoencephalography with local field potential recordings from the VIM of 19 ET patients and from the subthalamic nucleus (STN) of 19 patients with Parkinson's disease. Whole-brain maps of VIM-cortex and STN-cortex coherence were constructed in several frequency bands (alpha, low-beta, high-beta) using a beamformer and compared using a cluster-based permutation test. In order to estimate the directionality of coupling between cortical areas and subcortical nuclei spectral Granger causality was calculated. The topographies of VIM-cortex and STN-cortex connectivity resembled each other overall, but differed in coupling strength. Both nuclei were coupled to temporal cortex, brainstem and cerebellum in the alpha band, to sensorimotor cortex, brainstem and cerebellum in the low-beta band, and to ipsilateral sensorimotor cortex in the high-beta band. Coherence to deeper areas comprising brainstem and cerebellum was stronger for the VIM in the low-beta band ($p = 0.017$, cluster-based permutation test), whereas high-beta coherence to sensorimotor cortex was stronger for the STN ($p = 0.014$, cluster-based permutation test). The VIM led the sensorimotor cortex in the alpha band, while the STN was driven by cortical activity in the high-beta band. Our findings provide evidence for a spectral and spatial organization of thalamo-cortical coupling. The overall similar topographies of VIM-cortex and STN-cortex connectivity suggest that functional connections are not necessarily unique to one subcortical nucleus but might reflect larger frequency-specific networks. The directionality of VIM-sensorimotor cortex coupling supports the idea of a thalamic pacemaker for alpha oscillations. Elevated high-beta connectivity might be an electrophysiological marker of the hyperdirect pathway.

Nationwide Childrens Hosp., Columbus, OH

Abstract: Beta-propeller protein-associated neurodegeneration (BPAN) is the most common Neurodegeneration with Brain Iron Accumulation (NBIA) disorders comprising 35 to 45% of NBIA population. BPAN is an X-linked dominant disorder caused by de novo mutations in WDR45 gene, affecting approx. 1 in 500,000 individuals at the rate of 20 females for 3 males. With a childhood onset, BPAN is characterized by intellectual disability, developmental delay, and speech delay. Other common symptoms include sleep disorders, seizures or behaviors on the autistic spectrum disorder. While neurons are heavily implicated in BPAN disease pathogenesis, WDR45 is expressed in both neurons & astrocytes. To date, very little is known about the disease modifying impact of astrocytes towards the disorder. Astrocytes regulate extracellular environment of neurons promoting survival and regulating synaptic transmission and plasticity. Thus, identifying the role of astrocytes in disease pathology is critical as enhanced understanding of contribution of non-neuronal cell types may offer invaluable insights of underlying pathophysiology of BPAN and provide novel avenues for therapeutic development. To achieve this, we developed a novel in-vitro disease model system by reprogramming BPAN patient skin fibroblasts, carrying different mutations, using direct conversion method to induced Neuronal Progenitor Cells (iNPCs) which were further differentiated into induced astrocytes (iAs). We also generated induced neurons (iNs) directly from BPAN fibroblasts. These cells were further subjected to a battery of physiological, molecular and cell biology assays to evaluate their contributions to BPAN pathology. Our studies demonstrate that both BPAN iAs and iNs show novel disease phenotypes in vitro. With reduced levels of WDR45 protein expression, BPAN iAs show a highly significant decrease in mitochondrial respiration suggesting aberrant mitochondrial activity while BPAN iNs show reduced conversion rate and morphological defects. Moreover, treatment of BPAN iAs and iNs with various therapeutic molecules including AAV9 gene therapy, demonstrates rescue of disease phenotypes in mutation specific manner. Our work provides a robust model system to study the underlying disease mechanisms of BPAN pathology in mutation specific and cell type specific way. It also provides an excellent platform for high-throughput screening of multiple therapeutics with the potential to stratify patients based on the treatment responsiveness which is extremely crucial for optimal treatment development for this dreadful disease.

Abstract: Beta-propeller protein-associated neurodegeneration (BPAN) is a devastating rare neurodegenerative disease caused by mutations in the gene *WDR45* located on the X chromosome. Currently, there is no cure or disease altering treatment for this disease. While previous work has established WDR45's molecular role in autophagosome formation in vitro, its function in the development and maintenance of the CNS is still unknown. To explore these questions, we used CRISPR based genetic editing to generate a model of BPAN which mimics a patient mutation in *Wdr45* and confirmed that it ablates protein expression. We performed a comprehensive examination of the early pathophysiology of this model and explored the molecular role of WDR45 to understand its contribution to neural development and maintenance of cellular health. In WDR45 mutant animals, we observed neuroinflammation at 3 months of age and motor impairment consistent with disease progression in patients. This model additionally shows altered mitochondria and autophagosome number in the neurites of cultured neurons suggesting degradation and metabolic pathways are impaired in this disease. To build on this, we isolated the synapses from the cortex of WDR45 mutant animals through centrifugal fractionation. We found an accumulation of proteins labeled for autophagy degradation and elevated ROS response proteins. These data are supported by experiments using BioID biotin ligation to label proximal and interacting proteins with WDR45 in neuroblastoma cells. This analysis suggests novel interactions between WDR45 and proteins associated with mitochondrial metabolism and response to reactive oxygen species. Further, we performed RNAseq in cortical tissue of these animals revealing perturbed expression of genes previously linked to symptoms of BPAN and neurological disorders more broadly. This study provides key insights into the

pathological progression of BPAN and sheds new light on the potential role for this protein in establishing and maintaining proper function in the brain.

Title: Autoreactive antibodies from pediatric transverse myelitis patients induce stress in astrocytes

Authors: *C. SMITH, K. TSE, K. TELESFORD, W. ZHANG, B. GREENBERG, N. L. MONSON;
Neurol., UT Southwestern Med. Ctr., Dallas, TX

Abstract: B cells play a critical role in the progression of central nervous system autoimmune diseases such as Multiple Sclerosis (MS). Adult patients who present with transverse myelitis (TM) symptoms and later evolve to MS diagnosis, display an expansion of neuron-targeting plasmablasts (PBs), a subpopulation of antibody-secreting B cells. In this study, we examined the cellular and genetic immune profile of PBs in pediatric TM patients and found a decreased frequency of peripheral PBs compared to healthy controls. Also in contrast to adult TM patients, pediatric TM patients did not display an overuse of VH4 heavy chain genes in PBs. To examine PB autoreactivity, we cloned recombinant human antibodies (rhAbs) and performed immunostaining in human neuroblastoma and human astrocytic cultures, as well as spinal cord and brain from mice who were either healthy or displayed MS-like symptoms due to disease induction. We found that rhAbs derived from pediatric TM patients preferentially targeted astrocytes in mouse tissue and human cell culture, with increased reactivity in antibodies that had accumulated somatic hypermutation. These antibodies induced stress granules in human astrocytes compared to controls, demonstrating functional significance of autoreactivity in live human astrocyte cell cultures. These studies indicate that pediatric TM patients have a distinct autoimmune profile that separates them from adult TM patients and highlights the need for thorough investigation of inflammatory mechanisms that may lead to adult MS.

Title: Novel splicing of UBQLN2 and its potential pathological implication in amyotrophic lateral sclerosis and frontotemporal dementia

Authors: *A. S. H. KOO, R. S. TIBBETTS;
Human Oncology, Univ. of Wisconsin Madison, Madison, WI

Abstract: *Ubiquilin 2* (*UBQLN2*) is a mono-exonic gene located on chromosome X (coordinates: 56,563,627:56,567,868) that encodes a 624 amino acids protein belonging to the eukaryotic ubiquilin family of ubiquitin chaperones. All ubiquilins harbour N-terminal ubiquitin-like (UBL) and C-terminal ubiquitin-associated (UBA) domains that mediate the shuttling of ubiquitylated substrates to the proteasome for degradation. Mutations in the proline-rich-repeat unique to UBQLN2 cause X-linked dominant inheritance of amyotrophic lateral sclerosis and frontotemporal dementia (ALS/FTD) (Deng *et al.*, 2011). These mutations are associated with cytosolic aggregation of UBQLN2; however, how these mutations cause ALS/FTD is unknown. Our analysis of long-read sequencing data from Pacific Biosciences Iso-seq public datasets revealed a cryptic intron with two alternative 3' splice sites at the 5' end of the UBQLN2 coding sequence (CDS), which are not currently annotated in NCBI and Ensembl. The alternatively spliced UBQLN2 transcripts, dubbed UBQLN2$^{\Delta 193}$ and UBQLN2$^{\Delta 210}$, are predicted to encode truncated UBQLN2 proteins lacking the first 193 or 210 amino acids of the UBQLN2 CDS. Both truncated versions lack the UBL domain, which mediates proteasome targeting, and the first STI1-like domain that mediates chaperone binding. We verified the presence of UBQLN2$^{\Delta 210}$ transcript in human cell lines (HeLa and U-2 OS) and a commercial human brain RNA sample (Invitrogen AM7962) via Sanger sequencing and RT-qPCR. An initial screen of short-read RNA-sequencing data from TargetALS, which were done in Illumina sequencing platforms, detected the splice junctions of both UBQLN2$^{\Delta 193}$ and UBQLN2$^{\Delta 210}$ transcripts. However, these novel transcripts were not detected in C57BL/6J mouse brain tissues (cortex, cerebellum, and hippocampus) by PCR and RT-qPCR. Experiments to verify the expression and localisation of truncated UBQLN2 isoforms in human cell lines are ongoing. We postulate that these human-specific truncated UBQLN2 species possess altered biochemical and functional properties that may impact cellular proteostasis as well as pathologic protein aggregation and neurotoxicity in UBQLN2-associated ALS/FTD. Future studies on the function and splicing regulation of UBQLN2 isoforms will inform better diagnostic and therapeutic options for ALS/FTD patients.

Title: Characterizing the Multifunctional Roles of Neurodegeneration-associated TDP43 in Regulating Neuronal DNA Mismatch Repair

Authors: *V. E. PROVASEK;
HMRI, Houston, TX

Abstract: The DNA mismatch repair (MMR) pathway is widely recognized for its role in preventing replication-associated mutations. MMR proteins are also expressed in nondividing neurons, yet their function remains unknown. TDP43 is an essential RNA/DNA binding protein whose nucleocytosolic mislocalization has been linked to neurodegeneration in frontotemporal dementia (FTD) and Amyotrophic Lateral Sclerosis (ALS). Most FTD/ALS cases develop sporadically, and ~95% of these show TDP43 pathology. Over the disease course, neurons accumulate DNA damage and exhibit diminished repair capacity. These observations suggest multiple DNA repair pathways (DRPs) are defective. To this end, we questioned which neuronal DRPs are affected by TDP43. Here, we report for the first time that TDP43 exerts a multifactorial role in the regulation of MMR in neurons. Initial RNA microarray analysis of cells treated with TDP43 siRNA showed dysregulation of several DRPs, including MLH1, MSH2, MSH3, MSH6. Subsequent immunoblot and qRT-PCR of differentiated SH-SY5Y cells confirmed these results. We also discovered that TDP43 modulates splicing of multiple MMR transcripts. Endpoint PCR analysis using primers covering intron-exon boundaries of these transcripts revealed specific accumulation of MLH1 and MSH6 pre-mRNA. Furthermore, we show that loss of TDP43 results in accelerated degradation of MSH3 and MSH6 transcripts. Importantly, we confirmed altered expression and splicing of MMR transcripts in a subset of ALS patient CNS tissues. Finally, we show that TDP43 may also affect MMR at the protein level, as proximity ligation and co-immunoprecipitation assays show TDP43 interaction with MSH3 increases following DNA alkylation treatment of neuronal cells. Taken together, these data reveal multiple novel means by which TDP43 pathology may contribute to neurodegeneration associated genomic instability.

Title: Mitigating aberrant Cdk5 activation alleviates mitochondrial defects and motor neuron disease symptoms in spinal muscular atrophy

Authors: N. MILLER[1], A. JI[1], Z. XU[2], ***Y. MA**[2];
[2]Lurie Children's Hosp. of Chicago, [1]Northwestern Univ. Feinberg Sch. of Med., Chicago, IL

Abstract: Spinal muscular atrophy (SMA), the top genetic cause of infant mortality, is characterized by motor neuron degeneration. Mechanisms underlying SMA pathogenesis remain largely unknown. Here we report that the activity of cyclin-dependent kinase 5 (Cdk5) and the conversion of its activating subunit p35 to the more potent activator p25 are significantly upregulated in mouse models and human induced pluripotent stem cell (iPSC) models of SMA. The increase of Cdk5 activity occurs before the onset of SMA phenotypes, suggesting it may be an initiator of the disease. Importantly, aberrant Cdk5 activation causes mitochondrial defects and motor neuron degeneration, as the genetic knockout of *p35* in a SMA mouse model rescues mitochondrial transport and fragmentation defects, and alleviates SMA phenotypes including motor neuron hyperexcitability, loss of excitatory synapses, neuromuscular junction (NMJ) denervation, and motor neuron degeneration. Inhibition of the Cdk5 signaling pathway reduces the degeneration of motor neurons derived from SMA mice and human SMA iPSCs, suggesting a potential therapeutic strategy. Our findings highlight a positive feedback loop in SMA formed by motor neuron hyperexcitability-induced high bioenergetic demand and increased intracellular Ca^{2+}, which leads to Ca^{2+}/calpain-dependent conversion of p35 to p25 and aberrant Cdk5 activation, and subsequent Cdk5 hyperphosphorylation-mediated mitochondrial defects in energy production and Ca^{2+} buffering. Activation of this loop in SMA exacerbates energy shortage and Ca^{2+} homeostasis disruption, turning motor neuron hyperexcitability into excitotoxicity and degeneration. Altogether, our studies reveal a critical role for the aberrant activation of Cdk5 in SMA pathogenesis and suggest a potential avenue for therapeutic intervention.

Title: Cystamine as a potential therapeutic agent to restore altered heat shock response in the fibroblasts from a neuropathy patient with DNAJB2 c.823+6C>T mutation

Authors: *R. PRADHAN, H. S. ILIEVA;
Farber Inst. of Neurosci. Thomas Jefferson Univ., Philadelphia, PA

Abstract: Neuropathy is a debilitating disorder characterized by peripheral nerve dysfunction and damage. Homozygous mutations in DNAJB2 have previously been shown to cause early neuropathy. A heterozygous DNAJB2 c.823+6C>T mutation was found in a patient with adult-onset severe, sensory-motor polyneuropathy and is predicted to affect both isoforms of the protein. DNAJB2 (HSP40) belongs to a class of Heat Shock Proteins (HSPs) that play a crucial role in cellular protection and stress, including heat stress. HSP40 traffics unfolded proteins to another heat shock protein, HSP70, and activates its ATPase activity to result in a correctly folded protein. In our study, we investigated the effect of heat stress on the heat shock response of fibroblasts obtained from a neuropathy patient with a heterozygous DNAJB2 mutation. In order to elicit a stress response, these cells were subjected to one hour of heat shock, and the expression levels of HSP40 and HSP70 were analyzed after 0, 3, 8, and 24 hours by Western Blot and Immunocytochemistry. Additionally, we evaluated the therapeutic efficacy of Cystamine, a transglutaminase inhibitor, which has been shown to modulate DNAJB2 levels in cellular and animal model of Huntington's disease.While the baseline levels were similar to controls, we found a decreased response to heat shock in the fibroblasts with the DNAJB2 mutation compared to healthy controls, as evidenced by reduced HSP40 and HSP70 levels. Experiments are ongoing to assess if Cystamine can improve/correct expression compared to untreated cells.
In summary, this study demonstrates a diminished heat shock response in the fibroblasts carrying the c.823+6C> DNAJB2 mutation, indicating a loss-of-function pathogenic mechanism. Moreover, Cystamine treatment is evaluated as a potential therapeutic agent to correct DNAJB2 levels. Additional experiments to elucidate Cystamine mechanism of action are planned.

Title: Targeting ferroptosis by clinically approved and brain penetrant HIF Prolyl hydroxylase inhibitors improves recovery in diverse neurological disease models in mice

Authors: *S. KARUPPAGOUNDER, C. CORONA, I. G. CHAMBERS, Y. CHEN, R. R. RATAN;
Burke Neurolog. Inst., White Plains, NY

Abstract: Ferroptosis is a non-apoptotic form of cell death which is dependent on iron. The prevailing view is that iron's role in ferroptosis emerges from its direct ability to drive lipid peroxidation. Here we provide evidence that target-selective iron chelation can also block ferroptosis. Specifically, we show that roxadustat, a clinically approved inhibitor of the iron-dependent, HIF prolyl hydroxylases (HIF PHDs), and adaptaquin, a brain-penetrant HIF PHD inhibitor, abrogated erastin and RSL3-induced ferroptotic death in mouse primary cortical neuronal cultures and a HT1080 human fibrosarcoma cell line. Molecular deletion of all three HIF PHD isoforms in each cell type also reduced ferroptosis. The protective effects of HIF PHD inhibition were correlated with suppression of ferroptosis-induced ATF4 activation but not a reduction in non-chelatable iron levels or inhibition of lipid peroxidation. A dose of adaptaquin that inhibited the HIF PHDs in the brain and eye vivo were validated using HIF-reporter mice and in vivo bioluminescence imaging. At this concentration (30 mg/kg), we found that adaptaquin could reduce cell death and improve functional recovery after ischemic stroke, traumatic brain injury and in a genetic model of retinal degeneration. Together, these findings demonstrate that iron chelators can participate in ferroptosis via target-selective inhibition of the iron-dependent HIF prolyl hydroxylases. Target selective iron chelation offers the opportunity to interdict ferroptosis and neuropathological events in vivo without negatively affecting the physiology of iron in the nervous system.

Title: Measuring serum proteins for potential biomarkers of endoplasmic reticulum stress following acute ischemic stroke in mice

Authors: *L. K. GRASSO[1], J. J. HINKLE[1], K. A. TRYCHTA[1], Y. LI[2], M. TANG[2], M. W. HALTERMAN[2], B. K. HARVEY[1];
[1]Natl. Inst. on Drug Abuse, Baltimore, MD; [2]Univ. Med. Center, Stony Brook, Stony Brook, NY

Abstract: Acute ischemic stroke (AIS) has been shown to induce endoplasmic reticulum (ER) stress. Our lab has identified a form of ER stress called exodosis whereby ER resident proteins exit the cell via the secretory pathway. In vitro experiments demonstrate that hypoxia and hypoglycemia can induce exodosis. The current exploratory study examines ER exodosis in vivo using a mouse model of AIS to identify ER-resident proteins that may be affected by stroke. Blood serum was collected from male mice twenty-four or seventy-two hours after middle cerebral artery occlusion (MCAO) or sham surgery. Serum cytokine levels were analyzed via an Ella multiplex immunoassay, which measures multiple chemokines and inflammatory markers within one sample. Serum IL-6 and TNF-a were increased twenty-four hours post-MCAO compared to sham and seventy-two hours. Mesencephalic astrocyte-derived neurotrophic factor (MANF), a marker of ER exodosis, was measured via ELISA to correlate MANF serum levels with the timing and severity of AIS. No significant difference in MANF levels was detected across groups; however, MANF levels trended higher in twenty-four-hour MCAO serum than all other groups. To screen for additional serum markers of ER exodosis in AIS, western blots were exposed to a polyclonal antibody that reacts with proteins containing an endoplasmic reticulum retention sequence (ERS). Increased immunoreactivity with this antibody suggests an increase in exodosis. No significant trend was seen for any of the ERS proteins detected by the antibody. A higher *n* value may reveal more trends in this data set. Additional timepoints, including baseline serum, may aid in characterizing ERS secretion in AIS. Identifying a panel of ERS proteins that react in measurable ways to AIS would allow us to establish a new timeline of post-stroke cellular mechanisms. With this knowledge, we may be able to therapeutically target ER exodosis and attenuate post-stroke symptomology in those who have experienced AIS.

Title: A Meta-Analysis of Glibenclamide after Experimental Intracerebral Hemorrhage (ICH)

Authors: *T. KUNG, C. M. WILKINSON, L. J. LIDDLE, F. COLBOURNE;
Univ. of Alberta, Edmonton, AB, Canada

Abstract: Edema has occasionally been shown to worsen behavioural outcomes and often contributes to mortality after intracerebral hemorrhage (ICH), a devastating subtype of stroke.

Glibenclamide (GLC) is a sulfonylurea 1- transient receptor potential melastatin 4 (Sur1-Trpm4) channel blocker, and attenuates edema in ischemic stroke models, suggesting possible benefits in ICH. As clinical interest in GLC is high with multiple clinical trials in ischemia currently underway, this meta-analysis was performed to synthesize all animal studies investigating a post-ICH administration of GLC vs. no-treatment controls on behavioural outcomes, edema, hematoma volume, and injury volume after ICH. Six studies were included in our meta-analysis, two null (i.e., GLC did not affect any endpoints) and four positive (i.e., GLC improved one or more endpoints). GLC significantly improved behaviour (standardized mean difference (SMD) = −0.63, [−1.16, −0.09], n = 70-74) and edema (SMD = −0.91, [−1.64, −0.18], n = 70), but did not affect hematoma volume (SMD = 0.0788, [−0.5631, 0.7207], n = 18-20), or injury volume (SMD = 0.2892, [−0.4950, 1.0734], n = 24). Although it appears that significant benefit may be realized with GLC after ICH, limitations suggest these results should be interpreted with caution. Publication bias was significant in edema (p = 0.0001) and indicated missing negative data, and the same trended towards significance in behaviour (p = 0.0766). Experimental quality was generally low, and risk of bias was generally high among studies. Experiments were often low-powered; future researchers should employ sample sizes of 33 to detect our observed effect in edema, and 41 to detect our observed effect in behaviour. Lastly, many important experimentally rigorous recommendations to improve translatability of pre-clinical findings (e.g., use of female, aged, and co-morbid animals) have not yet been completed. Thus, missing negative data, generally low study quality and high risk of bias show that additional high-powered confirmatory animal work is needed prior to future clinical GLC work in ICH.

Sci., Texas A&M Hlth. Sci. Ctr., Houston, TX

Abstract: In brain hemorrhage, toxic hemin, a degradation product of hemoglobin, accumulates, potentially leading to cell death. The cells respond by expressing Heme Oxygenase-1 (HO-1), which breaks down hemin into biliverdin and free iron (Fe2+). Our recent studies highlighted that hemin triggers DNA double-strand breaks (DSBs) and a cellular senescence-like phenotype. The causal relationships between these observations remain unknown. In this study, we illuminate how DNA damage response (DDR) signaling directly mediates the induction of this senescence-like phenotype and HO-1 expression. We studied both cultured neurons and endothelial cells exposed to hemin, as well as in brain cells near the site of hemorrhage. Senescence induction may enable cells to survive and avoid ferroptosis, while simultaneously degrading hemin through HO-1. In culture and in tissue from individuals with intracerebral hemorrhage, we observed a co-localization of senescence-associated β-galactosidase expression and HO-1 positivity. DDR signaling inhibitors reduced both senescence markers and HO-1 expression. Interfering with senescence directly using p21 inhibitors during hemin exposure or pre-emptive HO-1 overexpression resulted in apoptosis and ferroptosis, suggesting that addressing only one aspect of hemin-induced toxicity was insufficient to prevent cell death. Therefore, we designed a multifunctional nanoparticle that incorporates deferoxamine (DEF), an iron chelator, with a pleiotropic nanozyme of oxidized, medical-grade coconut shell activated charcoal (OAC) and poly(ethylene)glycol (PEG). This nanoparticle efficiently mitigated hemin-induced senescence while also preventing iron-induced cell death. These findings emphasize the crucial function of DDR-induced senescence-like phenotype and HO-1 expression in the context of hemin degradation and cell survival in experimental brain hemorrhage, suggesting potential new therapeutic strategies for treating brain hemorrhage.

Abstract: Germinal matrix hemorrhage-intraventricular hemorrhage (IVH) is a common complication of extremely premature newborns and results in reduced neurogenesis, cortical atrophy and subsequent cerebral palsy, learning and memory disabilities. Significantly, the dentate gyrus (DG) of the hippocampus produces neuronal precursor cells throughout life. Despite this, survivors of Grade III-IV hemorrhage show smaller hippocampal volumes on MRI consistently with impaired hippocampal function and related cognitive scores (Strahle et al 2019). We hypothesize that following IVH, RBC lysis-released toxic mediators (hemin, free hemoglobin, Fe^{+++} accumulation) will disturb postnatal hippocampal formation of CA3, CA2, CA1 and dentate gyrus (DG) structures. To address this, we are evaluating the combined treatment with deferoxamine (DFN, Fe^{+++} chelator) and sulforaphane (SFN) an activator of the Nrf2 transcription factor, which enhances many antioxidant enzymes attenuating free radical toxicity and proinflammatory responses leading to preferential macrophage polarization (M1 vs M2). Using a preterm rabbit pup model of glycerol-induced IVH (Georgiadis et al, 2008 and Vinukonda et al, 2019), after DFN+SFN (SFN 25mg/Kg, 2 doses, DFN 50mg/Kg, twice a day starting from day 1 of IVH), we identified a reduced size of the parenchymal hematoma *qualitatively* on hippocampus sections using H&E staining control vs IVH alone on postnatal d3 (equivalent to term). Ongoing experiments will *quantify* free Hb and Fe^{+++} accumulation/clearance after combined treatment. $NeuN^{+}$ (mature neuron specific antibody) immunofluorescence staining showed a 5-6-fold increase in total cell density in the dentate gyrus (QuPath-software program) after IVH. Due to region-specific functions within the hippocampus, we also examined inner-pyramidal (DG_{inner}) and outer-pyramidal (DG_{outer}) blades of the dentate gyrus. We observed that after IVH, $NeuN^{+}$ neurons were densely distributed in both DG_{inner} and DG_{outer} blades; whereas in healthy controls, only the DG_{outer} blade was densely populated. DFN+SFN treatment after IVH resulted in ~40% reduction in overall and densely populated $NeuN^{+}$ in the DG_{outer} blade. We observed a two-fold increase in Iba-1^{+} microglia in IVH pups vs control that was reduced to near normal on day 3 after SFN-DFN treatment. These data suggest beneficial effects of SFN-DFN treatment at early IVH that may later impact long term memory or neurobehavioral function.

Title: Modulation of microglial polarization in hematoma clearance in hemorrhagic stroke by immunoproteasome inhibition

Authors: *W. HU[1], *W. HU[2], C. LEE[3,5], H. YU[4], H. LIU[4], C. LIN[1], C. PANG[3,4], H. LIEW[1,3,4]; [1]PhD Program in Pharmacol. and Toxicology, Tzu-Chi university, Hualien, Taiwan; [2]Tzu-Chi Univ., Hualien, Taiwan; [3]Neuro-medical Scientific Ctr., [4]Dept. of Med. Res., Tzu-Chi general hospital, Hualien, Taiwan; [5]Dept. of Neurosurg., Tzu Chi general hospital, Hualien, Taiwan

Abstract: Objective: Our objective was to investigate the impact of proteasome over-activation induced by intracerebral hemorrhage (ICH) on endoplasmic reticulum (ER) stress, protein homeostasis disruption, and neuroinflammation. We explored the role of proteasome inhibition in reducing proteasome activation, alleviating ER stress, and mitigating neuroinflammation. Additionally, we studied the diverse phenotypes of microglial activation, namely M1 polarization (inflammatory activation) and M2 polarization (anti-inflammatory/phagocytic activation), which are influenced by different signals received by microglial receptors. We aimed to elucidate the expression pattern of proteasome and their involvement in hematoma clearance. **Materials & Methods:** We examined the expression of proteasomes and neuroinflammation in rats with ICH using RT-qPCR and Western blotting, respectively. Immunofluorescent staining was employed to identify the cell types expressing specific proteasome subtypes. In an in vitro erythrophagocytosis assay, microglia were incubated with CFDA-labeled red blood cells (RBCs), and some groups were co-treated with ONX-0914 (a specific inhibitor of immunoproteasomes at a concentration of 100 nM). Phagocytic ability was measured by using water to induce cell swelling and dissolve the fluorescent dye. Microglial polarization levels were determined by flow cytometry, and the expression of inflammatory and anti-inflammatory genes was assessed using qPCR. **Results:** Immunoproteasomes were found in the vicinity of the hemorrhagic area and primarily co-localized with microglia expressing the clearance marker CD163. The *in vitro* erythrocyte phagocytosis assay revealed that co-treatment with ONX-0914 enhanced phagocytic ability and promoted microglial polarization toward an anti-inflammatory phenotype. **Conclusion:** Inhibiting immunoproteasomes exerts neuroprotective effects by facilitating hematoma clearance and suppressing inflammation.

Abstract: EVALUATION OF THE ANTIOXIDANT AND ANTIAPOPTOTIC EFFECT OF ACOMBINATION OF CANNABIDIOL AND DAPSONE AGAINST IN VITRO BRAINISCHEMIA AND REPERFUSION IN SH-SY5Y CELLS.Marcela Islas-Cortez[1,2], Araceli Diaz-Ruiz[2], Camilo Rios[3], Ricardo Perez-Pastén-Borja[11]Laboratorio de Toxicología Molecular y Celular, Escuela Nacional de Ciencias Biológicas-CampusZacatenco, Instituto Politécnico Nacional, Ciudad de México 07738, Mexico[2]Departamento de Neuroquímica Instituto Nacional de Neurología y Neurocirugía Manuel VelascoSuárez, Ciudad de México, México.[3]Dirección de Investigación, Instituto Nacional de Rehabilitación Luis Guillermo Ibarra Ibarra, Ciudadde México, México | Laboratorio de Neurofarmacología Molecular, Universidad AutónomaMetropolitana Xochimilco, Ciudad de México, México.**Introduction:** Brain ischemia is the result of interruption of blood flow of a cerebral artery.This event is characterized by oxygen and glucose deprivation, which produces neuronaldeath. The**objective** of the present study was evaluated the effect of treatment with Cannabidiol (CBD)and Dapsone (DDS) administered alone or in combination in vitro model of ischemic cerebral with reperfusion in SH-SY5Y cells by means of an isobolographic study. **Experimental procedures:** This study was carried out in SH-SY5Y cells to evaluate the interaction of the combination of CBD and DDS for which concentration-response curves of DDS and CBD were performed. Where LC50 values were established separately for each drug. Concentration-response curves of the drugs were made on the model of brain ischemia through oxygen and glucose deprivation (OGD) to obtain the EC50. Once the EC50 of the DDS-CBD mixture was obtained, the interaction index was calculated and the isobologram was performed. Once the type of interaction between the drugs was determined, the mixture was evaluated on cell viability, cytotoxicity, caspase3 enzymatic activity, and determination of the production of reactive oxygen species. **Results:** The isobolographic results indicated a synergistic effect, this effect is of great interest since it is possible to increase the cell viability of the SH-SY5Y line after undergoing conditions of OGD followed by 24 h. of reperfusion. The results of the group treated with DDS-CBD showed a significant decrease in lactate dehydrogenase (LDH) release, ROS and caspase 3 enzyme activity, as well as an increase in cell viability and reduced glutathione. **In conclusion**, the results suggest that the combination of CBD and DDS could be a suitable alternative to achieve a good antioxidant antiapoptotic effect, safely maintaining cell viability.

Title: A neuroprotective state of suspended animation

Authors: *L. ANGENENDT DA COSTA[1], A. SHEHADAH[2], R. SOHUR[2], C. B. SAPER[3], N. L. MACHADO[4];
[1]Univ. of São Paulo, Ribeirao Preto, Brazil; [2]Beth Israel Deaconess Med. Center, Harvard Med. Sch., Boston, MA; [3]Harvard Med. Sch. Dept. of Neurol., Harvard Med. Sch. Dept. of Neurol., Boston, MA; [4]Beth Israel Deaconess Med. Ctr. - Harvard Med., Beth Israel Deaconess Med. Ctr. - Harvard Med., Boston, MA

Abstract: Suspended animation is a state in which life processes in a body are temporarily slowed down but can be restarted without damage. Some animals enter such a state naturally in response to a chronic low environmental temperature or times of food scarcity. These animals lower their body temperature and enter torpor or hibernation states, a deep hypothermic and hypometabolic condition that conserves energy. We have recently demonstrated that median preoptic neurons expressing the prostaglandin EP3 receptor (MnPOEP3R) are necessary and sufficient to cause torpor, and activating them promotes deep hypothermia - an artificially induced state of suspended animation without injury to the animals.Here we characterized the wake-sleep behavior of mice during a state of suspended animation and tested the neuroprotective benefits of deep hypothermia after ischemic stroke. We recorded the patterns of the electroencephalogram (EEG) and electromyogram (EMG) of mice during hypothermia or baseline (normothermic) conditions. We found that during deep hypothermia, there is a substantial reduction of the EEG power, an increase in time spent in NREM sleep, and a suppression of REM sleep. We also tested the ability of mice to be aroused from the deep hypothermic state by gently handling them and showed that these mice are responsive to external stimuli.Then, in a separate set of experiments, we used a permanent middle cerebral artery occlusion (pMCAO) or promoted a transient MCAO for 4 hours, followed by reperfusion (tMCAO). Thirty minutes from the MCAO onset, we promoted deep hypothermia by activating MnPOEP3R neurons. Body weight, survival rate, and neurological severity score were evaluated 24-72 hours following a stroke. Our deep hypothermic model caused core temperature to drop (23.84 ± 0.7 ℃) at room temperature for up to 72 h. Hypothermic mice had no evidence of weight loss during the first 48 hours of hypothermia, while normothermic mice showed 15% and 20% in body weight loss 48 hours from the onset of the permanent or transient stroke, respectively. Hypothermia also drastically reduced stroke severity, increasing survival by 30% (pMCAO) or 70% (tMCAO) after 72 hours. The hypothermia length also correlated with better neurological outcomes after tMCAO.Our results suggest that suspended animation is neuroprotective after ischemic stroke, and its therapeutic benefits are likely to be translatable from mice to humans.

Title: Inhibition of histone deacetylase 3 improves functional outcomes post-intracerebral hemorrhage via reduction of neuroinflammation.

Authors: ***N. J. WATSON**, F. BONSACK, S. SUKUMARI RAMESH;
Augusta Univ., Augusta, GA

Abstract: Secondary brain injury is a leading cause of neurological deficits after intracerebral hemorrhage (ICH), a severe stroke subtype. Stimulation of the immune system at the site of a brain hemorrhage, characterized by microglial activation, leads to neuroinflammation and secondary brain damage. We previously reported that genetic knockdown of HDAC3 in a macrophage cell line significantly attenuated hemin-induced release of TNF-α and IL-6 compared to a control, while genetic knockdown of both HDAC1 and HDAC2 significantly augmented hemin-induced release of TNF-α from cells without an effect on IL-6. To extend this observation further, we have now generated microglia-specific HDAC3 conditional knockout using Cre-Lox technology. Our ongoing preliminary studies indicate improved neurobehavioral outcomes in HDAC3 flox/flox: Cx3cr1 CreER post-ICH compared to experimental control in both males and females. Further, analysis of levels of pro- and anti-inflammatory cytokines in ipsilateral brain regions post-ICH via rt-qPCR have demonstrated a highly significant reduction of pro-inflammatory cytokines, a corresponding increase in anti-inflammatory cytokines, a reduction of activated microglia in both male and female subjects, and an increase in M2 microglial polarization. Additionally, use of a HDAC3 inhibitor, RGFP966, in mice has demonstrated an improvement in functional recovery in treated mice compared to control animals. RGFP966 treated mice also show a reduction in pro-inflammatory cytokines, indicating HDAC3i as a potential novel therapy for ICH.

Title: Inhibiting Integrated Stress Response in a Stroke Model of Vascular Dementia

Authors: *M. HOVANESYAN[1], S. AZARAPETIAN[1], W. DAI[1], M. ZARAFSHAN[1], I. LORENZO LLORENTE[1], S. CARMICHAEL[2];
[1]UCLA, UCLA, Los Angeles, CA; [2]UCLA Sch. Med., UCLA Sch. Med., Los Angeles, CA

Abstract: White matter stroke (WMS) is a debilitating disorder, characterized by the formation of ischemic lesions along the white matter tracts in the brain. The accumulation of these white matter lesions leads to vascular dementia, which is the second leading cause of dementia, and accelerates the pathology of Alzheimer's Disease. As of today, there are no therapy options available to halt the progression of this debilitating disease. Evidence from genetic diseases that affect the cerebral white matter, a support cell (or glial cell), termed the astrocyte, senses the injury and undergoes a prolonged stress response. This stress response, termed the integrated stress response (ISR), contributes to progressive damage in the white matter. We targeted the ISR response by using an inhibitor, 2BAct, in a mouse model of vascular dementia. We initially performed white matter strokes in C57BL/6J mouse models, and measured the behavioral recovery of these cohorts through drug administration. We conducted tests of motor control (cylinder and grid-walking) at baseline, 1-week, 1-month, 2-month, and 4-month timepoints to assess recovery after injury in the white matter. Our data indicates that there is an initial recovery in grid-walking at the 1-month timepoint, and a recovery in cylinder tests at the 2-month timepoint for cohorts that received a WMS + 2BAct administration. This data suggests that the ISR is an important target to promote recovery in a model of vascular dementia. Supported by a grant from Calico Labs

Title: Roles of equilibrative nucleoside transporter-1 in modulating energy homeostasis and meningeal lymphatics in mice with permanent ischemic stroke

Authors: *C.-J. HO[1], K.-C. WU[1], J. LIN[1], W.-R. CHEN[1], C.-F. CHANG[1], Y. CHERN[2], C.-J. LIN[1];
[1]Natl. Taiwan Univ., Taipei, Taiwan; [2]Inst. of Biomed. Sciences,, Academia Sinica, Taipei, Taiwan

Abstract: Main purpose
During ischemic events, adenosine serves as a neuromodulator with a 100-fold upregulated level in the brain extracellular fluids. The equilibrative nucleoside transport 1 (Ent1) distributed in the neuron and glial cells is responsible for cellular uptake and the homeostasis of adenosine in the brain. Meanwhile, meningeal lymphatics have been found in transporting metabolites, wastes, and immune cells in the brain and therefore play a crucial role in neurological diseases. The objective of the present study was to explore the roles of Ent1 in the modulation of energy homeostasis and meningeal lymphatics in ischemic stroke.
Methods
$Ent1^{-/-}$ ($B6.129X1\text{-}Slc29a1^{tm1Msg/J}$) mice and its littermate controls were originally purchased from Jackson Laboratory. Mice (8-12 weeks old), both male and female mice, were subjected to permanent middle cerebral artery occlusion (pMCAO) to induce permanent ischemic stroke. The mRNA expression of adenosine-related enzymes was measured by RT-qPCR. The metabolomic profiles of adenine nucleotides were conducted by UPLC-QTOF/MS analysis. The infarct volume was measured on D1 post injury. Behavioral tests, astrogliosis, microgliosis, BBB integrity, and lymphagiogenesis were examined on D14 post injury.
Results
Metabolomic results showed that intracellular adenine, adenosine, and AMP were significantly decreased in mice with pMCAO. Meanwhile, the mRNA level of Ent1 was increased. $Ent1^{-/-}$ mice reduced the infarct volume on D1 with improved motor and recognition function until D14. In terms of meningeal lymphatics, $Ent1^{-/-}$ mice exhibited enhanced lymphagiogenesis in both uninjured and ischemic injury conditions. $Ent1^{-/-}$ mice also preserved neuron density and BBB integrity in the penumbra of the cortex, along with reduced neuroinflammation in mice with MCAO.
Conclusion
Ent1 deletion attenuated the injury in mice with permanent ischemic stroke. These findings indicate the important role of Ent1 in the pathogenesis and treatment of ischemic stroke.

Medicine, Natl. Autonomous Univ. of Mexico, Mexico, Mexico; [7]Natl. Inst. of Cardiol., Mexico, Mexico

Abstract: Stroke is a leading cause of death and mortality, despite that it affects mainly the elderly in a homogeneous way, there are differences in terms of epidemiology, recovery, motor and cognitive impairments, and the response and effectiveness of the treatments between men and women. Initially, the research for treatments was focused on limiting the damage; however, regeneration therapies have attracted attention. Regeneration is a process naturally activated after cerebral ischemia damage, in part in response to the neurotrophins. One of its main advantages is that these therapies are not limited by time. However, is an insufficient process due the presence of proinflammatory molecules. In relation to treatments, the S-allylcysteine (SAC), has been used by its antioxidant and antiinflammatory properties, showing to have protective effect against acute ischemia/reperfusion injury in male young animals. However, the protective mechanism is not fully understood and its effects on regenerations have not been studied yet. Thus, the aim of this work was to evaluate the effect of SAC on motor defict and the neurotrophins levels in young female rats after 1 h of ischemia and 15 days of reperfusion. The ischemia was induced by the middle cerebral artery occlusion. Daily doses of SAC (100 mg/kg) were administered via intraperitoneal. The motor deficits were analyzed, and the neurotrophins vascular endothelial growth factor (VEGF), neuronal growth factor (NGF) and brain derived neurotrophic factor (BDNF) were quantified by immunohistochemistry. Animals treated with SAC showed fewer motor deficits and higher levels of NGF in cortex and striatum, VEGF in striatum and BDF in subventricular zone. This project was partially supported by CONACyT A1-S-21433 to PDM.

Title: Cofilin knockdown with siRNA prevents microglial activation, neuroinflammation, and cofilin-actin rods/aggregates after intracerebral hemorrhage in young and aged mice

Authors: *D. ALMARGHALANI[1], G. BAHADAR[2], F. SHEHJAR[2], W. ANTONISAMY[2], Z. A. SHAH[3];
[1]Pharmacol. and Toxicology, Taif Univ., Taif, Saudi Arabia; [2]Univ. of Toledo, Toledo, OH; [3]Medicinal & Biol. Chem., Univ. of Toledo Col. of Pharm. and Pharmaceut. Sci., Toledo, OH

Abstract: Studies from our lab have shown that cofilin-actin rods/aggregates are localized within the microglia and around the hematoma of the human autopsy brain and young mouse brain after intracerebral hemorrhage (ICH). Considering age as a risk factor for ICH and associated with higher mortality rates than young, this study focused on the role of cofilin in aged mice, and the results were compared to young mice. Furthermore, cofilin siRNA gene therapy in mice subjected to inter-striatal collagenase injection-induced experimental ICH was tested. The outcomes were assessed 15 days after ICH. The cortex and hippocampus of the mouse brain were analyzed for cofilin-actin rods/aggregates, microglial activation, and neuroinflammation and serum was collected to evaluate proinflammatory cytokines (IL-6 and IL-1β). Cofilin-actin rods/aggregates were observed in the cortex and hippocampus of aged males and females but not in young-adult males and females. The length and intensity of cofilin-actin rods/aggregates increased in adult and aged males and females around the hemorrhagic area. Activated microglia increased in both young and aged males and females but were prominent in aging male and female mice. However, cofilin gene therapy with siRNA mitigated cofilin-actin rods/aggregates and microglial activation in young adults and aged male and female mice. There were no changes in IL-1β in the cortex and hippocampus of young males and females. An increased expression of IL-1β was observed in the hippocampus of aged males and females, but cofilin siRNA treatment significantly reduced IL-1β in old females but not males. The serum IL-6 levels were significantly increased in aged males and females compared to young-adult males and females and attenuated by cofilin siRNA treatment. The serum IL-1β levels were diminished in the cofilin siRNA treatment of young and aged males and females compared to ICH groups, but the results were insignificant. These results suggest that reducing cofilin-actin rods/aggregates with siRNA gene therapy could potentially treat ICH-related pathology in aged and young mice.

Title: 6-phosphofructo-2-kinase/fructose-2,6-biphosphatase 3 (PFKFB3) blockade is neuroprotective in an acute mouse model of ischemic stroke

Authors: *R. E. GUNRAJ, J. LAROCHELLE, S. STANSBURY, C. YANG, L. LIU, E. CANDELARIO-JALIL;
Univ. of Florida, Gainesville, FL

Abstract: Stroke is the second leading cause of death and the leading cause of adult disability worldwide. Ischemic stroke, characterized by the blockage of a blood vessel, is the most

prevalent type. A major hallmark of stroke is the dysregulation of normal metabolic functions. In the ischemic environment, cells shift towards glycolysis, a metabolic pathway that is associated with a prolonged inflammatory response and delayed apoptotic cell death. One primary driver of glycolysis is 6-phosphofructo-2-kinase/fructose-2,6-biphosphatase 3 (PFKFB3). This enzyme is upregulated after injury and synthesizes fructose-2,6-biphosphate, an allosteric activator of phosphofructokinase-1 which catalyzes the first-rate limiting step in glycolysis. In diseases involving glycolytic shift such as atherosclerosis, pulmonary hypertension, and endotoxemia, PFKFB3 inhibition has been shown to increase survival rate and reduce injury; however, little research has been conducted in stroke. We hypothesize that because aberrant glycolysis contributes to inflammation and cell death and PFKFB3 upregulates glycolysis after injury, inhibition of PFKFB3 is neuroprotective in stroke. We administered a 45-minute transient middle cerebral artery occlusion in male C57BL/6J mice followed by treatment with a highly selective PFKFB3 inhibitor, AZ67 (N=10) or vehicle (N=11). The vehicle or the inhibitor (30mg/kg) were administered starting at the onset of reperfusion via the jugular vein with three repeated retro-orbital doses over the course of 48h. Open field, vertical grid, weight test, and neural deficit scorings were conducted at 24 and 48h post stroke after which the mice were euthanized by perfusion with saline and stained with TTC to quantify infarct size. Our findings show a neuroprotective effect of PFKFB3 inhibition in ischemic stroke with improved functional and behavioral recovery and smaller infarct sizes. These results support the hypothesis that PFKFB3 inhibitors may be used as a novel pharmacological treatment for reducing delayed cell death after ischemic stroke. Future studies are underway to investigate the molecular mechanisms and cell types involved in the protection conferred by PFKFB3 blockade in the context of ischemic stroke.

Title: Iron overload and the protective effects of deferoxamine and a cofilin inhibitor

Authors: *F. SHEHJAR, R. MAHAJAN, W. ANTONISAMY, Z. A. SHAH;
Medicinal and Biol. Chem., Univ. of Toledo, Toledo, OH

Abstract: Background: Iron overload plays a critical role in neurodegenerative disorders, particularly hemorrhagic brain injury, characterized by brain bleeding. Increased iron levels contribute to oxidative stress, inflammation, and neuronal damage. Cofilin-1, an actin-binding

protein, is implicated in neurodegeneration, including hemorrhagic brain injury, as it regulates actin dynamics essential for neuronal survival. Understanding the role of iron overload and cofilin-1 in hemorrhagic stroke is crucial for developing targeted therapies. **Methods:** To mimic iron overload, we investigated protein expression modulation in SH-SY5Y cells treated with ferric ammonium citrate (FAC). We examined the potential protective effects of deferoxamine (DFX) and a cofilin inhibitor (CI). Cells were treated with FAC (150uM), FAC+DFX (150uM+150uM), FAC+CI (150uM+5uM), and vehicle (control group). Western blot was used to assess protein levels associated with neurodegeneration. **Results:** FAC-treated cells exhibited significantly increased protein expression of BAX, caspase-1, BIP, eIF2-α, STAT-1, AIF, cleaved PARP, cleaved caspase-3, COX-2, ferritin, HO-1, NRF-2, and SOD-2 compared to the vehicle (control group), suggesting activation of apoptotic pathways, endoplasmic reticulum stress, and elevated oxidative stress. In contrast, the DFX and CI groups showed significantly decreased expression of these proteins compared to the FAC-treated group, indicating potential protective effects by attenuating pro-apoptotic, pro-inflammatory, and oxidative stress responses induced by iron overload. **Conclusions:** Our findings highlight the potential of DFX and CI as therapeutic strategies to mitigate iron-induced neurotoxicity in hemorrhagic brain injury. Targeting iron overload and cofilin-1 signaling pathways may offer novel approaches to preserve brain tissue and promote recovery in neurodegenerative diseases associated with iron dysregulation.

Title: The NFkB-cIAP2 axis is essential and sufficient to protect oligodendrocyte from ischemic insult

Authors: *J. CHOI[1], H. KIM[2], S. KOH[1], B. KIM[2], B. KIM[1];
[1]Departments of Brain science and Neurol., [2]Departments of Brain science, Ajou Univ. Sch. of Med., Suwon-si, Korea, Republic of

Abstract: Myelinating glia, oligodendrocyte (OL), provides saltatory conduction and various support to the axon through axomyelinic synapse. White matter stroke (WMS) is an important clinical entity that comprises one-fourth of ischemic stroke and is the second most common cause of senile dementia but underestimated neurologic disorders. The main pathology of WMS

is ischemic OL loss. Thereafter, a therapeutic strategy for WMS should focus to reduce the ischemic OL death. Previously, our group showed Toll-like receptor 2 in OLs protects OLs from ischemic damage, promotes OPC migration to the WMS lesion through interaction with the one of the endogenous TLR2 ligands, the high-mobility group box 1 released from dying OL. However, there is a need to uncover more detailed intracellular survival pathways mediated from TLR2 in oligodendrocytes. We investigated primary OL culture from P1 pups and oxygen-glucose deprivation as an in vitro ischemic model. Firstly, we examined the phosphorylation or activation of canonical TLR2 pathway signaling proteins, such as AKT, ERK1/2, p38, CREB, or NF-kB in OL after Pam3CSK4, a TLR2 agonist. TLR2 activation didn't phosphorylate AKT but phosphorylate ERK1/2, p38, and CREB and activate NF-kB. Secondly, we used a chemical inhibitor or siRNA to each signal pathways proteins and found p38 and NF-kB were essential for TLR2-mediated OL protection from ischemic insults but not ERK1/2 and CREB. To validate our findings, we performed bulk RNA seq in OL with or without Pam3CSK4 or OGD. According to RNA seq data, NF-kB is located in the central position of TLR2-mediated OL protection. Also, we found that cIAP2 and Bcl2 have upregulated in TLR2-NFkB dependent manner. After the acquisition of RNA seq, we transfected OL with various constitutive active plasmids or siRNA to manipulate signaling pathways. cIAP2 rather than Bcl2 was increased after transfection in either p38 or NF-kB active state. Interestingly, p38 constitutive activation with NF-kB knockdown couldn't increase cIAP2 and protect OLs from OGD. On the contrary, NF-kB constitutive activation with p38 knockdown could increase cIAP2 and protect OLs from OGD. Additionally, cIAP2 overexpression with NF-kB knockdown also showed OLs protective effects but not vice versa. To confirm the protective effects of NF-kB, we injected AAV-mMBP-Flag-IKK2 into right internal capsule. Similarly with in vitro results, activation of NF-kB in OLs showed reduced WMS lesion volume and improved neurobehavioral deficit measured by adhesive removal test. These findings show TLR2 in OLs exerts a protective effect through NF-kB and cIAP2 and suggest a novel therapeutic target to overcome ischemic OL death and WMS.

Title: A Mendelian Randomization Study of PCSK9 Inhibition and Stroke: Evidence for Benefits Beyond Low-Density Lipoprotein Cholesterol Lowering

Authors: *L. M. PARK[1], D. B. ROSOFF[1,3], L. A. MAVROMATIS[1], A. S. BELL[1], A. M. HAMANDI[1], J. JUNG[1], J. WAGNER[1], P. MUKHOPADHYAY[1], P. PACHER[1], L. F. VENDRUSCOLO[2], G. F. KOOB[2], F. W. LOHOFF[1];

[1]NIAAA, NIH, Bethesda, MD; [2]NIDA, NIH, Baltimore, MD; [3]Univ. of Oxford, Oxford, United Kingdom

Abstract: Background: Stroke is the second leading cause of death globally, and recent clinical trials have found that pharmacological proprotein convertase subtilisin kexin 9 (PCSK9) inhibition (PCSK9i) reduces stroke risk. However, the impact of long-term PCSK9i on stroke risk and the complex interplay of PCSK9 with various lipids remains unknown. Our goal was to leverage data on PCSK9 protein levels using drug-target Mendelian randomization (MR) and multivariable MR (MVMR) to investigate the impact of genetically-lowered PCSK9 levels on stroke risk. Methods: We created genetic instruments using *PCSK9* variants associated with plasma PCSK9 concentration ($N_{primary}$=35,559; $N_{replication}$=10,186); low-density lipoprotein cholesterol (LDL-C), high-density lipoprotein cholesterol (HDL-C), and triglycerides (TG; N=1,320,016); apolipoprotein B (ApoB; N=439,125); lipoprotein a (Lp[a]; N=361,194); stroke (N_{cases}=40,585); ischemic stroke (IS; N_{cases}=34,217); and stroke subtypes ($N_{cases}\leq$7,193). We performed drug-target MR investigating relationships between plasma PCSK9 and stroke phenotypes as well as MVMR assessing PCSK9 inhibition on stroke risk while controlling for five major lipid subfractions (LDL-C, HDL-C, TG, ApoB, and Lp[a]). Results: We identified a strong protective association between genetically-lowered PCSK9 protein levels and stroke (odds ratio (OR)=0·86, 95% CI [0·83-0·88], P=$1.74x10^{-28}$), ischemic stroke (OR=0·88, 95% CI [0·85-0·90], P=$1·70x10^{-18}$), cardioembolic stroke (OR=0·84, 95% CI [0·76-0·93], P=0·001), and large artery ischemic stroke (OR=0·74, 95% CI [0·68-0·80], P=$1·28x10^{-14}$). We replicated these findings with complementary MR methods and two genetic instruments from independent data. MVMR analysis suggested that genetically proxied circulating PCSK9 inhibition was protective both for ischemic stroke (OR=0·89, 95% CI [0·82-0·97], P=0·008) and cardioembolic stroke (OR=0·83, 95% CI [0·69-1·00], P=0·04) supplementary to its established effect on lowering lipid levels, while PCSK9 inhibition was protective against large artery atherosclerosis entirely through its lipid pathways. Conclusions: Our data provide new evidence that plasma PCSK9 protein levels inversely associate with stroke risk, resolving discrepancies between randomized clinical trials and previous genomic studies. MVMR suggested pleiotropic relationships of PCSK9 on stroke risk beyond its effects on lipid fractions, underlining that future studies are needed to investigate the protective effect of PCSK9i beyond LDL-C-related pathways. Broadly, our study should reassure clinicians that anti-PCSK9 therapies reduce stroke.

Abstract: Secondary neurodegeneration in brain regions remote to the infarct impedes functional recovery after ischemic stroke. The complement system has been implicated as a driver of neuroinflammation, neuronal dysfunction and synapse loss associated with aging and Alzheimer's disease type neurodegeneration. We previously showed that signaling through the receptor for complement-derived peptide C3a (C3aR) stimulates peri-infarct neural plasticity and intranasal treatment with C3a facilitates recovery of sensorimotor function after ischemic stroke. Here, we investigated the role of the C3a-C3aR axis in secondary neurodegeneration following cortical ischemic stroke. We found that mice lacking C3aR had increased beta-amyloid accumulation and more prominent reactive microgliosis in the ipsilesional thalamus 21 days after stroke. Daily intranasal treatment of mice with C3a for 2 or 3 weeks starting 7 days after stroke induction reduced beta-amyloid accumulation and reactive gliosis, and increased density of synaptophysin-positive presynaptic terminals in the ipsilesional thalamus. Using in vivo magnetic resonance imaging, we assess stroke-induced long-term changes in the ipsilesional thalamus. We conclude that the C3a-C3aR axis is an important modifier of post-stroke secondary neurodegeneration. Intranasal treatment with C3a presents an attractive therapeutic strategy to inhibit secondary neurodegeneration after stroke.

