Abstract: The descending motor drive and somatosensory feedback via the spinal reflex converge on spinal motor neurons for limb movements. However, it remains unknown how descending motor drive coordinates with the spinal reflex to generate adequate muscle activity for the achievement of intended limb movements. Here, we show that the primary motor cortex (M1) prospectively computes future spinal reflex to provide appropriate motor commands to spinal motor neurons. We simultaneously recorded activities in motor cortices, afferent neurons, and forelimb muscles of monkeys performing reaching movements and analyzed the sequential flow of neural information. We found that the activity of motor cortices encodes subsequent afferent activity. Multivariate information decomposition elucidated that motor cortical activity influences muscles not only through the direct descending pathway but also through the "transafferent pathway" composed of the descending plus subsequent spinal reflex pathways. Selective disruption of the afferent pathway reduced the estimated transafferent component of muscle activity, providing causal evidence for delayed activation of limb muscles through the

transafferent pathway. Furthermore, among the motor-related areas, the M1 encodes the most information about muscle activity transmitted via the direct descending and transafferent pathways. Thus, the M1 leverages spinal reflex action to drive limb muscles efficiently in voluntary movements.

Title: The Influence of Uncertainty on Preparatory Activity in Motor Cortex During Reaching

Authors: *T. ARAKERI[1], J. M. DILL[1], R. C. MANJAREKAR[1], K. M. GOTHARD[2], A. J. FUGLEVAND[1];

Abstract: In our daily lives we are constantly forming and correcting motor plans to flexibly interact with the external world. Often times the information available during the process of planning is incomplete, thereby causing uncertainty about the movement goal. It is unclear how the motor system prepares movements under different levels of uncertainty, and how this uncertainty affects the ability to re-prepare movements. Using a forced reaction-time paradigm, a rhesus macaque was trained to produce center out reaching movements to one of two diametrically opposing potential targets. In this task, a timing cue flashed three times in succession (500 ms between flashes). The third flash was the go-cue and the monkey had to launch the movement coincident with it (within 100 ms). The two potential targets were displayed at the time of the first flash and then disappeared. The actual target was then displayed at varying times prior to 'forced' movement initiation at the go-cue. We manipulated uncertainty about the target location using a coloring scheme that indicated the probability (p) of where the final target would appear. For example, when both potential targets were white, $p = 0.5$, and the final target could appear at either location with equal probability. When the time between actual target display and movement onset was briefer than typical visual processing time (~ 100 ms), the monkey had to 'guess' the location of the target. In these cases, and when guessed incorrectly, the monkey corrected the movement midstream. We found that the monkey was able to re-prepare movements faster with increasing levels of uncertainty. While the monkey performed this task, we recorded 202 neurons from the dorsal pre-motor and primary motor

cortex. During the preparatory period, we observed a graded reduction in the distance between neural states for the two potential movements with increasing levels of uncertainty. Such an outcome in neural state-space could theoretically explain the faster re-preparation times under higher levels of uncertainty. Regardless, differences in preparatory states still led to highly similar population dynamics during movement execution. Furthermore, we also found a dimension in neural state-space that separated the neural states based entirely on the level of uncertainty during both movement preparation and execution. Whether this dimension overtly represents uncertainty is an open question. Overall, these results provide insight on the structure of neural population activity in the motor cortex while preparing and executing movements under conditions of uncertainty.

Title: Neural dynamics common to reaching movements executed by the native arm and using a brain-computer interface

Authors: *H. MAO, B. A. HASSE, A. B. SCHWARTZ;
Univ. of Pittsburgh, Pittsburgh, PA

Abstract: Neural activity in the primary motor cortex has long been associated with controlling muscle activation and movement generation. The successful operation of many brain-computer interfaces, on the other hand, relies on motor cortical activity in the absence of movement. How neural activities are similar, or different, between these two scenarios is still not well understood. To further explore neural correlates under these different control modes, we compared activity patterns in the primary motor cortex during arm- and BCI-controlled reaches. Two rhesus monkeys were trained to perform a standard center-out reaching task in a virtual-reality setup. The task requires moving a cursor in VR from the center to one of the 16 peripheral targets. All targets are located on a circle within a vertical plane facing the subjects. Movement of the cursor was controlled by either the hand's trajectory (HC condition) or via a brain-computer interface (BC condition). Subjects performed HC and BC trials in separate sessions. Neural activity in the primary motor cortex was recorded using two Utah arrays. Offline spike sorting identified 208 units (both single- and multi-unit) from monkey R and 291 from monkey N. This study analyzed 116 and 189 units from the two subjects, with firing rate modulation greater than 5 spikes/s across both time and task conditions. Trial-averaged firing rate profiles for the 16 movement