Title: Progesterone Reduced Behavioral Deficits in MCAo Rat When Delivered Intraperitoneally Using PAMAM Dendrimers

Authors: *A. UPRETY, A. POUDEL, M. J. M. KING, B. SRINAGESHWAR, N. DAY, J. D. GROSS, R. C. SCHALAU, L. K. BOLEN, S. SCHWIND, B. M. GALVIN, S. R. SHUHAG, O. SMITH, A. SHARMA, D. SWANSON, G. L. DUNBAR, J. ROSSIGNOL;

Abstract: A stroke occurs when the blood supply to a specific area of the brain is interrupted, resulting in brain tissue damage, loss of brain function, and neuroinflammation. Ischemic stroke, the most common type, happens when a blood clot or narrowed artery blocks the flow of blood to the brain. Developing effective treatments for stroke is challenging due to the complex nature of events and circuitry within the central nervous system. Tissue plasminogen activator (tPA) is the first FDA-approved treatment for acute ischemic stroke, which dissolves blood clots that obstruct brain blood flow. For maximum effectiveness, tPA must be administered within 3-4 hours of ischemic stroke onset. Progesterone, a hormone naturally produced in the body, has neuroprotective and anti-inflammatory properties and might be a potential treatment for an ischemic stroke. Previous studies have indicated that progesterone may be a viable option for mitigating the effects of neuroinflammation and oxidative stress. In this study, we used G4 PAMAM dendrimers for the systemic delivery of progesterone in rat models with middle cerebral artery occlusion (MCAo). The rats received intraperitoneal (IP) injections of dendrimer-progesterone complex, dendrimer only, and HBSS every other day for 10 days, starting on the sixth day after surgery. The dosage was reduced to half of the previous dose for the ninth and tenth injections to prevent potential withdrawal effects. Behavioral assessments, including the ladder test, cylinder test, and modified Garcia scale for neuro-scoring, were conducted weekly to evaluate motor function. The study results indicated that the use of dendrimers to deliver progesterone as a treatment in the stroke rat model showed positive outcomes by improving motor function. Results of the ladder test showed reduced left paw slips in dendrimer-progesterone and dendrimer-only treated MCAo rats. The cylinder test showed improved left paw placement in dendrimer-only treated MCAo rats. The neuro-scoring test showed improvement in score in dendrimer progesterone-treated MCAo rats. These findings confirmed that dendrimers could cross the blood-brain barrier when injected intraperitoneally. These results further suggest that dendrimers have potential as a promising delivery method for drugs targeting the brain. In the future, we will perform immunohistochemistry to see GFAP, IBA-1, and Progesterone receptor A/B expression in brain sections.

Title: Neuroplasticity of the central noradrenergic system following chronic mild-to-moderate closed-head traumatic brain injury in rats

Authors: *F. THOMPSON[1,2], S. TSUDA[1,3], G. M. DOOLEY[1,3], K. KLIPPEL[1,3], G. HWANG[1,3], J. HOU[1,3], P. BOSE[1,3,4];
[1]North Florida/South Georgia Veterans Hlth. Syst., Gainesville, FL; [2]Neurosci., [3]Anesthesiol., [4]Neurol., Univ. of Florida, Gainesville, FL

Abstract: Anxiety disorder, balance disability, and motor impairments are common and frequent co-morbidities following closed-head traumatic brain injury (cTBI) in humans, although the precise pathological mechanisms are not well understood. Our previous work showed that chronic mild-to-moderate cTBI resulted in significant injury to the major noradrenergic (NA) cell cluster (i.e., locus coeruleus, LC), whose NA neurons play critical roles in the regulation of emotion, balance, and motor functions. Therefore, it is likely that LC injury contributes to cTBI-induced morbidity. However, studies have not examined to what extent compensatory mechanisms for the LC injury might be mobilized by other NA-cell clusters. Therefore, the purpose of this study was to investigate cTBI-induced NA cell loss in the LC and potential changes in NA cell numbers in alternative NA cell clusters (A1 and A2 cell groups), respectively. It was hypothesized that cTBI-induced LC cell loss would be compensated by increased DβH cell expression in the A1/2 cell groups. Adult female rats were randomly assigned into the normal and cTBI groups (n = 5 per group), and a weight-drop model of mild-to-moderate cTBI was induced in the latter group. Eighteen weeks later, the animals were perfused (4% paraformaldehyde), the brains were further fixed and the brain stems cryosectioned in 40-µm thickness. Every other section was incubated with primary antibodies against neuronal nuclei (NeuN) and dopamine beta-hydroxylase (DβH). On the next day, the sections were incubated

with secondary antibodies conjugated to fluorescent dyes. Then, confocal pictures taken for quantitative analyses of NA cells, revealed cTBI-induced severe loss of NeuN/DβH-immunoreactive NA cells in the LC. However, the number of NA cells in subregions of the A1/2 cell groups was observed to be significantly increased following chronic mild-to-moderate cTBI, compared to normal animals ($p < 0.05$). These studies indicate that the total number of NA cells in the central nervous system (i.e., LC and A1/2 cell groups) was potentially conserved following TBI via enhanced NA expression properties of a subpopulation of the A1/2 cell groups (DβH-positive). Accordingly, the critical roles of NA cells in a variety of essential functions following a severe loss of NA cells in the LC might have been potentially compensated by the elevation of the NA expression in a subpopulation of A1/2 cells. However, our current and previous studies showing lingering significant disabilities, suggest an incomplete neurobehavioral compensation likely, in part, associated with the lingering dysregulation in multiple structures uniquely innervated by LC.

Title: Therapeutic effects of electroacupuncture on TBI-induced facial and somatic allodynia/hyperalgesias in a rodent model

Authors: *J. HOU[1,2], K. KLIPPEL[2,1], S. TSUDA[2,1], G. M. DOOLEY[2,1], G. HWANG[2,1], D. PLANT[1], G. S. FABER[1], J. L. MURPHREE[2,1], D. A. MONDAL[2], J. A. BREINER[1], G. A. VARGAS[1], M. FEBO[3], F.-C. YEH[7], F. J. THOMPSON[1,4], H. P. RAMIREZ[5], P. BOSE[1,2,6]; [1]North Florida/South Georgia Veterans Hlth. Syst., Gainesville, FL; [2]Anesthesiol., [3]Psychiatry, [4]Neurosci., [5]Animal Care Services, [6]Neurol., Univ. of Florida, Gainesville, FL; [7]Neurolog. Surgery, Univ. of Pittsburgh, Pittsburgh, PA

Abstract: Traumatic brain injury (TBI)-induced pain, such as headache and hypersensitivity (allodynia) to mild tactile and thermal stimuli, are common comorbidities observed in TBI patients. Currently, no effective therapy is available. More worryingly, TBI induces high

vulnerability to addiction since the common use of addictive pain medication makes dependency and ultimately leads to addiction. Therefore, finding an alternative therapeutic approach to treat TBI-induced pain is urgent. In this study, we evaluated the therapeutic effects of electroacupuncture (EA) on TBI-induced pain in a rat model of TBI. Twenty-four Sprague Dawley rats received mild/moderate closed-head TBI and were randomly divided into TBI-Ctrl and TBI-EA groups (n=12/group). The TBI-EA group received a total of six sessions of EA treatments (30 min/session) starting immediately after TBI and then every other day for two weeks. Three pairs of acupuncture points: ST 36 (Zusanli), LI 4 (He Gu), and LIV 3 (Tai Chong), were used in this study. Operant orofacial allodynia testing (OPAD), lick-guard responses (thermal pain testing), and Magnetic Resonance Imaging (MRI) were conducted at pre-injury, and post-treatment (PO Tx) weeks 1 and 3. The animals were then euthanized with 4% PFA and the spinal cord and brain tissues were collected for immunohistochemistry (IHC) study. Our data to date showed that TBI significantly reduced the lick/facial contact ratio at 42 °C in OPAD testing compared to pre-injury, but the EA treatment significantly improved this ratio. In the lick-guard responses testing, both groups showed a significant reduction in hind paw lick latency compared to pre-injury; but the TBI-EA treated animals showed significant recovery compared to the TBI-Ctrl group. Magnetic resonance diffusion tensor imaging (DTI) detected the recovery of the fiber integrity of the trigeminothalamic pathway in the TBI-EA group. IHC studies showed TBI-induced significant upregulation of the pain signaling molecules [Substance P (SP), Calcitonin gene-related peptide (CGRP), and Piezo2], activated microglia marker (Iba-1), and the pro-inflammatory cytokine interleukin-1β (IL-1β) in spinal cord dorsal horn, spinal trigeminal nuclei, ventral posteromedial nucleus (VPM) of the thalamus, and sensorimotor cortex. Interestingly, the TBI-EA treatment significantly reduced the upregulation of these pain and inflammation molecules. Our data showed that the EA treatment significantly alleviated TBI-induced orofacial and somatic allodynia/hypersensitivity via the downregulation of pain and inflammatory signaling. Thus, EA could be an effective therapeutic approach for TBI-induced pain/headache.

Title: NaHBED iron chelator therapy improved hallmark traumatic brain injury (TBI) disabilities by reducing hemorrhagic iron toxicity and inflammation in a rodent model of acceleration/deceleration TBI

Authors: *S. TSUDA[1,2], J. HOU[1,2], D. PLANT[1], G. M. DOOLEY[1,2], K. KLIPPEL[1,2], G. HWANG[1,2], H. C. SHROCK[1], P. S. AWAL[1], E. M. HAACKE[6,7], R. J. BERGERON[3], F. J. THOMPSON[1,4], P. BOSE[1,2,5];
[1]North Florida/South Georgia Veterans Hlth. Syst., Gainesville, FL; [2]Anesthesiol., [3]Medicinal Chem., [4]Neurosci., [5]Neurol., Univ. of Florida, Gainesville, FL; [6]Radiology, [7]Biomed. Engin., Wayne State Univ., Detroit, MI

Abstract: Acceleration/deceleration TBI causes microvessel shear injury, blood-brain barrier dysfunction, and hemorrhage. Iron deposited by diffuse bleeds fuels inflammation through reactive oxygen species, and other inflammatory pathways may further induce progressive disabilities. There is a growing concern that TBI may significantly elevate risk factors for long-term chronic inflammation-induced progressive diseases. Currently, effective therapies to address these issues are hindered by the insufficient neurobiological foundation to guide the refinement of therapy and prevention strategies for chronic diseases. The current studies tested the therapeutic impact of an iron chelator, NaHBED, on hallmark disabilities in a rodent model of acceleration-deceleration closed head TBI model. Mild/moderate TBI was produced using our previously reported protocol (450 g/1.25m). NaHBED or saline treatment was initiated at both acute and chronic time points (NaHBED, 50 mg/kg/day; saline, equal amount, SQ). Behavioral tests for motor, anxiety, and cognitive functions were conducted at multiple time points during 9 months of post-injury. Clinically relevant MRI (SWI/QSM, T2* map, and DTI), immunohistochemistry (IHC), and histology were performed to chart the time course for iron deposition and inflammation. Our data revealed long-term enduring disabilities in motor/vestibulomotor, anxiety, and cognitive behaviors following TBI, and significant reductions in these disabilities in the NaHBED-treated animals. IHC and histology studies of TBI tissues showed disruption of BBB, patterns of iron deposition, increased expressions of proinflammatory molecules in neuronal cells, and loss of regulatory noradrenergic and BDNF trophic supports in the specific regions essential for the motor, executive, cognitive, and anxiety behaviors. Tissue from the NaHBED-treated animals exhibited robust normalization of each of these markers. Collectively, these studies demonstrate that TBI-induced microhemorrhage contributes to the development and persistence of multiple chronic disabilities. This collective trauma portfolio of chronic disabilities and inflammation was attenuated by NaHBED iron chelator therapy. Taken together, NaHBED iron chelator therapy offers a potential mechanism-based therapy that provides a significant contribution to attenuate long-term TBI disabilities, contributes to trophic support for neuronal and vascular healing, and enhances neuroplasticity for adaptive compensation.

Title: Neurobehavioral and physiological effects of traumatic brain injury in spontaneously hypertensive rats

Authors: M. BOZENKO[1], P. RENNERFELDT[1], E. MOSCHONAS[1], N. RACE[2], J. CHENG[1], A. KLINE[1], *C. BONDI[3];
[2]Physical Med. and Rehabil., [3]PMR, [1]Univ. of Pittsburgh, Pittsburgh, PA

Abstract: Approximately 2.8 million people sustain a traumatic brain injury (TBI) yearly, with many experiencing long-term disabilities often exacerbated by pre-existing comorbidities. In the United States, an estimated 45-50% of adults suffer from hypertension, which may lead to blocked or damaged arteries, heart attacks, strokes, and premature death. There is a critical need to investigate TBI in hypertensive rats to better characterize neurological, physiological, and cognitive impairments, and to enhance clinical translatability of the TBI models. This study explores the effects of TBI on Spontaneously Hypertensive Rats (SHR) via a battery of behavioral assays, such as motor coordination/balance, hippocampal-dependent learning, sustained attention, and anxiety-like symptoms. Firstly, a novel pathophysiological study was conducted on SHR rats compared to normotensive Wistar Kyoto (WKY) rats. Adult male rats (17 weeks of age) were assigned to receive a controlled cortical impact (CCI; 2.8mm cortical deformation depth, 4 m/s) or a sham injury. Both sham and TBI rats underwent the Beam Walking Task (motor) as well as the Morris Water Maze (MWM; spatial learning). Open field testing (OFT) was performed to examine anxiety, while Shock Probe Defensive Burying Task (SPDB) inspected passive/active coping behavior. 3-Choice Serial Reaction Time Task (3-CSRT) was employed in a separate cohort of SHR rats to examine sustained attention and distractibility. Before surgery, rats underwent 3-CSRT training for 1-2 months to a 2 s cue in operant chambers. Starting on post-op day 14, rats underwent 10 days of 3-CSRT re-testing. Data were analyzed using ANOVAs followed by Newman Keuls post hoc tests. Adult male SHR TBI rats exhibit 10% higher heart rate and 30% higher mean arterial pressure than injured WKY counterparts. Moreover, injured SHR rats display impaired beam-walking capability, as well as reduced spatial learning compared to SHR shams ($p<0.05$). SHR TBI rats presented more immobility and anxiety-like behavior in comparison to SHR shams, seen as reduced center area exploration in OFT and less time approaching and burying the shock probe in SPDB ($p<0.05$). SHR TBI rats also displayed markedly reduced percent accuracy and increased omissions during 3-CSRT suggesting impairments in sustained attention ($p<0.05$). Results indicate that TBI in rats with a hypertensive phenotype renders neurobehavioral deficits across a variety of behavioral tasks. Understanding the impact that underlying conditions such as hypertension may have on TBI pre-clinically is critical to further developing clinically-relevant therapies

Title: Combining a α7 nicotinic acetylcholine receptor allosteric modulator and environmental enrichment improves sustained attention and cholinergic neurotransmission after controlled cortical impact injury in male and female rats

Authors: *E. M. ANNAS[1], E. H. MOSCHONAS[1], P. L. RENNERFELDT[1], T. S. RANELLONE[2], M. A. BERTOCCHI[1], N. S. RACE[1], J. P. CHENG[3], A. E. KLINE[4], C. O. BONDI[1];
[1]Physical Med. and Rehabil., Univ. of Pittsburgh, Pittsburgh, PA; [2]Physical Med. and Rehabil., Univ. of Pittsburgh, Oakland, PA; [3]Phys Med. Rehab, Safar Ctr. Resuscitation Res., [4]Physical Med. & Rehabil., Univ. of Pittsburgh, Pittsburgh, PA

Abstract: Introduction: Traumatic brain injury (TBI) is a leading cause of cognitive impairment. Pharmacological strategies that enhance acetylcholine (ACh) transmission may ameliorate cognitive deficits and the benefit may be greater when combined with a noninvasive rehabilitative strategy, mirroring clinical approaches. Hypothesis: Chronic NS-1738, a novel α7 nicotinic ACh receptor (α7-NAChR) positive allosteric modulator (PAM), will improve sustained attention post-TBI when provided alone and in combination with environmental enrichment (EE). Additionally, blocking α7-NAChRs with methylycaconitine (MLA) will negate the effects of NS-1738, confirming its mechanism of action. Methods: Adult male and female rats were trained in the 3-choice serial reaction time task (3-CSRT) prior to a right parietal controlled cortical impact injury (2.8 mm cortical deformation depth) or sham surgery. Rats were randomized to NS-1738 (5 mg/kg) or vehicle (saline; 1 mL/kg), as well as 6 h of daily EE (or standard housing) for 28d starting on post-injury day 1(PID 1). Male subgroups also received daily α7-NAChR blockade via MLA (3 mg/kg; i.p.). 3-CSRT retrials occurred on PID 14-24. Tissue from the medial prefrontal cortex (mPFC) was utilized for Western blot assessment of the cholinergic markers [acetylcholinesterase (AChE), choline acetyltransferase (ChAT), and α7-NAChR]. Microarray analysis examined inflammatory gene expression. Statistical analysis

utilized ANOVAs and Newman-Keuls post-hoc tests. Results: TBI rats of both sexes exhibited impaired sustained attention ($p<0.05$) and ChAT disruptions in the mPFC and basal forebrain. Sex differences were evident for therapeutic efficacy of treatment paradigms, such that attentional deficits in male rats improved by EE alone or in combination with chronic NS-1738 ($p<0.05$), whereas sustained attention was partially restored in females after NS-1738 treatment alone or when combined with EE ($p<0.05$). Moreover, NS-1738+EE rendered an additive effect on lowering omissions and improving inflammatory markers ($p<0.05$), including TREM-1 (triggering receptor expressed on myeloid cells-1) and IL-1 RA (interleukin-1 receptor antagonist). Moreover, a reinstatement of performance deficits was observed in the male TBI group following MLA. Taken together, the data support the hypothesis. Conclusions and Significance: The findings support the use of α7-NAChR PAM and/or EE treatment after preclinical TBI to benefit sustained attention and cholinergic neurotransmission

Abstract: Early life stress (ELS) affects neurogenesis, cognitive performance, and increases neuroinflammation after a pediatric mild traumatic brain injury (mTBI). Previous studies have

shown that ELS has minimal effects in juveniles, but it shows an age-dependent effect in adults. Hence, we aimed to evaluate if ELS affects cognitive performance, hippocampal microglial activation, and neurogenesis after a mTBI in adult male rats. Maternal separation for 180 min per day (MS180) during the first 21 post-natal (P) days was used as an ELS model, while controls (CONT) remained undisturbed. At P110 the rats were subjected to a mild controlled cortical impact (2.6 mm) or sham injury. Cognition was evaluated in the Morris water maze (MWM) 14 days after injury and both hippocampal microglial activation and neurogenesis were quantified 24 h after the last day of behavioral testing. The results indicate that MS180 + mTBI, but not CONT + mTBI, rats show cognitive deficiencies in the MWM. mTBI equally increased hilus and cortical microglial activation; however, only MS180 + mTBI rats showed an increase in microglial activation in the CA1 hippocampus subfield. ELS and mTBI independently caused a decrease in hippocampal neurogenesis and this effect was not increased further in MS180 + mTBI rats. The findings demonstrate that ELS and mTBI synergistically affect cognitive performance and neuroinflammation, and suggest that ELS may cause an increase on TBI vulnerability that is only evident after mTBI.

Abstract: Environmental enrichment (EE), a rodent model of neurorehabilitation promotes cognitive recovery after pediatric traumatic brain injury (TBI). It has been suggested that the gut

microbiota could be involved in TBI pathophysiology. Because rats are coprophagous, we proposed that microbiota transference due to cohabitation with non-injured controls during traditional EE exposure could be related to recovery. Male Sprague-Dawley rats received a controlled cortical impact (2.5 mm tissue deformation at 4 m/s) or sham surgery at PND 21 then randomly assigned to EE or standard (STD) housing conditions with different cohabitation settings and allowed to recover for 14 days. Cognitive performance was evaluated in the Morris water maze (MWM) on post-injury days 14-19. Microglial morphology was evaluated by immunostaining after the behavioral assessments. The TBI+STD rats showed cognitive impairments during the training phase of the MWM. Additionally, the EE groups showed cognitive recovery, but the TBI+EE rats cohabitating with sham controls did not perform as well as the TBI+EE alone group. TBI increased microglial activation in the ipsilateral cortex, the hippocampus CA1, and the hilus subregions. An increase in the percentage of active cells in both the ipsilateral CA1 and cortex was observed in the TBI+EE rats cohabitating with sham controls compared to the TBI+EE group with no sham cohabitants. There was no significant effect in the contralateral regions. These results suggest that there is an effect of cohabitation that could be related to microbiota transference in cognitive recovery after a pediatric TBI and may be explained by the role of microbiota in the immune response.

Title: Environmental enrichment improves cognitive performance in adult female rats experiencing early life stress and a mild traumatic brain injury

Authors: *M. A. ROQUE[1], S. GAONA[1], E. ARREOLA[1], A. E. KLINE[2,3], N. LAJUD[1]; [1]Ctr. de Investigación Biomédica de Michoacán, Morelia, Mexico; [2]Physical Med. & Rehabil., [3]Phys Med. & Rehab, Safar Ctr. Resuscitation Res., Univ. of Pittsburgh, Pittsburgh, PA

Abstract: Traumatic brain injury (TBI) induces cognitive and motor deficits and is more common in females with a history of early life stress (ELS). EE has been shown to reverse the effects of ELS on behavior and brain connectivity, however the effects on cognition in female rats with ELS after mild TBI (mTBI) have not been studied. Our aim was to evaluate the effects of EE on cognitive performance in female rats experiencing early stress after mTBI. Maternal separation for 180 min/day (MS180) from postnatal day 1 to 21 was used as the ELS model, while control (CONT) rats remained undisturbed. At P75 the rats were subjected to a mild controlled cortical impact (2.6 mm tissue depth) or sham surgery. Rats were randomly assigned to standard (STD) or EE living conditions. Cognition was evaluated in the Morris water maze

(MWM) beginning 14 days after injury. Our results show that EE improves the acquisition of spatial learning in the MS180+TBI+EE and CONT+TBI+EE groups compared to the CONT+TBI+STD group at PD89 ($p<0.05$, and $p<0.01$, respectively). We observed effects of mTBI in the CONT+TBI+STD and MS+TBI+STD groups compared to the CONT+SHAM+STD group ($p<0.05$, and $p<0.01$, respectively). These results suggest that EE can be a therapeutic strategy to reverse effects on cognitive process after ELS and mTBI in females.

Abstract: Early life stress negatively impacts cognition, but not emotionality, after a mild traumatic brain injury in adult female rats. Naima Lajud[1], Ana Karen Almonte[1], Emmanuel Vargas[1], Fernanda Salinas-García[1,2], Jonathan Zamudio-Flores[1,2], Angelica Roque[1], Anthony E. Kline[3,4], Esperanza Meléndez-Herrera[5]*[1]División de Neurociencias, Centro de Investigación Biomédica de Michoacán – Instituto Mexicano del Seguro Social, Morelia, Michoacán, México.[2]Maestría en Ciencias en Ecología Integrativa – Instituto de Investigaciones sobre los Recursos Naturales – (UMSNH) [3]Safar Center for Resuscitation Research, University of Pittsburgh, Pitt., PA[4]Physical Medicine & Rehabilitation, University of Pittsburgh, Pitt., PA[5]Instituto de Investigaciones sobre los Recursos Naturales- UMSNH*
Early life stress (ELS) has been shown to have detrimental effects on emotionality, cognitive performance, and neuroinflammation in male rats. However, the impact of ELS on female rats remains a topic of controversy. Previous findings have demonstrated that ELS increases vulnerability to mild traumatic brain injury (mTBI) in males. Therefore, the aim of our study was to assess cognition, emotionality, and neuroinflammation following mTBI in adult female rats. We employed maternal separation for 180 minutes per day (MS180) during the first 21 postnatal (P) days and controls (CONT) as an ELS model. At P75, the rats underwent a mild controlled cortical impact (2.6 mm) to induce mTBI, while the control group received a sham injury.

Cognition was assessed using the Morris water maze (MWM) and the object location test (OLT), and emotionality was evaluated utilizing the open field and forced swimming test. Additionally, microglial morphology was characterized through Iba1 immunostaining. Our results revealed that mTBI caused a mild impairment in spatial learning in the MWM. Notably, this effect was further exacerbated in the MS180 + mTBI group, indicating an enhanced vulnerability in rats that experienced early life stress. In the OLT, only the MS180 + mTBI rats exhibited an inability to discriminate between familiar and relocated objects. Importantly, neither depressive-like behavior nor anxiety-like behavior were affected by any of the treatments. Furthermore, mTBI induced comparable levels of hippocampal neuroinflammation in both the control and MS180 rats. In conclusion, our findings suggest that ELS exacerbates the cognitive deficits associated with mTBI in adult female rats. However, these effects were specific to spatial learning, as depressive-like behavior, anxiety-like behavior, and neuroinflammation were not significantly influenced by either ELS or mTBI.

Abstract: Epilepsy is a neurological disorder characterized by recurrent seizures resulting from abnormal electrical activity in the brain. In addition to genetic factors, specific traumatic events or brain injuries can also trigger epileptic seizures. Understanding the mechanisms underlying epilepsy is crucial for developing effective treatments.One important aspect of epilepsy is the role of lysosomal dysfunction in the pathogenesis of the disease. Lysosomes are cellular organelles responsible for the breakdown and recycling of various substances within cells. Impaired lysosomal function can lead to the accumulation of toxic materials, contributing to neuronal damage and cell death.In this study, we focused on the enzyme phosphodiesterase-4

(PDE4) and its involvement in lysosomal function and neuroinflammation. PDE4 regulates cyclic adenosine monophosphate (cAMP) levels by breaking it down into adenosine monophosphate (AMP). Increased PDE4 activity can result in reduced cAMP levels, affecting lysosomal function and promoting neuroinflammation.To investigate the potential therapeutic effects, we used amlexanox, a non-selective PDE4 inhibitor with known anti-inflammatory properties. We utilized a pilocarpine-induced epilepsy animal model and administered amlexanox following seizures. Brain tissue samples were collected at different time points for analysis.The results demonstrated that amlexanox effectively improved lysosomal function, reduced inflammation, attenuated hippocampal neuronal death, and improved cognitive impairment associated with epilepsy. These findings suggest that amlexanox may hold promise as a therapeutic agent for the treatment of epileptic brain disorders. Further research is needed to fully elucidate the underlying molecular mechanisms by which amlexanox exerts its neuroprotective effects. Understanding these mechanisms will help in optimizing treatment strategies and developing targeted therapies for epilepsy and other brain disorders associated with lysosomal dysfunction and neuroinflammation. **Keywords:** Epilepsy, cAMP, Phosphodiesterase4, Protein Kinase A, Lysosome, Autophagy, Neuro-inflammation

Title: An acid sphingomyelinase inhibitor, imipramine, enhances the survival of newborn neurons after pilocarpine-induced seizure

Authors: *S. LEE[1], B. KANG[1], M. PARK[1], H. YANG[1], C. LEE[1], S. WOO[1], S. PARK[1], D. KIM[1], S. LEE[2], H. SONG[3], H. CHOI[4], S. SUH[1];

Abstract: Epilepsy is a progressive neurological disorder that can be triggered by factors such as traumatic brain injury (TBI) and abnormal neuronal activity in the brain. Acid sphingomyelinase (ASMase) is an enzyme involved in the breakdown of sphingomyelin, leading to the production

of ceramides. Excessive ceramide production has been implicated in various diseases, including cancer, cystic fibrosis, diabetes, Alzheimer's, and depression. Ceramide acts as a pro-apoptotic intracellular messenger and can promote the generation of reactive oxygen species (ROS), inflammation, and lysosomal damage. In this study, we aimed to investigate the role of ASMase and ceramide generation in epilepsy. We hypothesized that seizures induce ASMase activation, resulting in ceramide production, DNA damage, and neuronal apoptosis. To test this hypothesis, a pilocarpine-induced seizure model was used in rats. Imipramine, an inhibitor of ASMase, was administered continuously at a dose of 10 mg/kg via intraperitoneal injection for four weeks following the seizure induction. Histological analyses and cognitive function assessments were performed four weeks after the seizure. The results of the study revealed that post-seizure treatment with imipramine reduced markers of neuronal apoptosis and increased the number of newly generated neurons in the dentate gyrus of the hippocampus. Furthermore, imipramine treatment prevented seizure-induced cognitive impairment. These findings suggest that imipramine, through its inhibition of ASMase, may offer a promising therapeutic approach for enhancing the survival of newly generated neurons and improving cognitive function following seizures. By reducing ceramide production and apoptotic signaling, imipramine may mitigate neuronal cell death. Further research is needed to elucidate the precise molecular mechanisms underlying the effects of imipramine and to evaluate its potential clinical applications in the treatment of epilepsy-associated neuronal damage and cognitive dysfunction. **Keywords:** Epilepsy, Imipramine, Ceramide, Acid sphingomyelinase, Neuron death, Cell survival

Title: L-theanine, an inhibitor of AMPA receptors, prevents traumatic brain injury-induced neuronal death

Authors: ***M. PARK**[1], S. LEE[1], B. KANG[1], C. LEE[1], H. YANG[1], S. WOO[1], S. PARK[1], D. KIM[1], H. CHOI[2], S.-K. LEE[3], S. SUH[4];

Abstract: Traumatic brain injury (TBI) is a complex and debilitating condition characterized by brain damage and functional deficits. One of the key mechanisms contributing to TBI pathology is the excessive activation of glutamate receptors, particularly AMPA receptors. This overactivation leads to an influx of calcium and zinc ions into neurons, resulting in neuronal injury and oxidative stress. L-theanine, a bioactive compound found in tea leaves, has been shown to possess inhibitory effects on AMPA receptors, as well as antioxidant properties. In this study, we sought to investigate the potential neuroprotective effects of L-theanine in the context of TBI-induced hippocampal damage. Experimental rats were administered L-theanine at a dose of 200mg/kg immediately following the induction of TBI. After a 24-hour period, we performed histological analyses to assess various aspects of neuronal damage, including neuronal death, oxidative damage, microglial activation, and astrocyte activation, utilizing specific staining techniques. The findings of our study demonstrated that treatment with L-theanine effectively reduced neuronal death and mitigated cognitive impairments associated with TBI. These positive outcomes were attributed to the ability of L-theanine to suppress the excessive activation of AMPA receptors and enhance the production of glutathione, a critical antioxidant molecule. By modulating these pathways, L-theanine exhibited promising neuroprotective properties in the context of TBI-induced hippocampal damage. Further investigation is warranted to elucidate the underlying mechanisms through which L-theanine exerts its neuroprotective effects, as well as to explore its potential clinical applications in the management of TBI. The results of this study highlight L-theanine as a potential therapeutic intervention for mitigating neuronal damage and improving outcomes in individuals with TBI.

Title: Role of pyruvate kinase m2 (PKM2) on traumatic brain injury-induced neuronal death

Authors: *B. KANG[1], S. LEE[1], M. PARK[1], C. LEE[1], H. YANG[1], S. WOO[1], S. PARK[1], D. KIM[1], S. LEE[2], M. SOHN[4], S. SUH[3];

Abstract: Traumatic brain injury (TBI) is a severe condition caused by physical force trauma to the head, resulting in primary brain edema, hemorrhage, and swelling, as well as secondary injuries involving oxidative damage, neuroinflammation, and mitochondrial dysfunction. Astrocytes, a type of brain cell, play a crucial role in the astrocyte-neuron lactate shuttle (ANLS), which transfers lactate as an energy source from astrocytes to neurons. This study aimed to investigate the role of the pyruvate kinase m2 (PKM2) gene in astrocytes and its impact on neuronal survival following TBI. We hypothesized that deleting the PKM2 gene in astrocytes would lead to increased neuronal death due to the lack of lactate supply through ANLS. Additionally, we hypothesized that administering lactate after TBI would mitigate neuronal death, improve cognitive impairment, and promote neurogenesis. To test these hypotheses, we used tamoxifen to specifically delete the PKM2 gene in astrocytes of Aldh1l1-CreERT2; PKM2f/f mice. After inducing TBI in these mice, we immediately administered sodium L-lactate and sacrificed the animals 24 hours later. The analysis included evaluating neuronal death, oxidative damage, microtubule disruption, and the activity of enzymes related to ANLS. The results of the study confirmed that deleting the PKM2 gene in astrocytes increased neuronal death. However, administering lactate after TBI reduced neuronal death, improved cognitive impairment, and promoted neurogenesis. These findings suggest that lactate administration could serve as a potential therapeutic intervention for the treatment and prevention of neurological damage following TBI.

Title: Adjunct treatments positively impact mortality and recovery in a mouse traumatic brain injury and nerve agent exposure polytrauma model.

Authors: *J. LEIGHTON, E. JOHNSON, J. SAHARGUN, E. MILLER, J. JANSSEN, A. METHVIN;
Med. Toxicology, USAMRICD, Aberdeen Proving Ground, MD

Abstract: Polytrauma with traumatic brain injury (TBI) can complicate treatment with well-established pharmaceutical countermeasures in a military setting. Previously, our group established a TBI/nerve agent (NA) polytrauma mouse model that showed an increase in mortality, symptom incidence and severity, and impeded recovery compared to the individual

injuries even when standard countermeasures are utilized. This study used a TBI/NA polytrauma model with a unique human acetylcholinesterase knock-in/serum carboxylesterase knockout (C57BL/6-Ces1ctm1.1LocAChEtm1.1Loc/J; a.k.a KIKO) mouse strain to investigate the use of readily available pharmaceuticals as adjuncts to standard countermeasures to improve treatment of concurrent injuries. To produce polytrauma, male mice received a TBI and its countermeasures followed by NA exposure and its countermeasures. Mice were then administered either ketamine, scopolamine, hydromorphone, levetiracetam, diphenhydramine, promethazine, or hypertonic saline as an adjunct. Throughout and up to 72 hrs post-exposure, mice were monitored for physiological and behavioral changes, including but not limited to EEG signals, burrowing behavior, and nesting behavior. Results of this study indicate that several adjuncts have positive impacts on mortality following TBI/NA polytrauma. In addition, most adjuncts allowed for return to normal nesting and burrowing behavior, though changes in behavior associated with severe NA exposure symptoms were not entirely alleviated. These results provide plausible adjunct options to aid the treatment of TBI/NA polytrauma injuries alongside current countermeasures.

Title: Methodology of a novel subcutaneous EEG implantation and open craniotomy surgery for a novel traumatic brain injury and chemical exposure polytrauma mouse model

Authors: *J. G. JANSSEN, J. A. LEIGHTON, J. C. SAHARGUN, E. Z. MILLER, A. METHVIN, E. JOHNSON;
Med. Toxicology, USAMRICD, Gunpowder, MD

Abstract: Pharmaceutical treatments for traumatic brain injury (TBI) and chemical exposure polytraumas are relatively unexplored. To this end, a novel polytrauma mouse model was developed to investigate treatments for concurrent TBI and chemical exposures. We created a surgical technique with two main objectives: inserting subcutaneous EEG implant leads into the skull to observe and record seizure activity and introducing an open craniotomy for post-operative TBI administration. Although wireless EEG transmitter and open craniotomy surgeries are common, this study developed a technique where both surgeries are done in tandem and kept viable for multiple weeks. We determined that a two-week healing period was required in this polytrauma model after shorter recovery windows triggered oversensitivity to chemical exposures, a potential impediment for seizure progression and survival. Methods detailing the placement of EEG burr holes, surgical implantation of a DSI ETA-F10 transponder with two leads secured to the skull with dental acrylic, and drilling of an open craniotomy for TBI in the skull are discussed. Post-operative care procedures, including pain management, fluid support, and recovery assessments, are also discussed. We used 5 physical and behavioral metrics as a measure of post-operative recovery and determined that pre- and post-operative weight metrics are useful for predicting a successful surgical outcome.
 The experimental protocol was approved by the Animal Care and Use Committee at the United States Army Medical Research Institute of Chemical Defense and all procedures were conducted in accordance with the principles stated in the Guide for the Care and Use of Laboratory Animals (National Research Council, 2011), and the Animal Welfare Act of 1966 (P.L. 89-544), as amended. These studies were funded by the Combat Casualty Care Research Program (CCCRP). J. Janssen, J. Sahargun, J. Leighton and E. Title: Utilizing cardiopulmonary metrics to determine adjunct treatment efficacy in a traumatic brain injury and nerve agent exposure polytrauma mouse model

Authors: *J. SAHARGUN, J. LEIGHTON, E. MILLER, J. JANSSEN, A. METHVIN, E. JOHNSON;
Med. Toxicology Neurosci., USAMRICD, Gunpowder, MD

Abstract: Combat-related traumatic brain injury (TBI) may be accompanied by other injuries, such as nerve agent (NA) exposure, resulting in a polytrauma scenario. Pulse oximetry is a direct, combat medic-relevant diagnostic for assessing both TBI and NA exposure as each injury

initiates unique cardiopulmonary changes. Previously, our group created a TBI/NA polytrauma model using a transgenic mouse model with human acetylcholinesterase knock-in/serum carboxylesterase knockout (C57BL/6-Ces1ctm1.1LocAChEtm1.1Loc/J; a.k.a KIKO) that assessed cardiopulmonary outcomes following standard TBI/NA treatment strategies in a prolonged field care setting. This study expands on these findings by adding potential adjunct treatments that are readily available to medical providers to improve mortality and recovery. Heart rate, breath rate, and oxygen saturation (SPO_2) were recorded following polytrauma using a mouse pulse oximeter to assess the impact of adjunct treatments. Heart rate and SPO_2 changes were leading indicators of mortality, while breath rate increased in response to SPO_2 decline. In most outcomes, cardiopulmonary activity mostly recovered, but recovery was not observed in seizure outcome groups. When adjunct treatments were administered, polytrauma mortality rates decreased compared to controls, and cardiopulmonary metrics were consequently affected. This confirms the importance of pulse oximetry as a reliable diagnostic for combat medics based on the consistency of cardiopulmonary metrics at predicting mortality in a polytrauma model.

Abstract: The effect of polytrauma on the brain and potential treatment interaction is a topic of increasing interest as the medical field continues to widen its lens for approaches to effective medical care. Current paradigms are established for treatment of nerve agent (NA) exposure and of traumatic brain injury (TBI) separately, though little had been done to assess a combined treatment regimen and potential adjuncts. We previously developed and characterized a polytrauma model in a human acetylcholinesterase knock-in/serum carboxylesterase knockout (C57BL/6-Ces1ctm1.1LocAChEtm1.1Loc/J; 15-20 wks) mouse strain which combines these injuries and allows monitoring of several physiological and behavioral responses after challenge. Electroencephalogram (EEG) analysis showed an exacerbated severity of seizure status following NA exposure in animals given a TBI, as shown by increased frequency and amplitude of spikes, longer duration of status epilepticus (SE), and prolonged bursting/refractory status in the 72 hours following the polytrauma. The synergistic nature of these injuries resulted in outcomes that, while compatible with all standard treatments, is not as responsive to the current standard of care as either individual injury. Potential adjuncts (ketamine, scopolamine, hydromorphone, levetiracetam, diphenhydramine, promethazine, hypertonic saline) are evaluated here for efficacy at reducing morbidity and mortality when given alongside current treatment. Results indicate that while most adjuncts were effective in improving seizure termination, a few also resulted in kindling and potentiation of near-seizure status in mice whose response to the polytrauma was not initially as severe. Title: Immunomodulatory B Lymphocytes Promote a Neuroprotective Microenvironment After Traumatic Brain Injury Through Reciprocal Interaction with Infiltrating Peripheral Myeloid Cells

Authors: L. J. DWYER[1], S. MAHESHWARI[1], E. LEVY[1], M. C. POZNANSKY[1], M. J. WHALEN[1], ***R. F. SIRBULESCU**[2];

Abstract: Traumatic brain injury (TBI) remains a major cause of death and severe disability worldwide. Our work has demonstrated previously that exogenous mature naïve B220+/CD19+/IgM+/IgD+ B cells are potent modulators of inflammatory responses, and that therapeutic administration of B cells is associated with structural and functional neuroprotection after TBI. A single intraparenchymal injection of B cells at the time of injury significantly improved cognitive recovery after contusion TBI in multiple neurobehavioral paradigms, and reduced brain tissue loss by 40-60% as compared to injured groups treated with saline or equivalent numbers of splenic T cells. Naïve B cells placed in injured microenvironments become activated via Toll-like receptor (TLR) - MyD88-dependent signaling pathways and generate a variety of immunoregulatory cytokines. Here, we use a model of unilateral controlled cortical impact TBI in adult male mice to investigate cellular mechanisms of immunomodulation. Exogenous B cells show a complex time-dependent response in the injury microenvironment, including increased expression of IL-10, IL-35, and TGFβ, but also IL-2, IL-6, and TNFα. After 10 days *in situ*, B cell subsets expressing IL-10 or TGFβ dominate. In the presence of B cells, significantly more of the myeloid cells infiltrating at the injury site produced IL-10, TGFβ, and IL-35, and fewer produced TNFα, interferon-γ and IL-6 as compared to controls, up to 2 months post-TBI. B cell treatment significantly increased the proportion of

$CD206^+$ infiltrating monocytes/macrophages and reduced the relative proportion of activated microglia starting at 4 days and up to 2 months post-injury. Ablation of peripheral monocytes with clodronate liposomes showed that infiltrating peripheral monocytes/macrophages are required for inducing a regulatory phenotype in exogenous B cells. Reciprocally, B cells specifically reduced the expression of inflammatory cytokines in infiltrating $Ly6C^+$ monocytes/macrophages. We thus find evidence that infiltrating peripheral monocytes/macrophages are required for the regulatory activation of the transplanted B cells, and are in turn subject to the modulatory influence of the exogenous B cells, mediating their functional neuroprotective effects.

Milton S. Hershey Med. Cener, Hershey, PA

Abstract: Traumatic brain injury (TBI) is a major cause of mortality and morbidity worldwide and a significant risk factor for accelerated cognitive memory loss. Sexual dimorphism in cognitive dysfunction and recovery post-TBI are poorly understood. Treatment for secondary injury post-TBI is limited with no currently approved medications that improve functional outcome. We evaluated efficacy of Glibenclamide (GLI) in modulating TBI-induced cognitive dysfunction by sex. GLI is a promising drug that has shown promise in early clinical trials in stroke and contusional-TBI. Adult C57BL/6J mice were randomized into (n=6/group); Naive, TBI, TBI+Vehicle, TBI+GLI. CCI-TBI was induced :velocity=5.0m/s, depth=1.2mm, dwell time=50ms. GLI was injected post-TBI followed by 7D maintenance infusion. Cognitive function was analyzed by Morris water maze test (MWM). Immunofluorescence was performed at D21 post-TBI to study effects of GLI on neurogenesis and neurodegeneration post-TBI. We used markers of neurogenesis doublecortin (DCX), Sox2, Ki67, in the subgranular zone (SGZ) of dentate gyrus (DG) and subventricular zone (SVZ), neurodegeneration TDP43 and Tau. In females Sox2 and DCX expression increased post-TBI which was enhanced with GLI and expression of Ki67 in the SGZ and SVZ decreased post-TBI which increased with GLI ($p<0.001$). In males, similar expression pattern was observed for DCX and Sox2, Ki67 increased primarily in the contralateral SGZ. TDP43 and Tau expression was increased in both sexes in ipsilateral cortex, DG and thalamus which was restored after GLI treatment ($p<0.001$). Regional and sex based differences were observed in both neurogenesis and neurodegenerative markers after GLI treatment. Neurogenesis markers were increased with GLI in the SGZ in males and SVZ in females ($p<0.001$). In males, GLI had a more pronounced impact on decreasing TDP43 expression in the ipsilateral cortex versus females ($p<0.001$). Decreased expression of Tau after GLI was similar across sex in the ipsilateral cortex, and thalamus but more pronounced in DG in females ($p<0.001$). MWM results showed decrease in cognitive memory post-TBI which was restored with GLI treatment in both sexes ($p<0.001$), with more pronounced benefit in females. Our data suggest that GLI enhances markers of neurogenesis and decreases neurodegeneration in nuanced region and sex based manner. Nonetheless, based on current outcomes, GLI improves cognitive outcome in both sexes although there are sex-based differences in post-TBI deficits. Collectively, our data supports the therapeutic potential of GLI post-TBI and the critical need for rigorous and thoughtful study in large randomized human trials.

Title: Disodium Succinate as a Novel Therapeutic Agent for Secondary Injuries after Traumatic Brain Injury.

Authors: *C. A. HALL, K. BARANES, M. R. KOTTER, K. L. H. CARPENTER, P. J. A. HUTCHINSON;
Univ. of Cambridge, Cambridge, United Kingdom

Abstract: Following traumatic brain injury, several downstream cascades are initiated, including deranged cerebral metabolism and inflammation, contributing towards secondary injury. It has been shown that unfavourable patient outcome correlates with a high brain extracellular lactate/pyruvate ratio (LPR). Initial in-vitro research using rat mixed glia showed that succinate, an intermediate of the tricarboxylic acid cycle, protected against rotenone-induced metabolic dysfunction. Rotenone acts as an inhibitor of complex I of the mitochondrial electron transport chain (ETC), with succinate interacting with complex II, thus bypassing the induced injury mechanism. We have subsequently studied the effect of rotenone-induced metabolic dysfunction in both human induced neurons (iNs) and human induced astrocytes (iAs), as a model for TBI secondary injuries, further investigating the possible neurotherapeutic effects on these cell types. Using the novel cellular reprogramming technique Optimised Inducible Overexpression, we produced iNs and iAs through transcription factor overexpression. These cultures were then treated with varying concentrations of rotenone and disodium succinate. At select time points

(12hrs-48hrs), the cellular metabolism and LPR were assessed using an ISCUSflex analyser, and the cell viability was determined using selected cellular stains (Hoechst 33342 and propidium iodide). Furthermore, extracellular acidification rate and oxygen consumption rate have also been recorded. Whilst the iNs responded to treatment of both rotenone and succinate, they did not do so consistently. iAs, however, proved to behave more consistently in the testing regime and produced results suggesting metabolic rescue, such that LPR was decreased, and cell viability increased following treatment, compared with non-succinate control cells. Co-culturing experiments have also been performed to investigate a mechanism whereby the astrocytes may provide a supportive or protective role to the neurons. Furthermore, TBI has been linked to later Alzheimer's disease (AD) development, therefore, using a patient-derived AD cell line, we are investigating the link between succinate treatment and AD development.

Title: Integrated landscape of tectal glial heterogeneity and TBI responses across life stages in zebrafish

Authors: *H. QIN, J. HE;
Inst. of Neurosci. Chinese Acad. of Sci., Shanghai, China

Abstract: Glial populations are highly diverse and exhibit complex traumatic brain injury (TBI) responses. However, the temporal heterogeneity of glial cells in the traumatic injured vertebrate brain remains elusive. Here we obtained single-cell transcriptomes of 99,456 cells enriched with three major glial types from injured and uninjured zebrafish optic tectum across post-embryonic developmental stages spanning from larval to adult. Across stages, we identified five microglia subtypes, each exhibiting specific stage distribution pattern. Notably, the injury evoked the stage-dependent emergence of three transient MG substates representing different injury responses. For oligodendrocyte lineages, we identified six clusters, which responded to the injury by triggering the embryonic developmental program at larval stages but by inducing multiple

transient oligodendrocyte-lineage substates beyond larval stages. For radial astrocytes (RA), we identified six subtypes with distinct spatial temporal characteristics. A temporal loss of Notch signaling accounted for the TBI-induced RA proliferation beyond the early larval stage. Thus, our study systematically uncovered the temporal heterogeneity of glial cells under physiological and TBI conditions across life stages and laid the framework of vertebrate glial responding to traumatic injuries.

Title: Adenosine A1 receptor system is impaired in cortical organoids derived from patients with chronic mountain sickness

Authors: *H. YAO, J. WANG, H. ZHAO, G. G. HADDAD;
UCSD, La Jolla, CA

Abstract: Chronic mountain sickness (CMS) is manifested by neurological symptoms such as migraine headache, dizziness, and cognitive deficits. The underlying pathological mechanism has not been well understood. A recent functional MRI study has demonstrated an increased brain activity in CMS patients compared with their control counterparts, which is consistent with our previous findings showing the elevated neuronal network activity in CMS neurons under hypoxia (Yao, et al., SFN Abstract, 2018). Previous work has shown that hypoxia leads to increased adenosine secretion at synapses which can silence the synaptic transmission by preventing excessive glutamate release during hypoxia and hence protect the brain from hypoxia-induced excitotoxic damage. In this work, we examined if the adenosine A1 receptor system is altered in the CMS neuronal cultures. Skin biopsies were obtained from both CMS patients and healthy highlanders (non-CMS) who live in the Peruvian Andes (~14000 ft). Fibroblasts were grown and reprogramed into induced pluripotent stem cells (iPSCs) which then were differentiated into neurons in a 3D cortical organoid culturing system (human cortical organoid, hCO). Spontaneous activity was recorded extracellularly from hCOs using a multi-electrode array system (MEA, Axion Biosystems) and the firing rate (FR) was used to reflect the neural network activitiy. Our results show that pharmacological inhibition of adenosine A1 receptor with DPCPX increased FR in non-CMS neurons (increase by 146.0±10.5% of control, n=3, p=0.038) while its agonist CPA decreased FR (decrease by 78.2%±4.0% of control, p=0.030), suggesting the existence of adenosine A1 receptor-regulated presynaptic muting system in hCOs. Further, this CPA-induced decrease in FR in non-CMS disappeared in the hypoxia group (change

by 94.1±3.6% of control, p=0.363) although DPCPX still robustly enhanced FR under hypoxia (increase by 150.0±12.2% of control, p=0.046), probably due to the endogenous secretion of adenosine stimulated by hypoxia. In the CMS group however, both CPA and DPCPX did not affect the FR under either normoxia (CPA group: change by 108.5±19.5% of control, p>0.05; DPCPX group: change by 108.6±10.3% of control, p>0.05) or hypoxia (CPA group: change by 83.3±6.5% of control, p>0.05; DPCPX group: change by 83.3±9.2% of control, p>0.05). We conclude that adenosine A1 receptor may mediate presynaptic silencing under hypoxia in non-CMS organoids and this neuroprotection mechanism may be impaired in the CMS neurons which renders excessive network activity in the diseased neurons.

Title: The BDNF mimetic R-13 and exercise attenuate TBI pathogenesis

Authors: *Z. YING[1], P. THAPAK[1], G. SMITH[5], A. PAYDAR[6], N. G. HARRIS[2], F. GOMEZ-PINILLA[3,4];
[1]UCLA, Los Angeles, CA; [2]Neurosurg., UCLA, LOS ANGELES, CA; [3]Dept. Integrative Biol. and Physiol., [4]Neurosurgery, UCLA Brain Injury Res. Ctr., UCLA, Los Angeles, CA; [5]Neurosurg., Dept. Neurosurgery, UCLA, Los Angeles, CA; [6]Dept. of Neurosurgery, UCLA Brain Injury Res. Ctr., Univ. of California, Los Angeles, CA

Abstract: Background: Traumatic brain injury (TBI) is a global neurological burden that leads to cognitive decline and escalates to psychiatric disorders. The R13 is a TrkB agonist molecule much smaller and more effective than BDNF with great therapeutic potential, which capacity has not been shown in the TBI pathology (Thapak et al, Biochim Biophys Acta Mol Basis Dis. (2023), 1869 (7), 166781).**Methods:** Sprague Dawley rats received moderate lateral fluid percussion injury (FPI). R13 (7.25 mg/kg, i.p) and vehicle were administered at 7 days post-FPI for 7 consecutive days to rats that either had access to voluntary running wheel or were sedentary. Memory and anxiety-like behaviors were assessed two-week post-TBI. Magnetic resonance imaging (MRI) was performed on post-TBI days 1 and 7 in rats receiving R13 or vehicle intervention. Protein levels were measured in the ipsilateral to the injury hippocampus using quantitative western blots.**Results:** Animals exposed to FPI showed a reduction in spatial memory and anxiety-like behavior at 2 weeks post-TBI which was counteracted by R13 and

exercise. Injured animals showed a reduction in the p-TrkB protein level in the hippocampus at 7 days post-TBI which was counteracted by R13 intervention. MRI scans revealed distinct connectivity variations between injured rats treated with R13 and the vehicle group, determined by analysing functional connectivity (FC) at 1 and 7 days post-injury. R13 treatment significantly increased FC throughout the cortex compared to the vehicle treatment.**Conclusion:** This study showed that delayed administration of R13 or exercise counteracted cognitive deficits post-TBI and increased FC. Overall, these findings delineate the neuroprotective potential of R13 against TBI.

Title: Degradation of endocannabinoid in astrocytes promotes traumatic brain injury

Authors: *M. HU[1], D. ZHU[1], J. ZHANG[1], F. GAO[1], J. HASHEM[1], C. CHEN[1], P. J. KINGSLEY[2], L. J. MARNETT[2], K. MACKIE[3];
[1]UT Hlth. San Antonio, San Antonio, TX; [2]Vanderbilt Univ. Sch. of Med., Nashville, TN; [3]Indiana Univ., Bloomington, IN

Abstract: Traumatic brain injury (TBI) is an important risk factor for development of Alzheimer's disease (AD) and dementia. Previous studies show that administration of the endocannabinoid 2-arachidonoylglycerol (2-AG) or inhibition of 2-AG degradation by pharmacological inactivation of monoacylglycerol lipase (MAGL), a key enzyme hydrolyzing 2-AG, attenuates TBI-induced neuropathology. However, the mechanism of the neuroprotective effects produced by inactivation of MAGL in TBI remains unclear. In particular, little is known about whether genetic inactivation of MAGL produces neuroprotection against TBI and whether the protective effects of 2-AG signaling are cell type-specific. In the present study, we provide evidence that genetic inactivation of MAGL reduces neuropathology and averts synaptic and cognitive declines in mice exposed to repetitive mild closed head injury. Importantly, our study reveals that these neuroprotective effects primarily result from inactivation of MAGL in astrocytes, rather than in neurons. Single-cell transcriptomic analysis shows that mice lacking MAGL in astrocytes exhibit great resilience to TBI-induced upregulation of genes involved in inflammation and downregulation of genes associated with anti-inflammatory responses or

associated with maintenance of brain homeostasis in astrocytes and microglia. The MAGL inactivation-produced neuroprotection is apparently mediated via CB1R as pharmacological inactivation of MAGL failed to produce neuroprotection against TBI in CB1R knockout mice. In addition, our results indicate that peroxisome proliferator-activated receptor-γ (PPARγ) is a downstream signaling molecule of 2-AG and CB1R as silencing of PPARγ in astrocytes eliminates the protective effects against TBI in mice lacking MAGL in astrocytes and overexpression of human PPARγ in astrocytes prevents TBI-induced neuropathological changes and cognitive decline in wild-type mice. Our results reveal a previously undefined cell type-specific role of 2-AG signaling in alleviation of TBI-induced neuropathology and synaptic and cognitive deficits, suggesting that astrocytic MAGL is a promising therapeutic target for TBI-induced AD-like neurodegenerative disease.

Title: Humanin (HN) attenuates TBI pathology by influencing bioenergetic processes

Authors: *P. THAPAK, Z. YING, F. GOMEZ-PINILLA;
Univ. of California Los Angeles, Los Angeles, CA

Abstract: Background: Reduction in the bioenergetic capacity of the mitochondria to sustain cell functions is central to the traumatic brain injury (TBI) pathogenesis, resulting in oxidative stress, inflammation, synaptic dysfunction, and cognitive impairment. Recently, humanin (HN), a mitochondrially encoded micro-peptide, has shown promise to mitigate these fundamental molecular events in the brain, portraying HN as a potential therapeutic agent for the management of TBI. **Methods:** C57BL/6J mice (n=6) were exposed to moderate lateral fluid percussion injury and HN (40 µg/kg, i.p.) was administered 1 and 6 hr post-TBI. Memory was assessed 3 weeks post-injury. Protein and mRNA levels were assessed in the ipsilateral hippocampus using western blot and RT-PCR. Cytokine array was performed in plasma. Seahorse was used to access mitochondrial activity. **Results:** HN administration counteracted a TBI-related reduction in mitochondrial oxygen consumption rate. Mice exposed to TBI showed a significant decline in spatial memory in the Barnes maze which was counteracted by HN intervention. HN restored levels of synaptic proteins (synapsin 1 and p-CREB) important for learning and memory. HN

also counteracted TBI-related elevations of pro-inflammatory cytokines in plasma (TNF-α, INF-y, IL 17, IL 5, MCP 5, GCSF, RANNETS, sTNFRI) as well as in the hippocampus (gp-130 and p-STAT3). Histone acetylation is intimately associated with mitochondria bioenergetics and subsequent epigenetic modifications. Ongoing studies indicate that TBI increased mRNA levels of NLRP3, and HDAC2, and reduced SIRT3 levels in the ipsilateral hippocampus. These changes were counteracted by HN intervention. **Conclusion:** This study showed that HN intervention has a neuroprotective effect on molecular systems underlying mitochondria bioenergetics and cognitive function. Overall, these findings delineate the neuroprotective potential of HN against TBI.

Title: Thyroid hormone alleviates blood-brain barrier disruption after TBI

Authors: *F. GOMEZ-PINILLA[1,2], M. KHANDELWAL[1];
[1]Dept. Integrative Biol. and Physiol., [2]Dept. Neurosurgery, UCLA Brain Injury Res. Ctr., UCLA, Los Angeles, CA

Abstract: Traumatic brain injury is a life threatening with lifelong neurological disabilities. Blood-brain barrier (BBB) leakage is one of the major events that occur after TBI that threatens brain integrity and function. Astrocytes, surrounding endothelial and pericyte cells lining the ventricles are critical for controlling the influx and efflux of biological substances essential for maintaining BBB integrity, brain's metabolic activity as well as cellular functions. Our current study focusses on candent questions that are poorly explored. (A) Does TBI affect tight junction proteins like ZO-1, occludin-1. (B) Impact of TBI on hyperpermeability (MMP-9). (C) Role of A1 and A2 astrocytes 7 days post-TBI. (D) Specific interventions that can alleviate BBB disruption after TBI. Based on the results of single cell genomics data (Arneson et. al., Nature Communications, 2018), thyroid hormone BBB transporter gene is differentially expressed after TBI, such that here we used thyroid hormone to regulate BBB integrity post-TBI. Mice were subjected to fluid percussion injury (FPI) followed by acute T4 treatment (1 hour and 6 hours post-TBI). Barnes maze studies revealed that mice showed impaired spatial memory 7 days post-TBI while T4 treatment reversed the damaging outcomes. We also found BBB leakage in 7 days post-TBI mice evidenced by Evans blue staining and T4 administration counteracted these

changes. The gene expression of key markers for endothelial (CD31) and pericytes (CD13) were also found to be affected by TBI and changes were counteracted by T4 treatment. The ratio of C13:C31 plays critical role in determining the pericyte coverage and measures microvascular integrity. Our data shows that TBI compromised BBB integrity with subsequent neuroinflammation 7 days post-TBI. T4 showed a promising therapeutic action by improving BBB leakage and integrity in the TBI pathology.

Title: Investigating Protein Expression Within the Hyperacute Phase Following Impact in an Ex Vivo Porcine Brain Model

Authors: *B. HOFFE[1], G. KANG[2], R. BANTON[3], T. PIEHLER[3], O. E. PETEL[2], M. R. HOLAHAN[1];
[1]Neurosci., [2]Mechanical and Aerospace Engin., Carleton Univ., Ottawa, ON, Canada; [3]U.S. Army Res. Lab., Aberdeen Proving Ground, MD

Abstract: Brain tissue as a material presents unique properties with a multitude of cell types and densities, varying degrees of axonal fiber diameters and blood vessels. All of these neural components are contained within a very viscous environment that, within a gyrified brain, displays a high degree of cavitation. Cavitation in the depths of the sulci may make this area particularly vulnerable to biomechanical forces following an impact. Post-mortem analyses of human brain tissue have indeed shown a pattern of pathological outcomes with repeated impacts in midline structures and the apex of certain sulci where cavitation is prominent. The movement and subsequent forces loaded on to the brain have been shown to produce a variety of biomechanical responses that impair neurophysiological functioning at the cellular level. Excitotoxicity, brought on by biomechanical load, has been shown to result in synaptic dysfunction, as increased intracellular Ca2+ concentrations over-activate various kinases and proteases responsible for cellular survival. Previous work in our lab has shown that after a drop impact, there was a marked decrease in staining of the microtubule stabilizing protein MAP2, as well as preferential shift towards mushroom-type spines within the hyperacute phase post-impact (minutes to hours) in the *ex vivo porcine cortex*. For the current work, Western blot assays were conducted on predetermined regions of interest (ROI) within the porcine cortex. These ROIs consisted of both sulcal arms and sulcal depths to investigate the vulnerability of these regions to increased strain and altered protein expression. To follow up the changes observed from previous

work using the Golgi-Cox method and spine morphology changes, we analyzed excitatory synaptic remodeling markers Matrix metallopeptidase 9 (MMP-9), and neurogranin. Along with these synaptic markers, we investigated the activity of calpain-2, a microtubule protease involved in modulating the dynamics of microtubule associated proteins implicated in the progression of pathology resulting from multiple impacts. These outcomes were paired with strain data collected from markers implanted in the brain tissue to compare protein expression to strain placed on the tissue. These results further clarify the hyperacute protein dynamics following impact in gyrified brain tissue.

Title: Cerebral hypoperfusion impairs traumatic brain injury recovery in mice

Authors: *B. WHITEHEAD, D. R. CORBIN, N. ZHANG, K. KARELINA, Z. M. WEIL; West Virginia Univ., Morgantown, WV

Abstract: Traumatic brain injuries (TBI) produce cognitive and physical impairments and can induce lasting cerebrovascular dysfunction and increase the risk of neurodegenerative disease as patients age. Cardiovascular and metabolic dysfunction is common among patients with a history of TBI and can further increase the risk of secondary deterioration. One physiological process that is predictive of neurodegeneration, and exacerbated by both TBI and metabolic disease is cerebral hypoperfusion. We hypothesized that mild surgical hypoperfusion in mice would worsen both vascular outcomes and cognitive impairments after TBI. To test this hypothesis, we induced chronic hypoperfusion in adult Swiss-Webster mice via bilateral carotid artery stenosis (BCAS) or sham procedure for 30 days prior to either sham injury or moderate TBI, resulting in the following groups: sham-sham (control); BCAS-sham; sham-TBI; BCAS-TBI. We established baseline cerebral blood flow (CBF) via laser speckle flowmetry (LSF), with additional measurements at 30 days post-BCAS, and again 2 weeks following TBI. Cognitive dysfunction was assessed on Barnes maze one week following TBI. Finally, brains were collected following the final LSF session for immunohistochemical (IHC) analyses of vascular dysfunction including Fibrin(ogen) and IgG buildup within vessels and vascular density measurements. Results indicate that mice in the BCAS-TBI group had significantly reduced CBF by two weeks post-TBI compared to control animals. BCAS-TBI mice also exhibited significantly greater latencies to

reach the escape hole in the Barnes maze than control or BCAS-only mice . IHC analyses revealed that BCAS mice had decreased vascular density in the CA1 region of the hippocampus as well as the corpus callosum compared to non-BCAS mice. Additionally, BCAS-TBI mice exhibit significant vascular accumulation of Fibrin(ogen) and IgG compared to other groups. Together, these data suggest that TBI-induced vascular dysfunction can be worsened by a preexisting cerebral hypoperfusion, as evidenced by further CBF reduction, protein aggregation within vessels, loss of vessels, and impaired cognitive performance.

Abstract: Sex-based differences in hippocampal neurogenesis after TBI

Hannah C. Williams[1,2], Ashley Glover[1], & Kathryn E. Saatman[1,2]
1.Spinal Cord and Brain Injury Research Center (SCoBIRC), University of Kentucky, Lexington, KY 2.Department of Physiology, University of Kentucky, Lexington, KY

Moderate or severe contusion brain injury robustly increases cellular proliferation within the dentate gyrus, resulting in the generation of new neurons. The development, integration, and long-term survival of posttrauma-born neurons is poorly understood. To date, traumatic brain injury (TBI) neurogenesis studies have almost exclusively utilized male rodents, resulting in a significant gap in knowledge as to how this aspect of neuroplasticity may differ for females. To evaluate sex-dependent neurogenic responses to TBI, male and female Ascl1-CreERT2; R26R CAG-floxStopTom reporter mice were used to label and track neural progenitor cells (NPCs) born after injury. Mice received a controlled cortical impact (CCI) followed by tamoxifen injections on days 2 and 3 postinjury to permanently label NPCs born early after TBI. Injured (n=10 male, n=9 female) and naïve (n=8 male, n=12 female) mice survived 6 weeks after receiving two tamoxifen injections. Significantly fewer tdTom+ neurons were observed in the hippocampal dentate gyrus ipsilateral to impact compared to naïve controls ($p<0.005$), with

equivalent numbers for males and females. However, CCI-injured females exhibited a significant increase in tdTom+ neuron numbers in the contralateral hippocampus when compared to CCI-injured males ($p<0.0001$) or to naïve females ($p<0.005$). Sholl analysis of dendritic arbor complexity revealed a modest increase in branch complexity in neurons of female naïve mice compared to males. TBI-related changes to the dendritic arbor differed for females and males. Numbers of mossy fiber boutons formed by tdTom+ neurons extending axons to the CA3 region were reduced after TBI, with a more pronounced reduction in males. This reduction in bouton density appeared to be offset by an increase in bouton surface volume in females. TBI causes impairment in multiple aspects of hippocampal neurogenesis. Surviving posttrauma-born neurons show axonal and dendritic structural changes that suggest impaired connectivity. Responses consistent with compensatory plasticity were observed in female mice following TBI.

Abstract: Introduction: Traumatic spinal cord injury (SCI) results in local and systemic vascular changes, which make the spinal cord extremely vulnerable to ischemia, hypoxia, and energy dysfunction. Therefore, current clinical guidelines for the early management of spinal cord injury patients emphasize mean arterial pressure (MAP) augmentation for the first seven days post-SCI. However, to assess the effectiveness of MAP augmentation on spinal cord perfusion, we must develop new techniques to monitor the injury site continuously and in real-time. To address this clinical need, we embarked upon developing a miniaturized, implantable optical biosensor based on near-infrared spectroscopy (NIRS) to monitor spinal cord oxygenation and tissue hemodynamics from the injury penumbra. This study's objective was to compare the newly developed spinal cord NIRS system against 1.) an invasive, combined partial

pressure of oxygen (PO_2)/blood flow sensor and 2.) a second, research-grade NIRS sensor in response to a series of physiologic perturbations. **Methods**: We performed n=8 non-survival studies on uninjured female Yucatan miniature pigs. The NIRS system was laid onto the dura, and a pair of intraparenchymal OxyFlow sensors were inserted into the ventral aspect of the spinal cord tissue underneath the NIRS sensor. A second, research-grade NIRS device (PortaLite-Mini, Artinis) was placed caudal to this set-up. Subsequently, animals were challenged with multiple episodes of moderate-severe hypoxia and pharmacologically induced changes in MAP. **Results/Conclusion**: Our results suggest that the newly developed NIRS sensor can monitor intra-operative changes in spinal cord oxygenation and hemodynamics induced by various physiological perturbations, leading the way towards clinical translation. We are currently analyzing the data to establish the utility of NIRS monitoring and determine the dynamic relationship between spinal cord oxygenation and perfusion patterns with commonly tracked clinical indices such as fluctuations in MAP.

Title: Perineuronal Nets in the Spinal-intact and Injured Porcine Spinal Cord.

Authors: *S. JARLSDÓTTIR[1], J. WANG[1], N. MANOUCHEHRI[1], M. WEBSTER[1], K. SO[1], J. ETHRIDGE[1], A. WARNER[1], A. BILLINGSLEY[1], R. NEWSOME[1], F. STREIJGER[1], C.-Y. LIN[2], Y.-S. LEE[2], B. K. KWON[1,3];
[1]Intl. Collaboration On Repair Discoveries, Vancouver, BC, Canada; [2]Neurosci., Cleveland Clin., Cleveland, OH; [3]Dept. of Orthopaedics, Vancouver Spine Surgery Inst., Vancouver, BC, Canada

Abstract: Introduction: Perineuronal nets (PNN) are specialized extracellular matrix structures that encapsulate the soma and the proximal dendrites of a subset of motor neurons and spinal interneurons with a widely known role in synaptic stabilization. Therefore, manipulating PNN may provide the key to reactivating plasticity and restoring function, both of which are severely impaired following traumatic spinal cord injury (SCI). The objective of his study was characterizing the spatial expression of PNN in a porcine model of SCI. A more detailed characterization of the injury-induced changes within PNNs in the chronic phase of SCI, will

extend our knowledge of the pathophysiological events after SCI and further, help us determine how the porcine model correlates with human SCI to ensure its translational and predictive value. **Methods:** Following a T10 spinal cord contusion/compression SCI, lumbar porcine spinal cord samples were dissected, fresh-frozen and cryo-sectioned into 20µm thick coronal sections. Wisteria Floribunda agglutinin (WFA) and 5HT immunofluorescence was used to visualize PNNs and serotonergic fibres, to address post-traumatic changes in the lumbar spinal cord, distal to the initial injury. In addition, we evaluated the distribution of PNNs in intact porcine spinal cords. **Results:** Distal to the injury site, almost none of the large alpha motor neurons in the lumbar ventral horn were surrounded by PNNs. Instead, most of the framed motor neurons had small cell bodies, which are putatively gamma motor neurons. No bouton-like dots were observed surrounding the soma of motor neurons, instead 5HT was observed in the cytoplasm of motor neurons, illustrating a decrease in supraspinal synaptic input. Occasionally, isolated serotonergic fibres were seen in the motor pool area of the lumbar ventral horn. **Conclusion:** In conclusion, we demonstrated significant changes among PNNs and serotonergic boutons surrounding the motor neurons in the lumbar spinal cord in the porcine model of thoracic SCI. A better understanding of such long-lasting consequences distal to the injury site may be essential in the development of novel treatments to promote neuroplasticity and meaningful functional repair.

Title: Tracing the path; an emergent need to evaluate spinal cord optical properties

Authors: *G. FRANK[1,2], F. SAHRAGARD[2], K. RASCHDORF[2], N. MANOUCHEHRI[2], M. WEBSTER[2], K. SO[2], S. ASKARI[2], F. STREIJGER[2], B. SHADGAN[2], B. K. KWON[2,3]; [2]Intl. Collaboration On Repair Discoveries (ICORD), [1]Univ. of British Columbia, Vancouver, BC, Canada; [3]Vancouver Spine Surgery Inst., Vancouver, BC, Canada

Abstract: Introduction: The ability of near-infrared spectroscopy (NIRS) to non-invasively quantify blood oxygenation and volume in biological tissues with high temporal resolution, has made it increasingly popular in the last decade. While most NIRS applications have focused on the brain, investigators have recently begun to investigate NIRS to interrogate hemodynamics and oxygen delivery within the spinal cord. However, translation of such an approach to the

spinal cord remains a challenge due to the unique properties of the tissue and the effect of the extracellular layers surrounding the spinal cord. Therefore, the objective of this study was to evaluate the effect of the dura, cerebrospinal fluid (CSF) and spinal cord tissue on near-infrared light behavior. **Methods:** Intact, formalin-fixed, porcine spinal cord was harvested and cut to 40, 60, and 80 µm thickness in both axial and longitudinal orientations. A 1 mm diameter laser beam, at both 635 and 780 nm wavelengths, was passed through the samples and the intensity and direction of the transmitted light were simultaneously assessed. Furthermore, a Monte Carlo simulation was constructed to simulate light propagation through the spinal cord, CSF layer and dura mater using light wavelengths between 650 and 950 nm. **Results:** While axial samples resulted in a circular scattering profile, longitudinal samples caused an ovoid scattering profile with the long axis oriented perpendicular to axon orientation. Additionally, the Monte Carlo simulation predicted a significant amount of scattering caused by the dura mater. A large proportion of this scattered light tended to progress through the non-scattering CSF layer without entering the spinal cord. The presence of the dura mater paired with the CSF layer caused a 10-fold reduction in the peak fluence (optical energy density) within the spinal cord. Peak fluence appears to decay exponentially with increasing CSF thickness before plateauing at ~1.2 cm thickness with a corresponding 100-fold reduction in peak fluence. **Conclusion:** These results highlight experimental evidence of the directionally dependence of light propagation within the spinal cord. Peak fluence within the spinal cord is also strongly affected by the thickness of the surrounding CSF layer. Such knowledge is key for the success of accurate quantitative NIRS analysis and optical imaging techniques.

Abstract: Neurogenic lower urinary tract dysfunction remains a leading cause of morbidity after spinal cord injury (SCI). Urodynamics (UDS) is presently the clinical standard for the assessment of bladder dysfunction after SCI. However, this method presents many well-recognized limitations which may interfere with bladder function and its subsequent interpretation. To address this, we tested a wireless intravesical pressure sensor (the "UroMonitor"), as well as an implanted transmural pressure sensor to permit continuous bladder pressure recording without the use of catheters. The aim of the presented study was to compare the UroMonitor and transmural telemetric systems to conventional catheter-based pressure measurement and to characterize neurogenic bladder dysfunction during UDS and ambulatory urodynamic monitoring in a large animal model of SCI.

Yucatan minipigs (n=9) were used under IACUC and veterinary oversight. SCI was induced via contusion-compression impact at the 10^{th} thoracic level. A transmural telemetric sensor was implanted 4-weeks prior to SCI. UDS experiments were performed before and 4-, 8-, and 11-weeks after SCI. UroMonitor was inserted transurethrally before each UDS experiment under general anesthesia.

We demonstrated that the UroMonitor and transmural sensors reliably identified >90% of voiding and non-voiding contractions during UDS assessment before and after SCI. UroMonitor and transmural pressure recordings showed strong, statistically significant correlation to conventional UDS catheters. The amplitude of bladder contractions measured from wireless sensors were within ~4 cmH2O of the present clinical standard. During ambulatory monitoring, voided volumes were found to be significantly reduced relative to those collected during UDS in pre-SCI animals. Further, bladder contraction amplitudes were found to be greater during ambulation relative to UDS assessment in SCI pigs.

Wireless, catheter-free devices may offer an alternative to traditional bladder assessment techniques permitting more natural, comfortable observation of lower urinary tract dysfunction after neurological injury in pre-clinical animals and humans. The present study tested two devices that can reliably identify and quantify bladder contractions before and after SCI in a large animal model with a high degree of accuracy.

Title: Methodological framework for ultrasound, MRI, and histological detection and quantification of intraparenchymal hemorrhage in a porcine model of SCI

Authors: *A. ALLARD BROWN[1], K. SO[1], N. MANOUCHEHRI[1], M. WEBSTER[1], J. ETHRIDGE[1], A. WARNER[1], A. BILLINGSLEY[1], R. NEWSOME[1], K. BALE[2], A. YUNG[2], M. SENEVIRATNE[1], J. CHENG[1], J. WANG[1], S. BASNAYAKE[1], F. STREIJGER[1], P. KOZLOWSKI[2], B. K. KWON[1,3];
[1]Intl. Collaboration on Repair Discoveries (ICORD), Vancouver, BC, Canada; [2]Univ. of British Columbia MRI Res. Ctr., Vancouver, BC, Canada; [3]Dept. of Orthopaedics, Vancouver Spine Surgery Inst., Vancouver, BC, Canada

Abstract: Introduction: After traumatic spinal cord injury (SCI), intraparenchymal hemorrhage (IPH) is a common phenomenon that is associated with worsened neurologic outcome. A primary concern is that the blood itself and its breakdown products can be toxic to the injured spinal cord. Therefore, accurate evaluation and quantification of IPH following SCI are key to defining the effect of treatments on IPH progression and secondary neuronal injury. Thus, the purpose of our study was 1) to detect IPH by magnetic resonance imaging (MRI) and high-frequency ultrasound (US), 2) to associate IPH on MRI and US with histology and 3) to quantitatively monitor the time course of IPH following SCI. **Methods:** A porcine model of SCI was employed in this study using female Yucatan pigs. At 6 hours (n=3) or 7 days post-SCI (n=29), *in vivo* US and *ex vivo* MR images were captured. Spinal cord sections were stained with Hematoxylin and Eosin (H&E) for visualization of red blood cells and Prussian blue for iron. US and MR images were then co-registered with the corresponding histology images. **Results:** On MRI, IPH was visible as hypointense regions which visually matched regions stained for red blood cells and iron deposits, both at 6 hours and 7 days post-SCI. The appearance of IPH on US typically presented as a hyperechoic area. However, the correspondence with histology was observed at 6 hours post-SCI only, predominantly close to the epicenter of the impact. Overall, the size of the IPH developed rapidly after injury and was largest at the injury site and extended roughly 8 mm in both the rostral and caudal segments. Central IPH was usually seen within the gray matter of the spinal cord at the center of the impact and a variable proportion of adjacent white matter. In one case, remote IPH was detected as far as 2 cm caudal to the epicenter. **Conclusion:** Our semi-automated method provides a plausible pipeline for the segmentation and quantification of IPH from MR, US and histology images. Moreover, the study illustrated the power of using multiple imaging systems to investigate the progression of IPH following SCI, an approach that will hopefully become more frequently adopted for translational SCI research.

Abstract: Spinal Cord Injuries (SCIs) compromise tissues including nerves responsible for relaying and integrating signals between the brain and the body. These injuries frequently result in behavioral deficits in sensory and motor functions at and below the level of spinal cord injury, typically arising from physical trauma. Targeted injuries to the cervical spinal cord in monkeys can specifically impede skilled hand use. In our previous studies, we employed a machine-learning-based video analysis system - DeepLabCut - to quantify hand-reaching and grasping behavior. We detected subtle abnormalities in finger posture in monkeys with cervical spinal cord injuries, even when their end-point hand performance had returned to pre-injury level. However, our analysis was limited to a frontal view, overlooking relevant information from side and top perspectives. In the current study, we designed a 3D camera recording system to quantify the kinematic deficits of hand reaching and grasping behavior following injuries to C5-level. Four squirrel monkeys were trained to retrieve sugar pellets from seven different devices, six of which featured wells of increasing difficulty. Each behavioral session was recorded simultaneously from top, side, and front views and included one video per completed task trial. A single behavioral trial allowed evaluation of hand and finger behaviors during three dynamic phases: reaching, grasping, and retrieving. Using DeepLabCut, we tracked and quantified individual finger movement, speed and trajectory during grasping and retrieval, changes in finger orientation, alterations in hand shape and orientation, and task completion time. These parameters were quantified over a twelve-week post-injury period. We discovered that impairments in motor and sensory skills were more pronounced with deeper well depths and increased task difficulties. Our results demonstrate that an AI-assisted machine-learning-based video analysis system can robustly identify subtle behavioral impairments in finger posture and hand movement speed and trajectory, which are not discernible through conventional end-point performance analyses. This method enables separate quantification of motor and somatic sensory deficits. The insights obtained from this study will shed light on the compensatory mechanisms employed by monkeys to successfully complete the assigned tasks.

Title: Depth cameras provide accurate estimates of center of pressure measurement in seated leaning tasks for people with thoracic incomplete spinal cord injury and non-injured controls

Authors: *M. N. HATCH[1], R. MATTHEW[2];
[1]UCI Sch. of Med., Orange, CA; [2]Univ. of California at San Francisco, San Francisco, CA

Abstract: ABSTRACT*Objectives:* There exists a major gap in the field regarding trunk stability in people with spinal cord injury (SCI). This is somewhat surprising given the impact that trunk stability (or lack thereof) can have on one's activities of daily living and its ranked importance by people with SCI-- even above walking. However, existing trunk stability measures for SCI remain under-developed, outdated, and cost and space prohibitive. Small depth camera systems, such as the Microsoft Kinect, show promise for motion analysis and clinical testing in non-SCI populations for gait, Sit-to-Stand, and stair climbing. Here, we assess the feasibility of a single 3-dimensional (3D) depth camera to predict Center of Pressure (CoP), the gold standard for trunk/seated posture assessment, across various seated leaning task in persons with SCI and healthy controls. ***Methods/ approach:*** Five individuals with thoracic SCI and ten healthy controls were recruited for this study. Subjects were asked to perform seated lateral leaning tasks while being simultaneously recorded by a force plate and a 3D Microsoft Kinect sensor, twice, and to their fullest extend (CoP end excursion) while maintaining control. Data were post-processed in MATLAB using a custom allometrically-scaled skeletal model. Max CoP excursion and velocity were computed from both the force platforms and the estimated CoP from the depth camera. Bland-Altman was used to determine reliability between the devices.***Results:*** All participants, including those with SCI, completed the seated leaning tasks with no issues. A total of 53 leaning actions were recorded and processed for this study. CoP estimates from the 3D sensor displayed excellent correlations force plate metrics with R2 values of 0.92, 0.80, 0.74, and reliability coefficients of 2.4cm, 2.6cm/s, and 4.6cm/s for the maximum CoP excursion, maximum CoP outward speed, and inward speeds respectively. ***Conclusion(s):*** These initial results indicate that estimation of CoP from a single 3D camera system is comparable to standard force plate analyses. Given that 3D sensors are more cost and space efficient, they may be more feasible and suitable for trunk stability assessment in individuals with SCI.

Title: Mr imaging of intraparenchymal hemorrhage following cervical sci and the effect of map augmentation

Authors: *T. MALOMO[1], F. STREIJGER[1], M. DVORAK[1,2], C. G. FISHER[1,2], T. AILON[1,3], S. PAQUETTE[1,3], J. STREET[1,2], N. DEA[1,3], R. CHAREST-MORIN[1,2], C. DANDURAND[1,3], B. KWON[1,2];

Abstract: Introduction: Current practice guidelines for traumatic spinal cord injuries (SCI) recommend augmenting MAP to a target of 85-90mmHg for the first 7 days post-injury in acute SCI patients to maintain perfusion to the injured and ischemic spinal cord. While MAP augmentation with vasopressors may improve blood flow and reduce ischemia in the injured cord, it may also induce undesirable increases in intraparenchymal hemorrhage (IPH) within the injured spinal cord. Therefore, the present MRI-based clinical study determined whether MAP augmentation with vasopressors influences IPH within the injured spinal cord (ClinicalTrials.gov Identifier: NCT04758377). **Method:** Ethical approvals were obtained from the IRB and CREB of Vancouver General Hospital. Informed consent was obtained from each patient. Per institutional protocol, the target MAP of 85-90 mmHg was achieved using norepinephrine, vasopressin and midodrine infusion as required. T2WI images were collected on a 1.5T MRI scanner at baseline (>24 hours post-SCI), 2, 4, 7 and 14 days post-SCI. IPH progression (delta hemorrhage) was calculated between the first and subsequent MRI scans on Day 2, then from days 2-4, 4-7, and 7-14 post-SCI. Using simple linear regression and linear mixed effect models, we evaluated the associations between IPH progression and both time-weighted average MAP (TWA-MAP) and mean measures of MAP. **Results:** To date, we have enrolled 8x cervical SCI patients. At the baseline time point, all patients demonstrated IPH. On days 2 and 4, the extent of IPH progressed, followed by a reduction on days 7 and 14. During the first 48 hours after injury, TWA-MAP significantly correlated with delta IPH ($p=<0.0001$). Further analysis revealed a threshold-driving association whereby starting at a MAP of 85 mmHg and increasing the binary cut-off by 5 mmHg increments, TWA-MAP became a predictor of IPH progression in the first 2 days after SCI at a MAP upper threshold >90 mmHg ($p=0.035$). **Conclusion:** These results represent an important finding that to improve blood flow and reduce ischemia in the injured cord by augmenting MAP, clinicians may inadvertently promote undesirable bleeding within the spinal cord, thereby increasing the size of IP hemorrhage at the injury site.

University of Kentucky, Department of Physiology, Spinal Cord & Brain Injury Research Center, Lexington, KY 40536-0509
AbstractComplete high thoracic spinal cord injury (SCI) often leads to autonomic dysreflexia (AD), a condition that manifests as acute, episodic hypertension with and without bradycardia. AD is characterized by excessive discharge of sympathetic preganglionic neurons (SPN) in the intermediolateral cell column (IML) that are reflexively activated by noxious stimuli below the injury level. Most animal models of AD utilize a complete spinal cord transection at the T3 spinal level or above, however, anatomically complete spinal transection is relatively uncommon clinically, and individuals with incomplete injury still experience AD. We hypothesized that rats will develop AD over time following severe contusion SCI at the T3 spinal level. Thus, we designed an 8-week study with two different injury severities and evaluated the development of AD. Adult female Wistar rats were subjected to T3 contusion SCI with two different forces (300 kdyn (5s dwell time) and 400 kdyn (5s dwell time). Injured rats were subjected to weekly behavioral testing using Basso Beatie Bresnahan (BBB) locomotor rating scale for hindlimb function as well as the tail spasticity test for eight weeks. To evaluate changes in blood pressure, a telemetric probe was implanted in the descending aorta 2 weeks after the injury. Spontaneous AD events were recorded 3, 5, and 7 weeks post-injury. We also monitored induced AD by colorectal distension (CRD) at 4, 6, and 8 weeks post-SCI. We observed significant locomotor dysfunction and the development of spasticity regardless of injury severity. Both injury severities also resulted in significant increases in mean arterial pressure (MAP) but no change in heart rate (HR) after AD by CRD. This evoked AD was not significantly different between injury

severities. There was no significant difference in spontaneous AD events between injury severities. Tissue histology will be correlated with the magnitude of induced AD for both SCI severities. Collectively, our data support severe SCI contusion as a correlate for SCI-induced AD in humans.

Title: Magnetic resonance imaging-based tractography to evaluate mid-cervical neural tracts in the acute and chronically injured spinal cord of the rat

Authors: *E. J. GONZALEZ-ROTHI[1], D. PLANT[2], D. D. FULLER[1], G. S. MITCHELL[1], P. K. BOSE[3];

Abstract: Hemisection of the C2 spinal cord (CH2x) is an experimental model of incomplete cervical spinal cord injury (SCI) commonly used to study mechanisms of respiratory neuroplasticity and recovery. Extensive characterization of this model provides physiological and anatomical evidence that recovery of ipsilateral phrenic motor activity may arise from commissural axon tracts and/or propriospinal relays. Magnetic Resonance Imaging (MRI) of *ex vivo* spinal cords provides a powerful tool for visualizing neural tracts in high-resolution, enabling detailed characterization of neural pathways without need for sectioning/staining. Advanced methods such as Diffusion Tensor Imaging (DTI) and Susceptibility Weighted Imaging (SWI) enable characterization of cysts/hematomas, secondary injury progression, and efficacy of therapeutic interventions. We sought to determine if MRI and DTI tractography techniques could detect: 1) mid-cervical commissural (crossed-spinal) fiber pathways, and 2) growth/sprouting of neural fibers in the lesion vicinity after acute vs. chronic C2Hx. In ongoing studies, we are evaluating intact rats (n=9) and rats with acute (1 wk; n=8) and chronic C2Hx (>16 wks; n=7) using a 7 tesla MRI scanner (MR Solutions, Guilford, UK) with a coil

specifically designed for ex vivo rat spinal cord imaging. Axial and sagittal SWIs enable characterization of hematoma volume and extent of secondary injury, while T2-weighted spin-echo images enable evaluation of fluid-filled cysts/cavities. The DTI protocol uses a b-value of 2000 and is applied in 66 directions. Echo-time is 25 ms, and recycle time is 6 s to allow spins to fully relax, resulting in a total experimental time of 14.3 h. DTI processing is performed using DSI Studio software; DTI metrics and tractography are derived from these data. Preliminary analyses suggest alterations in DTI matrices (fractional anisotropy, mean diffusivity, and axial and radial diffusivity) with both acute and chronic injury *vs.* intact controls, particularly at the site of injury and within 2 mm rostral and caudal. The extent of tract abnormalities detected by DTI differ in acute *vs.* chronic C2Hx, with differing microstructural and density changes in descending tracts. Notably, after chronic C2Hx, the injury site is largely filled with viscous cysts and blood (iron hemosiderin), with evidence of significant fiber sprouting. We observe no evidence of injury or hematoma expansion with chronic injury. These data provide evidence of spontaneous axonal sprouting near a C2Hx lesion, and provide a baseline for studies assessing the impact of therapeutic interventions aimed at neuroprotection and/or axonal growth.

Title: Evaluation of spinal cord injury-induced neuropathic pain in a pig model

Authors: L. E. SCHNEIDER, T. L. NIEDZIELKO, ***C. L. FLOYD**;
Emergency Med., Emory Univ., Atlanta, GA

Abstract: Introduction: Neuropathic pain can be a debilitating occurrence after spinal cord injury (SCI). Treatment options for neuropathic pain remain suboptimal and discovery of novel therapeutics is limited, to some extent, by challenges in evaluating neuropathic pain in animal models. Most pain studies are conducted in rodents and focus evaluation predominantly on reflexive outcomes. Thus, there is an unmet need to develop novel animal models of neuropathic pain in non-rodent models that can be used as a translational tool to accelerate the development of new treatments for SCI-NP. The goal of this project was to assess neuropathic pain outcomes using methods back-translated from human clinical medicine to a clinically relevant porcine model of SCI. We also evaluated the effect of sex as a biological variable on outcomes. Methods: Adult male and female gonad-intact, adult pigs (n=8 each sex) were weight-matched and then received a mid-thoracic (T10) contusion-compression SCI. Starting at 2 weeks and continuing

for 12 weeks after SCI, pigs were evaluated using quantitative sensory testing (QST) methods and responses rated with the porcine evoked pain scale (PEPS) that we developed. The PEPS includes assessments of both reflexive (spinal) and affective/cognitive (supraspinal) outcomes. Results: Pain-like responses to QST stimuli were compared between pre-injury and post-injury responses. We found that over 80% of both male and female pigs exhibit a neuropathic pain-like phenotype after SCI, with percentage responding varying by QST modality. For mechanical detection threshold, we found that both male and female pigs exhibited a robust reduction in the withdrawal threshold. Similarly, both male and female pigs exhibited a loss of function in pressure pain threshold after SCI as compared to pre-injury values. For temperature sensitivity, both male and female pigs showed significantly greater pain responses in the heat pain threshold test, with significantly more female pig showing pain-like responses than males. Responses on the cold pain threshold test did not reach statistical significance. Conclusion: Taken together, these data show that using methods back-translated from the human clinical setting, pigs after SCI exhibit a neuropathic-pain phenotype that is similar to that exhibited in the human clinical setting. The data also show that the predictive validity of the pig model may be high and suggest that this porcine model may serve as a translational tool to accelerate development of novel therapies.

Abstract: Recent neuromodulation therapies are promising to help with some of the sensorimotor losses in spinal cord injury. One novel approach focuses on the functional electrical stimulation (FES) of the peripheral nervous system to induce neuroplasticity in addition to the

classical gains in sensory and motor function. We developed a low-cost impactor device to produce displacement-controlled and reproducible spinal cord contusions in rats, based on a linear servo actuator. The device probe includes force, acceleration, and displacement sensors to characterize the biomechanical parameters during the application of the injury. In preliminary experiments, optimal parameters were determined (contactor diameter: 2.3 mm, indentation peak force: 0.9-1 N, peak displacement: 1.5-1.75 mm, duration: 0.3-0.5 s) to produce moderate injury as observed with the Basso, Beattie and Bresnahan (BBB) locomotor rating scale at D1 post-op (T8-T9 laminectomy and contusion). High-speed video recordings of rats walking on a platform were obtained pre-op and at several time points post-op for subsequent gait analyses. Although the animals recovered considerably without particular treatment after a month, there were asymmetries in some gait parameters (e.g. stance duration, duty factor, relative paw position) which remained even up to 3 months. Similarly, evoked epidural field potentials recorded on S1 cortex of the right and left hemispheres were asymmetric to contralateral mechanical stimulation of the limbs (tactile and muscle receptors). We are currently studying these neuroplastic changes in a larger sample size, and the possibility to facilitate recovery by neuromodulation.

Title: Transduction of dorsal root ganglia neurons with AAV2-hSyn-hM3Dq-mCherry constructs via direct microinjection targets large diameter afferents and minimally transduces IB4+ neurons

Authors: *J. CAPALDI[1], H. SOBOTKA-BRINER[5], S. NICE[2], J. EISDORFER[6], G. MOUKARZEL[5], T. J. CAMPION[3], G. SMITH[7], G. KOMA[4], A. SPENCE[4];

Abstract: Transducing peripheral sensory neurons in a targeted manner has a number of uses across neuroscience. One example is to uncover the mechanisms by which epidural stimulation

improves recovery from a spinal cord injury. In this instance, it is unknown precisely which populations of neurons are critical to improving recovery from an injury, and it is important to trace which second and higher order neurons are influenced by afferent stimulation. Transduction of dorsal root ganglion (DRG) neurons with genetically encoded tools such as DREADDs packaged in an AAV is one way to achieve this. In using this approach it is important to establish that small diameter nociceptive afferents are not targeted to large extent. In order to validate this, we carried out an immunohistochemical (IHC) stain for IB4 to quantify the fraction of cells transduced by the virus that are IB4 positive. The right side L2-L5 DRGs of rats were injected with AAV2-hSyn-hM3Dq-mCherry. After 8 weeks, animals were euthanized and tissue harvested. Labelled DRG neurons were counted to determine the total number of cells infected by the virus and the subset that were IB4 positive (which are thought to be include many small diameter nociceptors). Histology revealed that the fraction of transduced cells that were IB4+ was small, at 10.9 ± 8.3% (mean ± s.e.m, n=8 DRGs from 5 rats, range 1 to 3 DRGs per rat). This small fraction of IB4 positive cells indicates that the AAV2 was effective in targeting large diameter neurons, and corroborates our recent finding that afferent activation with this approach does not cause changes in thermal nociception assays *in vivo*. These results suggest that transduction of DRG neurons through direct injection with AAV2 is a suitable method to target large diameter afferents for SCI studies.

Title: Infrared videography of a subcutaneous marker as a simple, inexpensive method to overcome skin motion artifact in rodent kinematics

Authors: *A. J. SPENCE[1], C. A. PATIL[1], B. RAUSCHER[2], G. MOUKARZEL[1];
[1]Bioengineering, Temple Univ., Philadelphia, PA; [2]Boston Univ., Boston, MA

Abstract: Here we show that infrared videography of a subcutaneous marker can dramatically reduce skin motion artifact in rodent kinematics. The method yields data similar to gold standard x-ray fluoroscopy systems at a fraction of the cost, does not affect the animals' locomotion, and results in markers that persist for at least 16 weeks. Knee joint movement under the skin causes errors in rat hip and knee angles of up to 50-75% (Bauman and Chang, 2009). Fluoroscopy,

while the gold standard, requires expensive x-ray systems (>$200k), and has a limited capture volume and short exposure times. We compared joint angles computed using our method versus skin derived markers in the same animals, as well as x-ray imaging of bone derived angles from the literature. No significant difference at the $p<0.05$ level was reported between skin and kinematic data from our method two weeks after surgery (n=7 rats; speed 32 cm/s). DeepLabCut detected our marker at ten weeks at similar rates to two weeks, and the marker remained visible out to 26 weeks. The difference in mean hip angle between our data (2 weeks post surgery; 48 cm/s) and x-ray data was reduced from 17° ± 6.0 to 3.1° ± 2.4; RMS error across the mean hip angle waveform was reduced from 20° to 5.3° (Fig 1: teal: x-ray gold standard; blue: IR marker; orange: skin). Skin derived kinematics overestimated the mean and underestimated the standard deviation of hip angle, while they overestimated the knee angle at touchdown (0 and 100% stride). The surgery required is minimally invasive and short (10 min), infra-red cameras are relatively inexpensive (~$1500), and the data processing workflow standard. Our results reveal between-animal or between-marker application errors result from placement of the knee marker on the skin, and large subcutaneous knee joint movement. Because the knee moves so substantially beneath the skin, no skin marker placement can be accurate throughout the stride. As the method is inexpensive and scalable to many animals and long bouts of locomotion, it will aid in establishing large databases of shared kinematic data with less between-lab variability.

Title: Unbiased and replicable assessment of locomotion changes for a rat spinal cord injury model using advanced gait analysis technology.

Authors: *J. BASTIDAS, M. LANG, R. BARRETT, S.-C. KIM, S. MONGIA, J. BELTRAN, D. BRUNNER, T. HANANIA;
PsychoGenics, Inc., Paramus, NJ

Abstract: Preclinical investigations into novel treatments for Spinal Cord Injury (SCI) have shown promise, but replicating these findings has been challenging thereby emphasizing the need for unbiased and reproducible methodologies in SCI research. In this study, we employed a graded thoracic (T8) SCI model using the IH impactor with 3 different force levels (170, 200, and 230 Kdyn) in female Lewis rats. Additionally, we evaluated the efficacy of well-known neuroprotective compounds (Rolipram, Riluzole, and Minocycline) in a 200 Kdyn SCI model. Our assessments included behavioral tests (BBB scale, horizontal ladder test), lesion size measurement and plasma biomarkers (GFAP, NF-H, Tau). We also utilized PsychoGenics' proprietary technology, NeuroCube® (NC), for automatic gait analysis. The NC system is a fully automated platform that uses computer vision and machine learning algorithms for gait analysis, limiting the possibilities for bias and error. A comprehensive collection of gait data was obtained, revealing clear distinctions between naïve rats and those with SCI in various gait parameters (increased base width, increased stride length, and decreased stand duration, and paw intensity). Furthermore, many of these gait changes displayed a strong correlation with BBB score and lesion size, indicating consistency and sensitivity in detecting changes based on injury severity in a SCI model. Particularly noteworthy were the significant changes and the strongest correlations observed in the front-limb gait parameters. The most robust changes in gait were found in SCI cohorts that underwent injury force of 200 and 230 Kdyn. When assessing the effects of various neuroprotective compounds, we found that only Rolipram showed a modest but significant change in BBB score and ladder test, while both Rolipram and Riluzole showed overall significant effects on gait geometry and dynamics. The sensitivity of the NeuroCube system and the richness of the data generated from evaluating multiple gait endpoints renders it very valuable in detecting efficacy of novel therapeutics. By considering these interconnected parameters within a multidimensional assessment, gait data can be analyzed and understood more comprehensively, resulting in enhanced sensitivity compared to unidimensional assessments.

Abstract: In the United States, nearly 250,000 people are affected with traumatic spinal cord injury (SCI), and nearly 17,000 new cases are diagnosed annually. Although once considered untreatable, significant advancements over the past century in the medical and surgical care of SCI have helped improve outcomes and reduce the likelihood of early mortality. These outcome improvements are largely due to early surgical decompression to reduce tissue injury and aggressive maintenance of elevated mean arterial pressure (MAP) to maintain spinal cord perfusion. Extensive physical rehabilitation is critical to maximizing neurological function after injury. Nonetheless, patients with traumatic SCI often face lifelong loss of motor, sensory, bowel, and bladder function. Ischemia, oxidative stress, loss of autoregulation, inflammation, and excitotoxicity follow and constitute the secondary phase of injury, the focus of this research. This secondary phase contributes to neuronal death, gliosis, hemorrhage, and cord edema, which can worsen the initial damage of the primary phase and last days to weeks. During this phase, spinal cord vascular resistance increases due to a rise in intrathecal pressure (ITP), which in turn decreases perfusion to the spinal cord. Recently, SCI patients have been treated with lumbar drains to reduce ITP and improve perfusion. Sampling the cerebrospinal fluid (CSF) for biomarkers in real time may potentially improve monitoring and response to therapy, including when considering newer modalities such as focused ultrasound stimulation. We have developed

a custom 4-lumen catheter capable of traditional CSF draining but also of measuring CSF biomarkers using fiber optics threaded through three peripheral lumens. These sensing fibers provide us with real-time continuous data related to intrathecal pressure, CSF temperature as well as chemical biomarkers, including total CSF protein concentration, which is often elevated following SCI as a result of cellular trauma and upregulation. We report on collection of pre-clinical data from a porcine model of spinal cord injury for multiple consecutive days for durations ranging from 15 minutes to four hours, examining the trends of the biomarkers in real-time and across multiple days. We observe rapid changes to CSF pressure in response to saline injections through the catheter and upon initial draining of CSF. Additionally, we collected real-time total protein data over the duration of the study and observed changes to its concentration over time. We believe these real-time data can be used to observe the evolution of the acute phase of spinal cord injury as well as impact of therapies during this phase.

Title: Non-contrast ultrasound for the determination of blood flow changes following spinal cord injury

Authors: *D. ROUTKEVITCH, E. BACA, Z. SOULE, N. KATS, A. M. HERSH, K. M. KEMPSKI LEADINGHAM, N. THEODORE, N. V. THAKOR, A. MANBACHI;

Abstract: Background There is currently a lack of evidence guiding cardiovascular control of spinal cord injury (SCI) in critical care, resulting in secondary damage that occurs hours to days after injury. Previously, contrast-enhanced ultrasound has been used to quantify spinal cord perfusion to investigate changes in blood flow after SCI, but the clinical translatability is limited. Therefore, we present the following use of non-contrast ultrasound to measure blood flow after spinal cord injury and relate it to injury severity. **Methods** An i22LH8 probe was used in conjunction with the Aplio i800 ultrasound machine (Canon, USA) to capture superb microvascular imaging (SMI) videos of 24 Sprague-Dawley *in vivo* rat spinal cords after T11-T13 laminectomy. A contusion spinal cord injury was delivered at various impact forces: mild (100 kDyn), moderate (175 kDyn), and severe (250 kDyn). Post-injury images were taken, and the resulting images were analyzed to obtain blood flow as a function of distance from the injury. Simple parameters were computationally extracted from these curves and compared amongst the experimental groups. These parameters included injury extent through distance as well as flow at sites around the injury, including the epicenter (umbra), neighboring tissue (penumbra), and distal healthy tissue. **Results/Discussion** Umbra flow showed significant decrease from pre- to post-injury ($p<0.0001$), and trends of decreasing flow as severity increased. Injury extent showed significant increase from the mild to severe injuries ($p<0.05$). Flow in the penumbra, both rostrally and caudally, was significantly elevated as compared to pre-injury values, both in raw flow (rostral: $p<0.05$; caudal: $p<0.01$) and difference from umbra (rostral: $p<0.0001$; caudal: $p<0.0001$). However, only the rostral penumbra had significant differences between injury types. The raw flow in the rostral penumbra was greater in the severe injury when compared to moderate ($p<0.01$). The distal flow was unchanged from pre-to post-injury. **Conclusions** Non-contrast ultrasound can detect differences in blood flow between pre- and post-injury images. Certain parameters were also affected by severity of injury, including injury spatial extent and flow in the rostral penumbra. Further work will focus on the biological and functional significance of the described injury zones.

Title: Functional Ultrasound Imaging Reveals Dynamics of Micturition in the Human Spinal Cord

Authors: *K. A. AGYEMAN[1], D. J. LEE[4], S. SAKELLARIDI[2], J. RUSSIN[5], W. CHOI[5], A. ABEDI[5], R. V. EDGERTON[5], C. LIU[5], V. N. CHRISTOPOULOS[3];

Abstract: The spinal cord was traditionally neglected in the study of neural function because it was predominantly viewed simply as a pathway between the brain and the peripheral nervous system. As a result, its anatomy and physiology are not well understood as those of the brain. While strong evidence from pre-clinical work exists for the presence of regulatory neural-network-circuits that are responsible for vital motor, sensory and autonomic functions, its demonstration in humans has been challenging. The facial enclosures and the small cross-sectional dimension of the spinal cord combined with susceptibility to artifacts make it an unfavorable target for traditional neuroimaging techniques. The lack of knowledge in humans consequently, results in sub-optimal therapeutic strategies for treating dysfunctions associated with disease or injury to the spinal cord - with devastating health and cost burdens. For instance, current care for urinary dysfunction that affect over 30 million Americans relies mostly on symptomatic management with the use of catheters to empty the bladder**.** Given this context, there is a distinct need for developing neurotechnologies that make the functional study of the human spinal cord more accessible.
Here, we investigate the human spinal cord hemodynamic response during bladder filling and emptying, by leveraging the superior spatiotemporal properties of functional ultrasound imaging (fUSI). We characterize the spatial and temporal responses to micturition using simultaneous power Doppler (pD) spinal cord signal acquired through a partial lamina opening and intravesical bladder pressure recordings from 6 patients. Utilizing 2 bladder-filling cycles and 1 emptying cycle, interspersed by hold periods, we identified spinal cord regions in which the pD signal is strongly correlated with the bladder pressure ($r = 0.86 \pm 0.03$, Mean ± SE). We further combined classwise principal component analysis (cPCA) with linear discriminant analysis (LDA) and decoded the bladder pressure dynamics with high accuracy (92.8 ± 7.2 %, Mean ± SE), as well as identified regions that encode the effects of micturition, based solely on the spinal cord pD signal.
Overall, our study provides the first in-human application of fUSI to characterize hemodynamic responses of the spinal cord during urodynamics and offers direct evidence of the existence of spinal cord networks that control micturition. The high accuracy for decoding the state of the bladder based on the pD signal provides proof-of-concept that fUSI is an essential component for investigating function and building spinal cord machine interface for patients with urinary dysfunctions.

Title: Decoding micturition from the spinal cord using functional ultrasound imaging

Authors: *S. SAKELLARIDI[1], K. AGYEMAN[1], D. LEE[2], E. KREYDIN[2], J. RUSSIN[2], W. CHOI[2], A. ABEDI[3], H. ZONG[4], V. EDGERTON[5], C. LIU[2], V. CHRISTOPOULOS[1]; [1]Bioengineering, UC Riverside, Riverside, CA; [2]Neurosurg., [3]USC, Los Angeles, CA; [4]Univ. of California Los Angeles, Los Angeles, CA; [5]Rancho Res. Inst., Downey, CA

Abstract: Micturition characterizes the process in which neural pathways coordinate the activity of smooth muscles in the bladder to expel urine. Disease or injury of the nervous system can cause the re-emergence of involuntary urination, leading to urinary incontinence (UI). Elucidating the functional circuities in normal bladder control is key to identify abnormalities in UI patients. Our understanding of the brain circuits involved in micturition has grown immensely over the past decades. Yet, assessing the functional attributes of spinal cord in relation to bladder function has proven to be a challenge. This study sought to utilize functional ultrasound imaging (fUSI) to characterize the spinal cord hemodynamics in response to micturition in rats. fUSI is an emerging neuroimaging technology that represents a new platform with high sensitivity, spatial coverage and spatiotemporal resolution. Based on power Doppler (pD) imaging, fUSI measures changes in blood flow by detecting backscattered echoes from red blood cells moving within its field of view. After inducing anesthesia, animals (N=8) underwent multi-level laminectomy at T12-L2 to expose the lumbosacral spinal cord. This window allows the position of a 15 MHz ultrasound probe in a sagittal plane. A transducer was inserted and secured to the bladder dome to record the pressure dynamics. A catheter connected to an infusion pump was inserted in the same location to fill the bladder with saline at a constant rate of 0.1 ml/min. We acquired fUSI images for 50 minutes during which the animals were spontaneously voiding. Voiding is associated with typical abrupt changes in bladder pressure, which was directly verified by observing (through camera) outflow of urine from urethra. We measured pD changes of the spinal cord with respect to baseline – 10 min before starting to fill up the bladder. We identified region-specific hemodynamical changes associated with bladder pressure changes during filling. We further extended these results to predict an impending voiding. We used principal component analysis (PCA) as a feature extraction to optimally discard shared information between the two classes (class 0: pre-voiding, class 1: voiding). We then used linear discriminant analysis (LDA) and found that the PCA-transformed images predict an impending voiding with cross-validated accuracy 89.4% ± 3.3% (MEAN ± SE) about 4 seconds before the actual voiding. These results provide the first proof-of-concept that fUSI is a viable modality for developing ultrasonic spinal cord machine interface technologies to restore bladder function in patients with urinary incontinence (UI) – a technology that currently does not exist.

Abstract: Muscle stiffness and spasticity cause severe disability in approximately 12 million people after neurologic injury of cerebral or spinal origin, such as a stroke. Muscle stiffness is thought to be caused by neural reflex-induced muscle overactivity. However, we hypothesized that non-neural alterations in the composition of the extracellular matrix of the muscle due to the accumulation of hyaluronan can produce muscle stiffness. Here we describe the effects of treatment of muscle stiffness using intramuscular hyaluronidase injections on hyperreflexia and motor impairment. Fourteen individuals with upper limb muscle stiffness after cerebral injury participated in a single-center, double-blind, randomized, placebo-controlled, Phase II trial of human recombinant hyaluronidase injections. All subjects received both human recombinant hyaluronidase and placebo injections in a random order in multiple upper limb muscles and were evaluated at baseline and 1-2 weeks after each injection visit. Resistance to passive movement was assessed using the modified Ashworth Scale (MAS), and reflex-induced muscle activity was measured using surface EMG from the medial biceps during tendon tap (n=45 per assessment) using an electronic hammer. Upper limb motor impairment was evaluated using the Fugl-Meyer Assessment (FMA). At baseline, the affected side showed a larger reflex EMG amplitude to tendon tap (mean ± SD= 9.24±10.58 V on the affected side vs. 1.81±2.28 V on the contralateral side). On the last post-injection visit, the muscle reflex EMG amplitude decreased by 3.31±12.68 V (36%) on the affected side. Moreover, on the last post-injection visit, compared to baseline, the MAS score for elbow extension decreased by 0.61±0.63 and the upper limb FMA increased by 7.29±5.72 on the affected side. The results suggest that peripheral modulation of muscle stiffness using hyaluronidase injections can reduce resistance to passive movement, hyperreflexia, and motor impairment after cerebral injury, suggesting that secondary changes in muscle composition contribute to these phenomena.

Title: Hyaluronic acid accumulation in shoulder muscles of patients with active versus latent post stroke shoulder pain

Authors: ***A. ETEMADIMANESH**[1], J. HUANG[3], A. GHASEMI[2], P. DEBS[2], R. MENON[4], L. M. FAYAD[2], P. RAGHAVAN[1];
[1]Physical medicine and Rehabil., [2]Russell H. Morgan Dept. of Radiology & Radiological Sci., Johns Hopkins Med. Institutions, Baltimore, MD; [3]Physical medicine and Rehabil., Johns Hopkins Hosp., Baltimore, MD; [4]Ctr. of Biomed. Imaging, Dept. of Radiology, New York Univ. Grossman Sch. of Med., New York, NY

Abstract: Recent studies suggest that the accumulation of Hyaluronic acid (HA) in muscles may contribute to myofascial post stroke shoulder pain (PSSP). PSSP can be classified as active or latent based on the severity of pain reported during shoulder external rotation and palpation of tender nodules in the pectoralis major (PMA) and infraspinatus (INF) muscles. T1rho MRI imaging of muscles has provided a novel avenue for investigating HA accumulation in muscles. In this study we assessed the T1rho relaxation time in the PMA and INF muscles of the affected and unaffected sides, as well as its relationship to active versus latent PSSP. 10 patients with unilateral PSSP (6 with Latent and 4 with Active PSSP) completed the T1rho MRI scans. Patients underwent 3T MRI with 3D-T1rho mapping at spinlock times of 0, 10, 20, 30 and 40 ms. T1rho relaxation times we derived using a non-linear decay model and mean T1rho values were extracted for the regions of interest for both the affected and unaffected sides. Both PMA and INF muscles had higher mean T1rho values on the affected side (PMA: 28.86±2.78, INF: 29.23±3.04) compared to the unaffected side (PMA: 27.87±2.11, INF: 26.26±1.89). Patients with active PSSP exhibited higher mean T1rho values in both muscles (PMA: 29.59±1.40, INF: 31.30±1.50) compared to those with latent PSSP (PMA: 28.37±3.46, INF: 27.85±3.09). These preliminary findings suggest that the level of HA accumulation may be associated with the severity of PSSP. Further investigations will lead to a better understanding of the underlying pathophysiology of myofascial pain in patients with stroke.

Title: Quantifying myofascial shear strain in chronic post-stroke shoulder pain with ultrasound shear strain measurements

Authors: *P. RAGHAVAN[1], M. ASHIKUZZAMAN[2], E. MONDRAGON[2], J. HUANG[3], L. ZHAO[2], S. BONWIT[3], A. ETEMADIMANESH[3], M. BELL[2];
[1]Johns Hopkins Med. Institutions, Baltimore, MD; [2]Johns Hopkins Univ., Baltimore, MD; [3]Johns Hopkins Med. Inst., Baltimore, MD

Abstract: Reduced shoulder joint mobility as a result of a stroke may lead to hyaluronic acid (HA) accumulation in muscles such as the pectoralis major and minor (PMA and PMI). We hypothesize that the accumulation of HA stiffens the muscles and prevents shear motion between the PMA and PMI muscles, eventually triggering post-stroke shoulder pain (PSSP). This study uses ultrasound shear strain imaging to quantify and compare the inter-layer relative motion between PMA and PMI muscles on the paretic and non-paretic sides of patients with PSSP. Our study included 7 PSSP patients with one shoulder predominantly affected by stroke. A bimanual arm trainer moved the patient repeatedly into shoulder external rotation at a rate of 0.5 Hz starting from a position of full internal rotation with a range of 30° excursion for each cycle. We acquired three ultrasound cine loops of 20 seconds from each side of a patient, using a Clarius L15 scanner held by a Sawyer robot, placed to access the pectoralis muscles. A cross-correlation-based speckle tracking technique was used to estimate the inter-frame lateral displacements, which were temporally accumulated to render the cumulative displacements. We included or excluded a particular trial based on the acquired data's usability and the reliability of displacement estimates, based on an independent rating by two co-authors with ultrasound speckle tracking expertise (MA, MALB). Shear strains between PMA and PMI muscles were calculated from the cumulative displacement fields. The shear strain (%) between the PMA and PMI muscles on the paretic side (median: 11.8) was generally lower than on the non-paretic side (median: 19.5). However, there were some discrepancies where the non-paretic side showed a lower shear strain and correlated with higher pain levels. Additional investigations are being conducted to understand the relationship between shear strain, myofascial pain, and HA accumulation. The results provide preliminary evidence of reduced shear strain in patients with post stroke shoulder pain suggesting a myofascial etiology. Ultrasound shear strain may serve as a biomarker for myofascial dysfunction and pain.

Title: Differentiating clinical characteristics of active versus latent myofascial shoulder pain post stroke

Authors: *J. HUANG[1], A. ETEMADIMANESH[2], S. BONWIT[2], R. NICKL[2], P. RAGHAVAN[3];
[1]Johns Hopkins Hosp., Baltimore, MD; [2]Johns Hopkins Univ., Baltimore, MD; [3]Johns Hopkins Med. Institutions, Baltimore, MD

Abstract: Post-stroke shoulder pain (PSSP) is a common condition significantly affects the quality of life for stroke patients. A large proportion of shoulder pain is thought to be myofasical. We sought to characterize patients with active versus latent myofascial pain based on clinical pain questionnaires and physical exam. Twelve patients with post-stroke shoulder pain completed the study. The patients were classified as having active vs. latent pain based on their subjective rating of pain during shoulder external rotation and the presence of palpable tender nodules in the muscle. Patients with active pain scored >/= 5/10 on the visual analog scale, where as patients with latent pain scored < 5/10. Six patients were classified as having active PSSP and 6 were classified as having latent PSSP on enrollment. The clinical assessments included HEAL core clinical pain questionnaires, physical examination (pain-pressure threshold using algometer, muscle stiffness assessment using the PACT device. Pain intensity and interference assessed using the PEG pain screening tool, the pain catastrophizing scale, geriatric depression scale, and the PHQ-2 showed higher levels of pain intensity, catastrophizing, and depression in patients calssified as having active PSSP compared to those classified as having latent PSSP. They also showed higher pain ratings when using an algometer and higher levels of stiffness using the PACT device, on both the stroke affected and unaffected sides compared to those with latent PSSP. The results suggest that compared to latent PSSP which appears to be largely localized to the affected side, active PSSP is more generalized and bilateral, suggesting possible underlying systemic inflammatory processes.

Title: The ER chaperone ER Oxidoreductin (ERO1) plays a critical role in determining nociceptive sensitivity

Authors: *A. D. MAGUIRE[1,2], J. RAO[3,1], G. TENORIO[4,1], B. J. KERR[4,3,2,1];
[2]Neurosci. and Mental Hlth. Inst., [3]Pharmacol., [4]Anesthesiol. and Pain Med., [1]Univ. of Alberta, Edmonton, AB, Canada

Abstract: Neuropathic pain (NP) is a debilitating condition caused by injury or disease of the somatosensory nervous system. Conventional pain treatments such as opioids are accompanied by severe side effects and are often ineffective against NP. Thus, there is a pressing need to develop more effective therapies. In many cases, NP originates in the peripheral nervous system (PNS) where primary pain-sensing neurons, termed nociceptors, become hyperexcitable and sensitized to stimuli. By understanding and manipulating neuronal hyperexcitability we may be able to develop new treatments for NP. Here, we focused on how excitability can be affected by endoplasmic reticulum (ER) and mitochondrial calcium dynamics. Particularly through calcium transfer from the ER to mitochondria at the mitochondrial associated membrane (MAM). The enzyme ER oxidoreductin 1 (ERO1) plays an important role in this process as it stabilizes ER IP3 receptors, allowing for efficient calcium transfer to mitochondria. We hypothesized that inhibiting ERO1 and thus reducing calcium transfer at the MAM would dampen nociceptor hyperexcitability and thereby reduce pain. First, we determined that the ERO1 antagonist EN460 can reduce pain. Using an acute model of nociception (tail flick test) and an acute inflammatory model (hind paw formalin injection), we found that 10 mg/kg intraperitoneal EN460 drastically reduced pain in male and female mice in both models. Additionally, we assessed the effects of EN460 on primary sensory neurons in culture. Because high levels of sprouting and complexity have been linked to NP, we assessed neurite outgrowth in the presence of EN460. We found that EN460 reduced the mean outgrowth, processes, and branches per cell, predominantly in female neurons. This suggests that EN460 may be able to impact the peripheral structural changes that underly NP. Finally, to confirm that EN460 can alter MAM calcium transfer we used a seahorse oxygraph and found that mitochondrial ATP production is decreased after EN460 treatment. Using a fluorescent live cell stain, we also found that mitochondrial reactive oxygen species (ROS) are decreased with EN460. Both results, much like the changes in outgrowth, were found to be stronger in female cells. Our findings suggest that ERO1 inhibition with EN460 can meaningfully impact calcium transfer at the MAM and sensory neuron plasticity. Based on these results we hypothesize that NP will be reduced with EN460 treatment, and that this effect may be stronger in females.

Abstract Typically rated as "the worst pain imaginable" by patients, neuropathic pain (NeP) results from damage to the somatosensory nervous system. NeP presents in many chronic pain conditions including but not limited to peripheral nerve injury (PNI) neuropathies such as from phantom limb pain, trigeminal neuralgia, and post-chemotherapy pain in cancer patients. Peripheral neuropathies are common yet debilitating and very difficult to treat due to a poor understanding of the complex underlying mechanisms. One fundamental initiator of NeP is the innate immune response to injury; the macrophages of the neuroimmune system initiate the NeP's well-characterized phenotype of prolonged hypersensitivity. Recent studies have found the acute impacts of tissue-resident macrophages (TRMs) at the dorsal root ganglion (DRG) under PNI; however, its roles throughout the shift from acute establishment to chronic maintenance of NeP remain to be known. To address a cell-specific targeting approach, our study employs a fate-mapping strategy with transgenic mouse lines to better define the localization, morphology, and dynamics of the TRMs in the spared nerve injury (SNI) model of PNI-NeP. Using $CX3CR1^{CreER}$ mice crossed with Ai9 mice (mice presenting the constitutive promoter line $ROSA26^{tdTomato}$), we follow the DRG resident macrophages over the acute-to-chronic timecourse and co-stain the DRGs to measure for proliferation and cell death. We observe that the TRMs increase in population density acutely at 7 days post injury (DPI) and then a decrease in density by 120DPI. Moreover, we observe that TRMs are morphologically diverse throughout the NeP timecourse. Ultimately, our findings provide evidence that TRMs dynamically change throughout the timecourse of the SNI model of PNI-NeP. By studying how DRG-resident macrophages change throughout NeP, we can understand the pathophysiology of NeP chronicity, thus providing context for future targets for immune-based neuropathic pain therapies.

Title: Neuroplasticity and pain: Examining the influence of exercise on nociception

Authors: *D. N. VILLARREAL[1], T. FRIEDMAN[1], A. D. MAGUIRE[2], G. TENORIO[3], B. J. KERR[3];

Abstract: Exercise is praised for its extensive health benefits, but for people experiencing chronic pain, exerting oneself with movement seems counterintuitive and may be challenging to adhere to. The advantages of exercise on chronic pain states are severely understudied. Inflammatory conditions, specifically those that result in chronic pain, have been shown to increase neurite outgrowth in the sensory ganglia of mice and affect their electrophysiological properties. Whether this outgrowth exacerbates pain remains to be fully elucidated. Our data suggest that sensory neurons from adult mice show increased outgrowth in response to an aerobic exercise regimen. We now aim to study the transition between acute and chronic pain in mice and how it is affected by aerobic exercise.
We employed a 'hyperalgesic priming' model to study the transition from acute to chronic pain. Mice are injected subcutaneously with tumor necrosis factor-alpha (TNFα, 5 ng) to mimic an acute noxious stimulus. Once sensory thresholds resolve, they are treated with a second injection of the inflammatory-mediator prostaglandin (PGE2, 100 ng), leading to a prolonged hypersensitivity state. Before priming, naïve mice were given two-weeks of voluntary wheel-running to analyze the effects of aerobic exercise. Control mice received either a saline injection or no running treatment. We hypothesize that active mice will exhibit increased neurite outgrowth, as observed in previous pilot studies. However, with the addition of a noxious stimulus, the mice will experience prolonged pain due to the simultaneous structural changes in the sensory neurons.
Sensory neurons were stained with βIII tubulin to visualize the cytoskeletal structure, and neurite outgrowth analysis was conducted using MetaXpress 3.1. Our data indicate that wheel running promotes neurite outgrowth, but the addition of an acute TNFα injection significantly impairs the growth-promoting activity of wheel running. Pain assessment revealed that non-running mice recovered seven days after the first TNFα injection while running prolonged this pain for 72 hours. Our data indicate that aerobic activity alters the growth of sensory neurons, and a noxious

stimulus counteracts this change in growth status. Sex differences in these responses are currently being explored.

Title: A role of CARTp/GPR160 in peripheral sensitization

Authors: *R. M. SCHAFER[1,2], L. A. GIANCOTTI[1,2], D. J. DAVIS[3], D. SALVEMINI[1,2]; [1]St. Louis Univ., St. Louis, MO; [2]Inst. for Translational Neurosci., St. Louis, MO; [3]Animal Modeling Core, Univ. of Missouri, Columbia, MO

Abstract: Chronic neuropathic pain occurs when there is damage or lesion to the somatosensory nerves. Understanding the mechanisms that cause neuropathic pain at the peripheral and central level offers possibilities to develop novel therapeutics as current therapeutics are inadequate and long-term use of opioids have adverse side-effects and abuse potential. We previously reported that activation of the G-protein coupled receptor 160 (GPR160) in the spinal cord by its ligand cocaine- and amphetamine-regulated transcript peptide (CARTp) contributes to the development of central sensitization associated with neuropathic pain states. The role of CARTp/GPR160 in the development of peripheral sensitization is not known and was explored in this study. Intraplantar (i.pl.) injection of CARTp in mice (n=7 males and n=4 females) evoked time-depended development of behavioral hypersensitivities (mechano- and cold-allodynia) that were completely lost in *Gpr160* knockout mice (n=3 males and n=5 females), suggesting GPR160 is dependent on CARTp-mediated hypersensitivities. *In vivo* and *in vitro* studies have shown CARTp signals via a $G_{i/o}$-GPCR. Similarly, an i.pl. injection of pertussis toxin (an ADP-ribosylating toxin that inactivates $G_{i/o}$ proteins) blocked CARTp-mediated behavioral hypersensitivities (n=4 males), supporting $G_{i/o}$-coupled signaling as a mode of action. In some studies, CARTp has been reported to exert its effects by modulating the N-methyl-D-aspartate receptor (NMDAR). The development of peripheral sensitization following an i.pl. injection of CARTp was not attenuated by the NMDAR antagonists, D-AP5 and MK-801 (n=3-6/group males). Therefore, CARTp-induced peripheral sensitization is not mediated by NMDAR activation; this supports our additional *in vitro* findings that CARTp is not a ligand for the NMDA receptor. In contrast, we have previously reported that, in the central nervous system, CARTp/GPR160-induced central

sensitization is mediated through mitogen activated protein kinases (MAPK) activation. We now extend these findings and show that at the molecular level, CARTp/GPR160-induced peripheral sensitization is driven by the MAPK, extracellular signal-regulated kinase (ERK). Thus, i.pl. injection of U0126, a well characterized ERK inhibitor, attenuated CARTp-induced peripheral sensitization (n=3 males). Our results suggest CARTp mediates peripheral sensitization in a $G_{i/o}$-coupled manner that is dependent on GPR160 and ERK.

Abstract: Chronic neuropathic pain is a major health issue, but the underlying mechanisms are not well understood. Moreover, the available treatment options are not effective in all cases, and some have serious side effects. Recently, we identified the purinergic G protein-coupled receptor, P2Y$_{14}$ receptor (P2Y$_{14}$R), as a potential therapeutic target. We demonstrated that systemic administration of P2Y$_{14}$R antagonists reversed mechanical hypersensitivity in a traumatic nerve injury model of neuropathic pain. However, the sites of action of the pharmacological effects caused by targeting P2Y$_{14}$R and the mechanism of action remain to be understood. To study that we used a peripheral nerve injury model of neuropathic pain, in which mice go through unilateral chronic constriction injury of the sciatic nerve (CCI). Proteomic analyses of the dorsal horn of the spinal cord at time of peak neuropathic pain (mechano-/cold allodynia hypersensitivities) after CCI revealed significant increase in P2Y$_{14}$R expression. Intrathecal (i.th.) injection of a selective P2Y$_{14}$R antagonist (PPTN) reversed neuropathic pain behavior sensitivities in CCI mice (n=5) identifying the spinal cord as a potential site of P2Y$_{14}$R activity. P2Y$_{14}$R antagonists are not ligands for and did not activate opioid receptors. Noteworthy, direct activation of P2Y$_{14}$R in the spinal cord with i.th. injection of UDP-Glucose or

a highly selective and potent $P2Y_{14}R$ agonist (MRS2690) in naïve mice (n=3 UDP-Glucose, n= 5 MRS2690) was sufficient to recapitulate neuropathic pain behavioral phenotypes. On a mechanistic level, this depended on pertussis toxin-sensitive ($G\alpha_{i/o}$-linked) and $P2Y_{14}R$-mediated extracellular signal-regulated kinase (ERK) and p38 pathways. Naïve mice (n=4 per group) failed to develop UDP-Glucose or MRS2690 induced mechanical hypersensitivity when pertussis toxin was injected i.th. beforehand. In addition, i.th. injection of ERK inhibitor (n=5) prior to MRS2690 blocked the development of mechanical hypersensitivity in naïve mice, while i.th. injection of p38 inhibitor (n=4) attenuated the development of MRS2690 induced mechanical hypersensitivity. We hypothesize that $P2Y_{14}R$ in the spinal cord is a non-opioid based therapeutic target for neuropathic pain and its antagonists produce analgesic effects through the mitogen-activated protein kinases (MAPKs) pathways. Thus, targeting $P2Y_{14}R$ represents an innovative, non-opioid receptor target for neuropathic pain therapeutic development to address the current and growing patient needs.

Title: Assessment of Psychometric Function Slopes in Individuals with Type 1 Diabetes and Diabetic Peripheral Neuropathy

Authors: *C. MORCH[1], J. MØLLER RØIKJER[2], S. S. CROOSU[3], J. B. FRØKJÆR[3], T. M. HANSEN[3], L. ARENDT-NIELSEN[4], N. EJSKJÆR[2];

Abstract: Introduction: Diabetic peripheral neuropathy (DPN) is a common complication of type 1 diabetes mellitus (T1DM), causing sensory impairments. These impairments are reflected in increased electrical and thermal thresholds jeopardizing nocifensive behavior. Paradoxical, concurrent to decreased pain perception often occurs. The aim of this study was to estimate the slope of the psychometric function to electrical stimulation to the foot as a proxy for perceptual accuracy. Methods: A total of 60 participants with T1DM (20 without (-)DPN, 20 with painless

(+)DPN, and 20 with painful (P)DPN) and 20 healthy controls (HC) were included in an initial cohort (MEDON: NCT04078516). The perception threshold to a 1ms rectangular electrical pulse was assessed as part of the assessment of peripheral nerve excitability using perception threshold tracking. Two types of specialized electrodes were used to preferentially active small and large sensory nerve fibers, respectively. During the experiment, the perception thresholds were estimated using a step up/down method. The slope and perception thresholds were estimated post-hoc by fitting the psychometrical function as a sigmodal function. The log-transformed slopes were compared between groups and nerve fiber types using a rmANOVA. Results: The excitability assessment could not be completed in 7 participants; therefore, data was reported from 73 participants. The slopes of the psychometric function were different between the groups ($p < 0.001$) being lowest for PDPN (0.14 [0.08; 0.24]mA^{-1}), followed by +DPN (0.31 [0.19; 0.52] mA^{-1}), -DPN (0.74 [0.46; 1,19] mA^{-1}) and HC (1.04 [0.64; 1.67] mA^{-1}). The slopes were generally not different between fiber types except for the +DPN group where, the slopes were lower for the large fibers (0.21 [0.11; 0.38] mA^{-1}) than the small fibers (0.48 [0.28; 0.82] mA^{-1}; $p<0.003$, Sidak) Discussion: In addition to an increased perception threshold which we have previously reported, this study showed lower slopes of the psychometric function in groups with more severe DPN, indicating an impaired discriminability of sensory stimuli. Individuals with lower psychometric function slopes are less accurate and reliable in distinguishing between stimuli there making perceptual protective judgments is impaired. Therefore, estimation of the psychometric function slope and thresholds appears to be valid tools for estimation the perceptual accuracy in persons with DPN.

Title: Mechanism of sensory neuron sensitization via $Na_V1.8$ in anti-CV2/CRMP5 autoimmune neuropathy

Authors: ***N. L. A. DUMAIRE**[1], L. SALIH[1], L. FRANÇOIS-MOUTAL[1], J. HONNORAT[2], A. MOUTAL[1];

Abstract: Mechanism of sensory neuron sensitization via Na$_V$1.8 in anti-CV2/CRMP5 autoimmune neuropathy Nicolas Dumaire[1, 2], Lyuba Salih[1, 2], Liberty François-Moutal[1, 2], Jérôme Honnorat[3], Aubin Moutal[1, 21]Department of Pharmacology and Physiology, and [2]Institute for Translational Neuroscience, Saint Louis University, Saint Louis, Missouri, [3] Team Synaptopathies and autoantibodies, Mechanisms in Integrated Life Sciences Institute, Lyon, France

Paraneoplastic neurological syndromes (PNS) are rare manifestations observed in cancer patients caused by autoantibodies. Upon immune-mediated apoptosis of tumor cells, naïve lymphocytes are exposed to the intracellular content which can trigger an autoimmune reaction. Recently classified "high-risk autoantibodies" such as CV2/Collapsin Response Mediator Protein 5 (CRMP5)-associated PNS are accompanied with a myriad of neurological symptoms, including peripheral painful neuropathy. The mechanisms by which autoantibodies can cause pain in more than 80% of patients with anti-CV2/CRMP5 are unknown. We found that anti-CV2/CRMP5 reacts with the sensory neurons of both rat and human dorsal root ganglion (DRG) expressing the pain voltage gated sodium channel Na$_V$1.8. In cultured DRG neurons, human anti-CV2/CRMP5 autoantibodies increased Na$_V$1.8 membrane localization. This suggested that the target of autoantibodies, CRMP5, could regulate Na$_V$1.8 trafficking. We found a single interaction domain between Na$_V$1.8 and CRMP5 in the first intracellular loop of the sodium channel. Using a peptide encompassing this unique amino acid sequence, we were able to dissociate the CRMP5/Na$_V$1.8 interaction. Consequently, the membrane localization of Na$_V$1.8 was potentiated in cultured sensory neurons. This shows that CRMP5 binding to Na$_V$1.8 regulates the trafficking of the channel. We next asked if anti-CV2/CRMP5 painful neuropathy relies on the increase of Na$_V$1.8 trafficking and function. Injection of human anti-CV2/CRMP5 antibodies in the paw, lowered the threshold to mechanical stimuli. This sensitization was prevented by concomitant administration of a Na$_V$1.8 inhibitor. Together, our results show that pain sensitization in anti-CV2/CRMP5 painful neuropathy is mediated by a dysregulation of Na$_V$1.8 trafficking, probably resulting from a loss of Na$_V$1.8/CRMP5 interaction.Funding: NINDS R01NS119263

Title: Evaluation of the role of α6 nicotinic receptor subunit in chronic pain using α6-GFP transgenic mice

Authors: *D. WEI[1], R. PARKER[2];
[1]Small Animal Clin. Sci. VA-MD Col. of Vet. Med., Radford, VA; [2]Small Animal Clin. Sci. VA-MD Col. of Vet. Med., Blacksburg, VA

Abstract: Novel treatments for chronic pain are needed as current treatment options are either inconsistent in efficacy across patients, or they have negative side effects. Nicotinic acetylcholine receptors (nAChRs) are attractive targets for pain studies because the various subunits assemble to form pentameric receptors expressed in many neuronal cell types, and there is a wide range of ligand sensitivity depending on the receptor subtype. We are studying the role of nAChRs during chronic pain to determine if they may be appropriate drug targets in the treatment of pain. One specific nicotinic receptor subunit of interest is the α6 subunit, which has been shown to be downregulated during the development of allodynia (Wieskopf et al., 2015; PMID: 25972004). We evaluated the α6-GFP transgenic mouse by performing von Frey withdrawal testing after unilaterally treating the mice with a spared nerve injury (SNI), injection of complete Freund's adjuvant, or a sham treatment (Mackey et al., 2012; PMID: 22836257). The tester is blinded to treatment. The 50% withdrawal threshold is then measured using the up-down method and the threshold is compared between the ipsilateral and contralateral limbs. In the SNI model, using a mixed effects model, we found that there are no significant differences between the transgenic (Tg) and wildtype (WT) mice (n_{Tg} = 11 and n_{WT} = 9); furthermore, no significant sex differences were observed (n_{males} = 11 and $n_{females}$ = 9). We did measure a change in withdrawal threshold in the treated limb up to four weeks after surgery (n=20), p = <0.0001. We quantitated α6 gene expression in dorsal root ganglion (DRGs) by qPCR (n = 9; n_{Tg} = 4, n_{WT} = 5) and saw no significant difference between WT and Tg animals when analyzed via two-way ANOVA. This preliminary data confirms that the α6-GFP mouse is a good model to evaluate α6 nAChR gene expression during allodynia using immunohistochemistry (IHC) or whole cell patch clamp electrophysiology. Quantitative IHC is used to measure α6-GFP expression in CGRP positive and negative cells. Additionally, we are recording nicotinic receptor currents in freshly isolated DRG after induction of allodynia. Therefore, we may evaluate the role of the α6 nAChR subunit during the induction of allodynia.

Title: Bladder inflammation alters CGRP and TRPV1 expression in paw afferent-rich dorsal root ganglia in a mouse model of visceral pain

Authors: *E. L. TRAN, S. A. STUEDEMANN, L. A. HAHN, L. K. CRAWFORD; Pathobiological Sci., Univ. of Wisconsin Madison, Madison, WI

Abstract: Bladder pain syndrome, which can stem from bladder inflammation, is often accompanied by referred somatic pain that is poorly understood and may be underdiagnosed in patients. In mice, bladder inflammation, or cystitis, produces secondary mechanical hypersensitivity in the hind paw skin, mirroring lower limb hypersensitivity seen in clinical studies of bladder pain patients. Yet, the mechanisms underlying this “referred pain” in mouse models of cystitis remain unclear. Literature suggests calcitonin gene related peptide (CGRP) and transient receptor potential channel V member 1 (TRPV1) increase in bladder afferents after cystitis. However, paw afferents are seldom examined in cystitis studies, despite the compelling paw phenotypes. We hypothesized that cystitis increases TRPV1 and CGRP in hind paw afferents. The L3-L5 dorsal root ganglia (DRG), rich in paw afferents, were analyzed 48 hours after induction of the intravesicular acrolein model of cystitis in adult female mice. Image analysis of multiplex immunofluorescent staining was conducted by experimenters blinded to treatments groups. Compared to vehicle-treated controls, mice with cystitis exhibited fewer CGRP-positive neurons ($p = 0.0493$, mixed effects model); however, there was a simultaneous increased density of CGRP expression amongst CGRP-positive cells, as measured by a shift towards higher area fraction ($p = 0.042$, Kolmogorov-Smirnov (KS) test). Cystitis also increased the density and intensity of TRPV1 expression amongst the TRPV1-positive cell population ($p = 0.0106$, KS test). While there was no difference in TRPV1-positive neuron counts, there was a significant shift towards increased cell size of TRPV1-positive neurons ($p = 0.0048$, KS test), suggestive of phenotype switching. Collectively, these data strongly suggest that cystitis induces molecular changes in L3-L5 DRGs, potentially altering paw afferents. In parallel, we used dual retrograde tracer injections to determine if bladder and paw afferents co-populate any of the T13 to S1 DRG in our mouse lines. While mice demonstrated zero bladder afferents in L3 and sparse bladder afferents in the L4 and L5 DRGs, the next caudal L6/S1 DRG was a site where both bladder and paw afferents were more routinely found, supporting the possibility of peripheral, intraganglionic mechanisms for referred hind paw pain. Ongoing studies examine cystitis-induced changes in L6/S1 DRG and correlate molecular findings to severity of hind paw pain. Further understanding of paw-innervating DRG will elucidate biological mechanisms of referred pain in bladder disease, perhaps highlighting the DRG as a promising target for improved pain therapies.

Title: Increased Nav1.8 Resurgent Currents Contribute to Nociceptive Neuron Hyperexcitability Induced by Spinal Cord Injury

Authors: *Y. XIAO[1], Y. PAN[1], N. LIU[2], T. CUMMINS[1];
[1]Dept. of Biology, Sch. of Science, Indiana University-Purdue Univ. Indianapolis, Indianapolis, IN; [2]Spinal Cord and Brain Injury Res. Group, Stark Neurosciences Res. Institute, Dept. of Neurolog. Surgery, Indiana Univ. Sch. of Med., Indianapolis, IN

Abstract: Chronic neuropathic pain associated with spinal cord injury (SCI) is a major medical problem. Studies have shown that moderate thoracic (T10) SCI can substantially up-regulate excitability of small diameter dorsal root ganglion (DRG) neurons in rodents. This suggests that SCI pain may arise from pathological changes in peripheral neurons. However, the underlying molecular mechanisms remain unknown. In this study, we show that SCI significantly increases classical TTX-resistant sodium currents (Nav1.8 and Nav1.9), but not TTX-sensitive sodium currents, in rat small DRG neurons. We also show that SCI almost doubles the proportion of small DRG neurons that produce TTX-resistant resurgent currents, which are unusual currents typically evoked during the repolarization phase of action potentials. These currents have a very slow onset and decay, indicating that they are mainly carried by Nav1.8. SCI increases the amplitude of the slow resurgent currents but fails to affect voltage-dependence of activation of the currents. We also show that the increase in Nav1.8 induced by SCI can be reversed by ZL0177, a small molecule that mimics the critical residues in FHF4A binding to the C-terminus of sodium channels. In SCI small DRG neurons, ZL0177 not only decreases the classical and resurgent currents of Nav1.8, but also reduces the percentage of the neurons with Nav1.8 resurgent currents. Furthermore, we show that ZL0177 significantly downregulates hyperexcitability of small DRG neurons induced by SCI. Therefore, our data demonstrate that Nav1.8 dysfunction contributes to SCI-induced hyperexcitability of nociceptive neurons and that the FHF-binding site on Nav1.8 C-terminus might be a promising therapeutic target for the treatment of SCI pain.

Title: Voltage-gated $Ca_v2.2$ calcium ion channels mediate CFA- induced heat hypersensitivity via interleukin signaling

Authors: *A.-M. SALIB[1,2], M. J. CRANE[3], A. M. JAMIESON[3], D. LIPSCOMBE[2];
[2]Dept. of Neurosci., [3]Dept. of Mol. Microbiology & Immunol., [1]BROWN UNIVERSITY, Providence, RI

Abstract: Voltage-gated calcium ion channels (Ca_v) are essential for the detection and transmission of noxious stimuli. Previously, our lab demonstrated that transient capsaicin-induced heat hypersensitivity in peripheral Trpv1 nociceptor nerve endings in skin depends on $Ca_v2.2$ channel activity (DuBreuil et al., 2021). Here, we show that Cav2.2 channels are also critical for the development of prolonged Complete Freund Adjuvant (CFA) induced heat hypersensitivity. Within one day of intraplantar CFA injection, wild type (WT) mice exhibit robust heat and mechanical hypersensitivity (n=8), while global $Ca_v2.2$ knockout mice (KO) only develop mechanical allodynia (n=12). Using CFA as a model of prolonged neuroinflammation, we show that $Ca_v2.2$ channels have a highly specialized role in the development of heat, but not mechanical, hypersensitivity, further supporting our previous studies using a capsaicin model of transient neuroinflammation. Within one day of intraplantar CFA injection, we measured increased levels of ten different cytokines in hindpaw interstitial fluid at the site of injection. Here, we show that the cytokine imprint, particularly levels of interleukins IL-1α and IL-6, are altered in mice lacking $Ca_v2.2$ (KO) and in wild type (WT) mice co-injected with CFA and the highly selective $Ca_v2.2$ inhibitor, ω-conotoxin GVIIA (n=8/group). The precise mechanism by which $Ca_v2.2$ channels mediate heat hypersensitivity in peripheral nerve endings is not fully understood, but it is likely that $Ca_v2.2$ channels are the major source of intracellular calcium that triggers vesicular release of proinflammatory mediators from nerve endings. The vesicular cargo of sensory neurons includes signaling molecules such as neuropeptides (e.g., CGRP and Substance P), glutamate, and damage-associated molecular patterns such as ATP. Reducing the release of these signaling molecules from neurons drives changes in plasma extravasation, dendritic cell migration, adhesion of immune cells to the vasculature, and the production and release of proinflammatory cytokines from stimulated leukocytes. Our data show that $Ca_v2.2$ channels in skin are critical for neuroimmune signaling cascades that trigger both transient and prolonged forms of heat hypersensitivity. Our ongoing studies will establish the relationship between $Ca_v2.2$ channel activation and interleukin release, and the resulting downstream effects of interleukins on the development of transient and prolonged hypersensitivity.

Title: Contributions of keratinocytes to traumatic nerve injury induced mechanical and cold hypersensitivity

Authors: *C. M. MECCA, A. R. MIKESELL, O. ISAEVA, C. L. STUCKY;
Cell. Biol. Neurobio. and Anat., Med. Col. of Wisconsin, Milwaukee, WI

Abstract: Neuropathic pain is a debilitating health condition that affects nearly 10% of the general population and is often associated with severe cutaneous mechanical and cold allodynia. Despite its prevalence, neuropathic pain remains one of the most challenging types of chronic pain to manage effectively. The study of non-neuronal peripheral keratinocytes in neuropathic pain may uncover novel peripheral analgesic targets that reduce the potential for undesired central nervous system (CNS) side effects and provide increased efficacy in treating pain. Recent evidence suggests that keratinocytes, a major cell type in the epidermis, play an important role in the initial processing of mechanical and thermal information and may contribute to neuropathic pain. The aim of this study is to evaluate the role of keratinocytes to touch and cold pain after traumatic nerve injury, where the keratinocytes themselves are not directly injured. To investigate this, a surgical model of traumatic nerve injury, the tibial spared nerve injury (tSNI), was used. We found that optogenetic inhibition of keratinocytes can attenuate tSNI-induced cold and mechanical allodynia but does not alter behavioral responses to radiant heat. Furthermore, extrudate collected from cultured keratinocytes isolated from tSNI mice promotes (1) behavioral mechanical hypersensitivity when injected into naïve mouse paws and (2) increased calcium responses to a low potassium test stimulus (20mM KCl) in naïve sensory neuron cultures in calcium imaging experiments. Together, these findings highlight the importance that keratinocytes may play in hypersensitivity after nerve injury.

Title: Monocyte-derived cells control the induction of hyperalgesic priming through intracellular NAAA-regulated lipid signaling

Authors: Y. FOTIO, ***A. MABOU TAGNE**, E. SQUIRE, H.-L. LEE, F. AHMED, D. PIOMELLI;
Univ. of California, Irvine, Irvine, CA

Abstract: Chronic pain is a burdensome condition necessitating improved management strategies. Understanding the mechanisms underlying chronic pain development is crucial for identifying therapeutic targets. The hyperalgesic priming (HP) model, involving prolonged hypersensitivity following an initial inflammatory insult, sheds light on the molecular mechanisms contributing to pain chronification. We investigated the role of N-acylethanolamine acid amidase (NAAA), a cysteine hydrolase, in HP induction. HP was induced by injecting a low dose of IL-6 into the hind paw of male and female mice, causing acute hypersensitivity to heat stimuli lasting less than 24 hours. Subsequent administration of PGE2 one week later prolonged heat hyperalgesia in primed mice, while non-primed animals experienced transient hyperalgesic effects. Pharmacological inhibition of NAAA using ARN19702 was employed to assess its contribution to HP. Preemptive ARN19702 administration relieved IL-6-induced heat hyperalgesia yet had no effect on long-lasting hypersensitivity caused by PGE2 in primed animals. However, post-IL-6 injection ARN19702 administration prevented HP development, as indicated by the absence of lasting hyperalgesic effects of PGE2 in primed mice. Genetic loss-of-function experiments in NAAA-deficient mice confirmed these results. Investigation with the peripherally-preferring NAAA inhibitor, ARN726, suggested that NAAA likely drives HP in peripheral tissues. Increased NAAA activity disrupted PEA-regulated PPAR-α signaling in the periphery, while PEA administration effectively halted HP induction. Monocyte-derived cells were identified as the cellular substrate for NAAA-mediated HP induction. Mice lacking NAAA in CD11b+ cells exhibited reduced IL-6-induced hyperalgesia and failed to develop lasting hypersensitivity to PGE2, while NAAA overexpression in these cells resulted in persistent hypersensitivity. Disruption of PPAR-α signaling in monocyte-derived cells abolished HP, emphasizing intact PPAR-α signaling requirement. Together, these findings underscore the indispensable role of peripheral NAAA-regulated PPAR-α signaling in monocyte-derived cells for HP induction. Insights gained into the underlying mechanisms of HP may contribute to novel therapeutic approaches for chronic pain management.

Title: Exploring the role of Gβ5/R7-RGS complex in nociceptors of the trigeminal ganglion

Authors: *N. MOKHASI, J. STAPLES, J. ZHANG, K. DEGNER, M. PANDEY, W. SIMONDS;
Natl. Inst. of Diabetes and Digestive and Kidney Dis., Bethesda, MD

Abstract: The trigeminal ganglion contains cell bodies of the sensory nerves that innervate the face and head to mediate itch, pain and other sensations. Chronic damage to these nerves may cause painful conditions like trigeminal neuralgia. Clinical treatment of trigeminal pain often relies on anticonvulsant drugs with significant neurological side effects. Lack of effective and convenient treatments of the disease highlights the need for more effective and targeted therapeutic approaches. GNB5 encodes the protein Gβ5, a divergent member of the G protein β family, that binds with each member (RGS6, 7, 9 and 11) of the R7 subfamily of the regulators of G signaling (R7-RGS) to form obligate Gβ5/R7-RGS complexes. The Gβ5/R7-RGS complex proteins are expressed primarily in neuronal cells and function as GTPase-Activating Proteins to dampen signaling downstream of Gi/o-coupled receptors. Studies in our lab of conditional knockout of Gnb5 from sensory neurons mediated by Advillin-Cre in *Gnb5*$^{fl/fl}$ mice have shown significant reduction in mechanical, thermal and chemical nociception. However, Rgs7-cre mediated conditional Gnb5 knockout only diminished mechanical nociception. Additionally, treatment with 2- hydroxysaclofen (a GABA-B receptor antagonist) abolished the decrease of mechanical nociception in both Advillin- Cre$^{+/-}$; *Gnb5*$^{fl/fl}$ and Rgs7-Cre$^{+/-}$; *Gnb5*$^{fl/fl}$ mice implicating the involvement of GABA-B receptor signaling in Gβ5/Rgs7-associated mechanical nociception. To further understand the cellular and molecular mechanisms of Gβ5/R7-RGS complex-mediated nociception in trigeminal ganglion, we conducted bioinformatic analysis of publicly available scRNAseq datasets using the established sensory neuron markers, in order to find the cell-type expression patterns of Gnb5 and R7-RGS transcripts. We found high levels of Gnb5 expression in all sensory neuron cell types of the trigeminal ganglion while the expressions of members of R7-RGS subfamily showed distinctive patterns among different cell types. Rgs7 and Rgs11 were found highly expressed in non-peptidergic neuron clusters, while Rgs9 was mainly localized to peptidergic clusters. Rgs6 showed little or no expression across the trigeminal ganglion. Using RNAscope Hi-Plex in-situ hybridization techniques, we aim to verify these findings and explore the potential mechanisms of the behavioral test results.

Title: Meteorin Treatment Resolves Cisplatin Induced Peripheral Neuropathic Pain in Mice

Authors: *L. HE[1], I. SANKARANARAYANAN[1], T. M. MADSEN[2], K. A. PETERSEN[2], G. MUNRO[2], T. J. PRICE[1];

Abstract: Cisplatin is a potent alkylating agent that can induce chemotherapy-induced peripheral neuropathy (CIPN) and chronic pain. This severely limits its usefulness as a cancer treatment and negatively impacts patient outcomes. Evidence suggests that CIPN arises as a consequence of molecular alterations in dorsal root ganglion (DRG) neurons and their neighboring satellite glial cells that lead to functional changes generating hyperexcitability. CIPN is also associated with a more distal loss of intraepidermal nerve fibers in the skin. Meteorin is a secreted protein that plays a fundamental role in the development of the nervous system. Previous studies have shown that systemic treatment with recombinant mouse meteorin (rmMeteorin) produces robust, long-lasting antinociception in rodent models of peripheral neuropathic pain and paclitaxel induced peripheral neuropathy. To investigate a broader role for Meteorin therapy in CIPN, we treated female ICR mice with 2 cycles of cisplatin (2mg/kg, 5 x i.p.) or vehicle through Days 1-15 in the current study. Hind paw withdrawal thresholds to mechanical stimulation were assessed using Von Frey filaments. Once hypersensitivity was established, rmMeteorin (1.8mg/kg, 5 x s.c.) or vehicle was administered every other day from Day 18, and withdrawal thresholds routinely assessed until Day 79. Lumbar DRGs and hind paw skin were collected from 4 mice for each treatment group on Day 34 for immunohistochemical processing. Cisplatin-induced mechanical hypersensitivity was significantly reversed after a second injection of rmMeteorin and persisted throughout, and even beyond the dosing duration. Moreover, cisplatin-mediated changes in DRG expression of the gap junction protein Connexin43 and the satellite glial cell marker glutamine synthase were both restored by rmMeteorin administration. Intraepidermal nerve fibers in the skin were also protected from cisplatin-induced loss by rmMeteorin. The resolution of preclinical behavioral and cellular correlates of CIPN in cisplatin mice with rmMeteorin treatment, supports similar findings obtained in mice with paclitaxel-induced neuropathic pain.

Title: Pro-inflammatory macrophages transfer of miR-155 enriched extracellular vesicles to dorsal root ganglia neurons

Authors: F. PICCO[1], L. ZEBOUDJ[2], S. OGGERO[2], V. PRATO[3], N. GAMPER[4], *M. MALCANGIO[5];
[1]Wolfson CARD, [2]King's Col. London, London, United Kingdom; [3]Fac. of Biol. Sci., Univ. of Leeds, Leeds, United Kingdom; [4]Nikita Gamper, Univ. Leeds, Leeds, United Kingdom; [5]Kings Col. London, London, United Kingdom

Abstract: Peripheral nerve damage is associated with up-regulation of non-coding RNAs such as miR-21 in sensory neurons and accumulation of macrophages in the dorsal root ganglia (DRG). We have previously reported that sensory neurons communicate with macrophages by shuttling exosomes that regulate nociceptive mechanisms under neuropathic pain conditions (PMID: 29176651). Here, we investigated whether macrophages release extracellular vesicles (EVs) containing specific microRNAs which are transferred to sensory neurons. We polarised bone marrow derived macrophages (BMDMs) to M1-like phenotype by lipopolysaccharide incubation (LPS 100 ng/ml for 16 h), isolated EVs in supernatants by ultracentrifugation at 100,000 g at 4ºC for 1 h and performed EV size distribution analysis (NS300 Nanoparticle Tracker). In both vehicle and LPS supernatants we quantified $2*10^8 \pm 0.4$ particles/ml and mean size of 150 ± 7.3 nm (n=4 replicates). Next, using Western blot we quantified BMDM-derived EV markers and found expression of tumour susceptibility gene 101 (TSG-101; exosome marker), but not annexin-A1 (ectosome marker) and calnexin (intracellular marker that rules out extracellular contamination). Thus, these results suggest that BMDMs release mainly exosomes after LPS stimulation, and we then evaluated whether such exosomes contain a signature microRNA (miR). Using RT-qPCR of six selected miRs we found that LPS induced intracellular upregulation of miR-155 (427 ± 74 -fold increase over internal Spike-in control) that was also found in the EVs (24 ± 7 -fold increase; n=5-6 replicates). Relevantly, miR-155 was not enriched in cultured DRG neuron-released EVs following incubation of LPS (100 ng/ml, 3 h) and capsaicin (1µM, 3 h) whilst as expected miR-21 was found in capsaicin-released EVs (2 ± 0.3 -fold increase; n=3 replicates). Having found miR-155 in EVs derived from LPS polarized BMDMs, we next transfected BMDMs with pHluorin-CD63 plasmid, isolated CD63-pHluorin-tagged EVs and exposed DRG neurons for 24h with these EVs (100 µg). We analyzed possible EV occurrence in neurons by AiryScan high resolution confocal microscopy and observed that some neurons (marker Tuj1) contained pHluorin-EVs. Moreover, we detected higher levels of miR-155 (4 ± 0.7 -fold increase), interleukin-6 (*Il-6*, 53 ± 20 -fold increase) but not *glycoprotein gp130* or miR-21 in DRG neurons incubated with LPS-BMDM-derived EVs (n=4 replicates). Our findings suggest that miR-155 is enriched in EVs released by M1-like macrophages and such EVs are taken up by neurons and modulate gene expression.

Title: Effects of systemic oxytocin administration on UVB-induced nociceptive hypersensitivity and tactile hyposensitivity in mice.

Authors: *M. BOADA, **S. GUTIERREZ**, J. EISENACH;
Anesthesiol., Wake Forest Univ. Baptist Med. Ctr., Winston Salem, NC

Abstract: UVB radiation induces cutaneous inflammation, leading to thermal and mechanical hypersensitivity. Here we examine the mechanical properties and profile of tactile and nociceptive peripheral afferents functionally disrupted by this injury and the role of oxytocin (OXT) as a modulator of this disruption. We recorded intracellularly for L4 afferents innervating the irradiated area (5.1 J/cm2) in 4-6 old week male mice (C57BL/6J) after administering OXT IP, 6 mg/Kg. The distribution of neurons characterized was shifted by UVB radiation to a pattern observed after acute and chronic injuries and reduced mechanical thresholds of A and C- high threshold mechanoreceptors while reducing the sensitivity of tactile afferents (low threshold mechano receptors). UVB radiation did not change somatic membrane electrical properties or fibers conduction velocity. OXT systemic administration rapidly reversed these peripheral changes toward normal in both low and high-threshold mechanoreceptors and returned the distribution of characterized neurons toward normal. OXT and V1aR receptors were present on the terminals of myelinated and unmyelinated afferents innervating the skin. We conclude that UVB radiation, similar to local tissue surgical injury, cancer metastasis, and peripheral nerve injury, alters the distribution of low and high threshold mechanoreceptors afferents and sensitizes nociceptors while desensitizing tactile units. Acute systemic OXT administration partially returns all of those effects to normal.

Title: Involvement of Lysophospholipids in trigeminal ganglion in neuropathic pain of orofacial region

Authors: *R. KURISU, Y. YAMAZAKI, S. MAEDA;
Tokyo Med. and Dent. Univ., Bunkyo-ku / Tokyo prefecture, Japan

Abstract: Object: The mechanism of neuropathic pain in the orofacial region is still unclear, and treatment is often difficult. Neuropathic pain refers to a type of chronic pain that is caused by damage or dysfunction in the nervous system. Lysophosphatidic acid (LPA), one of the lysophospholipids, is involved in neuropathic pain. In this study, we aimed to elucidate the involvement of LPA in facial mechanical allodynia that develops after infraorbital nerve injury (IONI) in a rat model of infraorbital nerve injury.
Methods: We used male Sprague Dawley rats in all experiments. The rats were deeply anesthetized with an intraperitoneal (i.p.) injection of a mixture containing butorphanol (2.5 mg/kg; Meiji Seika Pharma, Tokyo, Japan), midazolam (2.0 mg/kg; Sandoz, Tokyo, Japan), and medetomidine (0.15 mg/kg; Zenoaq, Fukushima, Japan). The top of the head was shaved, and the rats were then placed in a stereotaxic apparatus. After exposing the skull, a small hole with a diameter of 1 mm was drilled directly above the ipsilateral trigeminal ganglion to the infraorbital nerve injury (IONI) or sham operation. The guide cannula was extended into the trigeminal ganglion through the hole and was fixed. Following cannulation, the rats were allowed to recover for seven days before conducting experiments. One week later, the left infraorbital nerve was partially ligated under deep anesthesia to induce the IONI model in rats treated with LPA (IONI-LPA). Other groups included naïve rats treated with LPA (naïve-LPA), IONI rats treated with saline (NS) (IONI-NS), and naïve rats treated with NS (naïve-NS). The mechanical head-withdrawal threshold (MHWT) of the left whisker pad skin was measured using von Frey filaments every other day before and up to 14 days after the injury. Lysophosphatidic acid (LPA; 1 µl, 1 mM) or vehicle (NS) was administered daily into the trigeminal ganglion under 2% isoflurane anesthesia from day 1 to day 7 after suborbital nerve injury, and the MHWT in the moustache area was measured until day 14 after injury.
Results: MHWT in the IONI-LPA group was significantly lower than that in the naïve-NS group from day 2 to day 10 after injury. The naïve-LPA group showed significantly lower MHWT than the naïve-NS group from day 2 to day 10 and day 14 after injury. There was no significant difference between the IONI-LPA and naïve-LPA groups.
Discussion: This result suggests that LPA may be involved in facial mechanical allodynia that develops after infraorbital nerve injury. Further research is needed to explore the underlying mechanisms and potential interventions targeting LPA in the management of neuropathic pain.

Title: Small molecules with neuroprotective effects against in vitro bortezomib-induced axonopathy and altered cytosolic calcium responses in dorsal root ganglia sensory neurons

Authors: *J. VALENCIA LESMES[1], L. MURPHY[1], I. UTKINA-SOSUNOVA[4], S. PRZEDBORSKI[4], D. BAUTISTA[2], E. LUMPKIN[3];
[1]Mol. and Cell Biol., UC Berkeley, Berkeley, CA; [2]UC Berkeley, BERKELEY, CA; [3]UC Berkeley, Berkeley, CA; [4]Columbia Univ., New York, NY

Abstract: Chemotherapy-induced peripheral neuropathy (CIPN) is a dose-limiting adverse outcome of many cancer chemotherapeutics that results in permanent symptoms and disability in up to 40% of cancer survivors. Individuals with CIPN can experience numbness, pain and/or burning sensations in the feet and hands. Among chemotherapeutics, Bortezomib (BTZ) is commonly used to treat multiple myeloma. To date, there is no standard for prevention and/or treatment of BTZ-induced CIPN (BIPN). We developed a high-content, live-cell imaging assay to validate potentially neuroprotective hits from an FDA-approved small molecule library screen (Utkina-Sosunova et al., 2022). Adult mouse dorsal root ganglia (DRG) neurons from 8-9 week old *Pirt^{Cre}; tdTomato/+* males were cultured in 96-well plates for 4 days *in vitro* (DIV4) followed by 48 h of either vehicle (0.1% DMSO), 3 nM BTZ treatment, or BTZ plus a small molecule of interest. Fluorescence imaging was performed at 24-h intervals to assess neurite outgrowth and BTZ-induced axonopathy. On DIV6, cultured cells were loaded with Fluo-4 AM for live-cell calcium imaging to assess neuronal responsiveness to a nociceptive stimulus (1 μM capsaicin) and depolarization (70 mM K^+). As previously observed, BTZ reduced the neurite length per cell by 63 ± 11% compared with vehicle-treated control neurons (DMSO 3039.0 ± 240.5 μm/cell, BTZ 1120.0 ± 341.8 μm/cell; P=0.01, Student's t test, two-tailed; n=3 biological replicates, n=4-8 technical replicates). Two compounds from this secondary screen showed neuroprotection in this assay, with reductions of neurite lengths of 29.1 ± 8% and 35.4 ± 10.4% (n=3 biological replicates, n=4 technical replicates). In live-cell calcium imaging experiments, BTZ increased the resting cytosolic calcium concentration, decreased the number of capsaicin responding neurons, and decreased the calcium response to high K^+-evoked depolarization. The two neuroprotective compounds partially reversed these effects. We are now poised to test these validated molecules in human DRG neurons for the treatment of BIPN. *These authors contributed equally. REFERENCES I. **UTKINA-SOSUNOVA**, H. LI, E. TATISHEV, C. Title: Modulation of TRPV1 Activation via Direct Binding of GLP-1R Antagonist, Exendin 9-39

Authors: ***E. GO**[1], H. JO[1], M. RAHMAN[1], Y. JO[2], Y. KIM[1], C. PARK[1];
[1]Gachon Univ. of Med. and Sci., Yeonsu-gu, Korea, Republic of; [2]Dept. of Anesthesiol. and Pain Med., Gil Med. Center, Gachon Univ., Yeonsu-gu, Korea, Republic of

Abstract: Transient receptor potential vanilloid 1 (TRPV1) channels, polymodal nociceptors activated by factors such as capsaicin (CAP), protons, or heat, are known to contribute significantly to chronic pain states. Upregulation of TRPV1 channels under such conditions reduces stimulation thresholds and exacerbates pain perception, manifesting as hyperalgesia or allodynia. Despite ongoing efforts to discover drugs targeting these channels, side effects like hyperthermia have hampered clinical development. In light of recent studies revealing the antinociceptive effects of glucagon-like peptide 1 (GLP-1) analogs in neuropathic pain through GLP-1 receptor (GLP-1R) activation, we investigated the role of Exendin 9-39, a GLP-1R antagonist, in modulating TRPV1 activation. Our finding showed that Exendin 9-39 exhibited the greatest inhibitory effect (IC50 28.18 ± 3.92 nM) on CAP-induced TRPV1 channel activation among all tested GLP-1R agonists. Additionally, cell-attached and inside-out patch clamp recordings indicated that Exendin 9-39 likely binds an extracellular site of human TRPV1 channels, thereby preventing activation. Given the hyperthermia side effect associated with previously developed TRPV1 antagonists, we examined the impact of Exendin 9-39 on the proton activation mode of the TRPV1 channels. Exendin 9-39 demonstrated minimal impact on TRPV1 even when applied at concentrations 30 times greater than its IC50 for CAP, indicating its potential to act as a modality-selective antagonist of the TRPV1 channels. Lastly, the analgesic effect of Exendin 9-39 was tested in an acute mouse pain model. Intraplantar administration of Exendin 9-39 following a CAP injection resulted in a dose-dependent alleviation of CAP-induced spontaneous pain. This finding supports the potential candidacy of Exendin 9-39 as a therapeutic agent in pain management.

Title: Elevated heme drives evoked and ongoing pain behaviors in WT mice by sensitization of dorsal root ganglia neurons

Authors: *S. ZORN[1], V. L. EHLERS[2], C. L. STUCKY[3];
[1]Med. Col. of Wisconsin, MILWAUKEE, WI; [2]Med. Col. of Wisconsin, Milwaukee, WI; [3]Cell Biology, Neurobio. & Anat., Med. Col. of Wisconsin Neurosci. Doctoral Program, Milwaukee, WI

Abstract: Individuals with sickle cell disease (SCD) suffer from complex stimulus-evoked and ongoing pain that is mediated in part by the hyperexcitability of their peripheral sensory neurons. However, it is unclear whether acute or chronic elevation of cell free heme, a key pathological feature of SCD, contributes to the aberrant activity of sensory neurons. Thus, determining whether heme drives pain behavior and enhanced excitability of dorsal root ganglia (DRG) primary sensory neurons involved in pain signal transduction is critical for the development of targeted pain therapies for SCD. In the current experiments, we use evoked and ongoing pain behavior assays and in vitro calcium imaging to evaluate the hypothesis that acute increases in heme causes direct sensitization of nociceptive DRG neurons in wildtype (WT) mice. Our preliminary data reveal that similar to pain behaviors in the mouse model of SCD, hind paw injection of heme into WT mice induces mechanical and cold hypersensitivity. These data suggest that axon terminals in the skin become sensitized when exposed to elevated heme. We next administered heme to primary cultured DRG neurons in vitro and observed calcium flux across the neuronal cell membrane that was dependent on extracellular calcium. Together, these data suggest that heme opens calcium channels on sensory neurons to drive acute pain behaviors. As ongoing activity of nociceptive neurons may cause pain signal transduction in the absence of external stimuli, we will next use current clamp electrophysiology to determine whether application of heme to cultured DRG neurons is sufficient to induce action potential generation. We will further determine whether exposure to heme enhances the intrinsic excitability of mechanical and cold-sensitive neurons that may lead to our observed acute onset mechanical and cold hypersensitivity in heme-injected mice. Completion of these experiments will shed light on the contributions of cell free heme to SCD pain and illuminate downstream effectors that may be targeted to provide analgesic relief for this historically understudied and debilitating disease.

Title: Early life pain alters the response to an immune challenge in adult male and female rats

Authors: *M. GOMEZ, M. MACIK, H. HARDER, M. PANDIT, A. Z. MURPHY;
Neurosci. Inst., Georgia State Univ., Atlanta, GA

Abstract: Premature infants are more likely to be admitted to the Neonatal Intensive Care Unit (NICU) where they experience upwards of 10-18 painful procedures each day, often without anesthesia or analgesia. Preclinical and clinical studies have shown that neonatal pain disrupts normal CNS development in multiple ways that persist into adulthood. We have previously reported that early life pain results in an exaggerated febrile response to an immune challenge (administration of lipopolysaccharide; LPS) in adulthood. Administration of LPS induces the release of inflammatory cytokines in the periphery to stimulate prostaglandin E2 (PGE2) production. Centrally, PGE2 binding to the EP3 receptor (EP3R) within the hypothalamic median preoptic area (MnPO) induces a pyrogenic (fever) response. Microglia also change their morphology and release cytokines into the CNS as part of the immune response. Here, we investigate if early life pain (ELP) alters PGE2 signaling within the MnPO and the involvement of microglia in this response. Male and female rats were exposed to a short-term inflammatory insult induced by intraplantar administration of 1% carrageenan on the day of birth (P0). In adulthood (P60-P90), Thermicron iButtons were implanted to monitor core body temperature; 14 days later, LPS was injected to elicit an immune response. Rats were sacrificed at one of 3 time points post-LPS: 24 hours, peak fever, or 2 hours (fever initiation). Brain tissue was analyzed via immunohistochemistry for VGAT, VGLUT, Fos, prostaglandin receptor 3, and Cd11b within the MnPO and Cox-2 within the organum vasculosum of the lamina terminalis (OVLT). A whole brain survey of Fos activation patterns was also conducted to analyze the global brain response to LPS. Reconstructions and analysis of morphological changes in Cd11b+ microglia were conducted using Imaris. LPS administration resulted in an elevated febrile response in ELP males and females compared to controls and increased sickness behaviors in ELP females. Immunohistological analysis revealed sex and treatment differences in cellular activation in several brain regions and increased receptor and transporter expression in the MnPO in ELP rats. Cox-2 expression is also increased at peak fever in ELP rats. Together, these studies are consistent with clinical studies reporting that children experiencing unresolved pain during the perinatal period show increased severity of sickness behavior and altered immune signaling following exposure to a pathogen and will provide a foundation for future studies examining the biological underpinnings.

Title: Spinal adenosinergic signaling mechanisms inhibit lamina I NK1 receptor-expressing neurons following electrical stimulation of Aβ-fibers after nerve injury

Authors: *N. C. FORD[1], X. CUI[1], S.-Q. HE[1], C. ZHANG[1], G. ZHU[1], X. DONG[2], S. N. RAJA[1], Y. GUAN[1];

Abstract: Background: Peripheral nerve stimulation (PNS) is an emerging candidate for effective opioid-sparing pain treatment. The Gate Control Theory asserts that spinal pain signal transmission is gated by inhibitory interneurons which can be activated by Aβ-fiber impulses. However, the detailed mechanisms that contribute to synaptic inhibition after PNS, such as 50 Hz Aβ-fiber stimulation, remain partially understood. Although adenosine A1 and A3 receptors (A1Rs/A3Rs) are expressed in the spinal cord, their roles in PNS-induced inhibition of spinal projection neuron synapses were unclear.
Methods: We used a multidisciplinary approach to investigate the influence of PNS-induced A1 and A3R signaling onto lamina I NK1R-GFP neurons, ~80% of which are projection neurons. Moreover, we examined the impact of endogenous adenosine metabolism modulation on PNS-induced synaptic inhibition. *NK1R-GFP* knockin mice were developed to facilitate the identification of NK1R+ neurons in the spinal cord. Neuropathic pain was induced by tibial spared-nerve injury (SNI-t) to the left hindlimbs of NK1R-GFP mice. Immunohistochemistry, RNA scope, and western blot analysis were used to investigate A1R and A3R expression in NK1R+ neurons in the spinal cord from naïve and neuropathic mice. Patch-clamp electrophysiology was used to elucidate the influence of A1 and A3R signaling and 50 Hz PNS on C-fiber-evoked excitatory post-synaptic currents (C-eEPSCs) in NK1R-GFP neurons.
Results: NK1R-GFP+ neurons in lamina I express A1 and A3Rs, and SNI-t significantly increased the level of both in the spinal cord. Importantly, 50 Hz PNS inhibited C-eEPSCs, which was significantly attenuated by bath-application of both A1 and A3R antagonist DPCPX (1 μM) and MRS1523 (30 nM). In contrast, blocking the adenosine deaminase-dependent conversion of adenosine to inosine with bath-applied deoxycoformycin (dCF; 1 μM) significantly increased the synaptic inhibition of NK1R-GFP neurons by 50 Hz PNS.
Conclusion: Nociceptive transmission in lamina I NK1R-GFP neurons may be dampened by 50

Hz PNS through activation of A1 and A3Rs. Moreover, inhibiting adenosine deaminase which would increase the level of adenosine accumulated in the synapse enhanced the overall synaptic inhibition produced by 50 Hz PNS. Thus, AR activation may serve as a key mechanism for the synaptic inhibitory effects of 50 Hz PNS, the effects of which can be amplified with enzyme inhibitors to increase its clinical efficacy for the management of neuropathic pain.

Title: General anesthesia-activated neurons in the central amygdala regulates pain and pain-induced anxiety in mice

Authors: *J. ZHAO[1], A. MCGINNIS[1], M. YUAN[1], J. MATHEW[1], F. WANG[2], R.-R. JI[1]; [1]Duke Univ., Durham, NC; [2]MIT, Cambridge, MA

Abstract: General anesthesia, such as isoflurane, produces analgesia (loss of pain) and loss of consciousness via different mechanisms, but the underlying mechanisms are not well understood. Recent study showed that a distinct population of GABAergic neurons in the central amygdala can be activated by general anesthesia and play an important role in analgesia. To further characterize the electrophysiological properties and analgesic effects of these general anesthesia activated neurons, we used 1.2% isoflurane to induce c-Fos activation in the mouse brain and validated the c-Fos expression by *in situ* hybridization. Our results showed that several brain regions, including the central amygdala (CeA), paraventricular nucleus of the thalamus (PVT), paraventricular nucleus of the hypothalamus (PVN), and supraoptic nucleus (SON), were robustly activated by isoflurane. Using three-color fluorescence *in situ* hybridization, we found that c-Fos$^+$ neurons in CeA were mainly GABAergic neurons (Vgat$^+$), while c-Fos$^+$ neurons in other regions were mainly glutamatergic neurons (Vglut2$^+$). Additionally, we confirmed that c-Fos$^+$ neurons in CeA were mostly protein kinase C (PKC)-delta (Prkcd$^+$) neurons and not somatostatin (Sst$^+$) neurons. Our *ex vivo* electrophysiological recordings in brain slices revealed that c-Fos$^+$ neurons in CeA had increased neuronal excitability and exhibited a distinct action potential pattern compared to c-Fos$^-$ neurons. To investigate the analgesic effects of the isoflurane-induced c-Fos$^+$ CeA neurons, we used a chemogenetic approach (DREADDs) to activate these neurons. Our results showed that chemogenetic activation of isoflurane-induced c-Fos$^+$ neurons in CeA was sufficient to increase pain thresholds in both naïve mice and mice with

nerve injury and neuropathic pain. In addition, chemogenetic activation of these neurons in CeA abolished pain induced anxiety-like behaviors. These findings suggest that targeting isoflurane-induced c-Fos$^+$ CeA neurons may provide therapeutic benefits for pain and its comorbidities management.

Title: Activating Fc-gamma Receptors Mediate Sciatic Nerve Injury-induced Neuropathic Pain

Authors: *F. LIU[1], L. ZHANG[2], X.-S. YIN[1], W. QIU[1], C. MA[1];
[1]Inst. of Basic Med. Sci. Chinese Acad. of Med. Sci., Beijing, China; [2]Beijing Friendship Hospital, Capital Med. Univ., Beijing, China

Abstract: Neuropathic pain is difficult to treat in clinical practice, and the underlying mechanisms are insufficiently elucidated. Previous studies have demonstrated that Fc receptors may be involved in pain. However, the mechanisms of FcγRs in neuropathic pain remain to be explored. Here, we found that Fc-gamma receptors (FcγRs), including FcγRI, FcγRII, and FcγRIII, and Fc-epsilon receptor I gamma (FcεRIγ) mRNA were upregulated in the spinal dorsal horn (SDH) of a mouse model of sciatic nerve injury (CCI) using mRNA sequencing. FcεRIγ associates with activating Fc-gamma receptor on the cell surface to form a functional signaling complex and regulate immune responses. Our work also revealed that FcγRI, FcγRIII and FcεRIγ were expressed in microglial cells of the SDH after CCI. Meanwhile, sciatic nerve injury persistently and significantly increases the protein levels of FcγRI, FcγRIII and FcεRIγ in the SDH after neuropathic pain. Furthermore, knockout of the FcγRs or FcεRIγ-encoding gene *Fcer1g* significantly alleviated neuropathic pain in mice after CCI. Overexpression of FcεRIγ in the SDH by the adeno-associated virus (AAV)-*Fcer1g* vector evokes chronic pain in wild-type mice. These results indicate that the microglial complex of the SDH plays an important role in

the development of neuropathic pain in chronic constriction injury mice. The findings may provide novel insights into potential therapeutic targets for neuropathic pain.

Title: Parvalbumin gates chronic pain through the modulation of tonic firing in inhibitory neurons

Authors: *H. QIU, L. S. MIRAUCOURT, A. DAVIDOVA, R. SHARIF NAEINI; Dept. of Physiol., McGill Univ., Montreal, QC, Canada

Abstract: Spinal cord dorsal horn inhibition is critical to the processing of sensory inputs, and its impairment leads to mechanical allodynia. How this decreased inhibition occurs and whether its restoration alleviates allodynic pain is poorly understood. Here, we show that the calcium (Ca^{2+})-binding protein, parvalbumin (PV), controls the activity of inhibitory PV-expressing neurons (PVNs) by enabling them to sustain high-frequency tonic firing patterns. Upon nerve injury, PVNs transition to adaptive firing and decrease their PV expression. Interestingly, decreased PV is necessary and sufficient to the development of mechanical allodynia and the transition of PVNs to adaptive firing. This transition of firing pattern is due to the recruitment of calcium-activated potassium (SK) channels and blocking them during chronic pain restores normal tonic firing and alleviates mechanical allodynia. Our findings indicate that PV is essential to the firing activity of PVNs and in preventing allodynia, these observations may lead to novel strategies for chronic pain relief.

Title: Acute and chronic neuropathic pain impact on corticostriatal circuit function

Authors: *A. J. GEORGE, D. J. MARGOLIS, V. E. ABRAIRA;
Cell Biol. and Neurosci., Rutgers Univ., Piscataway, NJ

Abstract: Chronic pain (>3 months) affects over 50 million Americans, limiting their life and daily activities, and creating a public health crisis. Although there are available treatments for those experiencing acute pain, there is a lack of understanding of the central circuits involved in chronic pain. One candidate involved in pain is the striatum which is known for sensorimotor integration and facilitating voluntary movement, particularly with the interplay between the GABAergic dopamine receptor 1 (D1N) cells and dopamine receptor 2 (D2N) -expressing principal neurons. The striatum can mediate analgesic action in orofacial pain by activating striatal D2N pathways. However, the striatal mechanisms underlying chronic neuropathic pain are largely unknown. The striatum also has inputs from the primary somatosensory cortex (S1) that contribute to pain processing. S1 is known to process somatic sensations including nociception and touch and its activity changes during pain. In addition to the spinothalamic tract,

S1 also has direct projections to the striatum, and plasticity changes in this pathway could point to a mechanism involved in the transition from acute to chronic pain. Our overarching hypothesis is that the transition from acute to chronic pain results in the heightened expression of pain-related behaviors driven by the hyperactivity of S1 leading to overactive striatal D2N populations to mediate analgesic action. We tested this hypothesis using D1-Cre::Ai14 and A2A-Cre::Ai14 mice in a neuropathic pain model using spared nerve injury and optogenetically stimulating the S1-D1N and S1-D2N pathways. We expect to find changes associated with acute and chronic pain states. Furthermore, we characterized specific striatal populations during pain behavioral assessments, and we expect to find differences in D1N and D2N bulk calcium signaling in response to innocuous and painful stimuli during the acute and chronic pain states. The collective results will provide an understanding of the functional role of corticostriatal pathways, and the activation of striatal D1N and D2N circuits, in the transition from acute to chronic pain.

Title: Chronic Neuropathic Pain Alters Representation of Noxious Stimuli in the Primary Somatosensory Cortex: A Longitudinal Study in a Mouse Model of Infraorbital Nerve Constriction

Authors: *E. LENDARO[1], M. LEVY[2], A. PEARCE[3], V. PREVOSTO[2], F. WANG[4];
[1]MIT, Boston, MA; [2]Brain and Cognitive Sci., [3]Massachussets Inst. of Technol., Cambridge, MA; [4]Brain and Cognitive Sci., Massachussets Inst. of Technol., cambridge, MA

Abstract: Nociception, the sensory nervous system's response to harmful stimuli, is fundamental to the perception of pain and essential for survival. Chronic pain conditions, such as neuropathic pain, can disrupt the processing of noxious and innocuous stimuli, leading to exacerbated perceptual correlates such as hyperalgesia, allodynia, and spontaneous pain.
In this longitudinal study, we investigate how infraorbital chronic nerve constriction, a mouse model of trigeminal neuropathic pain, affects the cortical processing of innocuous and noxious somatosensory stimuli applied to the face (whisker pad region). We focused on two sub-areas of the primary somatosensory cortex (S1): the barrel cortex (S1bc) and the dysgranular zone (S1dz). S1dz has been proposed to be a homolog of primate area 3a and implicated in the processing of proprioceptive inputs as well as in face nociception. However, how nociceptive, proprioceptive

and motor information are integrated in S1 during nocifensive behaviors and how it changes during chronic pain states is currently unknown.
We performed weekly wide-field and two-photon calcium imaging before and for one month following surgical induction of chronic neuropathic pain, tracking cortical responses at the mesoscale and cellular levels during the application of two distinct types of somatosensory stimuli: mechanical ("pin-prick" pole and 0.02g-1g von Frey filament) and thermal (0-200ms infrared laser pulse). At the same time, we tracked the animal movements during nocifensive behaviors and analyzed them using DeepLabCut. We found that infraorbital chronic nerve constriction decreases the threshold for wiping in response to mechanical stimuli, in agreement with previous findings. Similarly, the wiping threshold was also reduced for thermal stimuli. These results provide the behavioral foundation to identify the cortical correlates of nocifensive behaviors in S1, and to reveal the progressive neural changes associated with chronic neuropathic pain in the somatosensory cortex.
Understanding these cortical alterations will provide critical insights into the neural mechanisms underlying chronic neuropathic pain and potentially guide the development of new therapeutic strategies aimed at normalizing the cortical representations of nociception.

Title: A stimulus-evoked EEG study for chronic pain patients and healthy controls

Authors: *G. KENEFATI[1], M. ROCKHOLT[1], D. OK[1], M. MCCARTIN[1], Q. ZHANG[1], G. SUN[1], J. MASLINSKI[1], A. WANG[1], B. CHEN[1], Z. S. CHEN[2], J. WANG[1], L. DOAN[1]; [1]Anesthesiology, Perioperative Care and Pain Med., [2]Psychiatry, NYU Grossman Sch. of Med., New York, NY

Abstract: Previous work has implicated brain areas such as the prefrontal cortex (PFC), insular cortex (IC), anterior cingulate cortex (ACC), and primary somatosensory cortex (S1) in pain processing and perception. Furthermore, neural oscillations at alpha (7-13 Hz), low-gamma (30-60 Hz), and high-gamma (60-100 Hz) frequencies have been shown to reflect both evoked pain perception and chronic pain states. However, a suitable biomarker for chronic pain has not yet been developed. In this observational, cross-sectional study, EEG was recorded in patients with chronic lower back pain (CP) (n = 51) and healthy control (HC) subjects (n = 24). Pinprick stimuli at three intensity levels (low: 32 mN, medium: 128 mN, high: 256 mN) were applied to

the lower back region and to the back of the hand. Subjective pain scores (0-10) were reported. Kruskal-Wallis test with Post Hoc 1-way ANOVA test was applied for independent parameters to compare groups, using Bonferroni test for adjusted significance. CP subjects were able to distinguish medium and high stimuli from the low stimulus both on the lower back and hand ($p < 0.05$), whereas HC subjects were only able to distinguish high stimulus from low stimulus on the hand ($p < 0.05$), suggesting the presence of allodynia (heightened sensitivity) in CP subjects. Stimulus-evoked EEG data were source-localized to six regions of interest (medial-PFC, lateral-PFC, IC, rostral-ACC, caudal-ACC, S1) and event-related desynchronization and synchronization (ERDS) in the low-stimulus and high-stimulus conditions were compared in the frequency bands mentioned. Stimulus-evoked EEG data are then used to correlate with behavioral findings.

Title: Distinct roles of differential populations of efferent neurons from the parabrachial nucleus in mechanical allodynia

Authors: J. HUO, X. LIU, F. DU, G. YIN, K. DUAN, ***D. DONG**, L. CHENG;
Southern Univ. of Sci. and Technol., Shenzhen, China

Abstract: Mechanical allodynia (MA)-pain evoked by innocuous tactile stimuli-represents one prevalent symptom of chronic inflammatory and neuropathic pain. For some devastating patients, a local injury can lead to full-blown body-wise pain that lasts for long time, whereas for most patients the pain could be short-lasting or confined to the unilateral injury side. Our recent study reported a descending pathway that controls the latent sensitization induced by chemical

irritants, inflammatory reagents or nerve injury. This circuit starts with neurons located in the lateral parabrachial nuclei (lPBN) (marked by the expression of μ-opioid receptors (MORs)), which control the activity of hypothalamic neurons in the dorsal medial regions (dmH) that are marked by the expression of the prodynorphin (Pdyn) and that send bilateral projections to the spinal dorsal horn (SDH) ($lPBN^{MOR+}$→dmH^{Pdyn+}→SDH circuits). However, the underlying mechanisms for the induction of bilateral MA, particularly the contralateral MA, are, however, still remain unsolved. Here we observed that proenkephalin (Penk) neurons were highly expressed in lPBN and partially overlapped with MOR+ neurons in el-dvlPBN. We did behavioral experiments to study their functional roles in modulating MA. In contrast to ablation of MOR+ neurons, ablating or silencing the el-dvlPBN^{Penk+} neurons, or retro-ablating or chemogenetic silencing el-dvlPBN^{Penk+}→dmH projecting neurons had no significant effect on the lasting duration of bilateral MA, suggesting cell type-specific roles of $lPBN^{MOR+}$ neurons in negatively modulating the lasting duration of MA. However, retro-ablation/chemogenetic silencing the slPBN^{Penk+}→dmH projecting neurons before hind paw capsaicin injection completely prevented the induction of bilateral MA. In contrast, chemogenetic silencing the slPBN^{Penk+}→dmH
projecting neurons post-capsaicin injection had no significant effect on the expression of bilateral MA, suggesting that this population of neurons are required for the induction, but not expression of bilateral MA. Chemogenetic silencing of slPBN^{Penk} neurons post-capsaicin injection abolished bilateral MA, suggesting that slPBN^{Penk} neurons are required for the transmission of bilateral MA. In addition, chemogenetic activation of the slPBN^{Penk}→dmH projecting neurons opened the gate for bilateral MA in naïve mice. Overall, our study suggested distinct roes of differential populations of efferent neurons from the lateral parabrachial nucleus in mediating MA in mice.

Title: Sex differences in Central Amygdala response to Parabrachial Calcitonin Gene Related Peptide (CGRP) release

Authors: R. LORSUNG[1], J. ALIPIO[2], Y. JI[3], N. P. CRAMER[4], J. KOENIG[5], R. MASRI[6], ***A. KELLER**[5];
[1]Univ. of Maryland Sch. of Med. Program In Neurosci., Baltimore, MD; [2]Harvard, Boston, MA; [3]Univ. of Maryland Sch. of Dentistry, Dept. of Oral Sci. and Therapeut., Baltimore, MD; [4]Anat.

and Neurobio., Univ. Maryland, Baltimore, Baltimore, MD; [5]Univ. of Maryland Sch. of Med., Baltimore, MD; [6]Dept. EPOD, Univ. Maryland, BALTIMORE, MD

Abstract: Calcitonin gene-related peptide (CGRP)-expressing neurons in the parabrachial nucleus (PB) densely project to several brain structures implicated in aversive-affective pain processing, including the central amygdala (CeA). We are testing the overarching hypothesis that these projections are causally involved in the affective component of chronic pain. We first tested whether CGRP release from PB potentiates post-synaptic responses. We performed whole-cell, voltage-clamp recordings in CeA slices from $CGRP^{Cre}$ mice in which an excitatory opsin was expressed in PB_{CGRP} terminals. Stimulation of these PB terminals in the CeA potentiated optically-evoked excitatory postsynaptic currents only in females. This potentiation lasted approximately one minute and was blocked by a CGRP-antagonist. This suggests that CGRP release from PB terminals potentiates PB glutamatergic inputs from PB to CeA of females, potentially tuning these synapses to respond more strongly to further aversive input. To investigate whether this sex difference arose from transcriptional sex differences in the CeA subpopulation expressing CGRP receptor (CGRPr+), we examined previously published single cell CeA datasets. GO term and DEG analysis between males and females revealed that female CGRPr+ CeA neurons are enriched for both asymmetric synapse markers, indicating a greater number of presumptive excitatory synapses, and nitric oxide signaling compared to males. As postsynaptic nitric oxide release can play a role in strengthening synapses via retrograde signaling, we tested whether CGRP-dependent potentiation in females affected presynaptic release by performing paired pulse ratio (PPR) analysis. PPR significantly decreased in female neurons following endogenous CGRP release from PB terminals in the CeA, indicating that CGRP induced an increase in presynaptic release probability. This suggests that CGRP-driven potentiation in female CeA neurons is at least partly due to a presynaptic mechanism. We also tested for sex-differences in the presynaptic PB neurons by quantifying CGRP expression in the PB using RNAscope. Females expressed slightly *less* CGRP than males, despite being more responsive to its endogenous release in the CeA *in vitro*. This suggests that females release less CGRP at baseline conditions, but are more responsive to elevations in CGRP signaling in the CeA, such as those that occur in chronic pain states. Taken together, our data suggests that the PB to CeA pathway demonstrates significant sex-differences in both expression of various markers as well as functional response to CGRP.

Title: Single cell transcriptomic analysis of DNA methylation machinery in the prefrontal cortex of transient and persistent neuropathic pain mouse models

Authors: *S. LEE[1], M. RIEDL[2], L. VULCHANOVA[2], L. STONE[1];
[1]Anesthesiol., [2]Neurosci., Univ. of Minnesota, Minneapolis, MN

Abstract: Chronic pain is associated with molecular, cellular, structural, and functional changes throughout the neuroaxis including in the prefrontal cortex (PFC). PFC plays a crucial role in the processing and modulation of pain sensation and in the integration of sensory, cognitive, and emotional information. Epigenetic modifications including DNA methylation can impact gene regulation without altering the genetic code. DNA methylation is regulated by DNA Methyltransferases (DNMTs), and ten-eleven translocation (TET) enzymes and is read by Methyl-CpG-binding Domain (MBD) proteins. We previously reported changes in DNA methylation in rodent PFC following spared nerve injury (SNI) that are associated with the transition from acute to chronic pain. However, the cell phenotypes driving these changes have not been identified. In this study, we aimed to map changes DNA methylation machinery expression in PFC using a single nuclei RNA sequencing approach in mouse models of transient vs persistent neuropathic pain. To model transient and persistent neuropathic pain, the sciatic nerve crush and SNI models were induced in 10 to 12 week old C57BL6 male mice, respectively. Sham surgery consisted of exposing the nerve without damaging it. Mechanical and cold sensitivity on the ipsilateral hind paws were monitored for 6 weeks, then PFC was collected for single-nuclei RNA sequencing. Data was analyzed by the R package Seurat (v4.3). Expression levels of DNMTs, TETS and MBDs were compared between Sham vs SNI, Sham vs. Crush and Crush vs SNI groups within cellular phenotypic clusters. Increased mechanical and cold sensitivity persisted in SNI but the nerve crush mice showed a progressive recovery over time. Upregulation of MBD1 and Tet1 was observed in some non-neuronal cells (e.g., Oligodendrocytes, Endothelial cells) in SNI compared to both sham and crush groups. Tet3 expression was upregulated in excitatory neuron subpopulations (Slc17a7+) in SNI but downregulated in the crush model compared to SNI. DNMT3b expression was downregulated in inhibitory neurons (Gad1, 2+) in SNI but was similar in crush and sham. Together, dynamic changes of DNA methylation machinery in PFC following nerve injury could contribute to the establishment and persistence of chronic neuropathic pain through modulating the epigenetic genes.

Title: Anterior cingulate cortex metabotropic glutamate receptor type-2 expressing neurons regulate complex pain behaviors: dependence on sex, estrous cycle, and injury.

Authors: *A. KIRRY, S. DAVIDSON;
Univ. of Cincinnati, Cincinnati, OH

Abstract: Our lab previously determined that metabotropic glutamate receptor type-2 (mGluR2) containing pyramidal neurons of the anterior cingulate cortex (ACC) become hyperexcitable following neuropathic and inflammatory pain in mice. The consequence of pain-induced hyperexcitability of mGluR2 expressing neurons of the ACC is unknown but can be informed by examining the function of ACC mGluR2 expressing neurons in naïve and injured mice. We aim to determine the function of ACC mGluR2 neurons using a multidimensional behavioral approach which includes pain-related affective, motivational, and sensory assays. Sex and ovarian cycle influence the multidimensional experience of pain, and we included sex and estrous stage as a factor in analyses. The discovery of the neural nodes involved in pain-related affect, motivation, and sensory processes across sex and estrous cycle may lead to better pain therapies.
We utilized transgenic mice that express cre recombinase specifically in mGluR2 expressing cells. We delivered a viral vector containing a cre-dependent caspase to ablate ACC mGluR2 neurons. We also crossed our mGluR2-cre transgenic line with a cre-dependent channelrhodopsin transgenic line to optogenetically activate ACC mGluR2 neurons. Mice underwent a thermal pain tolerance assay and a complimentary array of pain threshold and affect related tests, including hot plate, Hargreaves, open field, and conditioned place preference. We found that estrous cycle interacts with thermal pain tolerance. Females in proestrus, a putatively high estradiol state, have higher pain tolerance for a sucrose reward. Ablation of ACC mGluR2 neurons prevents the increase in pain tolerance of proestrus females. Independent of sex, optogenetic activation of ACC mGluR2 neurons results in conditioned place aversion and produces antinociception. We next used neuropathic and inflammatory pain models to determine if ACC mGluR2 neurons are required for the development of affective and pain processing changes in chronic pain conditions. Initial studies suggest that ablation of ACC mGluR2 neurons blocks affect-related pain processing changes following chronic pain. These data show that ACC mGluR2 neurons participate in motivational responses to noxious stimuli in both sexes, and likely contribute to emotional and sensory dysregulation seen in pathological pain conditions.

Title: Sexual dimorphism in the spinal effects of the VGF derived peptide TLQP-62

Authors: *T. XIE[1], R. E. SCHORN[2], E. MARRON FERNANDEZ DE VELASCO[3], G. L. WILCOX[4], C. A. FAIRBANKS[5], L. VULCHANOVA[2];
[1]Dept of Pharmaceutics, [2]Dept of Neurosci., [3]Dept of Pharmacol., [4]Dept Neurosci, Pharmacol, Dermatol, [5]Dept of Pharmaceutics, Pharmacology, Neurosci., Univ. of Minnesota, Minneapolis, MN

Abstract: VGF (non-acromymic) is a neurosecretory protein implicated in neuroplasticity associated with depression, learning and memory, and chronic pain. Our previous work has demonstrated that VGF-derived peptides contribute to the establishment of hypersensitivity in mouse models of persistent pain. We have also shown that the peptide TLQP-62 potentiates calcium responses to glutamate (Glu) in a subset of spinal neurons in naïve male mice. This study aims to determine the mechanisms of this TLQP-62 effect. Work in the hippocampus has suggested that the actions of TLQP-62 are mediated in part by BDNF/TrkB signaling, and in spinal dorsal horn BDNF/TrkB signaling has been shown to participate in neuroplasticity mediated by the NMDA receptor subunit GluN2B. Therefore, we hypothesized that the potentiation of spinal Glu responses by TLQP-62 requires GluN2B. To address this hypothesis, we conducted imaging of calcium transients in transverse spinal cord slices from male and female GluN2B*fl/fl* mice, in which GluN2B can be deleted in a Cre-dependent manner. GluN2B*fl/fl* mice were injected intraspinally at the L3 and L4 spinal levels (300 nL/injection) at 3-4 weeks of age with AAV9-hSyn-GCaMP6s-Cre or control AAV9-hSyn-GCaMP6s-ΔCre, in which Cre-recombinase is inactive and does not induce GluN2B deletion. Imaging was performed 4 weeks after viral injections. GCaMP6s fluorescence intensity was captured as time-lapse images by single plane two-photon microscopy (Nikon A1RMP system). Cre-dependent deletion of GluN2B was confirmed by loss of ifenprodil inhibition of NMDAR-mediated calcium transients (n=3/sex, $P<0.01$, Student's t-test). Slices were sequentially exposed to the following treatments: 1) 100 uM Glu (10 s); 2) 50 nM TLQP-62 or aCSF (15 min); 3) 100 uM Glu (10 seconds); 4) 1mM Glu (10 s). The fold change in response amplitudes to the two 100 uM Glu treatments was calculated for each cellular profile and was found to be significantly reduced in TLQP-62-exposed cells from Cre- compared to ΔCre-injected male mice ($p < 0.05$, Student's t-test). Similarly, the proportion of profiles with potentiated responses, defined as fold change greater than the mean+2SD of profiles from aCSF treated slices, was significantly reduced in Cre- compared to ΔCre-injected mice (5/32 and 16/60, respectively; $p = 0.011$, Fisher's exact test). These Cre-dependent differences were not observed in cellular profiles of female mice. These results suggest that GluN2B mediates TLQP-62-induced potentiation of Glu responses in male but not in female mice. Ongoing experiments are investigating the contribution of TrkB to the spinal actions of TLQP-62.

Title: Evaluating The Role of Perineuronal Nets in Mice With Chronic Pain

Authors: *S. CERMAK[1], G. SEKERKOVA[1], M. MARTINA[2], A. APKARIAN[1];
[1]Northwestern Univ., Chicago, IL; [2]Northwestern Univ. Med. Sch., Chicago, IL

Abstract: Approximately one in five individuals in the United States will experience chronic pain (CP), contributing to a significant annual economic burden of around $560-635 billion. The societal burden is just as drastic, causing a great deal of suffering in patients and taxing healthcare systems. Despite decades of advances in research, there is no cure to CP, and limited effective therapies exist. A mechanistic understanding of the neurobiological basis of chronic pain is essential to the development of effective treatments.Perineuronal nets (PNNs) are specialized extracellular matrix structures that surround certain neurons that may play a role in the development of chronic pain. Recently, PNNs have been implicated in pain in rodents. However, the dynamics of these changes in the brain are not well understood in neuropathic pain, particularly in corticolimbic brain regions- areas that have repeatedly been implicated in CP in both humans and rodent models.We use a spared-nerve injury (SNI) model of neuropathic pain in C57 mice to assess changes to PNNS over the development of CP. Control animals received sham surgery, in which the sciatic nerve was exposed rather than ligated. Both male and female mice were 8-12 weeks old. We quantified PNNs in corticolimbic brain regions at multiple time points, 7 days (7d) post-surgery, 14d, and 28d. We used immunostaining with Wisteria Floribunda Agglutin (WFA) to stain for PNNS, as well as anti-aggrecan and anti-Parvalbumin antibodies for double immunofluorescent staining.Quantification revealed increased PNNs in brain regions at multiple time points in animals with CP. Specifically, there were increased PNNs in both prelimbic and infralimbic components of the prefrontal cortex 7d post-surgery, but no change in anterior cingulate or motor cortex. We next characterized PNNs in key regions by assessing aggrecan-positive PNNs in this region, which were primarily aggrecan-negative. Ongoing research will confirm the trend of increasing PNNs at later time points. Establishing how PNNs change temporally and spatially would capture their importance into the mechanisms underlying CP and pave the way for novel clinical applications. Funded by P50 DA044121

Title: Virtual Reality treatment of severe neuropathic pain in an adolescent child

Authors: *J. H. SORENSEN[1], A. KNUDSEN[2], M. VLACHOU[3], I. MILIDOU[3,4], K. MEIER[2]; [1]Neurosurg., Danish Neurosci. Ctr. - Aarhus Univ. Hosp., Aarhus N, Denmark; [2]Neurosurg., [3]Neurol., Aarhus Univ. Hosp., Aarhus N, Denmark; [4]Pediatrics, Regional Hosp. West Jutland, Herning, Denmark

Abstract: *Introduction:* Virtual reality (VR) has successfully been used over the past years as an adjunct therapy in acute pain management. In this case report we present a thirteen-year-old boy where virtual reality (VR) was used as a successful intervention on both short and long term to treat serious chronic neuropathic pain following calcaneus extension orthopaedic surgery in a boy aged 13. After the surgery, he developed severe chronic allodynic pain on the lateral aspect of the right foot. Medical and psychological interventions were unsuccessful. Nerve blockade gave transient relief, and spinal cord or peripheral nerve stimulation was not possible.
Virtual Reality treatment: Inspired by mirror therapy we recommended the boy to experiment with various 3D VR games, which either stimulated his mobility, or other games in which he could see an embodiment of himself. One such engaging VR game was "Beat Saber" developed by Beat Games, where you wield two lightsabers, slicing geometric boxes flying against you, all the while you must avoid obstacles in the VR game space. In addition, the patient also used "VR chat" which is a virtual forum, where you can walk around in cityscapes and see yourself as an avatar. Especially a VR rendering, where the patient could see himself in a mirror, enabled him to touch his virtual (and real self) without pain.
Discussion: This case report documents the beneficial role of VR immersion and engagement as a possible new treatment modality for severe neuropathic pain after surgery. Different theories about the pain alleviation mechanism of VR are generally divided into two main types. One is that VR provides a short-term analgesic effect, which emanates from pain distraction and anxiety reduction, resulting from the VR immersion and diversion of attention to another stimulus. The other theory posit that neuroplasticity is the underlying mechanism contributing to the analgesic effect of VR by inducing a long-term structural change in neuron populations in sensory and motor brain regions. We hypothesize that the embodiment and immersion in virtual gaming and play in the present case modulated the central pain sensitization of the patient's right foot neocortical representation, thereby reducing and ultimately abolishing his chronic pain. The case shows promising prospects for the use of VR to treat chronic pain where current pharmacological and other medical treatments failed. The encouraging results presented in the current case study highlight the importance of further studies investigating the potential of immersive and embodying VR technologies in providing pain relief.

Title: Impaired GluD1-Cbln1 Trans-Synaptic Signaling in the Central Amygdala Contributes to Autophagy Deficits and Chronic Pain

Authors: *K. S. NARASIMHAN[1], T. KIRITOSHI[3], G. JI[3], V. NEUGEBAUER[3], S. DRAVID[2]; [1]Pharmacol. and Neurosci., [2]Creighton Univ., Omaha, NE; [3]Texas Tech. Univ. Hlth. Sci. Ctr., Lubbock, TX

Abstract: Chronic pain is a debilitating condition affecting more than 100 million Americans, with more than half of them showing comorbid depression and anxiety. Neuroplasticity in the central amygdala (CeA) is an important contributor to the emotional and affective aspects of pain. GluD1, a delta glutamate receptor is one of the ionotropic glutamate receptors that play a critical role in inhibitory and excitatory neurotransmission. We have recently demonstrated that in chronic pain, dysfunction of GluD1 and its binding partner Cbln1 mediated trans-synaptic signaling in CeA. Studies have indicated that the activation of autophagy, a cellular process for recycling and degradation, leads to the internalization of AMPARs (AMPA receptors) and enhances long-term depression (LTD). Furthermore, it has been demonstrated that GluD1 regulates autophagy mechanisms in multiple brain regions. Based on these findings, we hypothesized that the loss of GluD1 contributes to chronic pain by causing autophagy deficits and impairing LTD. To test this hypothesis, we conducted experiments using sham, complete Freund adjuvant (CFA)-induced, and spinal nerve ligation (SNL) surgery-induced pain models. Initially, we assessed mechanical hypersensitivity in the right paw of the animals using the Von-frey test and observed that both the CFA and SNL models induced hypersensitivity. Subsequently, we analyzed the levels of autophagic proteins in the synaptoneurosomes of the CeA using western blotting. Interestingly, we discovered hyperactive Akt-mTOR signaling in the CeA of animals with CFA and SNL-induced pain, compared to the sham group. This heightened mTOR signaling cascade inhibited beclin-1, disrupting the maturation of autophagosomes. Additionally, we observed increased p62 levels and a decline in the LC3-II/LC3-I ratio in the CeA of animals with CFA and SNL-induced pain, compared to sham mice. These alterations in autophagy deficits were strongly correlated with the downregulation of GluD1 and Cbln1 in the CeA. Furthermore, CFA and SNL models led to impaired LTD, as evidenced by elevated surface expression of GluA2 (AMPAR). These findings further support the connection between autophagy defects resulting from GluD1 downregulation and pain. Interestingly, when we administered recombinant Cbln1 (rCbln1) directly into the CeA through intracerebroventricular (i.c.v.) injection (250ng), we observed a reversal of both autophagy impairment and LTD.

Overall, our results suggest that the restoration of GluD1-Cbln1 impairment alleviates pain by reversing autophagic signaling deficits and restoring synaptic function.

Title: The Role of Endogenous Dopamine Signaling in the Lateral Parabrachial Nucleus in Somatosensation

Authors: *H. KOO, J. WANG, R. PARIYAR, R. HAMMOND, J. CHUNG, J.-H. LA; Univ. of Texas Med. Br., Galveston, TX

Abstract: The lateral parabrachial nucleus (LPBN), a relay and modulatory station for various sensory information, is known to express dopamine D1 and D2 receptors and receive dopaminergic inputs. However, it remains unclear how endogenous dopamine signaling in the LPBN modulates somatosensation. Therefore, here we investigated the effects of the D1 antagonist SCH 23390 and the D2 antagonist Eticlopride, microinjected at the right LPBN in mice, on mechanical and thermal sensory responses measured as the threshold of paw withdrawal from von Frey filament stimulation and the latency to paw withdrawal from radiant heat, respectively. The D1 antagonist SCH 23390 (0.01-1 ug) did not significantly affect either mechanical or thermal sensory responses. In contrast, Eticlopride (0.3 and 1 ug) significantly inhibited both mechanical and thermal sensory responses. These findings indicate that endogenous dopamine in the LPBN activates D2 dopamine receptors, facilitating mechanical and thermal sensory responses. Therefore, interfering with this dopaminergic signaling may result in hyposensitivity to mechanical and thermal stimulation.

Title: Clinical phenotype matters: Thalamic structural changes in neuropathic low back pain

Authors: *R. YUAN[1], J. D. MARKMAN[2], J. GEWANDTER[3], Z. ZHANG[5], P. GEHA[4]; [2]Neurosurg., [3]Anesthesia and Perioperative Med., [4]Psychiatry, [1]Univ. of Rochester Sch. of Med., Rochester, NY; [5]Statistics, Univ. of North Carolina, Chapel Hill, Chapel Hill, NC

Abstract: Chronic low back pain (CLBP) has a significant impact on the lives of millions, yet treatment options are limited. CLBP can be classified into musculoskeletal and neuropathic (sciatica) pain conditions, which are believed to have distinct mechanisms. We aim to investigate whether careful phenotyping of CLBP can reveal brain differences, particularly in the somatosensory system, between sciatica and musculoskeletal CLBP. We recruited 55 CLBP patients and 36 age- and BMI-matched healthy controls (HC) for this study. All subjects completed the Standardized Evaluation of Pain (StEP) assessment, and CLBP patients were categorized into either the musculoskeletal pain group (MSK, N=29) or sciatica group (SC, N=26). Volumetric and vertex analyses of the thalamus were performed with the FSL-FIRST toolbox using T1-weighted MRI. Groups were compared using permutation testing ($p < 0.05$). We observed significant thinning of the posterior-medial aspect of bilateral thalami (Fig 1) in the SC group compared to both MSK group and HC. The altered region lay in the pulvinar - the thalamic association nucleus. In contrast, no significant differences in morphometry were observed between the MSK group and HC, and there were no differences in total thalamic volume among the 3 groups. As the altered region is closely connected to the pre-frontal cortex (PFC), we used resting state functional MRI to compare the connectivity of the posterior thalami to the dorsal-lateral PFC (DLPFC). The SC group showed increased connection between the left posterior thalamus and the right DLPFC compared to the MSK group. These findings suggest that the posterior-medial thalamus shape change may be specific to sciatica. Moreover, the enhanced connection between this area and the DLPFC indicates functional changes in pain perception and modulation. Our study corroborates mechanistic differences between neuropathic and musculoskeletal pain and highlights the potential role of the pulvinar in sciatica. Understanding the central modulation of neuropathic CLBP may facilitate future development of targeted therapies.

Title: Cellular Mechanism of 10kHz Spinal Cord Stimulation: Insights into Neuromodulation

Authors: *D. WANG, K. LEE, D. LEE, Z. KAGAN, K. BRADLEY;
Nevro Corp, Redwood City, CA

Abstract: Spinal cord stimulation (SCS) has emerged as a promising therapeutic approach for the management of chronic pain. Among various SCS modalities, 10kHz SCS has shown superior efficacy without paresthesia compared to traditional SCS techniques. However, the underlying mechanism by which 10kHz SCS exerts its analgesic effect remains incompletely understood. In this study, we aim to elucidate the mechanisms of action of 10kHz SCS through a comprehensive examination of the neural circuitry and molecular changes associated with its application.
By calcium imaging and electrophysiological recording approaches, we found that 10kHz SCS-mediated spinal cord neuron activation was eliminated by sodium channel blocker (TTX) and significantly reduced by NMDA/AMPA receptor blockers (AP5/CNQX). These data suggest that 10kHz SCS may activate the voltage-gated sodium channels and trigger the release of endogenous neurotransmitters to reduce the pain. To further identify SCS-mediated neurotransmitters, we applied GABA inhibitor (Bicuculine) during the recording and found that 10kHz SCS induced spinal neuron activation was significantly abolished by the Bicuculine. This work suggests that 10kHz SCS works primarily through enhanced GABAergic neurotransmission, thus augmenting inhibitory control over pain pathways and may potentially involve the facilitation of primary afferent depolarization (PAD) and restore the sensory information transmitting to the spinal cord dorsal horn neurons.
Our study demonstrated the neurochemical profile of 10kHz SCS on the GABA-mediated pain processing pathway. The enhanced GABAergic neurotransmission observed with 10kHz SCS may contribute to its clinically superior analgesic efficacy. These findings deepen our understanding of the specific neurochemical mechanisms underlying 10kHz SCS and pave the way for targeted modulation of GABAergic signaling in the development of novel pain management therapies.

Title: Changes in myelin in the somatosensory barrel cortex after unilateral whisker loss

Authors: *C. WINT[1,2], *C. WINT[3], E. PETRUS[1];
[1]Anatomy, Physiol. & Genet., Uniformed Services Univ. of the Hlth. Sci., Bethesda, MD; [2]Henry

M. Jackson Fndn. for the Advancement of Military Med., Bethesda, MD; [3]Anatomy, Physiol. & Genet., Uniformed Services Univ., Bethesda, MD

Abstract: More than one million people in the US live with limb loss; this number is expected to continue rising. Amputees can recover from their injuries by learning new motor skills to navigate daily life, but others experience maladaptive consequences such as chronic pain conditions. It is likely that changes in neural circuitry underlie both adaptive and maladaptive outcomes after injury. Myelin is a membrane that wraps around neuronal axons and enhances electrical communication between neurons. Motor learning, neuronal activity and synaptic plasticity all influence myelination in the central nervous system. After unilateral limb loss, magnetic resonance imaging (MRI) detects reduced myelin in patients and animal models, in particular in areas that connect bilateral limbs. It is unknown if this loss is maladaptive, and if so, if interventions could restore myelin density to support and enhance motor learning after injury. We used a mouse model of unilateral whisker denervation to investigate changes in myelin in the whisker processing region of the brain: primary somatosensory barrel cortex (S1BC). We hypothesized that myelin immunohistochemistry staining would be reduced in the deprived S1BC in injured mice due to the loss of the primary input (whiskers) to that brain region. Thin brain slices were stained for Myelin Basic Protein (MBP). Three groups of male and female mice were analyzed: two weeks after injury, two months after injury, and 2 months after injury combined with a whisker behavior task. Two weeks after injury a surprising increase in myelin staining was observed, followed by a decrease two months after injury. Training on a whisker task made the reduction of myelin after whisker loss less severe. Myelin may increase immediately after injury to support wiring new connections within the S1BC after unilateral whisker loss. On a longer time-scale, myelin may be reduced due to the loss of primary inputs to S1BC, but intensive whisker training may support increased neuronal activity. This increased activity may combat the myelin loss that normally occurs. Myelin formation supports motor learning, thus identifying therapies that promote myelination may be beneficial for amputee recovery.

Title: Transcriptional Heterogeneity of Layer 4 Barrel Cortex Neurons after Unilateral Amputation

Authors: *L. IYER, E. PETRUS;
Anatomy, Physiol. and Genet., Uniformed Services Univ. of the Hlth. Sci., Bethesda, MD

Abstract: There are nearly 2.1 million people living with limb loss in the United States. Some patients recover well after their injury by learning new motor skills, but others suffer from chronic pain conditions. Brain activity measured by functional magnetic resonance imaging (fMRI) in both subsets of patient populations has similar patterns. This makes predicting patient outcomes challenging and also impossible to determine if this neural activity is related to a beneficial or maladaptive recovery. Our research seeks to discover the neurons, synapses, and circuits that underlie these variable adaptations. Stimulation of the intact whiskers in a rodent model of unilateral whisker nerve transection (IONX) produces a robust fMRI response in bilateral primary somatosensory barrel (whisker) cortices (S1BC), similar to the activity in sensory/motor cortex of human patients. This model allows the detection of the neurons and pathways that are altered after amputation. Our hypothesis is that there are neurons in the sensory cortex that drive brain changes after injury. Previously we found that the increased intact S1BC activity is due to the stronger connection between the thalamus and Layer 4 (L4) neurons in S1BC. These L4 neurons have historically been considered a homogenous group; however, our recent single-nucleus RNA sequencing has detected at least 3 subtypes of neurons. The presence of these neuronal clusters has been identified by co-labeling them with Rorb (L4 marker) using HiPlex RNAscope. Further, genes related to synaptic plasticity such as Gria2, Homer1, and mGluR5 have increased after injury. Electrophysiology has confirmed that the changes in RNA expression have concurrent effects on synaptic function. These events likely influence downstream cortical activity in response to intact whisker use. Our work connects neural gene expression and activity patterns to behavioral phenotypes of our mouse model of amputation. This project will enhance our understanding of how the brain adapts to injury, aiming for targeted interventions to improve outcomes in amputees.

Title: Behavioral Adaptations after Unilateral Whisker Pad Amputation in Mice

Authors: *E. PETRUS[1], E. MCCALL[2], P. WRIGHT[2], F. JOHNSON, III[1], A. KORETSKY[2];
[1]Uniformed Services Univ. of the Hlth. Sci., Bethesda, MD; [2]NINDS, NIH, Bethesda, MD

Abstract: There are 1.6 million people living with limb loss; this number is expected to more than double by 2050. Successful recovery after amputation requires that patients learn new motor skills, such as using their residuum, intact limbs, or a prosthesis. Impediments to recovery include chronic pain conditions, anxiety/depression, or the absence of motor learning. The variety of patient outcomes may depend on the unique neural and behavioral adaptations that patients develop after injury. We have developed a rodent model of unilateral amputation by transecting the infraorbital nerve (IONX) connecting the whisker pad to the brain. Neural activity measured by functional magnetic resonance imaging (fMRI) in IONX mice closely mimics that of amputees. fMRI detects increased activity in the spared whisker barrel cortex and takeover of the injured whisker barrel cortex by the intact cortex; the synaptic plasticity mechanisms underlying these changes have begun to be assessed. This amputation model allows for the study of neural and behavioral adaptations of male and female mice after IONX injury. We hypothesized that the loss of one set of whiskers would negatively impact exploratory and whisker-task related behaviors. While IONX injury did not impact exploration of the open field, animals missing one set of whiskers did inspect novel objects more frequently with their nose. Performance on a pole localization task with the intact whisker set was equal to sham-operated mice. Finally, IONX mice had impaired performance on a gap crossing task, which requires bilateral whisker inputs. Interestingly, the injury group had variable performance on many of these tests. These results indicate that observed human variability of responses to limb loss might reflect unique neural adaptations underlying their behavioral outcomes and is not necessarily only a byproduct of the inhomogeneity of patients and/or their injuries. Further tests using chemogenetics to isolate the brain region or cell types underlying these adaptations may improve our understanding of how the brain adapts to injury and produces various behavioral outcomes. If behavioral adaptations influence beneficial or maladaptive recovery in rodents, these results may be extrapolated to inform better clinical interventions for patients after limb loss.

Title: Alterations in homeostatic plasticity in Fmr1 KO mice following unilateral whisker deprivation

Authors: *A. LAKHANI, P. WENNER;
Emory Univ., Atlanta, GA

Abstract: Fragile X Syndrome (FXS) is the most common form of inherited intellectual disability. It is caused by a loss-of-function of the FMR1 gene on the X chromosome, resulting in the absence of fragile X messenger ribonucleoprotein (FMRP). Although there are many interventional and pharmacological treatments, there is no cure for FXS. Altered cortical activity is an underlying pathology of FXS that is associated with sensory hypersensitivity and epileptic vulnerability. Normally, networks maintain activity levels within an appropriate range through a set of homeostatic plasticity mechanisms including compensatory adjustments in synaptic strength and/or intrinsic excitability. It is not clear why homeostatic plasticity cannot correct altered activity levels associated with FXS, but previous work suggests that homeostatic mechanisms are impaired in FXS models. Unilateral whisker deprivation (trimming all whiskers on one side of the snout) is a behaviorally relevant in vivo perturbation that has been shown to trigger homeostatic responses in the whisker-responsive barrel cortex. This has been expressed as an increase in whisker-evoked responses in L4 and L2/3 regular spiking (RS) excitatory neurons. In order to determine if and how homeostatic plasticity was altered in the Fmr1 KO mouse model of FXS, we trimmed whiskers every other day from postnatal day 14-21 (PD 14-21). Whiskers were deflected using a 3x3 array of piezoelectric actuators to stimulate the principal/most responsive whisker and surrounding whiskers at multiple velocities. Spiking activity was recorded using a 64-channel multi-electrode probe in the somatosensory cortex of lightly anesthetized mice. Preliminary results suggested that spiking in L5/6 RS neurons in control mice were reduced in the KO compared to WT littermates. In addition, following 7 days of whisker deprivation, the sensitivity to whisker stimulation was very different in the whisker-deprived KO compared to whisker-deprived WT littermates. Future work will focus on recording whisker-evoked spiking from fast spiking (putative inhibitory interneurons) and L4 neurons to evaluate homeostatic plasticity in FXS mice in different layers and cell types.

Title: Investigating the role of Parvalbumin interneurons in experience-dependent plasticity of the somatosensory cortex

Authors: *B. CAMPOS[1], B. VASQUEZ[2], W. ZEIGER[3];
[1]UCLA, Covina, CA; [2]UCLA, UCLA, Los Angeles, CA; [3]Univ. of California Los Angeles, Univ. of California Los Angeles, Los Angeles, CA

Abstract: The primary somatosensory barrel cortex (S1BF) of rodents is a site of robust experience-dependent plasticity, undergoing structural and functional changes in response to peripheral sensory inputs. One of the most commonly studied paradigms for experience-dependent plasticity in the S1BF is chronic whisker trimming. In this protocol, all whiskers on one side of the face are trimmed, with the exception of one or a few spared whiskers. The cortical map representation of the spared whisker(s) increases, while the cortical map representation of the trimmed (deprived) whiskers shrinks. However, the exact microcircuit mechanisms that drive experience-dependent plasticity remain incompletely understood. In deprived barrels, changes in the intrinsic excitability of inhibitory Parvalbumin (PV) interneurons are thought to homeostatically balance the loss of feedforward excitation. Yet, the precise role of PV cells in mediating map expansion of spared whiskers is unknown. We hypothesized that PV cells serve as key regulators of experience-dependent plasticity in the S1BF. To test our hypothesis, we have been recording the activity of PV cells in Layer 2/3 (L2/3) of S1BF longitudinally using two-photon (2P) calcium imaging. We investigated responses of PV cells during chronic whisker trimming. We recorded responses of PV cells to whisker stimulation in the C1 and D1 barrels and then trimmed all the whiskers except the D1-whisker. After trimming, the number of PV cells responding to the D1 whisker increased (from 65.23% to 79.52%) in the C1 barrel, while there was no change in the number of D1 whisker responsive PV cells in the D1 barrel. Given that chronic whisker trimming shifts the responsivity of pyramidal cells in surround barrels toward the spared whisker, these results are consistent with homeostatic scaling of PV-mediated inhibition with excitation to maintain proper excitation to inhibition balance during cortical map plasticity. To define the casual role of PV cells in mediating experience dependent plasticity, we are now using chemogenetics to manipulate PV cell activity. Acute inhibition of PV cells leads to a dose-dependent reduction in whisker-evoked responses of both PV and pyramidal cells, but no change in the number of responsive cells. On the other hand, activation of PV cells reduces both the number of whisker responsive PV and pyramidal cells and whisker-evoked responses. These results are somewhat paradoxical and may reflect highly recurrent connectivity between PV and pyramidal cells in the S1BF. We are now testing the effect of chronic PV cell manipulation on cortical map plasticity induced by whisker trimming.

Title: A novel whisker-based texture discrimination task for freely moving mice towards defining the roles of PV and VIP neurons via chemogenetics

Authors: *A. CETIN, J. GUY, J. F. STAIGER;
Univ. Med. Ctr. Goettingen, Goettingen, Germany

Abstract: Because of the precisely defined somatotopic map, the barrel cortex (wS1) is a favorable model for the study of microcircuits and investigation of the roles of neuronal subtypes in the processing of sensory information. Physiological mechanisms of wS1 of whisker-dependent behavior have mostly been investigated on head-fixed animals to gain better control of stimulus presentation and behavioral measurement. However, there is a limited number of studies investigating whisker-based perceptual detection during natural behavioral conditions. Also, the behavioral relevance of parvalbumin (PV) and vasoactive intestinal polypeptide (VIP) expressing GABAergic neurons remains unclear. We aimed to define the contributions of PV and VIP expressing populations within wS1 towards texture discrimination in freely moving mice using chemogenetic manipulation. To this extent, we have established a textured T-maze task, which is an operant conditioning protocol for whisker-based tactile discrimination and to measure the perceptual detection threshold of freely moving mice. In this protocol, food-restricted animals were trained for a 2-choice reward task in a T-maze. Goal arms of the T-maze were cued by 2 types of texture (i.e. coarse vs smooth) blocks and the animal was expected to learn to differentiate these two textures to find the food reward in one of the arms. After reaching a 70% success level on 2 consecutive days, the contrast between these two textures was decreased to find out the discrimination threshold of the animals. Once animals' performance dropped to chance level with one of the lower contrasts, this contrast was taken as the perceptual detection threshold of the animal. We started with validating our paradigm and controlling the effect of stereotactic injection into wS1, and IP injection of Compound 21 (C21). Mice were first trained in the textured T-maze to determine baseline success, then underwent stereotactic surgery for sham injections to wS1. After recovery time, animals were retested in the T-maze for the same task, including IP injections of C21 and saline. A paired t-test on the highest 3 scores pre- and post-OP showed that surgery did not change animals' success rates in texture discrimination ($t(14) = 1.101$, $p = 0.46$). A one-way ANOVA revealed that there was no difference in animals' performance with IP injection of C21 and Saline compared to no IP injection condition ($F(2,23) = 0.142$, $p = 0.87$). Following these controls we will start with bilateral Gq-DREADD expression in both PVcre+ and VIPcre+ mice to figure out the role of PV and VIP neurons in texture discrimination via C21 administration.

Title: Distinct synaptic input profiles to layer 5 somatostatin neocortical interneuron subtypes

Authors: *A. VOURVOUKELIS, C. J. AKERMAN;
Pharmacol., Univ. of Oxford, Oxford, United Kingdom

Abstract: Important advances have been made in our understanding of different subtypes of cortical somatostatin-expressing interneurons (SSTs) in terms of their morphology, electrophysiology, molecular properties, and efferent connectivity (Gouwens et al., 2020; Muñoz et al., 2017; Naka et al., 2019). However, our understanding of their afferent connectivity, considering SST subtype heterogeneity, remains limited. We examined the connectivity of intralaminarly activated afferents to layer 5 (L5) SSTs in the mouse barrel cortex, including excitatory short-term plasticity and the balance between excitatory and inhibitory input. In vitro patch-clamp recordings from acute brain slices of SST-IRESCre;Ai9 mice of both sexes (P42-P77) were combined with optogenetic control of a subcortically projecting L5 pyramidal presynaptic subpopulation, by employing a retrograde AAV system. Clustering of 12 intrinsic electrophysiological properties from 169 L5 SSTs revealed three putative subtypes. Morphological reconstructions showed layer-specific axonal profiles, supporting their alignment with the subtypes of T-shaped Martinotti (TMC), fanning-out Martinotti (FMC) and non-Martinotti (NMC) SSTs (Nigro et al., 2018). Interrogating short-term plasticity of excitatory input to the L5 SST subtypes, we found that high-frequency stimulation of the presynaptic pyramidal neuron subpopulation resulted in facilitation for Martinotti subtypes (TMC facilitation index=2.65 ± 0.3, n=12; FMC=3.5 ± 0.4, n=9), but depression for NMCs (NMCfac=0.6 ± 0.2, n=2). The facilitation index represents the mean EPSC amplitude facilitation across stimulation pulses (normalization to the initial EPSC), with reported values as mean ± SEM. We also observed distinct subtype-specific profiles in the balance of monosynaptic excitation (E) and disynaptic inhibition (I), measured as an E/(E+I) ratio. TMCs received strong monosynaptic excitation (E/(E+I)=0.72 ± 0.08), NMCs received strong disynaptic inhibition (E/(E+I)=0.03 ± 0.03), while FMCs received both (E/(E+I)=0.55 ± 0.1) (Kruskal-Wallis, $H(2)=16.49$, $p<0.001$, Dunn's multiple comparisons (Holm method) $p<0.01$ for both TMC vs. NMC, and FMC vs. NMC; n=8 per subtype - reported values as mean ± SEM). Overall, our data characterise intralaminarly activated synaptic input to L5 SST subtypes, revealing excitatory short-term plasticity dynamics and differences in the balance between excitatory and inhibitory components. We therefore provide evidence for distinct SST subnetworks, which may be differentially recruited by presynaptic partners to generate layer-specific inhibition.

Title: Neurogliaform cells mediate interhemispheric modulation of cortical pyramidal neuron activity

Authors: *F. MARKOPOULOS[1], R. W. CHÉREAU[1], F. BRANDALISE[1,3], V. CHIPPALKATTI[1], J. PRADOS[1,2], A. DAYER[1,2], A. HOLTMAAT[1];

[3]Dept. of Biosci., Univ. of Milan, Milan, Italy

Abstract: Integration of bilateral sensory inputs requires effective communication between brain hemispheres. This interhemispheric communication is essential for sensory perception and involves reciprocal connections between homotopic sensory areas. A key role in this process is attributed to interhemispheric inhibition which, owing to its long-lasting form, is posited to operate largely through neurogliaform cells (NGCs). However, direct evidence on the role of NGCs in interhemispheric inhibition is missing. Here we show that NGCs in the mouse barrel cortex (BC) are engaged by interhemispheric callosal projections to modulate pyramidal neuron (PN) activity and sensory perception. Using optogenetics, ex vivo whole-cell recordings, and in vivo calcium imaging, we found that layer 1 and layer 2/3 (L1-3) NGCs are strongly activated by the callosal and suppressed by the thalamocortical pathway, suggesting that NGCs encode ipsilateral rather than contralateral whisker stimuli. We also found that direct stimulation of L1-3 NGCs modulates whisker-evoked activity in L2/3 and L5b PNs, and increases the perceptual threshold in a whisker deflection detection task. Furthermore, these effects were recapitulated by direct stimulation of callosal projections and deflection of the ipsilateral whiskers respectively, suggesting that the effect of the callosal pathway on sensory perception is mediated by NGCs. Our results not only prove that NGCs mediate interhemispheric inhibition, but also demonstrate their role in sensory perception via modulation of the main units involved in cortical input and output.

Title: Characterization of Cortical Layer 6b Ctgf Expressing Neurons in Mice

Authors: *R. KHALID, D. MASINI, A. LOCARNO, O. NETSYK, C. BROBERGER; Stockholm Univ., Stockholm, Sweden

Abstract: The cerebrocortical microcircuit has been the subject of intense investigation, but models often neglect the possible contribution of the deepest lamina, layer 6b (L6b; also known as the persistent subplate). Here, we aim to fill this gap by focusing on a subset of excitatory L6b neurons identified by the expression of connective tissue growth factor (CTGF). Using a mouse model expressing cre under the promoter of *Ctgf* (n=6) we show that L6b^{CTGF}neurons are restricted to L6b in the cortical column, expanding no further than 80µm superficial to the white matter and were not present among the white matter fibers. Next, we mapped L6b^{CTGF} projections and synaptic terminals across the brain using genetically restricted viral tracing (AAV5-hSyn1-DIO-mEGFP-Syp1-mRuby). Ctgf-cre mice were injected either in the primary somatosensory (S1-bfd; barrel field; n=3) or motor (M1; n=4) cortex. S1- L6b^{CTGF} neurons projected extensively within L6b, and local axonal projections traveled across cortical layers with prominent bouton density in L2/3 and L1. Meanwhile, M1-ctgf neurons showed less distinctive projection segregation, with dense connectivity limited to L1. We identified interregional connectivity characterized by ipsilaterally confined projections and reciprocal connectivity between S1 and M1. In S1-injected mice, projections towards M1 preferentially targeted L6a and L1. In M1-injected mice neurons innervating S1 preferentially targeted only L1. Subcortically, S1- L6b^{CTGF} neurons targeted thalamic structures that project back to the sensory-motor cortex, as well as thalamic polymodal association areas. M1- L6b^{CTGF} neurons gave rise to boutons in thalamic sensory-motor areas but avoided polymodal targets. We also performed electrophysiology of both L6b^{CTGF} and non-CTGF neurons in S1 slices. These neurons have a heterogenous firing pattern at baseline and in response to current pulses (n = 27 tdT+and n = 12 tdT-). Finally, using optogenetics, we demonstrate that CTGF+ neurons form glutamatergic monosynaptic connections in upper cortical layers targeting both pyramidal cells (n = 15/19 responsive neurons) and fast-spiking interneurons (n = 5/10 responsive neurons). Thus, L6b^{CTGF} neurons are anatomically and functionally integrated with the somatosensory-motor circuitry with long-range projections that span the local cortical column and travel intrahemispherically to target other cortical and subcortical regions.

Title: A consensus definition for layer 6b neurons in the neocortex of the adult mouse

Abstract: Layer 6b neurons are a population of cells in the deepest layer of the mouse cortex. These neurons are hypothesized to be equivalent to white matter neurons in the human brain, which are altered in multiple psychiatric disorders, including autism, bipolar disorder and schizophrenia. However, their functional role in the cortex remains unclear. Because previous studies have used different methods to identify L6b neurons in adult mice, it is difficult to compare their contributions to cortical function across experiments. Here, we compare commonly used methods for identifying white matter and L6b neurons to determine whether they captured the same population of neurons and a consensus definition of L6b neurons in an adult mouse. And we investigate their morphological, anatomical and electrophysical properties. We analyzed the expression of multiple molecular markers of subplate and L6b neurons using the publicly available scRNA-seq data sets and tested expression in L6b neurons retrogradely labeled from L1/2 of the cortex after early development. We confirmed that L6b neurons are identified consistently using three methods in an adult mouse: 1) expressions of Neurexophilin 4 (Nxph4) 2) expression of Connective tissue growth factor (CTGF) and 3) retrograde labeling from the L1/2 of cortex. To investigate the morphology of L6b neurons defined by the three methods, we reconstructed filled L6b neurons and imaged neurons in the Nxph4-creER mouse line. L6b neurons represent a population of spiny, multipolar excitatory neurons with homogeneous morphological properties in three cortex areas: primary motor cortex, primary sensory cortex and visual cortex. In addition, they exhibit consistent electrophysiological intrinsic properties across developmental age. We found that the primary motor cortex and primary motor cortex of L6b neurons have connections ipsilaterally. However, L6b neurons do not project to the thalamus. Furthermore, we showed that they receive synaptic input from the output neurons of the cortex, including layer 5 projection neurons and L6 corticothalamic

neurons using optogenetic experiments. Unlike subplate neurons, L6b neurons do not respond to activation of thalamic inputs. Our studies provide a consensus definition of L6b neurons and indicate that these neurons may play a role in regulating the activity level of large regions of cortex in response to ongoing cortical output, suggesting a possible mechanism whose dysregulation contributes to psychiatric disorder.

Title: Cortical area-specific distribution pattern of persistent subplate neurons in the mouse brain

Authors: *K. LEE[1], J. KIM[2], J. KIM[1];
[1]Korea Brain Res. Inst. (KBRI), Daegu, Korea, Republic of; [2]Daegu Univ., Daegu, Korea, Republic of

Abstract: Subplate neurons (SPNs) are the first generated cortical neurons, and they contribute to formation of thalamo-cortical neural circuits in the developing brain. Early studies reported large degeneration of SPNs in the early postnatal weeks, but recent studies suggest that they might persist to adolescent and adult stage. In the present study, we investigated whether SPNs can be found in the adult mouse brain, whether they are excitatory or inhibitory, and whether they show different localization patterns throughout different cortical regions. We used connective tissue growth factor (CTGF) to identify persistent SPNs and confirmed their existence in the brains of young and mature adult mice. By using cell markers of the two most common inhibitory cortical neurons in the cortex, parvalbumin and somatostatin, we determined whether they are excitatory or inhibitory neurons. Our immunohistochemical investigation confirmed that they are neither parvalbumin nor somatostatin interneuron in both ages. Interestingly, we found that the relative layer depth of the persistent SPNs in the entorhinal cortex is significantly thicker than other motor-sensory cortices. Our results show the first comparative results about the cell identity and relative layer depth throughout different cortical

areas in the young and mature adult mouse brains, highlighting the potential roles of persistent SPNs in the normal brain and in diseases.

Title: Sparse functional projection from barrel cortex to single SPNs in dorsal striatum and cell subtype-specific correlations with the spontaneous behaviours of mice.

Authors: *K. AMROUNE, D. ROBBE, I. BUREAU;
Aix Marseille Univ, INSERM, INMED, Marseille, France

Abstract: Animals take navigational decisions based on sensory cues. In rodents, the Barrel Cortex (BC), a region of the primary somatosensory cortex, integrates tactile information from the whiskers. Pyramidal neurons in BC project to the dorsal striatum (DS), the main input region of basal ganglia involved in decision making and motor control. Striatum has two projection-neuron populations that are in distinct pathways, direct (dSPNs) and indirect (iSPNs), which control with opposite manners a given action. Thus, the sensory corticostriatal projection onto d/iSPNs is one important determinant of basal ganglia outputs and motor control. We study the BC/DS coupling to better understand its function. Here, we used a functional mapping method, laser scanning photostimulation with glutamate uncaging, which allowed to localize the soma of presynaptic neurons in BC and to investigate the number and size of inputs received by individual SPNs. Our aim was to study the spatial organization of the corticostriatal projection and the eventual dSPN/iSPN differences. Our results demonstrate that despite diffuse and overlapping cortical axons in DS described in earlier studies, the inputs received by each SPN from BC is unique and fragmented, showing little overlap with the inputs received by nearby SPNs. Thus, it is only collectively that SPNs provide BG a full representation of whiskers. Nonetheless, projections from BC were organized topographically. Our results also confirm the dominance of the innervations from the top layer 5, although innervations from the superficial layers 2/3 strengthened with age. Variability in the extent and strength of the d/iSPN receptive field in barrel cortex was large and the differences between the dSPNs and iSPNs subtle.

Comparison between these receptive fields and the mouse spontaneous behaviours in an openfield revealed cell-subtype specific correlations.

Title: Integration between barrels and cell type-specific organization in somatosensory cortex

Authors: *J. M. JUDGE[1], M. B. JACKSON[2];
[1]Neurosci., Univ. of Wisconsin, Madison, Madison, WI; [2]Neurosci., Univ. of Wisconsin-Madison, Madison, WI

Abstract: Neural circuits process complex time-sensitive information from multiple inputs by mechanisms that are poorly understood. Primary somatosensory cortex (S1) is an appealing model system of these processes due to its modular structure: it is organized into six layers with distinct cytoarchitecture and connectivity. The cortex is further organized into columns, and in S1 of mice and rats each columnar barrel processes sensory input from one main whisker. Communication between neighboring barrels are thought to depend heavily on factors such as position in whisker rows or whisker arcs, as the barrel layout changes continuously along the anterior-posterior axis. Hybrid optical voltage sensors (hVOS) allow simultaneous imaging from many cells of fast action and synaptic potentials in genetically-defined subpopulations of cells in intact cortical microcircuits. In this exploratory study, we investigated excitatory cells (pyramidal and spiny stellate) expressing an hVOS probe targeted via non-voltage-gated sodium channel Cre driver (scnn1a-tg3-Cre) in brain slices of adult mice. We observed limited signal transmission across barrels in response to extracellular stimulation with glass microelectrodes in layer 4 (L4), with 6 barrel pairs showing signal crossings and 5 showing no signal crossing (n=3 slices). In contrast, layer 2/3 (L2/3) stimulation readily activates multiple barrels in L4 whenever it activates a single barrel in L4, with 15 barrel pairs showing signal crossing and none showing no signal crossing (n=5 slices). In many of these experiments with L4 stimulation, we observed signal crossing between L4 barrels in one direction but not the other. These observations correspond with expected cortical circuit behavior based on morphological studies of L4 axons and are consistent with previous explanations of how receptive fields of multiple whiskers may transform sensory input in S1. With particular interest in timing of circuit behavior, we further hypothesize that response latency differences between neighboring barrels may depend on site of stimulation varying continuously with distance from L4 into L2/3 . Since timing can impact

circuit behavior, we hypothesize that repeating measurements after blockade of inhibitory synapses can reveal further differences relevant to circuit function. This activation of multiple barrels and their relative timing are influenced by many inputs and circuit conditions beyond the sensory information moving through S1. Characterizing the conditions and integration mechanisms involved in the selective activation of barrels may reveal underlying principles of modular organization of columnar structures.

Title: Distinct brain-wide presynaptic networks underlie the functional identity of individual cortical neurons

Authors: *A. INACIO, K. LAM, Y. ZHAO, F. PEREIRA, C. R. GERFEN, S. LEE; NIH-NIMH, Bethesda, MD

Abstract: Neuronal connections provide the scaffolding for neuronal function. Revealing the connectivity of functionally identified individual neurons is necessary to understand how activity patterns emerge and support behavior. Yet, the brain-wide presynaptic wiring rules that lay the foundation for the functional selectivity of individual neurons remain largely unexplored. Cortical neurons, even in primary sensory cortex, are heterogeneous in their selectivity, not only to sensory stimuli but also to multiple aspects of behavior. Here, to investigate presynaptic connectivity rules underlying the selectivity of pyramidal neurons to behavioral state in primary somatosensory cortex (S1), we used two-photon calcium imaging, neuropharmacology, single-cell based monosynaptic input tracing, and optogenetics. We show that behavioral state-dependent neuronal activity patterns are stable over time. These are not determined by neuromodulatory inputs but are instead driven by glutamatergic inputs. Analysis of brain-wide presynaptic networks of individual neurons with distinct behavioral state-dependent activity profiles revealed characteristic patterns of anatomical input. While both behavioral state-related and unrelated neurons had a similar pattern of local inputs within S1, their long-range glutamatergic inputs differed. Individual cortical neurons, irrespective of their functional properties, received converging inputs from the main S1-projecting areas. Yet, neurons that tracked behavioral state received a smaller proportion of motor cortical inputs and a larger proportion of thalamic inputs. Optogenetic suppression of thalamic inputs reduced behavioral state-dependent activity in S1, but this activity was not externally driven. Our results revealed

distinct long-range glutamatergic inputs as a substrate for preconfigured network dynamics associated with behavioral state.

Title: Evolutionary Prototype for Auditory Combinatorial Semantics in a Macaque

Authors: *Z. ZHANG[1], J. NACEF[1], F. POLETIEK[2], B. WILSON[3], T. D. GRIFFITHS[1], Y. KIKUCHI[1], C. I. PETKOV[1,4];

Abstract: How human language evolved from cognitive systems shared with ancestors to living nonhuman animals remains an important open question, one with implications for the extent to which aspects of the human language system can be modelled in nonhuman animals. A key property of human language is combinatorial semantics, where information from a sequence of words is integrated to identify meaningful content. We designed a novel behavioural touchscreen task implemented with two rhesus monkeys (*Macaca mulatta*) in their home units. The task allowed us to study whether the monkeys could learn the meaning of individual nonsense speech sounds identifying colours or shapes, prior to integrating information from a sequence of two sounds identifying a specific object by its joint colour and shape properties. The paradigm was implemented in two key phases. In the first phase, the animals started by learning to associate the nonsense words with either specific colours or shapes. Learning the task was effortful and the two monkeys struggled to maintain high performance throughout the touch screen testing sessions in the colony. However, they also showed regular bouts of high performance, and they met predefined criteria for progression (i.e., majority of sessions in the testing week before progression showing above chance performance based on permutation tests). One of the monkeys recently progressed to the final phase where sequences of two sounds identified objects by both colour and shape properties. The macaque's choices were significantly greater for the objects whose colour and shape properties both matched the informative content in the two sounds, than for colour or shape foils, or foils incorrect in both colour and shape features (23

testing sessions; pairwise *t*-tests corrected for multiple comparisons: combined > foil performance, $p < 0.001$). Our next steps in this research program are to test whether the first monkey can generalize learning to probe trials of novel combinations not previously experienced and to progress the second monkey to this final phase of testing. The results provide tentative support for a primate prototype of auditory combinatorial semantics in nonhuman primates. They also demonstrate that such abstract learning is difficult for monkeys, altogether providing novel insights into language evolution.

Title: Heartbeat influences visual and auditory perception

Authors: *E. AL[1], S. TUNE[2], S. A. SHETH[3], J. OBLESER[2], S. HAEGENS[1];
[1]Columbia Univ., New York, NY; [2]Univ. of Luebeck, Luebeck, Germany; [3]Baylor Col. Of Med., Baylor Col. of Med., Houston, TX

Abstract: Our perception of the external world is not only influenced by the brain but also by the rest of the body. Here, we report two studies that investigate how body-brain interactions influence sensory perception. In the first study, we aim to answer whether cardiac and respiratory signals influence the perception of auditory signals. For this purpose, we conducted an experiment in which 19 subjects performed an auditory discriminatory and detection task. We measured respiratory and cardiac signals using a respiratory belt and ECG, and motor activity using EMG. We analyzed how (premotor) reaction times were influenced by the two phases of cardiac (i.e., systole and diastole) and respiratory activity (i.e., inhalation and exhalation) during discrimination and detection performance. During both tasks, we observed that subjects were faster to react when stimuli occurred during diastole compared to systole. No effect of the respiratory cycle was observed on reaction times. In the second study, we extended our analysis to the visual domain and asked how cardiac effects on sensory detection are influenced by distractors in the environment. We tested how the cardiac phase influences reaction times to visual stimuli in the presence and absence of distractors. Furthermore, we investigated how this interaction is reflected in broadband high-frequency activity (BHA) and visual-evoked potentials (VEP) using intracranial recordings in 18 patients with intractable epilepsy. Our results show that in the absence of distractors, subjects were slower at reacting to visual stimuli during systole compared to diastole. Furthermore, mean VEPs were observed to be attenuated in the time

windows of 98-122 ms and 258-278 ms following stimulus during systole compared to diastole in the absence of distractors. We did not observe any changes in BHA across the cardiac cycle. These effects show that the influence of heartbeat on perception depends on cognitive load.

Title: Modeling of perceived musical rhythms using intracranial electroencephalography

Authors: *M. DEXHEIMER[1], J. WALLNER[1], S. COLE[1], H. SHAH[1], C. HERFF[2], D. J. KRUSIENSKI[1];

Abstract: The neural correlates of auditory anticipation and perception in the human brain have been explored through various neuroimaging modalities and experimental protocols. Non-invasive neuroimaging typically lacks either spatial or temporal resolution and thus makes the identification and quantification of the relevant neural processes difficult. By leveraging the spatially and temporally resolute invasive sensing modalities of electrocorticography (ECoG) and stereoelectroencephalography (sEEG), it is possible to identify relevant spatiotemporal neural features and use them to model the temporal dynamics of an auditory stimulus. We collected data from epilepsy patients (n = 8) undergoing the localization of epileptogenic zones and eloquent cortex prior to surgical resection. Six of these participants were implanted with ECoG arrays and two with sEEG. The participants were instructed to passively listen to a systematic auditory presentation whereby a series of rhythmic drumbeats were presented with varying rhythm pattern, tempo, and complexity. Embedded in the trials were random silent intervals during which the participants were to imagine the rhythm pattern continuing. The resulting ECoG and sEEG data were used to reconstruct the imagined and perceived musical rhythms using participant-specific multiple regression models trained via Lasso regression. Two variations of the models were trained, each having a different temporal context. The first is a causal, anticipatory model that uses the past 250 ms of neural data to reconstruct the current stimulus amplitude envelope. The second is a non-causal, perceptual model that uses the future 250 ms of neural data to reconstruct the stimulus envelope. Both the perceptual and anticipatory models were able to reconstruct the perceived stimulus envelope ($p < .05$) with Spearman correlations between the actual stimulus and model output reaching $r = 0.49$, while the models were not able to reliably reconstruct the surrogate stimulus envelope for the imagined intervals. For both ECoG and sEEG, it was found that the temporal cortical regions were most relevant for both the anticipatory and perceptual models. The most relevant temporal contexts for the

perceptual and anticipatory models were between 50 ms to 150 ms and -50 ms to -150 ms, respectively. While the quality of the reconstructions varied across participants, the simple linear models were trained with a very limited amount of data from electrodes in suboptimal locations for this application. It is expected that the reconstructions can be significantly improved with better electrode coverage, larger amounts of data, and more sophisticated decoding models.

Title: Characterizing generators and spatiotemporal dynamics of spontaneous tau-rhythms in human temporal cortex

Authors: *N. SCHAWORONKOW[1], P. DONHAUSER[1], D. POEPPEL[1,2];
[1]Ernst Strüngmann Inst. for Neurosci., Frankfurt am Main, Germany; [2]New York Univ., New York City, NY

Abstract: Oscillations are omnipresent in human electrophysiological activity, with the most prominent rhythmic activity manifesting in the alpha-band (8-13 Hz). In the occipital and sensorimotor cortex, these rhythms have been shown to be important for excitability modulation, facilitating rapid processing of incoming stimuli, displaying a spatial organization capturing relevant dimensions of the modality-specific organization. In the auditory domain, the tau-rhythm is present in the human temporal cortex. On the premise that alpha-band rhythms are basic building blocks for processing functions that are reused across separate sensory domains, tau-rhythms are important to understand for auditory and speech processing. As the temporal cortex features a rich set of rhythmic and task-evoked activity in the theta- and delta-bands, a careful differentiated description of the spatiotemporal dynamics of tau-rhythms is needed. Therefore, we investigate generators and dynamics of tau-rhythms through the lens of high-resolution invasive electrophysiological data.
In a large iEEG dataset, encompassing both subdural grid as well as stereotactically placed depth electrodes, analysis of a diverse set of alpha-rhythm generators was performed, using segments of eyes open/eyes closed modulation as well as modulation by sound. Data-driven spatial filters were used to scan for rhythms with high alpha-band power, with an individually adjusted peak frequency. Identified alpha-band rhythms were mapped using a parcellation-based approach. Focusing on tau-rhythms in the temporal cortex, we found several independent oscillatory

sources for selected participants, with differential spatial spread across the temporal cortex and event-related desynchronization to sound. Next, we explored generative models of these rhythms using leadfield simulations, considering the possibility of traveling waves or separate oscillatory sources. The challenge to differentiate between those two cases arises because several oscillatory sources can result in apparent traveling waves due to spatial mixing. We identified wave propagation directions of prominent tau-oscillations, aligned with expectations based on different tau-generators, suggesting that the observed rhythms may arise from distinct sources within the temporal cortex.
We characterize the human tau-rhythm, identifying several oscillatory sources within temporal cortex. The findings contribute to the understanding of the family of different alpha-band rhythms and provide a necessary foundation for future investigation into functional significance of tau-rhythms in perceptual or cognitive processing.

Title: Distilling neural correlates of consciousness in auditory perception using fMRI

Authors: *T. DELLERT, H. BALSTER, R. MOECK, I. SCHLOSSMACHER, M. BRUCHMANN, T. STRAUBE;
Inst. of Med. Psychology and Systems Neurosci., Univ. of Münster, Münster, Germany

Abstract: What are the minimum neural mechanisms sufficient for conscious percepts? In the search for neural correlates of consciousness (NCC), predominant theories disagree about the role of posterior, sensory versus widespread, fronto-parietal brain activity. Previous research has focused on vision, while other sensory modalities have been neglected. Moreover, conscious perception was often confounded with task-related post-perceptual processes, such as decision-making and report. In the present study, we aimed at isolating NCC in auditory perception from task-related activity using functional magnetic resonance imaging (fMRI) and a no-report inattentional deafness paradigm. Sixty-three human participants (37 female, 26 male; 18-32 years old) performed an auditory distractor task, while task-irrelevant speech stimuli were presented in the background. Whereas one group was informed about the speech stimuli and later reported awareness of them, another group remained uninformed and experienced inattentional deafness. After awareness was assessed, both groups were able to detect the sounds. Brain responses to the task-irrelevant speech stimuli in aware compared to unaware participants were strongly increased in the bilateral superior and middle temporal gyrus. Awareness effects in fronto-parietal areas, however, were negligible. Thus, our findings suggest a dominant role of sensory rather than widespread fronto-parietal information processing in auditory consciousness.

Title: Auditory attention decoding through the classification of event-related potentials to glimpsed and masked events

Authors: *V. S. RAGHAVAN[1,2], J. O'SULLIVAN[1,2], S. BICKEL[3,4,5], A. D. MEHTA[4,3], N. MESGARANI[1,2];

Abstract: Objective. People suffering from hearing impairments often struggle to follow a conversation in a multitalker environment. Current hearing aids can suppress background noise; however, little can be done to help a user attend to a single conversation amongst many without first knowing which speaker a user is attending to. Cognitively-controlled hearing aids have been proposed using auditory attention decoding (AAD) methods; however, these methods have not been able to meet the demands of conversational speech or handle instances of distributed attention or inattention. Here, we propose a novel framework that directly classifies auditory event-related potentials (ERPs) to glimpsed and masked speech events to determine whether the source of the event was attended. Approach. We present a system that (1) identifies auditory events using the local maxima in the envelope rate of change, (2) assesses the temporal masking of auditory events relative to competing speakers, and (3) utilizes masking-specific ERP classifiers to determine if the source of the event was attended, ultimately amplifying the source of attended events to assist the listener. Main results. Using invasive electrophysiological recordings, we showed that ERPs from recording sites in auditory cortex can effectively decode the attention of subjects. This method of AAD provides higher accuracy and shorter switch times compared with traditional CCA-based methods, permitting the quick and accurate detection of changes in a listener's attentional focus. Significance. Our framework extends the scope of AAD algorithms by introducing a linear, direct-classification method for determining a listener's attentional focus that leverages the latest research in multitalker speech perception. This work moves us closer to the development of effective and intuitive cognitively-controlled hearing assistive devices.

Title: Attention allocation and level dominance: insights from an EEG study

Authors: *K. WATANABE, V. M. RICHARDS, R. SRINIVASAN;
Univ. of California Irvine, Irvine, CA

Abstract: Auditory level dominance is characterized by listeners' reliance on louder components when integrating information across a series of sounds. Past studies suggest that auditory attention is directed to the most intense elements of the sound sequence. The neural mechanisms underlying level dominance and the involvement of attention, however, remain poorly understood. This study investigated how the relative levels of neighboring sounds influence listeners' attention allocation to task-relevant sounds. In an intensity discrimination task, 12 normal-hearing listeners (18-34 years old) were presented with sequences of five sounds alternating between two intensity levels. The second and fourth sounds served as 'targets', where the increment in their levels was to be detected. During the experiment high-density EEG (128 channels) was recorded. Two conditions (figure left) were tested: 1) Low-Target condition (LT), where the 'non-targets' (first, third, and fifth) had a level of 70 dB, and the targets had a base level of 35 dB, and 2) High-Target condition (HT) was the converse of LT. Before the EEG sessions, listeners familiarized themselves with the task, and thresholds (ΔL in dB) were estimated for LT and HT conditions. Thresholds for the LT condition were significantly poorer than for the HT condition, indicating level dominance. During the EEG sessions, listeners performed the same tasks using fixed signal levels tailored to each individual. Because the two conditions share the same temporal structure (with reversed level patterns), inter-trial phase coherence (ITPC) was used to assess differences in neural phase-locking patterns between conditions. Preliminary results (figure right) suggest that listeners with lower threshold difference, or better performance, tend to exhibit *lower* ITPC in the LT than in the HT. This could be attributed to the fact they attend relatively better to the lower-level targets than those with higher thresholds, but their attention still tends to be directed to the higher-level non-targets.

Title: Auditory attention signatures across different neural frequency bands in the human auditory cortex

Authors: ***V. CHOUDHARI**[1,2], K. VAN DER HEIJDEN[2,3], P. M. PATEL[1,2], S. BICKEL[4,5], A. D. MEHTA[4,5], N. MESGARANI[1,2];
[1]Electrical Engin., Columbia Univ., New York City, NY; [2]Mortimer B. Zuckerman Mind Brain Behavior Inst., New York City, NY; [3]Donders Inst. for Brain, Cognition and Behavior, Radboud Univ., Nijmegen, Netherlands; [4]Hofstra Northwell Sch. of Med., Uniondale, NY; [5]The Feinstein Inst. for Med. Res., Manhasset, NY

Abstract: Auditory attention decoding involves using neural signals to decode the talker on whom attention is directed in a cocktail party setting. A common method for this is stimuli reconstruction in which a representation of the attended speech is reconstructed from neural signals and correlated with the speech representations of every talker in the acoustic scene. The decoded attended talker is determined as one whose speech representation yields the highest

correlation with the neurally reconstructed attended speech representation. If spatial separation between the talkers in the acoustic scene is assumed, another approach could be estimating the location where attention is directed, i.e., the location of the attended talker. A number of non-invasive and invasive studies have investigated auditory attention using the method of stimuli reconstruction, whereas studies investigating auditory spatial attention have mostly been non-invasive. For both the methods, it is important to determine which anatomical sites and frequency bands need to be targeted for achieving the best auditory attention decoding performance. Non-invasive techniques limit both anatomical specificity and reliable measurement of high frequency (40 - 150 Hz) neural activity. Intracranial recording techniques such as electrocorticography (ECoG) and stereo-electroencephalography (sEEG) help target specific anatomical regions and can reliably measure both low and high frequency neural activity. However, invasive studies (using the method of stimuli reconstruction) have rarely looked at signatures of auditory attention beyond the high gamma band (70 - 150 Hz). It is unclear how the neural activities across various frequency bands on different sites of the auditory cortex embed signatures of auditory attention. To answer this, we recorded invasively from neurosurgical patients as they (1) listened to spatialized single-talker speech stimuli and (2) selectively attended to a single talker in a spatially-separated multi-talker speech setting. Frequency analysis of the neural activity recorded from various sites on the auditory cortex reveals location and speaker selectivity patterns consistent across different subjects. We also characterize auditory attention decoding performance across different neural frequency bands and anatomical regions of the auditory cortex. Together, these results shed light on what regions and neural frequency bands can be used for auditory attention decoding depending on the method and level of invasiveness.

Title: Neural-attentional filtering does not predict individual change in aging adults' listening behaviour

Authors: *S. TUNE, J. OBLESER;
Univ. of Luebeck, Luebeck, Germany

Abstract: Preserved communication abilities promote social well-being and healthy aging. While sensory acuity deteriorates, an age-independent support mechanism for communication

arises when attention-guided neural filtering of relevant sensory information in auditory cortex is preserved. Yet, how longitudinally stable is such a compensatory brain-behaviour link? More generally, has neural filtering any potency in predicting inter-individual differences in future changes in behavioural functioning? We here tracked N=105 individuals neurally and behaviourally over approximately two years (age-varying cohort of 39-82 yrs). First, despite the expected decline in sensory acuity, listening-task performance proved remarkably stable. Second, when looking into each measurement time point separately (T1, T2), neural and behavioural metrics were correlated with each other. However, neither neural filtering at T1 nor its T1-T2 change were predictive of individuals' two-year change in listening behaviour, under a combination of modelling strategies. Our results cast doubt on the translational potential of attention-guided neural filtering metrics as predictors of longitudinal change in listening behaviour over middle to older adulthood. Our data support the conjecture that audiology-typical listening behaviour and neural filtering ability follow largely independent developmental trajectories associated with significant inter-individual variability.

Title: Are pupil size and neural alpha power similarly sensitive to reward prospect under demanding listening conditions?

Authors: *F. KRAUS[1], J. OBLESER[1], B. HERRMANN[2];
[1]Psychology, Univ. of Luebeck, Luebeck, Germany; [2]Baycrest, Rotman Res. Inst., Toronto, ON, Canada

Abstract: Pupil size and neural alpha oscillatory power are often used to indicate cognitive demand, but it is unclear how much these metrics covary with an individual's motivational state. Here we tested whether pupillometry and alpha power are sensitive to both listening demand and motivational state. Participants performed an auditory gap-detection task while pupil size or magnetoencephalogram (MEG) were recorded. Task difficulty and a listener's motivational state were orthogonally manipulated through changes in gap duration and monetary-reward prospect, respectively. While participants' performance decreased with task difficulty, reward prospect enhanced performance under hard listening conditions. Pupil size increased with both task difficulty and higher reward prospect. Importantly the reward-prospect effect was largest under difficult listening condition. Moreover, larger pre-gap pupil size was associated with faster response times on a within-participant level. In contrast, neural alpha power showed no effects of reward-prospect. Of relevance to the utility of pupillometry in audiology and translational neuroscience, pupil size indexed higher motivational state especially under demanding listening. However, we could not find a similar response of neural alpha power. These results add to the mounting evidence that pupil size and alpha power are not two interchangeable physiological indices of cognitive investment.

Group, Max Planck For Empirical Aesthetics, Frankfurt Am Main, Germany

Abstract: The predictive coding theory suggests that the brain swiftly detects any deviations or discrepancies by comparing incoming sensory signals with internally generated predictions based on prior knowledge and contextual cues. When these predictions are unexpectedly contradicted, local cortical circuits generate prediction error signals, leading to the updating of predictions. Despite its significance, the precise localization and nature of the prediction error and prediction signals during auditory sequence processing remains elusive. In this study, we utilized intracranial EEG (iEEG) recordings with a high spatiotemporal resolution to elucidate cortical regions generating auditory predictive signals and to characterize their relationships. In order to simultaneously examine neural responses to unexpected deviant sounds (prediction error) and omissions (prediction), we adapted an auditory oddball paradigm where syllables were repeated four times in a sequence. Occasionally, we replaced the last repetition with either a deviant syllable (20%) or omissions (20%). We evaluated the high-gamma responses, thought to reflect multi-unit activity, to the standard syllables, deviants and omissions. We found that electrodes in the superior temporal gyrus (STG), inferior frontal gyrus (IFG), and sensorimotor areas exhibited both oddball and omission responses, with their amplitudes positively correlated. Critically, these responses were not solely driven by motor preparation, as they were also observed in a passive listening condition without any motor response requirement. Next, to explore the predictive nature of omission signals, we trained a support vector machine (SVM) to decode the syllable identity. SVMs trained with sensory-evoked high frequency broadband (HFB) activity and event-related potentials (ERPs) successfully decoded the syllable identity. However, SVMs trained with HFB or ERP responses to omissions failed to decode above chance level. In summary, our results suggest a common neural substrate for oddball and omission responses, while highlighting that top-down driven prediction signals do not convey stimulus-specific information. These findings contribute to our understanding of auditory processing and the mechanisms underlying predictive coding in the human brain.

Title: Modeling Audiovisual Interference in Absolute Pitch

Authors: *D. ROSENZWEIG[1], E. NING[3], D. POEPPEL[2], C. PELOFI[2];
[2]New York Univ., [1]New York Univ., New York, NY; [3]Univ. of Illinois Chicago, Chicago, NY

Abstract: How neuronal systems support invariant object classification and labeling is a fundamental problem in neuroscience. Absolute pitch (AP) is the rare ability to identify and label tones without access to external reference, and as such represents an example of auditory object recognition. A simple model to account for this might consist of a classification task for a neural network retrieving labels corresponding to fundamental frequency, but it remains unknown how this computation is implemented in the brain. Altogether, AP serves as an identifiable behavioral marker for studying architecture in the left dorsal stream contributing to rapid identification and labeling of fundamental frequency.
In this study, we examine audiovisual interference in musicians with AP and determine whether retrieval processes occur automatically and without instruction. We recruited a group of trained musicians and identified AP participants through accuracy performance on a pitch labeling task. In a behavioral audiovisual Stroop task, we found that AP musicians demonstrated interference as measured by increased RT on mismatch as compared to match trials of the task. In contrast, non-AP musicians did not demonstrate this audiovisual incongruence effect, as reflected in similar RTs across match and mismatch conditions. These behavioral findings support the hypothesis that invariant pitch classification and labeling occurs automatically and without instruction in musicians with AP. In a follow-up MEG study, we investigate the hypothesis of automatic activation for phonetic representations when AP musicians perceive tones. We then analyze the time course of this interference process to gain insight into the computational underpinnings and neural architecture supporting AP pitch labeling.

Title: Brain state predictors of three canonical perceptual listening errors

Authors: *S. S. SMITH, J. A. SUGAI, K. E. HANCOCK, D. B. POLLEY, PhD;
Eaton-Peabody Labs., Mass Eye and Ear / Harvard Med. Sch., Boston, MA

Abstract: Our perception of sound is related to - but not determined by - the acoustic waveform entering the ear. The same fixed sound can be misheard as another (error of confusion), not heard (error of omission), or heard when no sound was presented (error of commission). An observer can produce each of these error classes despite static auditory evidence and task context. In animals, this variability has been causally linked to fluctuations in global brain state - endogenous patterns of neuromodulator activity linked to arousal and attention. Here, we hypothesized that neural and physiological indices of brain state are predictive of canonical forms of auditory perceptual errors in human subjects. To investigate, we developed a sustained vigilance task in which subjects were asked to monitor a stream of tone clouds for strings of repeating tones. The task was configured such that participants could misclassify the length of strings (error of confusion), fail to report detection of a string (error of omission), and/or report a string where there was none (error of commission). Simultaneously, 64-channel EEG, pupil diameter, eye gaze, and blinks were recorded. We derived the string-aligned profiles of these neurophysiological measures for each of the behavioral outcomes, comparing against correct trials. Measurements were made in a cohort of 41 normal hearing, neurotypical, young/middle-aged adults (≤50 years, 11 male). The occurrence of a target response string elicited a stereotyped neuroelectric, oculomotor, and autonomic pupillary response. These responses were suppressed for errors of omission, yet partially present for errors of commission. Misclassifications of string length (i.e., errors of confusion) were characterized by sustained power at the counting frequency (8 Hz), which was instead reduced during correct trials. Importantly, neuroelectric and autonomic signatures for particular forms of listening errors were identifiable seconds before the string initiation. For errors of confusion, pupil diameter and global EEG activity were reduced in size several seconds before target onset ($p<0.01$). This reduction was largest during later blocks when task performance was highest. Overall, these results show that, in neurotypical human subjects, auditory errors can be accounted for by dynamic neural and physiological indices of brain state. These findings may highlight biomarkers in neurodivergent populations who remain fixed in states of heightened commission errors (e.g., auditory hallucinations and tinnitus), omission errors (e.g., catatonia), or classification errors (e.g., dementia).

Title: Neural correlates of auditory working memory precision: an intracranial EEG study

Authors: *J. I. BERGER[1], A. J. BILLIG[2], P. E. GANDER[1], M. LAD[3], S. KUMAR[1], K. V. NOURSKI[1], C. K. KOVACH[1], A. E. RHONE[1], C. M. GARCIA[1], H. KAWASAKI[1], B. J. DLOUHY[1], M. A. HOWARD, III[1], T. D. GRIFFITHS[4];

Abstract: Working memory is the capacity to hold and manipulate behaviorally relevant information in mind. Previous work (Kumar et al., Neuropsychologia 2021 150:107691) examined auditory working memory (AWM) during maintenance of a tone using intracranial EEG and described oscillatory local field potential (LFP) correlates of AWM in auditory, frontal cortices, and the hippocampus. The present study sought to identify correlates of precision of working memory, reflecting cognitive resources available in models (Joseph et al., Brain Res 2016 1640:183-92). Neural correlates of precision were hypothesized to emerge in the hippocampus based on both LFPs and single units during maintenance and retrieval. Behavioral responses to the task and LFPs from the hippocampus (HC) were recorded in four adult neurosurgical patients undergoing invasive monitoring for presurgical localization of epileptic foci [wherein the hippocampus was subsequently found to be not a seizure focus]. In three patients, single units were also recorded in the HC and Heschl's gyrus (HG). For the AWM task, participants were presented with short target tones, each followed by a 3 s retention period. The task was to adjust a test tone to the target within 5 s. Working memory precision was calculated over all trials based on the reciprocal of the standard deviation of the response error. LFP data were analyzed using time-frequency analysis based on wavelet transforms, and single units were isolated with an automated spike-sorting procedure and examined with trial raster plots and peri-stimulus time histograms. Participants performed the task with similar precision to previously studied healthy controls (Lad et al., Sci Rep 2020 10:13997). Low-frequency LFP activity (<8 Hz) across all HC contacts persisted throughout the retention period. Low frequency activity was pronounced at the onset and following the offset of the tuning period, concurrent with high gamma (70-150 Hz) suppression. Desynchronization of theta (4-8 Hz) and alpha (8-15Hz) HC activity occurred at the end of the trial. In two participants with HG and HC electrode coverage, there was an increase in theta-band phase locking between these regions at the onset of the retention period and the offset of the retrieval period. Increases in single unit firing were evident during encoding, retention and retrieval in HG and HC. For some neurons, responses during retrieval correlated with behavioral performance. Overall, the data highlight neural correlates of precision of AWM and implicate the hippocampus in both maintenance and retrieval of non-verbal AWM.

Title: Modality-independent temporal segmentation principles

Authors: *L. GARAMI[1,2], C. ANGELONI[3], M. N. GEFFEN[2], J. FISER[4];
[1]Cognitive Sci. Dept., CEU, Budapest, Hungary; [2]Univ. of Pennsylvania Sch. of Med., Philadelphia, PA; [3]Univ. of Pennsylvania, Philadelphia, PA; [4]Dept. of Cognitive Sci., Central European Univ., Budapest, Hungary

Abstract: Sensory systems extract patterns at varying complexity from the input. Such extraction of meaningful patterns (chunking) is key to fast and efficient coding of environmental information, but it also biases sensitivity to changes and accuracy in recognition. Despite being a common feature across different modalities, organizing principles of chunking are usually tested modality-specifically preventing the detection of the modality-independence of chunking principles and their behavioral consequence. We hypothesized that certain chunking principles and the resulting perceptual biases are similar across modalities, and their neural correlates are already present in the primary cortical areas.To test our hypothesis, we focused on a well-known auditory chunking principle called the Iambic-trochaic law. In language processing, longer syllables have the tendency to signal word ends and similarly, longer duration of a tone in a sequence without any linguistic content also tends to be interpreted by both adults and six-month-old babies as the end of a chunk. Specifically, people tend to interpret the stream of an auditory stimulus train consisting of short (S) and long (L) tones separated by silence (… S S L S S L S S L …), as a repeating pattern of SSL rather than any other alternatives (e.g., SLS). Importantly, this chunking resells in a decreased detection accuracy of randomly inserted gaps at a perceived chunk's border compared to inside of the chunk.To test the universality of this chunking principle, we tested if bias in human performance in temporal change detection is comparable in the visual modality. We implemented the SSL stream segregation go/no-go paradigm for human participants identical in vision and audition. Human participants had a lower d-prime if an unexpected gap was inserted after the long object (tone or square) in both modalities.We recorded neuronal activity in the auditory cortex (AC) of awake, head-fixed mice passively listening to acoustic stimuli. We tested whether and how neurons in the AC detect gap insertion in a repeating pattern of a similar continuous stream. We found that activity in the AC was significantly higher in response to stimuli with unexpected gap insertion when the gap was

inserted prior to the long tone than when it was inserted prior to one of the short tones.We used identical paradigms across modalities (aud/vis) and models (human/mouse). Our results support the idea of domain-general non-linguistic grouping principles and raise well-testable further questions that have the capacity to lead to a domain-independent model of sensory processing.

Title: Changes in Cortical Directional Connectivity during Difficult Listening in Younger and Older Adults

Authors: B. SOLEIMANI[1], I. M. D. KARUNATHILAKE[1], P. DAS[3], S. E. KUCHINSKY[4], B. BABADI[2], ***J. Z. SIMON**[5];

Abstract: Fully understanding the neural underpinnings of speech comprehension in difficult listening conditions requires understanding the concurrent cortical connectivity. Granger causality is a useful measure of connectivity, typically employed in functional magnetic resonance imaging (fMRI) studies, but the limited temporal resolution of fMRI restricts the capture of higher frequency neural interactions crucial for complex speech processing. On the other hand, although magnetoencephalography (MEG) can capture neural interactions at the millisecond scale, its limited spatial resolution poses challenges in conventional connectivity analyses. A recently proposed cortical connectivity analysis methodology, network localized Granger causality (NLGC), can extract Granger causal interactions in MEG data without the need for any intermediate source-localization step. This one-shot approach also effectively addresses challenges related to false alarms and localization errors, providing a robust assessment of cortical connectivity. In this study, NLGC is applied to MEG recordings from younger and older adults while performing a speech listening task with varying background noise conditions. The analysis focuses on directional cortical connectivity patterns within and

between the frontal, temporal, and parietal lobes, specifically in the delta and theta frequency bands. The results demonstrate significant age- and condition-related connectivity differences, particularly in the theta band. In younger adults, increasing background noise leads to a shift from predominantly temporal-to-frontal (bottom-up) connections for clean speech to dominantly frontal-to-temporal (top-down) connections in noisy conditions. In contrast, older adults exhibit bidirectional information flow between frontal and temporal cortices regardless of the background noise. Furthermore, NLGC allows classification of connections as either excitatory or inhibitory based on their temporal relationships, enabling a more nuanced understanding of the neural mechanisms involved in speech perception. While delta band connection types show no significant age-related changes, theta band connection types exhibit substantial changes in excitation/inhibition balance across age and condition. Title: Recall of spoken narratives by adult users of cochlear implants and normal-hearing adults with noise-band vocoding: strategic pauses alleviate pupillometry-indexed cognitive effort while listening to time-compressed speech

Authors: R. M. O'LEARY[1], J. NEUKAM[3], T. A. HANSEN[1], A. J. KINNEY[1], N. CAPACH[3], M. SVIRSKY[3], *A. WINGFIELD[2];
[1]Brandeis Univ., Waltham, MA; [2]Brandeis Univ., Boston, MA; [3]NYU Langone Med. Ctr., New York City, NY

Abstract: Although current cochlear implants (CI) contain as many as 22 intra-cochlear electrodes, CI users may not have spectral resolution (perceptually separated bands of frequency information) beyond the equivalent of 4 to 8 frequency channels due to factors such as current spread and neural survival. It is thus not surprising that CI users find the perception of time-compressed speech especially challenging due to the combined effects of a sharply degraded CI signal, and the reduced acoustic richness of time-compressed speech. At the cognitive level, the rapidity of time-compressed speech can deprive the listener of the ordinarily available processing time present when speech is delivered at a normal speech rate. Two experiments are reported. Experiment 1, conducted with 27 young adults with normal hearing, used noise-band vocoding

to simulate the spectrally limited sound of the CI signal. Results showed that inserting silent pauses after sentence and clause boundaries within a time-compressed narrative ("time-restoration") improved recall accuracy to the level similar to that for speech heard a normal speech rate for clear speech, and speech heard with 10-channel vocoding, and to a significant but lesser extent with 6-channel vocoding. The measurement of task-related changes in pupil diameter as an index of cognitive effort, showed the insertion of pauses in the rapid speech to reduce processing effort to a level similar to that for speech heard at a normal speech rate. In Experiment 2, 15 adult CI users were tested using the same materials. Unlike the listeners with normal hearing, meaningful improvement in recall accuracy with time-restoration was limited to a subgroup of CI users defined by better scores on a test of working memory resources, as well as higher scores on tests of word and sentence recognition. These findings are interpreted in the context of sensory-cognitive interactions within data-limited and resource-limited processes among adult cochlear implant users.

Title: Eeg as an indicator for perceptual difficulties in noise?

Authors: *J. LIU[1], J. STOHL[2], T. OVERATH[1];
[1]Duke Univ., Durham, NC; [2]MED-EL Corp., Durham, NC

Abstract: This study aimed to investigate whether EEG could capture the internal noise associated with cochlear synaptopathy in humans and whether it correlates with hearing difficulties. Cochlear synaptopathy has been the subject of numerous studies in the past decade, but the reaction of the auditory cortex to it remains unclear. A recent mouse study suggested that with 90% synapse loss, the auditory cortex exhibits hyper-synchronized neuronal activity (‘internal noise’) only in missed tone detection trials in noise, which could contribute to degraded behavioral performance in noisy listening conditions (Resnik & Polley, 2021). In this study, 30 participants with near-normal hearing performed a monaural tone detection task in either quiet or noise while their EEG was recorded. They also underwent tasks that have been suggested to reveal cochlear synaptopathy. The analysis aimed to determine whether single-trial EEG could predict behavior (hit vs miss) and whether such EEG prediction correlated with other indicators of cochlear synaptopathy. Ongoing EEG analyses suggest that pre-stimulus EEG activity does not predict behavioral outcomes. In contrast, significant prediction performance of

post-stimulus EEG likely reflects the presence of the P300 component for hit trials, but not earlier auditory processing stages. This prediction performance was correlated with the Speech, Spatial and Quality of Hearing questionnaire, but not with any of the other measures, such as speech perception thresholds or extended-high-frequency audiometric thresholds. More data is needed to determine the effect robustly.

Imaging, [2]Otolaryngology, [3]Summer Undergraduate Program, ci2 Ctr. for Intelligent Imaging, UC San Francisco, San Francisco, CA; [4]Audiol., Univ. of Pacific, San Francisco, CA; [5]Minnesota Epilepsy Group, Saint Paul, MN; [6]Sch. of Med., Virginia Tech., Roanoke, VA; [7]Dept. of Psychology, Univ. of Texas at Austin, Austin, TX; [8]Dept. of Otolaryngology, Univ. of Minnesota, Minneapolis, MN; [9]Joint Program in Bioengineering and Therapeut. Sci., UC Berkeley - UC San Francisco, San Francisco, CA; [10]Surgical Services, DVA, San Francisco, CA

Abstract: Subjective tinnitus refers to conscious perception of sound for which no external auditory stimulus is identified. Models of tinnitus postulate increased connectivity between auditory cortex and basal ganglia, limbic areas, or frontal areas. Brain imaging may objectively determine presence and magnitude of percept and assist in understanding underlying physiology. At one of 2 study sites, 380 adults with (N = 185) and without (N = 195) tinnitus underwent 5 minutes of task-free eyes-closed magnetoencephalography (MEG), structural imaging (MRI), audiometry, and tinnitus assessment (TFI). A subset (N=44) repeated the study. Source imaging localized 1 to 4 minutes of MEG activity within brain anatomy. Voxel-based activity, parsed into

6 frequency bands and spatially-normalized, was mapped to 246 Brainnetome atlas regions. Imaginary coherence (ImCoh) and directional phase transfer entropy (dnPTE) were calculated between each unique pair of regions. Analysis of variance (rmANOVA), repeated across frequency with group, age, and site, provided F-ratios and FDR-corrected p-values for pairwise connectivity, as well as relation to TFI. Binomial linear regression queried contribution of band to group effects. Linear discriminant analysis with 10-fold cross validation assessed potential for classification. Groups differed at 4 pairs out of 30,012 queried. Using ImCoh, tinnitus exhibited increased slow oscillatory connectivity between regions in left temporal and right frontal cortex (LPHG-RIFC: $F=9.00$, $p<.01$) and (LITC-ROFC: $F=9.04$, $p<.01$), driven by delta (1 - 3 Hz, LPHG-RIFG: $B = 25.8$, $t=4.21$; LITC-ROFC: $B = 15.6$, $t=3.14$, both $p<.01$). For dnPTE, tinnitus showed decreases in intrahemispheric high gamma (63 - 117 Hz) connectivity between portions of cingulate and parietal cortex (Left: $F=12.4$, $B = -1.16$, $t=-4.67$, $p<.01$; Right: $F=12.31$, $B = -1.16$, $t=-3.97$, $p<.01$). Using connectivity of these pairs in identified bands as classifiers produced acceptable levels of diagnostic performance (AUC =.74 [.68 - .78]). TFI scores changed from Session 1 to 2 (paired $t=2.13$, $p=.045$), but with considerable distribution overlap (K-S test, $K=.27$, $p=.33$). Tinnitus-related differences in connectivity can adequately classify tinnitus and non-tinnitus participants. Commonalities among these 4 regions may further our understanding of the underlying physiology of tinnitus. Paradoxically, group connectivity differences did not relate to subjective scores used to diagnose tinnitus. However, TFI appeared to change from session-to-session, while connectivity largely did not, indicating that neural measures of tinnitus may be more stable than subjective measures.

Title: Analysis of Psychophysiological Interactions (PPI) with auditory stimuli in patients with unilateral severe hearing loss

Authors: *K. YAMAMOTO, T. TSUTSUMI;
Otolaryngology, Tokyo Med. and Dent. Univ., 1-5-45 Yushima, Japan

Abstract: Previously, unilateral hearing loss was not considered a significant disability. However, recent discussions have acknowledged the impairments and psychological burdens associated with this condition. Yet, in clinical practice, there are no tests to visualize the influence of psychological factors associated with different types of auditory inputs. Therefore, we investigated the impact of inherent mental processes in auditory tasks on the functional

connectivity in unilateral severe hearing-loss patients with PPI.The subjects included 20 healthy individuals, 9 left and 12 right hearing-loss patients. They underwent 3 dimentional high-resolution anatomical MRI in a 3 Tesla MRI scanner following hearing 2 monosyllables and 1 pure tone of both ears. After imaging, we analyzed the task specific psychological effects using Matlab and SPM12 software packages. During the tasks, activity was observed in both the auditory cortex and auditory association areas for all groups. In the healthy group during the monosyllables' task, the primary auditory cortex in the left temporal area demonstrated the most significant activity and we set it as the seed. For the right hearing-loss group, there was an increased connectivity with the left superior temporal gyrus. While for the left hearing loss group, there was an enhanced connectivity with the both mid-cingulate cortex. Upon examining the correlation between these connectivity and age, the right hearing loss group showed a strong positive correlation, while the left hearing loss group demonstrated a negative correlation. The Positive correlation may suggest that monosyllable-stimuli from the left ear intensify the connectivity within the auditory region. Conversely the negative correlation may suggest that monosyllables entering from the right ear might strengthen the connection between the monosyllable stimuli and the activity of the cingulate gyrus by modulating the primary auditory cortex's activity.PPI in the both hearing loss patients showed that the psychological effects obtained from auditory information activate different neural pathways depending on the side of ear. Furthermore, the negative correlation between the cingulate gyrus and age suggests that connectivity occurs in the early onset of hearing loss, but weakens over time. Conversely the positive correlation between the auditory related areas and age suggests that not only psychological factors, but also the amount of auditory information, can strengthen the connectivity. These findings may indicate that the area connected with the auditory cortex varies depending on the side of input and the type of information.

Title: The idiosyncratic nature of neuroplasticity: investigating the impact of congenital deafness on individual brain organization

Authors: *L. AMARAL[1], X. WANG[2], Y. BI[2,3], E. STRIEM-AMIT[1];
[1]Georgetown Univ. Med. Ctr., Washington, DC; [2]Beijing Normal Univ., Beijing, China;
[3]Chinese Inst. for Brain Res., Beijing, China

Abstract: The principle of "all different, all equal" presents a challenge in cognitive neuroscience, where studies have consistently demonstrated a universal organization of the human brain. However, these investigations have been limited in capturing individual variations in neural organization. Individual differences play a crucial role in shaping certain neural patterns, with environmental factors and personal experiences contributing significantly to observed variability. In this study, we aimed to examine the role of sensory experience in functional connectivity (FC) patterns, specifically focusing on FC from the deprived primary auditory cortex of congenitally deaf individuals (N = 39) compared to a hearing control group (N = 33). Our findings demonstrate that the absence of shared auditory experience leads to increased variability in FC patterns across deaf individuals, in contrast to the more consistent patterns observed in the hearing group. To investigate the specific effects of sign language deprivation and determine whether the variations in brain connectivity are influenced by auditory deprivation or language deprivation, common among deaf children of hearing parents, we also examined the FC patterns focusing on a subset of the deaf group consisting of individuals who are native signers. Our analysis revealed comparable patterns of individual variability in FC within this subgroup, when compared to a broader analysis that encompassed both native and nonnative signers. This finding provides evidence that the individual differences in FC of the auditory cortex in deafness primarily arise from auditory deprivation. Collectively, these results highlight the interplay between brain plasticity and individual variability, showcasing the varied manifestation of reorganization across individuals. Furthermore, our study elucidates the influence of sensory experiences in establishing consistency in brain organization. These findings have important implications for the development of individualized medicine for hearing loss, such as the design of sensory aids and the utilization of restoration techniques.

Title: Functional neuroanatomy of musical familiarity and temporal structure in frontotemporal dementia

Authors: *L. CORE, J. D. WARREN, J. L. AGUSTUS;
Dementia Res. Ctr., Univ. Col. London, London, United Kingdom

Abstract: Using music as an index of brain function and for intervention in dementia has received great attention. However, the neural correlates of music perception in different dementias remain poorly defined. In the frontotemporal dementia (FTD) spectrum, individuals with semantic variant primary progressive aphasia (svPPA) and behavioral variant frontotemporal dementia (bvFTD) often exhibit striking changes in musical function and/or retained musical skills, suggesting FTD may be an instructive disease model in which to assess brain mechanisms of music processing in neurodegenerative pathologies. We addressed this issue using functional magnetic resonance imaging (fMRI) in patients with FTD. Nineteen patients (10 svPPA, nine bvFTD) and 26 healthy age-matched controls underwent 3-Tesla 'sparse' fMRI where they passively listened to musical melodies. In a 2x2 factorial design, stimulus conditions were manipulated to assess two key dimensions of musical processing: semantic memory (familiarity: familiar vs. novel melodies) and perceptual features (temporal structure: isochronous vs. anisochronous melodies). Post-scan behavioral testing assessed participants' ability to discriminate melodies under each of the two manipulated stimulus dimensions. Information about participant demographics and musical background was also collected. Both groups exhibited a wide bi-hemispheric network of activation centered on primary auditory cortex in response to general auditory stimulation. The healthy older control group showed separable profiles of activation in anterior temporal and inferior frontal cortices for processing musical familiarity and in posterior superior temporal cortex for processing musical temporal structure. An interaction effect was also observed in left medial planum temporale whereby anisochrony had a greater impact on the processing of unfamiliar melodies than familiar melodies. Compared to healthy older listeners, the patient groups showed differential patterns of engagement of these distributed neural networks. In post-scan behavioral testing, patients with bvFTD were significantly impaired on musical familiarity judgments relative to healthy controls. This study illustrates that FTD syndromes show distinct functional neuroanatomical signatures of music perception. Future work should explore fMRI of music processing as a probe of neural function in particular molecular pathologies and a candidate marker of therapeutic potential in dementia.

Title: Neural Tracking Measures of Speech Intelligibility: Manipulating Intelligibility while Keeping Acoustics Unchanged

Authors: *I. KARUNATHILAKE[1], J. P. KULASINGHAM[2], J. Z. SIMON[3];
[1]Univ. of Maryland, College park, MD; [2]Linköping Univ., Linköping, Sweden; [3]Univ. Maryland, Col. Park, Chevy Chase, MD

Abstract: Neural speech tracking has advanced our understanding of how our brains rapidly map an acoustic speech signal onto linguistic representations and ultimately meaning. However, it remains unclear which aspects of the corresponding neural responses correspond to speech intelligibility, which is only loosely coupled to the acoustics. Intelligibility related neuro-markers derived from such neural responses would play a crucial role in advancing our understanding of the neurophysiology of the speech understanding, evaluation of auditory function across diverse clinical populations, and hearing device evaluation. Many studies addressing this question vary the level of intelligibility by manipulating the acoustic waveform, making it difficult to cleanly distinguish effects of intelligibility from the underlying acoustical confounds. In this study, speech intelligibility is manipulated while keeping the acoustical structure unchanged, using degraded speech plus a priming paradigm. Acoustically identical three-band noise vocoded (degraded) speech segments (~20 s duration) are presented twice, but the second presentation is preceded by the original (non-degraded) version of the same speech segment. This priming, which generates a 'pop-out' percept, substantially improves the intelligibility of the second presentation of the degraded speech passage while keeping the acoustics identical. We recorded magnetoencephalography (MEG) data from 25 younger adults and investigated how intelligibility affects auditory and linguistic neural tracking measures using multivariate Temporal Response Functions (mTRFs). As expected, behavioral results confirmed that perceived speech clarity is improved by priming. mTRF analysis revealed that auditory (speech envelope and envelope onset) and phoneme onset neural responses are influenced only by the acoustics of the sensory input (bottom-up driven mechanisms). Critically, our key findings suggest that neural measures associated with the segmentation of sounds into words emerges first with better speech intelligibility, especially those time-locked at N400-like latencies in prefrontal cortex (PFC), in line with engagement of top-down mechanisms associated with priming. Taken together, our results suggest that time locked neural responses associated with lexical segmentation may serve as novel objective measures of speech intelligibility.

Title: Neural tracking of linguistic features at different speech rates using a deep neural network

Authors: *C. PUFFAY, J. VANTHORNHOUT, M. GILLIS, B. ACCOU, H. VAN HAMME, T. FRANCART;
KU Leuven, Leuven, Belgium

Abstract: The extent to which the brain tracks a natural continuous speech stimulus can be measured by modeling the relationship between the stimulus features and the corresponding EEG. Typically acoustic features are used, but the neural tracking of lexical and linguistic features has also been shown. Lexical features (i.e., word and phoneme onsets) carry information about the prosody, while linguistic features (i.e., word surprisal, word frequency, phoneme surprisal, and cohort entropy) carry information about the value of a word or a phoneme considering the semantical context. Such information can be used as a marker of speech understanding. Nonlinear deep learning models have recently been used to assess the neural tracking of lexical and linguistic speech features. We here evaluate these models on a dataset with various speech rates to manipulate speech understanding and investigate how speech rate affects the neural tracking of linguistic features. We use the EEG of 18 participants who listened to stories at various speech rates. We developed a deep neural network, trained on a match-mismatch task to measure the contribution of linguistic features to neural tracking on top of the contribution of lexical features. In this task, the model must choose whether a segment of brain signal matches the auditory stimulus that evoked it (matched) or another arbitrary segment (mismatched). Without re-training, we evaluate this model on different speech rates. To assess whether neural tracking is related to speech understanding, we compare the model performance with behavioral measures. We hypothesize that neural tracking of linguistic features is affected by the speech rate, which provides an objective measure for speech understanding. As opposed to linear subject-specific models, our deep learning model can model nonlinearities in the brain response and does not require training on new subjects to perform the speech understanding assessment.

Title: Predicting intelligibility of continuous speech using scalp- and ear-EEG

Authors: *H. BORGES[1,2], J. ZAAR[2,3], E. ALICKOVIC[2,4], C. CHRISTENSEN[1], P. KIDMOSE[1];

[1]Ctr. for Ear-EEG, Univ. of Aarhus, Aarhus N, Denmark; [2]Oticon A/S, Eriksholm Res. Ctr., DK-3070 Snekkersten, Denmark; [3]Hearing Systems, Dept. of Hlth. Technol., Tech. Univ. of Denmark, Kongens Lyngby, Denmark; [4]Dept. of Electrical Engin., Linkoping Univ., Linkoping, Sweden

Abstract: In the clinic, speech intelligibility is measured behaviorally by determining the speech reception threshold (SRT). The SRT is the signal-to-noise (SNR) at which 50% of the presented speech is repeated correctly by the participant. This process requires the attention of the listener, depends on the experience of the examiner, and is very labor-intensive. As an alternative, studies have shown that the SRT of matrix sentences can be predicted from electroencephalographic (EEG) measurements. The present study aims to investigate whether the SRT can be predicted from EEG collected with a continuous speech stimulus to improve the ecological validity of the paradigm. An additional objective is to investigate whether the SRT can be predicted from ear-EEG recordings. Ear-EEG is a measuring technique where EEG is measured from electrodes placed in the ear with the potential to enable discrete recordings of EEG outside the lab in daily-life situations. Twenty-two subjects (19 female), 18-29 years old (mean age 24), were recruited. All subjects were normal hearing (thresholds≤20 dB HL) at audiological frequencies from 125-8000 Hz as determined by behavioral audiometry and an average threshold of maximum 10 dB HL. Sentences from the Danish Hearing-In-Noise Test (HINT) were used to determine the behavioral SRT via an adaptive procedure. To predict the SRT from EEG, scalp and ear-EEG was recorded while the subjects were listening to 96 audiobook clips, each lasting approximately 1 minute. The subjects were instructed to listen to the speech and answer a two-choice content-related question after each clip. The audiobook clips were presented at six different SNR levels: SRT, SRT±2dB and SRT±4 and clean speech. 16 clips per SNR were presented in a randomized order. To approximate the SRT from scalp- and ear-EEG, an auditory attention decoding model that reconstructs the envelope of the presented speech from the EEG data was used. Pearson's correlation between the reconstructed envelope and the actual envelope of the stimulus was used as a measure of reconstruction accuracy. A sigmoid function was fitted to the reconstruction accuracy-vs-SNR data, and the SNR corresponding to the midpoint of the function was taken as an estimate of the SRT. The results will be discussed with focus on the relationship between the behaviorally determined SRT and the SRT predicted from scalp- and ear-EEG.

Title: Prediction of speech-in-noise ability using a dynamic auditory figure-ground stimulus

Authors: X. GUO[1], E. BENZAQUEN[1], I. BRÜHL[2], M. LAD[1], ***T. D. GRIFFITHS**[3];
[1]Biosci. Inst., Newcastle Univ., Newcastle-upon-Tyne, United Kingdom; [2]Univ. of Koeln, Koeln, Germany; [3]Biosci. Inst., Newcastle upon Tyne, United Kingdom

Abstract: Auditory figure-ground stimuli have been developed as measures of central sound grouping in complex auditory scenes. Previous studies have shown that extracting a static figure comprising multiple fixed frequencies from a tone cloud correlates with speech-in-noise listening independently of peripheral hearing measured by the pure-tone audiogram (PMID: 31728002). In this study we used a dynamic figure in which the frequency components were harmonically related and followed the pitch contour of natural speech over sentences. We used this measure to predict speech-in-noise ability at the word and sentence levels, using hierarchal regression and structural equation models (SEM) that also incorporated age, peripheral hearing (pure-tone audiogram) and static figure-ground performance. We studied over 100 participants with varying age and hearing sensitivity.
Hierarchal regression showed improved predictive value of the dynamic figure-ground task (standardised coefficient: -0.28) compared to the static one (non-significant). SEM demonstrated that a latent variable based on both dynamic and static figure ground stimuli was an important predictor of speech-in-noise perception (effect size 0.52). Effect size for the audiogram was 0.32. Overall, this study has shown how peripheral hearing sensitivity, central sound grouping (of both static and dynamic sounds), and age interact with each other and their respective contribution to speech-in-noise perception.

Title: Mid-level auditory computations predict human speech recognition in natural environmental noise

Authors: *A. CLONAN[1,2], X. ZHAI[4,1], I. STEVENSON[3,1], M. A. ESCABI[1,2,3];
[1]Biomed. Engin., [2]Electrical and Computer Engin., [3]Psychological Sci., Univ. of Connecticut, Storrs, CT; [4]Biomed. Engin., Wentworth Inst. of Technol., Boston, MA

Abstract: Recognizing speech in noisy environments is a critical task of the human auditory system. While spectrum and modulation statistics both influence speech recognition in noise,

current modeling approaches are unable to predict human recognition sensitivity in distinct, real-world backgrounds. Here we assess how the spectrum and modulation statistics of natural sounds mask the recognition of spoken digits (0 to 9). We enrolled participants in a psychoacoustic study where digits were presented in various natural background sounds (e.g., water, construction noise, speaker babble; tested for SNR=-18 to 0 dB) and their perturbed variants. We perturbed the backgrounds by either 1) phase randomizing (PR) the sound spectrum or 2) spectrum equalizing (SE). PR retains the power spectrum but distorts the modulation statistics while SE distorts the power spectrum and retains modulation statistics. Even at a constant noise level, the ability to recognize foreground digits was substantially helped or harmed by these background perturbations, depending on the original background sound. To explore this interference, we used texture synthesis (McDermott & Simoncelli 2011) to manipulate individual modulation statistics from the backgrounds. We found that adding texture statistics decreased accuracy for background speech babble. Interestingly, however, adding statistics increased accuracy in a construction noise background with strong comodulations. We next developed a physiologically inspired model of the auditory system model to predict perceptual trends. Sounds were decomposed through a cochlear filter bank (peripheral stage) and a subsequent set of spectrotemporal receptive fields that model modulation selectivity in auditory midbrain (mid-level stage). Logistic regression was performed on these features to estimate perceptual transfer functions and predict human accuracy. The peripheral model (with spectrum cues alone) accounted for 67% of the perceptual variance, while the mid-level model (spectrum and modulation cues) accounted for 91%. Perceptual transfer functions allow us to identify spectral and modulation cues critical to recognition in noise. Stimulus SNR has a substantial (log-linear) influence on recognition accuracy but appears to act independently from background statistics. These findings show how the diverse spectrum and modulation content of environmental background sounds has complex effects that can either help or harm speech recognition. However, an interpretable model of mid-level auditory computations predicts perceptual sensitivity and identifies the specific acoustic cues contributing to listening in noise.

Title: Alterations of microstructural properties of white matter and structural brain connectivity in moderate hearing loss

Authors: *R. QUDDUS[1], A. ZINCHENKO[2], M. AL AMIN[3];
[1]Natl. Univ. Bangladesh, Gazipur, Bangladesh; [2]Psychology, Ludwig Maximilians Univ., Munich, Germany; [3]Indiana Univ., Stark Neurosciences Res. Inst., Indianapolis, IN

Abstract: Hearing loss affects almost 30% of elderly people (> 60 years of age) and has been identified as a risk factor for cognitive decline. Hearing impairment starts with loss of hearing sensitivity in the higher frequencies and advanced over time to the mild and lower frequencies. Previous studies showed an association between hearing loss and structural change in the brain. To date, there is limited knowledge of the structural connectivity of white matter and brain network topology in moderate hearing loss (>30 dB). To examine the integrity of white matter, identify vulnerable structural connectivity, and to assess network topology, we investigated the major white matter tracts of elderly subjects having moderate hearing loss (n = 22, mean age 70.5) and compared them with age-matched healthy controls (n = 26, mean age 68.4). We have analyzed diffusion and structural MRI data from Leipzig Study for Mind-Body-Emotion Interactions" (LEMON) dataset. Diffusion MRI data was acquired at TE 80 ms, 67 diffusion direction with 1000 b values (60 volumes) and b = 0 images (7 volumes), voxel size 1.71 x 1.71 x 1.7 mm. T_1-weighted images were acquired at a voxel size of 0.99 x 1 x 1 mm. Whole brain structural connectivity was also analyzed to identify vulnerable connections in the brain. We finally analyzed network topology to measure the properties of structural networks. We observed that the fractional anisotropy of the right corticospinal tract is increased in the subjects with moderate hearing loss. Along the tract, analysis showed that the last quarter of the superior part of the right corticospinal tract had a higher fractional anisotropy. We also identified a left putamen-centered disrupted brain network in moderate hearing loss. A total of eight brain regions had disrupted structural connectivity. Further network topology analysis showed a reduced betweenness centrality and small-world network in moderate hearing loss. Surprisingly, forceps major tract was negatively correlated with good hearing while positively correlated with moderate hearing loss individuals. In summary, our results first identified the putamen-centered disruption in structural connectivity in moderate hearing loss. Increased fractional anisotropy of the right corticospinal tract could play a compensatory role since it projects fiber to the right putamen. Reduced network topology suggests that the information flow is interrupted in moderate hearing loss individuals.
Taken together, the results of impaired white matter tracts in moderate hearing loss provide valuable clues to design novel therapeutics to prevent the progression of hearing loss.

Title: Can you tell the difference between time-reversed syllable pairs? Unraveling the question through behavioral and MEG responses

Authors: *Y. MENG, H. FAN, L. ZHANG, L. LIU;
Beijing Language and Culture Univ., Beijing, China

Abstract: Imagine a time-reversed speech even repeat a time-reversed speech, which would sound like a mission impossible. This is due to the fact that speech is essentially a continuous temporal signal. Time-reversed speech jeopardize the temporal sequence information in a continuous temporal signal, which holds the most valuable information of speech, including the sequences of words, phonemics, or acoustic features. Current research predominantly focuses on the impact of time-reversed sentences on speech intelligibility. The greatest challenge in understanding time-reversed sentences is to segment a continuous temporal signal into a sequence of discrete linguistic units, i.e, words or syllables. However, it remains unclear whether perceiving time-reversed syllables still poses a significant challenge, considering that they are already discrete units on the syllable level. Here, we used time-reversed syllable pairs as speech perception material combined with Magnetoencephalography (MEG) analysis to explore the differences in behavior and brain response to the time-reversed and normal (non-time-reversed) syllables, in order to further our understanding of the temporal sequence information encoding at the level of syllables.
During the experiment, participants were instructed to discern whether the presented syllable pairs were the same or different within two blocks. The first block is time-reversed syllable pairs, while the second block is normal syllable pairs. We created sixty-four pairs of syllables (i.e, bi1 vs bu4) that had different consonants, vowels and tones to assess the accuracy and the elicited representations of varying phonetic category information. Surprisingly, the behavioral results revealed that participants could distinguish almost all the time-reversed syllables pairs (above 90% accuracy), except for syllable pairs with different consonants (below 20% accuracy). Although their response to normal syllable pairs (mean RT=120ms) was significantly faster than time-reversed syllable pairs (mean RT=240ms) in all types, syllable pairs with different consonants exhibited notably longer reaction time compared to other types. Furthermore, the machine-learning based classification analysis of MEG response to perceived syllables revealed that the brain showed a more similar response to the time-reversed syllables and normal syllablea when it drew bottom-up attention (on the first syllable of compared syllable pairs), while it showed much different response when the syllable drew more top-down attention (on the second syllable of compared syllable pairs).

Title: Active representation of phonemic features in alignment with speech perception requirements

Authors: *H. FAN, L. ZHANG, Y. MENG, L. LIU;
Beijing Language and Culture Univ., Beijing, China

Abstract: How can humans effortlessly differentiate between similar-sounding words such as "bubble" and "double" based on their initial consonants? The ability to distinguish between phonemic features (i.e. consonants) from complex and transient acoustic signal, is a challenging component of speech perception. Although there has been extensive research on how the brain processes information from the syllable to the lexical level, the initial step in speech perception, i.e., the flexible and efficient processing of phonemic information, remains unclear. Here, we used Magnetoencephalography (MEG) combined with multi-voxel pattern analysis method to explore how phonemic information is represented in human brain during participants perform a speech perception task. During the speech perception task, participants were instructed to determine whether the tones (tone task, subject n=30) or consonants (consonants task, subject n=19) of the two preceding and following syllables were the same. To evaluate the specificity and precision of the elicited representations of varying phonetic category information, we constructed sixty- four pairs of syllables (eight by eight) that vary in their phonetic features of consonants, vowels, and tones. First, we used the machine-learning based classification analysis to explore the phonemic representation at the phonemic level. We found that consonants are represented left-lateralized, whereas vowels and tones are represented on both hemispheres. More interestingly, by comparing the tone discrimination task and consonant discrimination task, we uncovered that phonemic representations are adapted in response to the speech perception task at hand. Specifically, when perceiving the second syllable, the task-related phonemic features of the first syllable, such as the tone feature in the tone task and the consonant feature in the consonant task, will be automatically reactivated. Furthermore, we used representational similarity analysis (RSA) combined with multidimensional scaling analysis to explore the phonemic representation at the syllable level. Our results revealed that people actively align the second syllable to the phonemic features of the first syllable that relevant to the task, with the second syllable being reassembled to match the tone/consonant features of the first syllable for the tone/consonant task. Overall, our results indicate that the human brain is capable of effectively and flexibly handling phonetic information through active representation of phonetic features to match with speech perception task at hand.

Title: Sensory processing of native and non-native phonotactic patterns in the alpha and beta frequency bands

Authors: *M. WAGNER[1], M. RUSINIAK[2], E. HIGBY[3], K. NOURSKI[4];
[1]St. John's Univ., Queens, NY; [2]BESA, GMbH, Gräfelfing, Germany; [3]California State University, East Bay, Hayward, CA; [4]The Univ. of Iowa, Iowa City, IA

Abstract: The phonotactic patterns of one's native language are established within cortical network processing during development. Sensory processing of native language phonotactic patterns established in memory may be modulated by top-down signals within the alpha and beta frequency bands. To explore sensory processing of phonotactic patterns in the alpha and beta frequency bands, electroencephalograms (EEGs) were recorded from native Polish and native English-speaking adults (48 participants, 36 females) as they listened to spoken nonwords within same and different nonword pairs. The nonwords contained phonological sequence onsets that occur in both the Polish and English languages except for /pt/, which occurs in Polish but not in English onsets. High density 64-channel EEGs (96 data sets) were analyzed in response to the first nonword in the pairs within the context of counterbalanced listening-task conditions, which were presented on separate testing days. During one listening-task condition, participants performed a syllable identification task to the second nonword in the nonword pairs (with-task condition). For the alternate condition, participants were instructed to only listen to the stimuli (without-task condition). Sensory processing was compared in the listening-task conditions because unmasking native language patterns of speech perception has been shown to be influenced by listening and task condition. Spectral power in the low frequencies (2-29 Hz) was analyzed to the first nonword in the pairs from five dipole source-level channels and twelve regional sources, obtained through source localization modeling. Source localization modeling, using all 64-channels of EEG data, increased power for statistical analyses. The results revealed that sensory processing to native language phonotactic patterns was modulated by listening-task condition within the beta frequency band. Specifically, the with-task condition elicited beta suppression in response to native language patterns of speech perception. However, in response to the non-native language phonotactic pattern, the with-task condition found suppressed spectral power values for an expanded frequency range that included the alpha and beta frequency bands. These findings suggest that linguistic experience with phonotactic patterns modulates perceptual processing through feedback within the alpha and beta frequency bands.

Title: Visual Speech Differently Restores Temporal and Spectral Speech Information in the Auditory Cortex

Authors: *C. CAO[1], K. GANESAN[1], Q. NGUYEN[2], A. JAHN[2], J. BRISSENDEN[2], D. BRANG[2];
[1]Psychology; MICDE, [2]Psychology, Univ. of Michigan, Ann Arbor, MI

Abstract: Seeing a speaker's face facilitates accurate speech perception. Previously, research has shown that listeners make use of lipreading to restore degraded auditory speech information, but these influences fail to account for the full benefits imparted by visual speech. Prior work has hypothesized that visual speech can restore information from two additional features of speech: spectral (relative pitch) and temporal information (sound changes over time). For example, listeners can recover spectral information using speakers' mouth width and the speaker's lip closure helps listeners parse the temporal boundary between words. However, it remains poorly understood whether, and how, spectral and temporal information is restored in the auditory cortex. In the current study, we asked two questions: first, is visual speech integration regionally specific, where auditory temporal and spectral information is restored in separate areas, or regionally nonspecific, where the same region restores both kinds of information? Second, how does visual speech alter the spatial pattern of auditory system activity to improve audibility of speech? We hypothesized that visual speech restores the spatial pattern of auditory activity evoked by degraded auditory speech, making it more similar to the pattern of activity evoked by clear speech. We collected functional magnetic resonance imaging (fMRI) data from 64 subjects who listened to 200 sentences presented across five conditions-- auditory-alone original, auditory-alone temporally smeared, auditory-alone spectrally smeared, audio-visual temporally degraded, and audio-visual spectrally degraded. Univariate contrasts reveal that the same visual signal has different effects on auditory processing depending on the degraded auditory feature. Visual speech increased BOLD in the STG for both types of degraded speech, but differed across conditions in other regions: AV spectral recovery increased BOLD in Heschl's gyrus while AV temporal recovery increased BOLD in anterior STG. Second, using Representational Similarity Analysis, our preliminary results suggest that visual restoration of speech uses distinctly different mechanisms from auditory speech perception. To verify this finding, we plan to build a single-trial-based GLM regressor to examine if representational distance is closer between audiovisual filtered speech and original auditory speech than that of audio-alone filtered speech. Together, we show that auditory cortex uses visual speech signals to selectively recover features of the auditory signal that have been degraded.

Title: Motor synchronization to auditory and visual rhythmic input is supported by shared rhythmic-related neural mechanisms

Authors: *S. SONG, H. BIAN, L. LIU;
Beijing Language and Culture Univ., Beijing, China

Abstract: Synchronization between motor, auditory, and visual processing is essential for effective communication, both verbal and written. Studies have found that the brain's neural entrainments enable the connection between auditory processing and the production of synchronized movements, which is known as sensorimotor synchronization. Nevertheless, little is known about whether or not cortical activity that supports sensorimotor integration characterized by internal representation of rhythmic beat is similar in both modalities (audio-motor and visuo-motor). In the current study, the magnetoencephalogram (MEG) was recorded while participants performed three tasks in each modality. For the passive task, participants passively listened to an auditory metronome beat (audio rhythmic task) or watched a ball flashing within beat (visual rhythmic task) that was both delivered in 2.4Hz. For the hand tapping tasks, either by right or left hand, participants had to tap their fingers to every second visual (visuo-motor rhythmic task) or audio (audio-motor rhythmic task) pulse in attempt to disentangle the movement- and beat-related neural responses. During the passive audio/visual rhythmic tasks, MEG-derived cortical response spectrum reveals cortical tracking to audio and visual rhythms at 2.4Hz as well as at second (4.8HZ) and third (7.2HZ) harmonic frequency. During the visual-motor/audio-motor rhythmic tasks, MEG-derived cortical response spectrum reveals that there was a strong 2.4Hz beat-related entrainment and a 1.2Hz movement-related entrainment for both modalities as well as their harmonic frequencies. Most importantly, we observed sensorimotor coupling in the form of an additional 3.6Hz response during both auditory and visual tasks. Taken together, the data suggest that internal representation of rhythmic input and sensorimotor integration are supported by shared neural mechanisms that underlie time-related processing - regardless of modality. The data is relevant to growing evidence suggesting that rhythm perception and general time-related skills such as parsing may be the core deficit underlying speech and language processing deficits.

Abstract: Visual speech information aids understanding, particularly under challenging listening conditions. However, the brain mechanisms underlying audiovisual speech processing remain poorly understood. Compounding this issue is the challenge that everyday communication situations typically involve rich linguistic and environmental context not present in the majority of laboratory tests. To advance our understanding of audiovisual speech in everyday life we presented participants (n=50 adults) with a movie clip from The Good, the Bad, and the Ugly (1966). We manually identified speech events and classified these as either auditory-only or audiovisual based on the amount of the speaker's mouth that was visible. We then convolved these onset times with a canonical hemodynamic response function to provide predictors for modeling the measured response. We measured brain activity using high-density diffuse optical tomography (HD-DOT), a form of functional near infrared spectroscopy (fNIRS). HD-DOT provides even sensitivity and high spatial accuracy over a large portion of the superficial cortical surface, including large portions of the occipital, temporal, and frontal lobes, and permits localizing measurements to atlas space. Using this approach, we were able to identify responses in the temporal lobes related to auditory-only speech. Finally, we found that audiovisual speech recruited both auditory and visual cortices, as well as posterior superior temporal sulcus. Together these findings establish the feasibility of using movie-based paradigms for studying both auditory and audiovisual speech understanding.

Title: Differences in mismatch responses for harmonic and inharmonic sounds

Authors: *K. BASINSKI[1], A. CELMA - MIRALLES[2], D. QUIROGA-MARTINEZ[3], P. VUUST[2];
[1]Div. of Quality of Life Res., Med. Univ. of Gdansk, Gdansk, Poland; [2]Dept. of Clin. Medicine, Aarhus Univ. and Royal Acad. of Music Aarhus/Aalborg, Aarhus, Denmark; [3]UC Berkeley, Berkeley, CA

Abstract: Predictive processing accounts of perception suggest that the brain uses generative models to reliably predict incoming sensory stimuli. If these predictions are incorrect, a prediction error response is propagated that changes the generative model. A crucial tenet of predictive processing accounts is that prediction errors are precision-weighted. This means that only errors with high precision influence the generative model. Precision depends on the information content of the predicted stimuli and can be expressed as inverse variance or information entropy. Harmonic sounds are auditory signals that are composed of frequencies that are integer multiples of a fundamental frequency (F0). Inharmonic sounds can have spectra with unrelated frequencies. Importantly, the information content of harmonic sounds is smaller than inharmonic sounds, as their spectra can be described only with the F0. Thus, any prediction errors associated with inharmonic sounds should be down-weighted. In this study, we aimed to test the hypothesis that violations of predictions for harmonic sounds would elicit a stronger response (as measured with mismatch negativity, MMN) than inharmonic sounds, due to higher precision-weighting of prediction errors in harmonic sounds. Participants (N = 36) listened passively to artificially generated complex tones with spectra manipulated to be either harmonic, inharmonic (with a random pattern of jitters applied to frequencies above f0), or inharmonic-changing (with jittering patterns randomized between consecutive sounds). The tones were presented in a roving oddball paradigm with varying fundamental frequencies. We recorded electroencephalography with a 32-channel active system. We computed difference waves (deviant - standard) for harmonic, inharmonic, and inharmonic-changing conditions. We then contrasted these difference waves between conditions using a non-parametric, cluster-based permutations approach. Consistent with our hypothesis, the results revealed significantly stronger

MMN in the harmonic condition compared to the inharmonic-changing condition (cluster range 0.083 ms - 0.189 ms after stimulus onset, $p = 0.004$) but, surprisingly, not when compared to the inharmonic condition ($p > 0.05$). We have also found differences in later, P300 positivity, with weaker responses in the harmonic condition in comparison to the inharmonic condition (cluster range 0.215 ms - 0.359 ms, $p = 0.005$). These results offer only partial support to our hypothesis and reveal unexpected differences in P300 responses. Overall, this study provides new insight into precision-weighting of prediction errors in the auditory domain.

Title: Decoding maintenance and replay activity in the human auditory cortical mnemonic system

Authors: *R. M. CALMUS[1,2], Z. KOCSIS[3,1], Y. KIKUCHI[2], H. KAWASAKI[1], T. D. GRIFFITHS[2], M. A. HOWARD, III[1], C. I. PETKOV[1,2];

Abstract: There is substantial scientific interest in identifying neural signals that carry traces of the sensory past or an expectancy about the future. To date, memory traces of sensory sequences containing regularities have been decoded in auditory cortex and the hippocampus in animal models, or in humans using non-invasive neuroimaging studies. However, outside of research with animal models there is a dearth of insights on how site-specific neurophysiological signals from the auditory cortical mnemonic system may carry information reflecting maintenance activity to sounds over delays, and on the signals that may characterize the retrospective replay of regularities in a sensory sequence. We conducted an auditory statistical learning task containing non-adjacent dependencies with 12 neurosurgery patients during presurgical intracranial monitoring of refractory epilepsy. The patients listened to sequences of three nonsense words drawn from sets (X, A and B), with regularities between relevant pairs of sounds (A-B) in the sequence often separated in time by uninformative (X) words. We first analyzed the site-specific local field potentials from auditory cortex, hippocampus and frontal cortex using

traditional methods, demonstrating engagement of the fronto-temporal network in the processing of the sequence regularities. We also present the output of a time-resolved multivariate decoding analysis that reveals the latencies and timescales of sequence item representations in regions across the network. The results represent to our knowledge the first human intracranial electrophysiological evidence of hippocampal replay of stimuli during an auditory task, showing that time-compressed replay occurs before and after key sounds in the sequence. Furthermore, the results also revealed that the maintenance of sound representations within non-primary (superior temporal gyrus) auditory cortex appears to exceed that of primary (core) auditory cortex in duration. Finally, in further support of a previously presented computational model of sequence processing and binding (VS-BIND; Calmus et al., 2019), prefrontal areas including precentral gyrus appear to maintain an ordered buffer of the auditory item representations. These results elucidate critical roles for the auditory sequential mnemonic system in transforming individual sensory events into mental structures, providing insight into the specific mechanistic contributions of medial temporal, prefrontal and superior temporal regions in the maintenance, prediction and ordinal manipulation of sequential information.

Title: Space-time mixing in neural representation

Authors: *M. LEVY;
Salk Inst., La Jolla, CA

Abstract: Generally we think of neural computation as being a stack of filters which respond in meaningful ways to the external world. This framework underlies the success of artificial neural networks. However, we know that, while these filters capture something important about how information is brought into the brain, they don't tell us how information is created, decisions made, or really carefully characterize the response properties in response to perturbations. It is well understood that neurons adapt, which mostly falls outside of this paradigm, that the neural and perceptual responses vary predictably to both spatial and temporal modulation, and that these representations, though stable, tend to drift over time. We also know that the molecules at the synapses, where the memory is supposedly stored, have a much faster turn over rate than the memory itself, and that synapses tend to maintain their electrical properties and firing patterns in

the face of this turn over, not necessarily with the same type of proteins. Somehow there are emergent precepts which can last a lifetime despite this sea of variability and change. While we know that animals can have repetitive control over the actions of single neurons, we don't know how one-to-one this mapping is or what local computations underlie the read out. To better understand the properties of these neurons, we need to think of computation at a scale beyond that of a single cell. A phonon is an vibration that travels through a media: think of knocking on a table. The sound is carried through the table not by any single atom but by the coherent vibrations thereof. We think that in studying perception and neural computation we need to better grapple with the computational properties of the brain as a distributed computational system.

Title: Concurrent Decision and Confidence Signals in area LIP

Authors: *M. VIVAR-LAZO, C. FETSCH;
Johns Hopkins Univ., Baltimore, MD

Abstract: Decision confidence plays a key role in cognitive behavior, but exactly when and how it arises in the brain remains unclear. Bounded evidence accumulation models provide a candidate mechanism by exploiting an association between the amount of accumulated evidence—discounted by elapsed time—and the probability of making a correct choice. Consistent with this idea, neurons in macaque area LIP that represent the accumulated evidence (known as a decision variable, DV) also predict the monkey's confidence reports. However, the question still looms as to whether the updating and termination of a DV for choice and confidence can occur in parallel, as opposed to sequentially, and whether LIP activity can explain choice, reaction time (RT), and confidence when measured concurrently on the same trials.We designed a peri-decision wagering (Peri-DW) assay in which monkeys simultaneously reported choice and confidence in a random-dot motion task. Both components of the decision were reported when the subject initiated a saccade to one of four possible targets (left + high bet, left + low bet, right + high, or right + low), thereby isolating the temporal window that could directly inform the choice and wager. Quantification and modeling of behavior suggests that a bounded accumulation process can explain the animal's choices, reaction times, and confidence.

Specifically, psychophysical kernels indicate a coinciding stimulus epoch that informs choice and confidence, and predictions from the model agree with empirical findings: greater accuracy and faster reaction times for high- compared to low-confidence decisions. Analyses of 54 LIP neurons from one monkey reveal signatures attributable to an accumulation-to-bound process, including ramp-like firing rates graded by motion coherence, convergence to a common firing rate before the saccade, and expected patterns of variance and autocorrelation. Importantly, these signatures do not differ in their timing when the neurons are grouped by their preferred saccadic target (i.e., high vs. low wager), which argues against the possibility that confidence is purely post-decisional. To gain further insight into the LIP responses, we simulated a 4D accumulation process (anticorrelated race) mapped onto four populations in LIP, each having response fields overlapping one of the four choice targets. Early simulation results resemble the choice- and confidence-dependent modulation of LIP responses seen in the empirical data. Follow-up analyses will apply generalized linear models (GLM) to further elucidate the neural dynamics underlying concurrent evaluation of a decision and its associated degree of confidence.

Title: Pulvinar-prefrontal inputs facilitate adaptive updating with sensory history during visual decision-making

Authors: *Y. LEOW[1], A. BARLOWE[1], C. T. LUO[1], Y. OSAKO[1], M. JAZAYERI[3], M. SUR[2]; [2]Dept. of Brain and Cognitive Sci., [1]MIT, Cambridge, MA; [3]Massachusetts Inst. of Technol. Dept. of Brain and Cognitive Sci., Cambridge, MA

Abstract: Processing sensory information to generate decisions and action is a central component of learned, goal-directed behavior. Our sensory landscape is constantly filtered through our prior expectations and ongoing goals. Under greater perceptual uncertainty, perceptual processing becomes more susceptible to the influence of prior history, which can induce biases that compromise decision-making. However, trial history can also be used adaptively to guide decisions when perceived similarity across stimuli is used to guide switching

or repeating actions. We trained mice on a two-choice random dot motion discrimination task, varying sensory certainty with the proportion of coherent target dot directions. We found that mice adopted a strategy of comparing the similarity of stimulus directions across trials to make switch/stay decisions. The Anterior Cingulate Cortex (ACC) is a frontal region that integrates uncertainty for switch/stay decisions from diverse inputs including the pulvinar/lateral posterior (LP) nucleus (LP, rodent homolog), a higher-order visual thalamic nucleus. The pulvinar serves as an integrative hub with reciprocal connectivity with the ACC and many other visual and associative cortices. Pulvinar, specifically its interactions with the frontal cortex, has been implicated in effective visual decision-making and predictive processing, but the information conveyed by this pathway has been challenging to resolve given the broadly divergent projections of pulvinar neurons. Leveraging genetic tools available in rodent models, we performed projection-specific two-photon calcium imaging and optogenetic manipulations of LP-ACC axons in mice performing the visual discrimination task. We show that LP-ACC visual stimulus representations were gated by task engagement, and encoded multiple task variables scaled by stimulus uncertainty. LP-ACC responses were also highly modulated by previous trial information, which was also graded by the uncertainty associated with the previous trial. Critically, we found that estimated similarity in stimulus directions across trials also modulated LP-ACC activity. Optogenetic activation of LP-ACC axons during stimulus evaluation impaired perceptual discrimination and reduced psychometric slopes, due to altered interactions between current and previous trial information. Our findings demonstrate that the LP-ACC inputs support decision-making by providing a read-out of ongoing uncertainty, integrated over time with behavioral history, to adaptively tune neuronal responses and guide goal-directed behavior on a trial-to-trial basis.

Title: Computation of context in the midbrain reticular nucleus during perceptual decision-making

Authors: *J. R. SHAKER, D. BIRMAN, N. A. STEINMETZ;
Univ. of Washington, Seattle, WA

Abstract: Perceptual decision-making requires the integration of dynamic sensory evidence from the environment with internal state variables (e.g. context, priors, value) to choose an appropriate action plan. Classical models of perceptual decision-making ascribe decision formation to forebrain sensorimotor regions, with the midbrain existing at the end of a feedforward pathway to relay motor commands. However, there is substantial evidence that the midbrain, especially the superior colliculus (SC), participates in the visual decision process. Recent work has suggested that an additional midbrain region - the midbrain reticular nucleus (MRN) - may be part of the perceptual decision network, as it was one of the few regions that encoded visual and action selection signals in a brain-wide survey of 2-alternative forced choice (2AFC) task-related activity in mice (Steinmetz et al, 2019).
Previous studies have noted motor functions of the MRN, including roles in locomotion (Roseberry et al, 2016) and saccades (Waitzman et al, 2002), while more recent work has described a role in interacting with forebrain regions to guide cue-triggered actions (Inagaki et al, 2022). We sought to characterize whether the wide variety of motor and sensory signals found in MRN are topographically organized. Thus, we conducted Neuropixels 2.0 recordings throughout MRN while both task-naive and trained mice passively viewed task stimuli. We found topographic organization of sensory/motor coding in MRN and increased visual and auditory responses to task stimuli after task training.
Additionally, we sought to assess whether the MRN, in addition to containing action selection signals, contains internal state signals required to compute an abstract decision. We designed a novel visual discrimination wheel-turning task that allows for the distinguishing of visual, motor, and contextual signals by including a condition in which the same stimulus requires different motor responses depending on the task Block (i.e. context). In Neuropixels 2.0 recordings during task performance, we found contextual modulation of visual and action-related responses of single neurons in canonical decision-making regions including secondary motor cortex, caudoputamen, and SC as well as in the MRN. Analyzing the population activity structure in these regions, we find evidence for a computation in which context alters the integration of evidence by shifting the attractor landscape.
In sum, our results suggest that the MRN is not a passive motor command structure, but rather, a spatially organized and temporally dynamic player in distributed brain circuits for perception, cognition, and behavior.

Title: Mice adapt to temporal regularities in perceptual decisions

Authors: *M. FRITSCHE[1], A. MAJUMDAR[1], L. STRICKLAND[1], S. LIEBANA GARCIA[1], R. BOGACZ[2], A. LAK[1];
[1]Dept. of Physiology, Anat. & Genet., [2]MRC Brain Network Dynamics Unit, Univ. of Oxford, Oxford, United Kingdom

Abstract: Perceptual decisions not only depend on current sensory information, but are also influenced by recent choices and their outcomes. Such choice history biases are ubiquitous in psychophysical datasets and have been observed in mice, rats, monkeys, and humans. While maladaptive in standard randomized experiments, these biases are hypothesized to reflect advantageous strategies to exploit temporal regularities of natural environments. Crucially though, natural environments exhibit a multitude of temporal regularities whose exploitation requires an adaptive use of different history biases that match the prevailing temporal structure. However, it is unclear whether and how observers could adapt their choice history biases to different temporal regularities. To address this, we trained mice in a visual decision-making task. In each trial, we presented a grating patch on the left or right side of a computer screen and mice indicated the grating location by steering a wheel with their forepaws, receiving water reward for correct responses. After mice reached expert proficiency on random stimulus sequences, we systematically manipulated the temporal regularity of visual input by changing the trial-by-trial transition probabilities between successive stimuli across different days. In addition to neutral stimulus sequences in which stimulus location was chosen at random [p("Repeat") = 0.5], we exposed mice to a repeating environment in which stimulus locations were likely repeated across successive trials [p("Repeat") = 0.8], and an alternating environment in which stimulus locations likely switched from the previous trial [p("Repeat") = 0.2]. We show that mice can adapt their choice history biases to these different temporal regularities in the sequence of visual stimuli to facilitate successful visually-guided decisions. This adaptation was slow, evolving over hundreds of trials across several days. It occurred alongside a fast non-adaptive choice history bias, limited to a few trials. We show that these fast and slow trial history effects are well captured by a normative reinforcement learning algorithm with multi-trial belief states, comprising both current trial sensory and previous trial memory states. Our results thus reveal the adaptive nature of choice history biases and cast these biases as the result of a continual learning process to facilitate decisions in an uncertain world.

Title: Investigating the neural basis of cue combination in large cohorts of human subjects

Authors: *K. S. ALLEN, M. R. COHEN;
Neurobio., Univ. of Chicago, Chicago, IL

Abstract: Everyday life requires people to make decisions based on many sources of information. In the perceptual realm, this is called cue combination (combining information from multiple sensory cues, or information sources). The ability to effectively combine information sources is thought to be limited by trial-to-trial variability in neural responses. We and others have shown that response variability can be changed by cognitive processes such as attention or by drugs, like stimulants, used to repair cognition or treat patients with disorders of attention. These observations lead to the hypotheses that 1) cognitive processes and cue combination share neural mechanisms and 2) processes that affect cognition, like healthy aging, brain disorders, or drug use, might also affect cue combination. We therefore hypothesize that on a person-by-person basis, there will be a link between the way people combine information within a modality (e.g. two forms of visual information) and across modalities (combining visual and auditory information), and that these abilities will depend on age, self-reported use of stimulants (e.g. coffee or methylphenidate [Ritalin]), and other health or demographic information. We tested these hypotheses by measuring the ability of large cohorts of human subjects to combine information within and across sensory modalities in online psychophysical experiments. We designed a psychophysical task that enhances our ability to identify subtle changes and trial to trial variability in cue combination behavior by asking participants to make analog rather than discrete decisions. On each trial, participants observed between one and three sensory cues (motion direction, spatial arrangement of visual stimuli, and changes in pitch) and indicated a combined judgment by clicking on an appropriate target location on a circle. We assessed cue combination by comparing performance judging each individual cue alone, pairwise cues, and all three cues together. We analyzed participant data within and between groups using a combination of frequentist statistics and Bayesian inference.

Title: Reduced sensory processing efficiency after switching relevant sensory dimensions in flexible perceptual decision making

Authors: *T. LUO, M. XU, Z. ZHENG, G. OKAZAWA;
Ctr. for Excellence in Brain Sci. and Intelligence Technology, Chinese Acad. of Sci., Shanghai, China

Abstract: Humans can flexibly switch rules to categorize sensory stimuli, but categorization performance is known to degrade immediately after a rule switch. This switch cost has been extensively studied in a variety of experimental tasks, but the mechanisms responsible for this phenomenon remain controversial. Here, we examined what aspects of decision-making processes are affected at the moment of rule switch, based on a framework we built previously to quantitatively model face categorization behavior (Okazawa et al., Cell 2021; J Neurosci 2021). In the task, subjects switched between two categorization rules for the same face stimuli every 2-6 trials. Face stimuli were randomly chosen from a 2D face stimulus space, whose axes corresponded to the two categorization rules. Each axis was generated by continuously morphing two prototype faces, forming a range of task difficulty. During the stimulus presentation, the morph levels rapidly (~100 ms) fluctuated at a subliminal level; this enabled us to test how subjects weighted sensory evidence to make a decision. We found that, immediately after switching the categorization rule, subjects' choice accuracy remained unchanged while reaction times increased substantially for any stimulus difficulty level. Notably, psychophysical reverse correlation showed that this switch cost was accompanied by an initial reduction in sensory weighting aligned to stimulus onset. This reduction occurred regardless of the preparation time given after a rule switch was informed but recovered 200-300 ms after stimulus presentation. Fit to evidence accumulation models confirmed that the initial reduction in sensory weight accurately account for the observed patterns of choice accuracy, reaction times, and psychophysical kernels after task switch. These results suggest that, after switching relevant sensory dimensions, decision-making circuits must undergo fine tuning to optimize the efficiency of information flow based on the incoming sensory information.

Title: Double dissociation of spontaneous alpha-band activity and pupil-linked arousal on additive and multiplicative perceptual gain

Authors: *A. PILIPENKO[1], S. AFRAKHTEH[2], A. FEGHHI[2], A. GERGEN[2], N. GUPTA[2], J. SAMAHA[1];
[1]Dept. of Psychology, [2]UC Santa Cruz, Santa Cruz, CA

Abstract: Conscious visual perception of a weak stimulus is a probabilistic process governed not only by external stimulus properties but also by internal states of the observer. However, which internal states influence perception and via what mechanisms remain debated. Here, we studied the influence that spontaneous changes in alpha-band activity and spontaneous fluctuations in pupil size have on stimulus detection across a range of contrast values spanning each observer's contrast response function (CRF). We found that states of weak pre-stimulus alpha power induced an "additive" shift in the CRF, whereby stimuli were reported present more frequently at all contrast levels, including contrast of zero (i.e., false alarms). In direct contrast, pupil size measured during the same pre-stimulus window had a "multiplicative" effect on subsequent detection such that stimuli occurring during large pupil states (putatively corresponding to higher arousal) were perceived more frequently the higher the contrast level, without a corresponding boost in false alarms. In other words, alpha power impacted detection criteria equally across the CRF but not detection sensitivity (d') whereas changes in pupil-linked arousal impacted sensitivity, particularly for higher contrasts. Interestingly, spontaneous changes in pupil size and alpha power were positively correlated across trials, which could imply that some of the effect of alpha on detection may be mediated by pupil fluctuations. However, when we examined the effect of alpha power residualized for pupil size, we still observed the same additive effect of alpha on the CRF, corresponding to criterion shift. Our data imply that strong alpha power inhibits perceptual detection by an additive suppression factor, rather than by a divisive scaling of contrast responses, a profile which better described the effect of pupil-linked arousal. We suggest that fluctuations in alpha-band power do not correspond to changes in arousal as the two have dissociable effects on behavior. Rather, alpha power seems to reflect the baseline level of excitability in the visual system, independent of arousal.

Title: Towards proper visual psychophysics by and for marmosets

Authors: D. TROTTER[1], P. CHEN[1], L. DEFELICE[1], A. LAUDANO[1], D. P. ROWLEY[2], ***A. HUK**[3];
[2]UCLA, [1]UCLA, Los Angeles, CA; [3]UCLA Chapter, Los Angeles, CA

Abstract: Introduction.
Although the common marmoset has gained significant popularity as a model organism for systems neuroscience, reasonable concerns persist regarding their proclivity to perform conventional psychophysical tasks. If they could perform such tasks well, connections to work in

other NHP and rodent species would be greatly strengthened. Here, we sought to test the idea that the primary weakness in their task performance was species-inappropriate training approaches and task details (as implemented by human experimenters), rather than a general inability of this model organism to do psychophysics.
Methods.
Instead of adopting approaches from macaques, we started with a psychophysical paradigm recently developed to generate useful visual behavior in mice (e.g., International Brain Laboratory, eLife, 2021). This task involves presentation of a visual stimulus (sinusoidal grating) to the left or right of a computer monitor; the subject receives reward for using a steering wheel to move the stimulus to the center of the screen. If the subject can see the stimulus, they can do this easily and intuitively; if they cannot, the direction of their wheel-turns will be random. We developed a marmoset-centric steering wheel apparatus and attempted to train marmosets on this task, starting with high contrasts and gradually weaving in lower ones to make visibility challenging.
Results.
Marmosets learn the sensory-motor mapping in the first few sessions, clearly turning the wheel to make responses, and exhibiting clear indications of reward expectation. Within approximately 2 weeks of training, a test subject was capable of performing several hundred trials within an hour, even with threshold-level contrasts present. Contrast sensitivity fell within the expected range (< 10% contrast at ~5 deg eccentricity). Lapse rates were small. Incorporation of eyetracking is a promising extension for both confirming task engagement and constraining visual stimulus presentation.
Discussion.
Marmosets appear capable of performing relatively conventional psychophysics, so long as the apparatus and sensory-motor mapping are comfortable and intuitive for this species. Marmosets are likely neither stupid nor lazy, and the rapid success of task training we observed suggests this framework could be generalized to a variety of discrimination and detection tasks.

Title: Estimating and integrating the uncertainty of naturalistic stimuli

Authors: *C. R. PLATE[1], Z. M. BOUNDY-SINGER[2], C. M. ZIEMBA[2];
[1]Natl. Inst. of Mental Hlth., NIH, Bethesda, MD; [2]Ctr. for Perceptual Systems, Univ. of Texas at Austin, Austin, TX

Abstract: When our perception is uncertain, we make inconsistent perceptual decisions. We have the ability to reflect on the reliability of our decisions in the form of confidence. To usefully guide behavior, this sense of confidence should integrate all sources of decision-relevant uncertainty into a single decision reliability estimate. However, this metacognitive ability is not perfect, and can vary across individuals and contexts. Confidence is often studied in experiments where decision reliability is varied through changing a single dimension of stimulus strength (e.g. only varying the orientation of a simple visual pattern in an orientation discrimination task), or not varied at all. Here, we sought to test the limits of a subject's ability to appropriately integrate the uncertainty of complex, naturalistic stimuli into their perceptual confidence reports. We created a set of synthetic texture stimuli matched to the statistics of natural images and asked participants to judge in which direction their dominant orientation was rotated from vertical. Subjects reported their decision and binary confidence level with a single button press. Both accuracy and confidence reports were incentivized by awarding a large number of points for high confidence correct responses, but a substantial loss of points for high confidence errors. Points were added to a running total across trials, and paid out at the end of the experiment. To control decision reliability, we varied stimulus features known to increase orientation uncertainty as well as neural signatures of uncertainty in the primary visual cortex. These include orientation rotation strength, the dispersion of oriented image energy, and contrast. However, we additionally manipulated the presence of higher-order, naturalistic pixel correlations, which are known to decrease neural signatures of uncertainty in visual cortical regions downstream of V1 without affecting the orientation content of the stimuli. We fit the responses of subjects with the CASANDRE model for confidence which allows us to assess both the precision of uncertainty representation and the extent to which different sources of uncertainty are appropriately integrated into a single confidence signal. Our results indicate that subjects generally demonstrate the ability to represent and integrate naturalistic uncertainty into their perceptual confidence reports, but with some striking and idiosyncratic failures as well.

Title: Effects of recent sensory experience on cue weighting during multisensory integration

Authors: Y. R. HAILE[1], S. J. JERJIAN[2], *C. R. FETSCH[3];
[1]Neurosci., [2]The Zanvyl Krieger Mind/Brain Inst., [3]Dept. of Neurosci. & Mind/Brain Inst., Johns Hopkins Univ., Baltimore, MD

Abstract: Multisensory integration is fundamental to our rich perception of the world yet is not fully understood mechanistically. Studies across many different pairings of sensory modalities suggest that cues are combined in a linear weighted fashion, where the weights are proportional to a cue's relative reliability. This has been termed reliability-based cue weighting and is a signature of statistically optimal or near-optimal integration. The conventional interpretation is that reliability is estimated in a pure "bottom-up" fashion, i.e. exclusively from the stimulus-driven response of sensory neurons. However, recent findings in humans show that cue weights are influenced by explicit knowledge the task relevance of a cue, and by estimates of cue reliability from the recent past. Here we test for the first time in non-human subjects whether and how recent sensory experience influences cue-weighting behavior, with the long-term goal of understanding the neural basis of top-down influences on multisensory integration.Two rhesus monkeys performed a 2AFC heading discrimination task using visual and vestibular self-motion cues. On a given trial, the stimulus could be delivered as vestibular-only (inertial motion), visual-only (optic flow), or combined (both presented synchronously). Monkeys used a saccadic eye movement to report whether their perceived heading was to the left or right of straight ahead. The relative reliability of the cues was controlled by varying the optic flow coherence, and the weights were estimated from cue-conflict trials in which the heading specified by visual and vestibular cues were separated by a small conflict angle, Δ (3°). The effect of recent experience was examined by analysis of cue weights, conditioned on whether the previous N consecutive trials were (a) vestibular-only vs. visual-only, or (b) high coherence vs. low coherence.We found that as few as 2 consecutive trials of a given type had a substantial effect on the weights assigned to cues on the next trial. When cue-conflict trials are preceded by two vestibular-only trials, the vestibular weight is observed to elevate significantly. Similarly, consecutive visual-only stimuli alter animals cue weighting behavior, but in a manner dependent on their coherence. The results support the notion that cue weights are modulated by recent sensory experience rather than being solely driven by momentary estimates of cue reliability. Preliminary behavioral analyses of a post-decision wagering version of the task suggest that subjective confidence in the heading judgment plays a role in gating this top-down process, the neural substrate of which is under ongoing investigation.

Title: Distinct decision processes for 3D and motion visual stimuli in humans and macaques

Authors: *R. RANGOTIS[1], S. NOWAKOWSKA[1,3], E. KAKAEI[2], A. AKANDE[1], K. KRUG[1,4];
[1]Sensory Physiol., [2]Cognitive Biol., Otto-von-Guericke Univ., Magdeburg, Germany; [3]Inst. for Auditory Neurosci., Univ. Med. Ctr., Göttingen, Germany; [4]Dept. of Physiology, Anat. and Genet., Univ. of Oxford, Oxford, United Kingdom

Abstract: Neurophysiology localised perceptual decision signals for binocular 3D depth and motion stimuli to visual area V5/MT. Drift diffusion modelling (DDM) is widely used to investigate the underlying decision-making processes by simulating decisions as noisy evidence-accumulation which terminates once a threshold is crossed. Two key questions remain unexplored: 1. To what extent are modelled decision processes affected by the visual stimulus (here 3D depth vs. motion) and by the effector for the response (hand vs. saccades)? 2. Are the modelling parameters comparable between monkeys and humans? To answer these questions, we tested 2 male monkeys (*Macaca mulatta*) and 20 humans (13 females, 7 males, aged 18-40, mean age 29.6, range 18-40 years) on different stimulus/effector combinations in a 2-alternative forced-choice task. Stimuli were a 3D structure-from-motion cylinder or a random dot kinematogram (RDK), requiring perceptual decisions about binocular depth or direction of motion, respectively. Effectors comprised hand and saccadic eye movements. Monkeys only performed the cylinder task with saccadic responses and the RDK task with hand movements, whereas humans performed all combinations in a counterbalanced order. Psychophysical performance and reaction times were comparable between species on the same task. The parameter distributions of a hierarchical DDM model (distance to bound, non-decision time, drift-rate slope, drift-rate intercept, bias) indicated a difference in distance to bound specific to the visual stimulus in both species. Using dimensionality reduction, linear discriminant analysis (LDA) revealed a strong separation by stimulus type but not for the effector for the human data ($p<0.001$, ROC analysis). Nearly identical clustering was observed for the monkey data when it was projected onto the same space with almost complete overlap. We conclude that the DDM reveals distinct brain processes for perceptual decisions about visual motion and binocular 3D stimuli in humans and macaques, although perceptual signals for both have been localised to the same brain area. We found no distinction between hand and eye movement responses in either species.

Title: Dynamics of population neuron response to heading perception in different multisensory cortical areas

Authors: *F. ZENG[1,2], A. ZAIDEL[2], A. CHEN[1];
[1]Key Lab. of Brain Functional Genomics (Ministry of Education), East China Normal Univ., Shanghai, China; [2]Gonda Multidisciplinary Brain Res. Center, Bar-Ilan Univ., Ramat Gan, Israel

Abstract: Neurons in multisensory cortices involved in heading perception, respond to multiple task-relevant variables, for example heading direction and choice. However, that makes it difficult to distinguish the functional properties of these neuronal populations. In our study, we recorded neuronal activity from the ventral intraparietal cortex (VIP), dorsal medial superior temporal cortex (MSTd), and parietoinsular vestibular cortex (PIVC) in 6 adult male rhesus macaques during a heading discrimination task. We applied a targeted dimensional reduction analysis by projecting the activity of each neuronal population onto a low-dimensional subspace, defined by dynamic motion parameters. We found VIP has a strong choice component, acceleration is not so clear in visual condition, but present in vestibular condition. MSTd has strong velocity component in visual condition, but also has the other two components in vestibular condition. PIVC has weak visual response, but a strong acceleration component for vestibular condition. Our results show that dynamic motion variables can be decoded from the different cortical populations, in accordance with the prevalence of the signals in each area.

Title: Effects of focused-ultrasound disruption of the blood-brain barrier on parenchymal inflammation, behavior, and functional connectivity in the marmoset monkey

Authors: *I. ZIMMERMANN ROLLIN[1], T. PARKS[2,3], D. SZUZUPAK[2], S. CHOI[2], D. J. SCHAEFFER[2];
[1]Bioengineering, [2]Neurobio., Univ. of Pittsburgh, Pittsburgh, PA; [3]Ctr. for the Neural Basis of Cognition, Pittsburgh, PA

Abstract: The common marmoset monkey (*Callithrix jacchus*) is a species of rising prominence in the neurosciences due to their small size, ease of handling, fast breeding, and their shared functional and structural brain characteristics with Old World primates. With increasing attention on modeling human brain diseases in marmosets, understanding how to deliver therapeutic or neurotropic agents to the marmoset brain non-invasively is of great preclinical importance. In other species, including humans, transcranial focused ultrasound (tFUS) aided by intravenously injected microbubbles has proven to be a transient, reliable, and safe method for disrupting the blood-brain barrier (BBB), allowing for the focal passage of therapeutic agents that do not otherwise readily traverse the tight endothelial junctions of the BBB. The critical gap that we address here is to document parameters to disrupt the BBB reliably and safely in marmosets using tFUS. By integrating our marmoset brain atlases and the use of a marmoset-specific stereotactic targeting system, we conducted a series of systematic transcranial sonication experiments in nine marmosets. We demonstrate the effects of center frequency, acoustic pressure, burst period and duration, establish a minimum microbubble dose, estimate microbubble clearance time, and estimate the duration that the BBB remained open to passage. Successful BBB disruption was reported in vivo with MRI-based contrast agents, as well as Evans blue staining assessed ex vivo. Histology (Hematoxylin and Eosin staining) and immunohistochemistry (Iba1, TUNEL, CD68 and CD206) indicated that the BBB can be safely opened with the parameters derived from these experiments. Next, an in vivo longitudinal experiment was conducted in four adult marmosets to determine the effect of opening the BBB in the forelimb area of primary motor cortex (area 4ab) on both reaching behavior (as indexed by the Valley Task) and functional connectivity, as assessed by resting state fMRI (rsfMRI) acquired at 9.4 T MRI. Both the behavior assessments and rsfMRI were conducted longitudinally, before and after the BBB was perturbed. Performance on the Valley Task was recorded and scored for accuracy and the rsfMRI data was preprocessed via the Marmoset Brain Connectome seed-based functional connectivity pipeline. Increased variance in both contralateral arm reaching behavior and functional connectivity were observed following sonication. Together, we give a comprehensive account of the parameters necessary to open the BBB and concomitant effects on inflammation, behavior, and functional connectivity.

Title: Representation of a continuous decision variable in human extrastriate visual cortex

Authors: *A. ARAZI[1], H. PARK[2], B. TALLURI[4], A. STOCKER[5], T. H. DONNER[3];
[1]Department of Neurophysiol. and Pathophysiology, [2]Dept. of Neurophysiol. and Pathophysiology, [3]Univ. Med. Ctr. Hamburg-Eppendorf, Hamburg, Germany; [4]NIH, Natl. Eye Inst. (NEI), Bethesda, MD; [5]Univ. of Pennsylvania, Philadelphia, PA

Abstract: Subjects often infer the state of the environment by accumulating noisy sensory input over time. Neurophysiological studies of this process have focused on categorical decisions (e.g., upward vs. downward motion). Yet, many real-life decisions require inferring continuous environmental variables and translating them into continuous motor outputs. We aimed to identify the neural dynamics underlying visual evidence accumulation towards a continuous decision in the human cortex. We further studied the interplay between categorical and continuous formats of representation of a decision-relevant environmental variable. To this end, we employed a task combining a categorical judgment and continuous estimation, reported at different times of an evidence stream. 34 participants performed the task while we monitored their neural activity using Magnetoencephalography (MEG). On each trial, they viewed a sequence of 12 checkerboard patches ('samples') drawn from a Gaussian distribution with a fixed standard deviation (20°) and a mean that varied continuously from trial to trial (-14° to 14° relative to a reference line on the midline). After the sample sequence, they reported an estimate of the underlying mean by moving a cursor with a joystick. After half the sequence, they were either prompted to report a binary decision (mean left or right from reference line) or received a visual cue that indicated the true category with 75% validity. We tracked stimulus-selective neural processing via the lateralization (left vs. right hemisphere) of MEG signals. We analyzed the time courses of this lateralization for a range of frequencies and in 180 regions covering the cerebral cortex. We used encoding models and information theoretic measures to relate single-trial modulations of power lateralization to the mean sample positions and/or the behavioral estimation reports. In both conditions with intermittent choice and cue, the mean of the stimulus sample positions were encoded in the alpha (8-12 Hz) power lateralization in visual cortical areas, most prominently in the intraparietal sulcus. This encoding was sustained during a delay following the stimulus sequence and preceding the estimation report, but also present during the previous stimulus processing. Information-theoretic analysis indicated that subjects used this neural signal for generating their behavioral estimation reports. The strength of sample mean encoding predicted the individual estimation precision. We conclude that alpha-band activity in extrastriate visual cortex encodes the accumulated sensory evidence guiding a continuous visual decision.

Title: Consistency with previous judgment biases the readout, but not the encoding of sensory evidence for subsequent decisions

Authors: *H. PARK[1], A. ARAZI[2], B. TALLURI[4], M. CELOTTO[5], S. PANZERI[5], A. A. STOCKER[6], T. H. DONNER[3];
[1]Universitaetsklinikum Hamburg-Eppendorf, Hamburg, Germany; [3]Univ. Med. Ctr. Hamburg-Eppendorf, [2]Univ. Med. Ctr. Hamburg-Eppendorf, Hamburg, Germany; [4]NIH, Natl. Eye Inst. (NEI), Bethesda, MD; [5]Dept. of Excellence for Neural Information Processing, Ctr. for Mol. Neurobiology, Univ. Med. Ctr. Hamburg-Eppendorf, Hamburg, Germany; [6]Dept. of Psychology, Univ. of Pennsylvania, Philadelphia, PA

Abstract: Many perceptual decisions are formed by accumulating streams of sensory evidence across time. Recent psychophysical work has shown that human decisions are more strongly governed by evidence that is consistent compared to inconsistent with their previous categorical judgments, a form of confirmation bias. Here, we asked whether this biased processing results from a selective encoding or selective readout of consistent sensory evidence in the brain.34 healthy human participants performed a continuous visual decision-making task during magnetoencephalography (MEG) recordings. After viewing a sequence of checkerboard patches (samples; angular positions drawn from a Gaussian), they were prompted to report the underlying mean by moving a cursor on the screen with a joystick. After half of the sequence, they were also asked to report a binary decision about the category of the mean up to this point (left vs. right from a reference line). We reconstructed the fine-grained spatial patterns of MEG responses to stimulus sample for each of a large number of areas covering the complete cortical surface. For each area, we used mutual information to quantify the encoding of individual stimulus samples and subjects' estimations of the underlying mean in the local response patterns. Importantly, we also quantified the intersection information between sample, neural response, and estimation, as the statistical signature of sensory information representation which is also used for decisions. Participants' estimations of the mean were more strongly influenced by later samples that were consistent, compared to inconsistent, with their previous categorical choice. By contrast, there was no difference in the encoding of samples (mutual information) between consistent and inconsistent samples in visual cortex or any other cortical area. Yet, intersection information in dorsal and early visual cortex was larger for samples consistent than inconsistent with the categorical choice, and the individual strength of this neural readout effect correlated with the effect of consistency on behavioral evidence weighting.We conclude that the consistency of sensory evidence samples with previous categorical judgments selectively modulates their readout (not encoding) for the behavioral decision. In our task, these

computations entail the routing of the sample information to circuits involved in evidence accumulation for the estimation report and the updating of the decision variable resulting from this accumulation.

Title: Shaping perceptual decision formation by GABA-A and NMDA receptor manipulation

Authors: *A. TOSO[1], A. ARAZI[1], A. BRAUN[2], R. MARIN-CAMPOS[3], P. STERZER[4,2], K. TSETSOS[5], J. DE LA ROCHA[3], T. DONNER[1];
[1]Dept. of Neurophysiol. & Pathophysiology, Univ. Med. Ctr. Abstract: Theoretical work has implicated two neurotransmitter receptors in the accumulation of evidence for decision formation: N-methyl-aspartate glutamate (NMDA) receptors for the slow, recurrent excitation and gamma-amino-butyric acid (GABA)-A receptors for rapid inhibition. Here, we quantified the impact of GABA-A and NMDA receptors on perceptual decision-making under uncertainty.
We combined placebo-controlled, systemic pharmacological interventions with quantitative behavioral analysis in healthy human participants. 20 participants performed a visual decision-making task under NMDA receptor blockade (memantine, 15 mg), GABA-A receptor boost (lorazepam, 1 mg), or a glucose placebo (all oral administration, double-blind and cross-over design). Participants viewed circular drifting gratings in the left and right hemifield, each with independently fluctuating contrasts (10 contrast samples of 100 ms) and were subsequently prompted to report the side with the larger average contrast across the sample sequence, followed by auditory feedback. The sequence of stimulus categories (left or right stronger) across trials changed between repetition probabilities of 0.5 or 0.8 (blocks of 120 trials). This design promotes accumulation of information within trials (across contrast samples) and across trials. We quantified the impact of contrast fluctuations at each sample position on choice. The

resulting psychophysical kernels exhibited primacy, stronger weighting of samples occurring early compared to late in the sequence. This decay of evidence weighting was amplified under lorazepam. Trial history biased participants' choices dependent on the context, with significant repetition of previous-trial stimulus categories in repetitive but not random blocks. This adaptive history bias was reduced under memantine.
We conclude that GABA-A and NMDA receptors predominantly shape the formation of decisions at distinct timescales: GABA-A receptors affect the within-trial weighting of sensory evidence, while NMDA-receptors affect the across-trial accumulation of information into history-dependent biases. Reduction of the latter under NMDA-blockade may be due to interference with synaptic short-term plasticity. We currently use simultaneously collected magnetoencephalography (MEG) data to analyse the encoding of sensory samples in visual cortex and the build-up of a decision variable in premotor cortex. Drug-induced changes in these cortical decision dynamics will help constrain mechanistic interpretations of our behavioral findings.

Title: Past shifts present in a repulsive-followed-by-attractive two-stage process in human brains

Authors: *M. LUO, H. ZHANG, H. LUO;
Peking Univ., Beijing, China

Abstract: Past shifts present in a repulsive-followed-by-attractive two-stage process in human brains Authors Minghao Luo, Huihui Zhang, Huan Luo School of Psychological and Cognitive Sciences, IDG/McGovern Institute for Brain Science Peking University, China **Disclosures** M.L: None. H.Z: None. H.L: None. **Abstract** Serial bias refers to the automatic shifting of perception in current trial by preceding trials. The effect occurs on a wide range of features and in different directions, i.e., repulsive or attractive. Meanwhile, the underlying neural mechanism and how attention modulates the process remain unknown. Here we employed electroencephalography (EEG) and magnetoencephalography (MEG) recordings in a 2-D continuous spatial perception task to address the question. Participants were instructed to

memorize the location of a red dot stimulus within a 2-D continuous space (encoding period) and reproduce it later (decision period). In accordance with previous behavioral findings, location perception is attracted to that in the preceding trial. Importantly, time-resolved multivariate decoding reveals the co-occurrence of past and current trial information during both encoding and decision periods. Crucially, by examining the representational angle between the neural representation of past-trial reactivation and present-trial information, we demonstrate a two-stage past-present shifting neural profile - flipped and aligned relationships for early encoding and late decision periods, respectively. Moreover, only the late attractive neural shift is modulated by attention and correlates with serial bias behavior. Overall, our study provides novel neural evidence supporting that serial bias involves a repulsive-followed-by-attractive two-stage process, wherein past information first inhibits the present in a task-irrelevant way and is then integrated with the present based on attentional modulation.

Title: Neural basis of visual information integration and decision-making

Authors: *K. SLANGEWAL, M. CAPELLE, F. KÄMPF, A. BAHL;
Univ. of Konstanz, Konstanz, Germany

Abstract: Decision-making is a long-studied topic in neuroscience. We have an increasingly good mechanistic understanding of the neural circuits that allow animals to temporarily integrate specific decision variables. However, it remains unclear how these circuits combine, often conflicting, information from multiple sensory channels to form a single decision. Recently, we have described how the larval zebrafish anterior hindbrain integrates visual motion to decide about swimming direction. Other studies, focusing on different sensory stimuli, have identified the same brain area as a central processing structure for sensory-motor control. This raises the hypothesis that the anterior hindbrain forms a general integration hub for decision-making. Here, we employ a combination of behavioral experiments, computer simulations, and two-photon functional imaging to algorithmically and mechanistically describe how larval zebrafish integrate motion and luminance cues. Our behavior experiments and computational simulations argue for

a parallel arrangement, in which separate modules temporally integrate information from distinct visual processing streams. Our imaging experiments support these findings, revealing distinct and partially overlapping activation patterns with slow temporal dynamics. These results allow us to build detailed neural networks whose predictions we test using newly established circuit dissection tools. Together, this means we can describe in mechanistic detail how brains combine and evaluate information extracted from multiple visual features.

Title: Choice probability as movement planning

Authors: *P. LAAMERAD[1], L. D. LIU[2], C. C. PACK[2];
[1]Montreal Neurolog. Institute, McGill Univ., Montreal, QC, Canada; [2]Neurol. and Neurosurg., Montreal Neurolog. Inst., Montreal, QC, Canada

Abstract: Perceptual decisions involve the detection of sensory information, the accumulation of evidence, and the execution of motor responses. Although different brain regions specialize in individual functions, signals related to multiple aspects of decision-making are often found in the responses of individual neurons. For example, sensory neurons often exhibit fluctuations in firing rates that predict perceptual decisions. These fluctuations can be characterized with a metric called choice Probability (CP). CP might reflect a feedforward propagation of random variability in responses to sensory stimuli to higher-order decision-making structures. Or it might capture a top-down signal that relays the outcomes of perceptual decisions back to sensory neurons. Here we suggest a third possibility, based on the fact that most CP studies make use of a saccadic eye movement as the behavioral readout. This creates a possible link between CP and the phenomenon of movement selection that has often been reported in the oculomotor system. Specifically, firing rates are often higher in response to receptive field (RF) stimuli when the animal intends to make a saccade toward them and lower when saccades are planned in the opposite saccade direction. As a result, fluctuations in single-neuron activity can depend on oculomotor plans, and indeed, movement selection effects have frequently been reported in visual cortical areas. This led us to wonder whether previous observations of choice probability in the visual cortex could to some degree reflect the effects of movement selection for saccades. To investigate this, we trained monkeys on a standard visual motion discrimination task and recorded neural activity from the middle temporal (MT) area, a region with neurons encoding motion direction and exhibiting CP. We found that CP values were higher for neurons whose receptive fields were closer to the direction of an impending saccade. This suggests that fluctuations in MT firing carried information about oculomotor selection, and we found that this

encoding emerged through training. Furthermore, pharmacological inactivation of MT neurons led to a behavioral bias to make saccades away from the inactivated RFs, similar to the effects of inactivation in the oculomotor system. These results suggest that training on a task with fixed sensorimotor contingencies introduces movement-related activity in brain regions that are usually considered sensory, and that this plasticity can shape CP in individual neurons.

Title: Metacognitive Introspection Influences The Dynamics of Perceptual Evidence Accumulation

Authors: *W. DOU[1], S. AFRAKHTEH[2], D. ALONZO[2], K. CALLWOOD[2], J. SAMAHA[3]; [1]Univ. of California Santa Cruz, Santa Cruz, CA; [3]Dept. of Psychology, [2]Univ. of California, Santa Cruz, Santa Cruz, CA

Abstract: Metacognitive introspection refers to the ability to introspect upon the effectiveness of one's performance and is often studied as confidence in the outcome of a choice. Current models propose that confidence can be computed in an evidence accumulation framework where confidence is governed by the amount of pre- or post-decision evidence accumulated over time. However, these models make the untested assumption that sensory evidence is first accumulated, and only then evaluated for confidence. Here, we tested whether the act of introspecting about confidence alters sensory evidence accumulation as indexed by the Central Parietal Positivity (CPP) EEG component, a neural signature of the decision variable. Thirty-two participants perform a dot-motion discrimination task while electrical brain activity (via EEG) is recorded. On half of the trials, participants only reported the decision about the direction of the motion. On the other half of the trials, after participants reported the decision, they rated their confidence in the decision. The presentation of the two types of trials was counterbalanced across participants and motion coherence varied across three levels, providing various strengths of sensory evidence. The results showed that the CPP built up faster on the confidence-rating trials than on the decision-only trials, suggesting that introspection boosted evidence accumulation. Moreover, confidence signals were evident in preparatory motor activity prior to the first decision being made, which indicates that confidence evidence does not wait until the first-order decision threshold has been reached. Our results challenge the traditional accounts of confidence computation assuming that evidence accumulation and confidence rating occur sequentially.

Title: Neural substrate for the engagement of the ventral visual stream in motor control in the macaque monkey

Authors: E. BORRA, M. GERBELLA, S. ROZZI, *G. LUPPINO;
Med. and Surgery, Univ. of Parma, Parma, Italy

Abstract: Previous studies from our lab (Borra et al Neurosci Biobehav Rev. 75:65-90, 2017) showed that two interconnected hand-related areas involved in the "lateral grasping network", the ventrolateral prefrontal (VLPF) area 12r and the intraparietal area AIP, are targets of projections from an intermediate sector of the inferotemporal (IT) area TEa/m, located in the lower bank of the superior temporal sulcus. Furthermore, this same IT sector is a source of projections also to two areas involved in the oculomotor network, the caudal VLPF area 45B and the intraparietal area LIP (Borra and Luppino Neurosci Biobehav Rev. 126:43-56, 2021). The present study aimed to obtain a more comprehensive view of the possible involvement of this IT sector, located at the highest hierarchical levels of the ventral visual stream, in different aspects of motor control. To this purpose, the neural tracer Wheat Germ Agglutinin was injected in this intermediate part of TEa/m in five macaque monkeys at different AP levels. The results showed extensive connections to all subdivisions of areas TEa and TEp, extending rostrally in the temporal pole and caudally in areas TEO and FST, especially after more caudal injections. In the medial temporal lobe, rich connections were observed with the rostral area 36 and parahippocampal areas TF and TH. Extratemporal connections of TEa/m were rather selective. In the parietal cortex, there were connections at a variable extent across cases, involving the caudal part of the hand-related area AIP and the rostral part of the oculomotor area LIP, and, in the parietal operculum, the hand field of area SII. In the frontal lobe, the labeling tended to involve, in the VLPF, at a variable extent across cases, the hand-related area 12r, the oculomotor area 45B, and a caudal sector straddling over caudal area 46v and dorsal area 45A, which are part of the frontal oculomotor domain, and in the orbitofrontal cortex, areas 12o and 12m. A weak connection was also observed with the hand-related ventral premotor area F5a or the adjacent Granular Frontal Opercular area. Finally, in all cases, there were connections with a sector of the dysgranular insula connected with several parietal and frontal hand-related areas.

The present data strongly suggest that the inferotemporal area TEa/m is an integral part of the large-scale functionally specialized networks for controlling hand actions and oculomotor behavior. Accordingly, the ventral visual stream would not be involved just in perception per se but could play a fundamental role in guiding skeletomotor and oculomotor behavior. Furthermore, motor signals broadcasted to ventral visual stream areas could be crucial for perceptual processes.

Title: Input-shaped neural dynamics enhances robustness to microstimulation in motor cortex

Authors: *C. ZHENG[1,2], Y. XIAO[2,1], Q. WANG[2,1], R. ZHENG[2,1], H. CUI[2,1];

Abstract: Although accumulating evidence suggests that the motor cortex serves as a dynamical machine that generates motor commands by autonomous temporal evolution, it remains unclear how inputs contribute to neural dynamics for motor generation. Here, we trained two monkeys (*Macaca* mulatta, Gd and Lp) to perform delayed (200 or 900 ms) reaches toward visual targets, either static (center-out) or moving circularly (Li et al., 2018). Moving targets generally required longer preparation time and higher hand velocity. During the delay, moving targets evoked higher neuronal firing rates and less tangled neural trajectories. Demixed PCA and SVM decoding results revealed continuous target location coding and progressive sensorimotor transformation in moving-target condition. To further examine underlying neural dynamics, we delivered subthreshold intracortical microstimulation (ICMS) (100 ms @300 Hz) via single microelectrodes around the GO and simultaneously recorded neural activities using 64-ch S-probe in M1 or PMd. For static-target condition, ICMS prolonged reaction times (RTs, ΔRTs = +9.4 ms* for Gd; +13.6 ms*** for Lp), but had little effect on RTs for moving target (ΔRTs = -3.6 ms for Gd, n.s.; -6.5 ms for Lp, n.s.), especially for long delays. Accordingly, neural states evolved more slowly after ICMS for static versus moving-target conditions. The optimal

subspace hypothesis (Churchland and Shenoy, 2007) proposes that movement is delayed until errors in preparation are resolved. Hence, continuous target input for moving target may enhance motor cortical dynamic, enabling faster error resolution. To test this hypothesis, we adapted an E/I neural network model of optimal control (Kao et al., 2021) to simulate the tasks. Specifically, we made three empirical assumptions of interception: (1) a feedforward target location, (2) sequentially updating of optimal states organized in a circle, and (3) larger feedback input. In the model, moving target inputs drove richer preparatory activities throughout the delay period. Input was added to a random subset of neurons as simulated ICMS. The perturbation transiently increased potential motor error, resolving faster for moving- versus static-target condition, producing less error at movement onset. This suggests that target input shapes neural population geometry that facilitate efficient computations. Combined with continuous feedback input, neural dynamics in motor cortex becomes more resistant to unexpected perturbations.

Title: Joint specification of action in neocortex and striatum

Authors: *J. PARK[1], P. POLIDORO[2], C. FORTUNATO[3], J. ARNOLD[2], B. MENSH[2], J. A. GALLEGO[3], J. DUDMAN[4];
[1]Princeton Neurosci. Inst., Princeton, NJ; [2]Janelia Res. Campus, Ashburn, VA; [3]Imperial Col. London, London, United Kingdom; [4]HHMI, Ashburn, VA

Abstract: The interaction between two major forebrain structures, the cortex and subcortical striatum, plays a critical role in flexible, goal-directed action. Traditionally, it has been proposed that striatum is critical for selecting what type of action is initiated while the primary motor cortex is involved in the online control of movement execution. However, recent data suggests that the striatum may also play a crucial role in specifying movement execution. These alternative hypotheses about striatal function have been challenging to reconcile because they make indistinguishable predictions when comparing very different actions. To overcome this challenge, we developed quantitative models that led to a somewhat paradoxical insight: only by comparing neural activity during similar actions could we make strongly distinguishing predictions. To test this idea, we designed a novel reach-to-pull task that required mice to reliably select between two similar but distinct reach targets and pull forces. By recording neural activity simultaneously in both the cortex and subcortical striatum during the task, we found that the activity was uniquely consistent with a model in which both the cortex and striatum jointly specify movement execution. Overall, our findings provide new insights into the complex

interplay between the cortex and subcortical striatum in guiding goal-directed actions, and demonstrate the importance of using quantitative models and carefully designed experimental tasks to uncover novel insights into brain function.

Title: Similar encoding but unique timing of movement-specific signals across mouse forelimb sensorimotor cortex

Authors: *H. GRIER[1], S. SALIMIAN[2], M. T. KAUFMAN[3];
[2]Computat. Neurosci. Grad. Program, [3]Organismal Biol. and Anatomy, Neurosci. Inst., [1]The Univ. of Chicago, Chicago, IL

Abstract: Flexible and adaptive forelimb movements require close coordination between motor commands and sensory feedback. The primary motor (M1) and somatosensory (S1) cortices are richly interconnected, yet how they interact to coordinate these signals is not well understood. To characterize M1-S1 interactions, we developed a forelimb reach-to-grasp task where head-fixed mice made sound-cued reaches to grasp water rewards from two distinct spout targets (based on Galinanes et al. 2018). During this behavior, we recorded layer 2/3 excitatory cells of contralateral forelimb M1 and S1 using 31 Hz two-photon calcium imaging in GCaMP6f transgenic mice. We identified M1 neurons sending projections to S1 using AAVretro-tdTomato injections in ipsilateral forelimb S1. We recorded simultaneous activity of unlabeled M1 cells (M1-unl, 430-782 cells/dataset) and M1-S1 projection cells (125-135) in two mice, with forelimb S1 cells recorded in separate sessions (572-990). To characterize target-specific information, we decoded the cued spout target from single-trial population activity with a cross-validated linear classifier. Spout target was decoded with high accuracy from all three populations following the sound cue (92-97% M1-unl, 90% M1-S1, 85-90% S1). However, performance peaked first in

M1-unl cells, followed by M1-S1 cells, with S1 cells peaking last (43-75 ms, 63-94 ms, 118-119 ms). Further, we found that population activity in the classifier dimension was highly consistent across trials for M1-unl cells, whereas M1-S1 and S1 varied substantially. To quantify forelimb kinematics, we extracted 25 angular degrees of freedom across the forelimb from 3D markerless tracking data (DeepLabCut). We then decoded these joint angles from population activity using cross-validated ridge regression. Proximal and distal joint angles were best decoded from M1-unl cells (45-65% variance explained), with S1 decoding similarly well (43-52%). However, joint angle information was decoded less well from M1-S1 projection cells than the other two populations (25-42%). These results show that detailed movement signals are present across M1 and S1, with target-specific signals arising earliest in M1, yet suggest that the direct layer 2/3 pathway from M1 to S1 is not the sole source of this shared activity.

Title: Lfp independent components as markers for internal neural processes

Authors: *D. V. ORELLANA[1,2], C. ALVARADO-ROJAS[2], J. P. DONOGHUE[3,4], C. VARGAS-IRWIN[3,4];
[1]Facultad de Energía, Univ. Nacional de Loja, Loja, Ecuador; [2]Dept. of Electronics Engin., Pontificia Univ. Javeriana, Bogota, Colombia; [3]Dept. of Neurosci., Brown Univ., Providence, RI; [4]Robert J and Nancy D Carney Inst. for Brain Sci., Providence, RI

Abstract: To understand how signals generated by a single or ensemble of neurons relate to behavior it is necessary to link externally measured real-world events (external markers) to neural activity patterns, operationally defined here as trial alignment. An external marker is usually a time point that represents a notable event, such as the time of a stimulus or a behavioral response. Even when the timing of external events can be precisely recorded, the local timing of the related neural activity may vary depending on internal states (e.g. motivation, attention, reaction time) which can not readily be observed. These factors can lead to misalignment of neural responses, which can hinder the analysis of the informational content of spiking patterns (especially information reflected by precise spike timing patterns). Thus, it would be ideal to align neural data to internal signals representing internal cognitive and perceptual events. The present work evaluates a novel technique to extract signals from local field potentials (LFPs) which may reflect more precisely local cortical processing. We analyzed neural activity recorded using chronically implanted microelectrode arrays in primary motor cortex (MI), ventral

premotor cortex (PMv), and dorsal premotor cortex (PMd) of macaque monkeys performing a cued grasping task with instructed delay. Considering that local field potentials (LFPs) represent composite signals that receive contributions from multiple neural sources (synaptic currents and spikes), we applied a blind source separation approach to isolate their constituent signals. We found independent components (ICs) in the low frequency band of the LFP (0.1-3Hz) associated with every phase of the behavioral task. Initial results show that aligning neural activity using LFP ICs as internal markers produces more consistent spiking patterns leading to discrete classification of object and grip conditions matching or exceeding external task events. Classification was consistently improved (5-20% range) across all pre-movement events. Our results suggest that using internal markers to set temporal reference frames for spike train analysis could potentially improve decoding for BCI applications where external events such as the intention to initiate a movement are not associated with behavioral events that can be readily observed.

Title: Mirror neurons encode action kinematics

Authors: K. CHATZIMICHAIL, V. PAPADOURAKIS, *V. RAOS;
Univ. of Crete, Heraklion, Greece

Abstract: The relationship between the neuronal activity of mirror neurons (MirNs) and the kinematics of actions remains unexplored, despite reports of low-level movement features influencing MirNs' activity. This study aims to investigate whether MirNs encode observed action kinematics using multiple linear regression (MLR) to model kinematic parameters based on neural activity. MirNs were recorded from the ventral (n=120) and dorsal (n=140) premotor cortex of macaque brains during the execution and observation of grasping actions. We collected twenty (20) kinematic parameters, including 3D positions and velocities of the wrist, index finger tip, thumb tip, and the distance and its rate of change between the index and thumb. MLR was applied, using ten principal components, to estimate trial-averaged kinematic parameters from trial-averaged neural activity in each area. The results showed a strong correlation between neural activity and kinematics, with excellent fits for both areas and all kinematic parameters (R^2

values: 0.66-0.99 for PMd activity, 0.78-0.99 for PMv activity). To assess the relationship's strength and exclude overfitting, a decoding analysis was conducted. Predicted kinematics for individual trials were generated by multiplying single pseudo-population trials with previously determined regression coefficients. An SVM classifier was then trained on actual kinematic data and tested on predicted kinematic data, evaluating MLR's robustness with intertrial variability in neural and kinematic data. The decoding analysis revealed that grip information decoded from the twenty measured kinematic parameters reached 0.8 (maximum 1). When tested on predicted kinematics from both areas, the decoder showed significant performance during the epoch from the middle of the movement to the middle of object holding. Decoding performance was slightly higher for kinematics predicted by PMv activity compared to PMd activity (0.5 and 0.4, respectively; maximum 1). In both cases, the information decoded from predicted kinematics accounted for over half of the information obtained from measured kinematics. In conclusion, these findings demonstrate accurate prediction of kinematic parameters from neural activity using a simple linear model and indicate the presence of grip-related information within predicted kinematics, similar to measured kinematics. Thus, these results strongly support the population-level encoding of kinematics by MirNs.

Title: Visual activity modulates population dynamics during the initiation of identical grasp movements.

Authors: *N. ZDUN[1,2], H. SCHERBERGER[1,3], B. DANN[1];
[1]German Primate Ctr., Göttingen, Germany; [2]Systems Neuroscience, GGNB, [3]Fac. of Biol. and Psycology, Univ. of Göttingen, Göttingen, Germany

Abstract: An important objective in systems neuroscience is to comprehend how different movements are initiated and controlled in the neural network of the brain. In recent years, it was proposed that the neural population response at the onset of movement determines the subsequent movement-related neural dynamics independent of time and context, known as the optimal subspace hypothesis. In contrast, two studies have shown that the neural response at movement onset of the same movement can vary considerably between immediate and delayed movements. Furthermore, there is increasing evidence that neural activity in motor areas is not only modulated by movement preparation and execution, but also by active vision. We hypothesize that the differences in the neural response at movement onset for the same

movement can be explained by the presence of different amounts of visual processing. To investigate the visual, preparatory and movement related dynamics in the fronto-parietal grasping network, we recorded neural data from AIP, F5 and M1 of two monkeys performing a mixed immediate and withheld grasping task. By utilizing a targeted dimensionality reduction, we identified different orthogonal population subspaces for visual, movement preparatory and movement execution related activity. Neural subspaces were identified only based on the delayed trials, for which visual, preparatory and execution related activity is temporally separated by task design. Yet, the identified subspaces captured equal amounts of variance also for immediate movements, confirming the validity of the subspace decomposition. For delayed trials, visual-related processing of the cue signal was already completed at the time of movement onset, whereas for immediate trials, visual activity was also present at the time of movement onset. Interestingly, preparatory subspace occupancy at movement onset was similar for immediate and withheld movements, irrespective of the amount of visual activity. These results suggest that only the preparatory response at the time of movement onset determines the subsequent movement, but not the entire population response. Consequently, these findings indicate that visual activity can only be transformed into preparatory activity, and preparatory activity only into execution activity, even if visual activity is still present. Our results therefore refine the optimal subspace hypothesis for the presence of different population responses at movement onset.

Title: Using Neuropixels to compare neuronal population activity across the macaque fronto-parietal grasping network

Authors: *R. NOCERINO[1,2], J. CHURAN[1], B. DANN[1], H. SCHERBERGER[1,3];
[1]German Primate Ctr., Göttingen, Germany; [2]Sensory and Motor Neuroscience, GGNB doctoral program, Göttingen, Germany; [3]Fac. of Biol. and Psychology, Georg-August-Universität Göttingen, Göttingen, Germany

Abstract: In everyday life, primates perform a wide variety of grasping movements. The kinematics of grasping in primates depend on object characteristics such as fragility, size of contact surfaces, texture, and weight. As a result, specific grip types are used for each object and intended action. The frontoparietal grasp network, in particular the anterior intraparietal area (AIP) and the ventral premotor cortex (F5) is involved in the planning and execution of grasping

movements. Many studies have investigated various aspects of the visuo-motor transformation within and between these areas. However, our understanding of how population dynamics are distributed within these areas is limited due to methodological constraints. The recently developed Neuropixels probes allow to simultaneous record from 384 channels, and therefore from a large neuronal population, in a single electrode penetration. To explore intra-areal differences in neural population activity, we trained a female Macaca mulatta to perform a visually instructed delayed grasping task. Using Neuropixels probes, we simultaneously recorded from 384 channels per day at various locations in AIP and F5, and then investigated differences in the population dynamics at various locations within and across AIP and F5. Analysis of the peristimulus time histograms (PSTHs) suggest that there exist two distinct groups of neurons at the anterior pole of AIP. Furthermore, a comparison of responses under condition-dependent modulation across sites using the Euclidean distance measure or the population variance in the neuronal space indicated the presence of a gradient across the sulcal extension of AIP. More importantly, we conducted a decoding analysis based on single-trial activity. Since it is unlikely to find an exact correspondence between neurons across different recording sessions, we employed Procrustes analysis to align a 10-dimensional subspace of latent variables between individual recording sessions. Our aim was to achieve the best possible match between the sessions. Decoding analysis with separated decoder training and testing across recording locations showed similar decoding performances in AIP and F5, i.e., showing no apparent gradient, neither within nor across the two cortical areas. Future analysis will further investigate the population dynamics of the fronto-parietal grasping network.

Title: Synchronous and isolated beta burst dynamics following recovery from stroke in primates

Authors: *P. KHANNA[1], **B. FARROKHI**[2], I. S. HEIMBUCH[3], H. CHOI[4], L. NOVIK[5], K. THIESEN[5], R. J. MORECRAFT[6], K. GANGULY[2];
[1]UC Berkeley, Berkeley, CA; [3]Neurol., [2]UCSF, San Francisco, CA; [4]Neurol., UCSF, Davis, CA; [5]California Natl. Primate Res. Ctr., Davis, CA; [6]Basic Biomed. Sci., Univ. of South Dakota, Vermillion, SD

Abstract: Dexterous movements rely on coordinated cortical and subcortical networks, but how these networks support recovery of movement after stroke is poorly understood. Many studies

have focused on the role of perilesional motor cortex (pMoCtx) in vicariation, but relatively little is known about how pMoCtx regains coordination with perilesional subcortical networks (pSubCtx). This process is likely critical as recent work across hundreds of patients demonstrates that atrophy to subcortical gray matter structures is strongly associated with poor sensorimotor outcomes (Liew et al., 2021). Further, work in rodents has also indicated that increased cortical-subcortical coupling is predictive of recovery (Guo et. al. 2021). Uncovering how cortical-subcortical interactions re-emerge following recovery from stroke may lay the foundation for novel approaches to multi-area neuromodulation to improve movement control after stroke.
To investigate how cortical-subcortical interactions are re-established in pMoCtx and pSubCtx to support hand control following stroke, we trained rhesus macaques to perform a reach-to-grasp task. To model a stroke, aspiration was used to remove the forelimb region of primary motor cortex unilaterally after cauterization of the primary arterial supply. In the same surgery, chronic microwire electrodes were implanted into ventral premotor cortex (pMoCtx) and a chronic linear microelectrode probe was implanted subcortically targeting motor thalamus (pSubCtx). Here, we report that pMoCtx beta bursts can be divided into two types: 1) synchronous, high amplitude bursts involving most pMoCtx channels and 2) isolated, lower amplitude bursts involving only a few pMoCtx channels. Synchronous cortical bursts are frequently coordinated with pSubCtx beta bursts whereas isolated bursts are not.
We find that immediately following the lesion, synchronous bursts are prevalent during reach-to-grasp behavior. As dexterity recovers, these synchronous bursts become rare during behavior, but common during the post-movement period. In contrast, isolated bursts increase in prevalence both during behavior and during the post-movement period.
Overall, these results may reflect subcortical-cortical interactions that are pathologically synchronized early after stroke thereby over-entraining cortical spiking activity and disrupting movement. With recovery, pMoCtx and pSubCtx can flexibly couple or uncouple depending on behavioral phase. Further, these observations support a role for low amplitude isolated beta bursts rather than high amplitude synchronous beta oscillations in healthy movement control.

Hosp. and Univ. of Tuebingen, Tuebingen, Germany; [4]Bernstein Ctr. of Computat. Neurosci., Goettingen, Germany; [5]Leibniz ScienceCampus Primate Cognition, Goettingen, Germany

Abstract: Neural systems are constantly confronted with sensory uncertainty. During reaching sensory uncertainty can affect the position of one's own effector (feedback uncertainty) and the location of the desired movement endpoint (target uncertainty). Previous findings showed that during movement planning increased visual target uncertainty leads to a broadening of reach goal representations in the dorsal premotor cortex (PMd) of macaques. Here we test whether this finding generalizes to other brain areas within the frontoparietal reach network and if similar mechanisms can be observed between target and feedback uncertainty.
Two male rhesus monkeys performed a memory-guided center-out reach task while keeping ocular fixation. The animals moved a cursor by operating a haptic manipulandum. We introduced feedback uncertainty by replacing the cursor with a cloud of five randomly moving dots, the position of which was drawn from a 2D Gaussian distribution. The width of the distribution experimentally determined the level of feedback uncertainty; its center was controlled by the animal's hand movement. To vary target uncertainty, we either revealed the actual target location or presented an array of bars drawn from a random distribution centered on the actual target location. We recorded neural activity using implanted microelectrode arrays from the primary motor cortex (M1), PMd, and the parietal reach region (PRR).
We found that high target uncertainty led to decreased hit rates and increased initial reach errors. Conversely, high feedback uncertainty resulted in increased reaction times without affecting the initial reach error. In PMd, neurons with preferred directions opposite to actual reaching direction showed higher firing rates during movement when feedback uncertainty was high compared to when it was low. Neither uncertainty type nor level modulated neural activity in M1 during planning or movement periods. SVM decoding of reach direction showed lower accuracy for both types of uncertainty during late planning in PMd. Additionally, in PRR, we noticed a trend of reduced decoding performance during movement when feedback was uncertain.
Our findings suggest that PMd relies on sensory information about both hand and target location to form an appropriate movement plan and uncertainty of either type leads to impairment. In contrast, parietal areas seem to be mostly affected once the movement has already been initiated and sensory feedback about the hand position needs to be integrated to update the current motor command.

Title: Sensory predictions are embedded in cortical motor activity

Authors: *J. A. MICHAELS, M. KASHEFI, J. ZHENG, O. CODOL, J. WEILER, R. KERSTEN, A. PRUSZYNSKI;
Western Univ., London, ON, Canada

Abstract: When moving through the world, such as biking down a bumpy trail, we encounter external forces that cannot be predicted by our own motor output. Since delayed sensory feedback is too slow to allow accurate state estimation, predicting expected sensory input could make rapid feedback control more stable. However, we don't know how flexibly the nervous system can use prior information to make sensory predictions, nor how these predictions are implemented in the brain. To answer this, humans and macaques performed a reaching task where visual cues indicated the probability of the direction of upcoming elbow perturbations. Humans and monkeys integrated these priors into sensory predictions on single trials, biasing their responses to perturbations. High-density neural recordings in monkeys revealed a widespread signature of sensory predictions in prefrontal, premotor, and motor cortex, but not in somatosensory cortex. Artificial neural networks trained to perform generalized reaching tasks by controlling a biomechanical model of the arm with realistic sensory delays and noise emergently generated sensory predictions, showing remarkably similar muscle and neural activity to humans and monkeys, while other models with less realistic control or impoverished training did not match empirical results. Together, these results reveal a crucial role of sensory predictions in movement control.

Title: Preparatory cortical activity predicts moving target location for upcoming manual interception

Authors: *Y. XIAO[1,2], Y. ZHANG[1,2], R. ZHENG[1,2], C. ZHENG[1,2], H. CUI[1,2];

Abstract: Dynamical systems perspective posits that preparatory activity is promoted toward a movement-specific optimal subspace to set initial states seeding the motor generation. However, it remains to be determined how the initial states for generating movements toward moving target are formed in accordance with target motion. To probe how motor cortex prepares for manual interception, we trained one monkey (*Macaca mulatta*) to perform a delayed reach task to a target static or moving circularly (Li et al., 2018). We recorded single-unit activity from the primary motor cortex (M1, ~80 units), dorsal premotor cortex (PMd, ~80), primary somatosensory cortex (S1, ~50), and posterior parietal cortex (PPC, ~50) with four 8*8 Utah arrays. Each dataset consisted of a recording session encompassing ~260 single-unit and multi-unit recordings. To analyze preparatory population activity, we identified the two-dimensional 'preparatory subspace' via principal component analysis (PCA), based on M1 and PMd neurons' activity in both static- and moving-target conditions. In the static-target condition, subspace activity depended on reach direction and seemed stable over the delay period, consistent with Elsayed et al. 2016. However, in moving-target conditions, preparatory activity appeared to change gradually from target onset to the GO cue, suggesting tuning was time-locked to target motion, rather than final motor goal. Furthermore, the neural state angle between the first two PCs (35.1% explained variance) of the preparatory subspace predicted future target locations (lead time ~ 460 ms) in each moving-target condition. Our results show that motor cortex predicts moving target trajectories to initiate interception. Preparatory activity in motor cortex may play an important role in coordinating actions that demand dynamic spatiotemporal transformation.

Title: Local network connectivity underlying goal-directed neural activity in the motor cortex

Authors: *A. FINKELSTEIN[1,2], K. DAIE[5,2], M. ROZSA[6,2], R. DARSHAN[3,1], K. SVOBODA[5,4];

Abstract: Brain functions are an emergent property of network connectivity. Previous studies linking local network connectivity to neural coding in the mammalian brain focused mainly on the sensory cortex, without reference to behavior. Little is known about the relationship between connectivity and behavior-related activity within higher-order cortical areas. Here we focused on the motor cortex, using naturalistic behavior in which mice gathered rewards with multidirectional tongue reaching. This behavior, which does not require training, allowed us to study the motor cortex before its activity is shaped by learning a specific task. Motor cortex neurons exhibited conjunctive tuning to reward position and reward outcome. We used an all-optical method for *rapid* large-scale mapping of causal functional connectivity *in vivo*. Mapping connectivity between ~25,000,000 excitatory neuronal pairs revealed fine-scale columnar architecture in layer 2/3 of the motor cortex. Specifically, nearby neurons displayed a 'Mexican hat' spatial profile of excitation and inhibition, with local like-to-like connectivity according to reward-position tuning. The local connectivity patterns were non-uniform, with a preponderance of weakly coupled neurons and sparse strongly coupled neurons that function as network hubs. Hub neurons had weak reward-position and reward-outcome tuning but strongly influenced neighboring neurons. This network of neurons, encoding position and outcome of movements to different motor goals, may be a general substrate for reinforcement learning of complex, goal-directed behaviors.

Title: Visual feedback uncertainty during BCI movements reflects in fronto-parietal neural population activity in rhesus macaques

Abstract: Sensory feedback guides movement but can also be uncertain. For example, visual feedback about hand position might be less accurate when reaching in low light conditions. Here we asked whether and how visual feedback uncertainty affects frontal and parietal sensorimotor areas in the neurophysiology of movement planning and execution. We trained two rhesus macaques to perform memory-guided center-out reaches controlling either a cursor (low uncertainty) or a cloud (high uncertainty). The cloud consisted of five randomly moving and short-lived dots, whose initial position was repeatedly drawn from a 2D Gaussian distribution. The width of the distribution determined the level of positional uncertainty about the center, which was controlled by the animal. Monkeys performed the task through a brain-computer interface (BCI) to neutralize proprioceptive feedback and to require them to rely exclusively on visual feedback. We recorded from chronic microelectrode arrays in the fronto-parietal reach network, including primary motor (M1) and dorsal premotor (PMd) areas, used as input to the BCI decoder, and the parietal reach region (PRR). Behavioral results showed that movement control was impaired with the cloud compared to the cursor and this was mostly reflected in the late stage of reaches. Analyzing neural population dynamics, we found that activity patterns corresponding to high and low uncertainty conditions, respectively, laid in separate subspaces, demonstrating an influence of feedback uncertainty across the three cortical areas. Trial-to-trial variability of population activity patterns was increased for high uncertainty in M1 and PMd during the late planning period, and for all three areas during early movement. Furthermore, SVM decoding of target direction based on neural activity performed worse in high compared to low uncertainty trials around early movement. Our results suggest that feedback uncertainty increases state exploration during planning for frontal areas, whereas parietal areas reflect feedback uncertainty once movement starts and updates of state estimate are relevant for movement control. Reduced decoding performance in high uncertainty trials suggests at least partial representation of target relative to effector position in frontal and parietal areas. Overall, our results show that frontal and parietal sensorimotor areas take into account the uncertainty of visual feedback and provide novel evidence on how this affects the representation of movement-related parameters at the neural population level.

Title: Dynamic modulation of cortico-cortical interactions during visuomotor behavior

Authors: *G. BARDANIKAS[1], S. JANA[1], F. BARTHELEMY[1,2], A. RIEHLE[1,2], S. GRÜN[2], A. BROVELLI[1], T. BROCHIER[1];

Abstract: The cortical networks involved in the control of visuomotor behaviors include various regions ranging from the parietal to the frontal lobe. It has been hypothesized that feedback connections originating from motor areas exert top-down influences on the posterior parietal cortex during visuomotor behavior.[1] A detailed description of the dynamic reciprocal flow of information within the fronto-parieto-occipital network, however, is still lacking. The current study aims to investigate the functional relevance of motor information processed in visual-parietal areas and understand its role during behavior. To this end, two rhesus macaques were trained in a visuomotor sequential reaching task. At each trial, animals reached visual targets appearing sequentially by means of a robotic exoskeleton. Neural recordings were acquired by extracellular multi-electrode Utah arrays (Blackrock Neurotech) implanted in five cortical regions along the visuomotor pathway, including the dorsal premotor (PMd) and primary motor cortex (M1), the parietal areas 7A and dorsal prelunate (DP) and the visual areas V1 and V2. Eye and hand positions were recorded by EyeLink 1000 (sr-research) and Kinarm (Bkin Technology), respectively. To assess cortico-cortical interactions during this task, we focused on the high-gamma activity (HGA, 55-150 Hz) of the local field potentials, which reflects a mesoscopic measure of neural activation correlating with multi-unit spiking activity.[2] We observed transient area-specific modulations in the power of the HGA related to relevant task events, such as stimulus onset and movement onset. To segregate independent sources of neural activation, an Independent Component Analysis was applied on the HGA. In order to unravel the network's dynamic reciprocal interactions, we performed directed functional connectivity analysis based on Transfer Entropy between the independent sources. Preliminary results reveal the co-existence of significant feedforward visuo-parietal interactions, as well as feedback fronto-parietal interactions. They are both more prominent after the initiation of the hand movement. Ongoing analyses are exploring how these interactions are modulated in relation to the behavioral performance of the monkeys in the task.

Title: Temporal eye-hand coordination may be subserved by connections between PRR and LIP

Authors: *J. KANG[1], E. MOOSHAGIAN[1,2,3], L. H. SNYDER[1];
[1]Washington Univ. Sch. of Med., SAINT LOUIS, MO; [2]Univ. of California San Diego, La Jolla, CA; [3]Salk Inst. for Biol. Studies, La Jolla, CA

Abstract: The lateral intraparietal area (LIP) in macaque posterior parietal cortex has been proposed to participate in motor preparation for saccades, spatial attention, salience mapping, categorization, and evidence integration. Forelimb movement planning also influences LIP and thus LIP has been proposed to be involved in eye-hand coordination. We revisited the coding of reaching movements in LIP and the possibility of a role in eye-hand coordination. LIP population activity is increased by movements of the contralateral arm but is not affected by movements of the ipsilateral arm. Since most LIP cells have contralateral receptive fields, this finding is consistent with coding reaches that do not cross the body midline (uncrossed). Most reaches in the home cage are uncrossed. However, by separately considering cells with ipsilateral response fields, we found that activity reflects only the identity of the arm that is reaching and not whether or not the reach crosses body midline. We previously showed that the parietal reach region (PRR) encodes plans for contralateral arm movements and sends information to LIP prior to a reach. This is consistent with LIP activity being modified by a reach with the contralateral arm. We tested for a causal role for this information transfer. It is difficult to block within-hemisphere PRR to LIP connections. However, callosal connections are easily blocked by injecting lidocaine into the portion of the corpus callosum that contains crossing fibers from PRR. Blocking these fibers degraded the temporal coordination between the eye and arm for crossed reaches compared to uncrossed reaches. In contrast, inactivating LIP with muscimol had the reverse effect, degrading coordination in uncrossed compared to crossed reaches. This is consistent with interactions between LIP and PRR subserving temporal eye-hand coordination, with signals related to the contralateral arm sent from PRR to LIP in either the same or opposite hemisphere, depending on whether the reach is into the contralateral or ipsilateral field (uncrossed or crossed). Interestingly, LIP inactivation not only degraded coordination for uncrossed reaches, but also improved coordination for crossed reaches. This could reflect a

competition between left and right LIP during crossed reaching. Inactivating the LIP that would subserve the more common uncrossed reach relieves this competition and results in an improvement in crossed-reach eye-hand coordination.