directions were calculated for each unit, in HC and BC sessions respectively. A linear dimensionality reduction method was then used to identify three neural subspaces: Qhc, Qbc and Qmix, where Qhc explains neural activity variance during HC but not BC trials, and vice versa for Qbc. Qmix accounts for variances of both HC and BC data. Each of the three subspaces is 7-dimensional and is orthogonal to the other two subspaces. Qhc and Qmix together explain 90.8% HC data variance for monkey R (89.5% for monkey N), and Qbc and Qmix capture 89.3% (87.0%) BC variance. Among these three neural subspaces, Qmix captured more data variance than the other two. For BC neural activity, Qmix explained 50.3% (44.2%) variance whereas Qbc 39.0% (42.8%). For HC data, Qmix explained 65.3% (62.8%) variance while Qhc 25.5% (26.2%). Although some firing rate variance was isolated to the subspace specific for HC or BC, these results show that the subspace assigned to both HC and BC data (Qmix) explains most of the motor cortical activity. Since only a small amount of variance was accounted for in the HC-only subspace (Qhc), and since the muscles were active only in the HC session, this result suggests that much of the neural activity in the motor cortex is independent of muscle activation.

Abstract: Calcium imaging through head-mounted miniature microscope has become a common technique to analyze the activity of neuronal ensembles in awake animals. However, the use of this technique in non-human primates remains limited. Here, we report the use of calcium imaging and miniature microscopes in rhesus macaques to study the activity of neurons in the primary motor cortex (M1) and the supplementary motor area (SMA), two regions essential for the planning and execution of movement. We used GCaMP6f to monitor calcium transients in

M1 and SMA neurons in three rhesus macaques. We co-injected AAV5-Thy1s-tTA and AAV5-TRE-GCaMP6f into the arm region of M1 and SMA, in the right and left hemispheres, respectively. A microendoscope gradient-index (GRIN) lens was chronically inserted in the same regions. Two to four weeks later, we performed imaging experiments with a miniature microscope (Inscopix), while animals were sitting quietly in a primate chair (spontaneous activity) then while performing an arm-reaching task to touch targets on a screen to receive a juice reward. The data was processed to reflect changes in fluorescence (Δf/f), and the calcium dynamics were quantified using spike deconvolution method (OASIS). We analyzed the relation of calcium transients to spontaneous and task-related movements in groups of M1 and SMA neurons and present preliminary results from 4 sessions (1-2 sessions per animal). Across sessions, we identified 17 ± 11 (mean ± SD) and 9 ± 6 cells in M1 and SMA. So far, Therecordings in SMA showed lower activity (0.08 ± 0.1 calcium spikes/s) and lower amplitude (3.7 ± 1.0 Δf/noise) than recordings in M1 (0.24 ± 0.3 calcium spikes/s; 5.3 ± 3.4 Δf/noise) in the spontaneous state. This calcium activity tends to decrease when the animal is involved in the reaching task compared to spontaneous state, with a decrease to 0.06 ± 0.09 calcium spikes/s in SMA and 0.2 ± 0.3 in M1 during the task. Cross-correlation analyses of the activity recorded in the spontaneous state are currently underway to identify clusters of cells with correlated activity in M1 and SMA, as are studies of movement-related activation patterns. Post-mortem histology in two animals indicated strong and extensive GCaMP expression at the site of injection, with the lens being located at the center of the GCaMP expression. Histology is still in progress for the other animals. This is the first report of calcium imaging of ensembles of M1 and SMA neurons in macaques. Our preliminary results suggest that M1 and SMA differ in the degree of spontaneous activities and support our planned use of this technique to study the activity of cortical regions in NHP models of neurodegenerative diseases.

Title: Design and optimization of a low-noise scalable multiplexed neural interface

Authors: *G. SHULL[1,2], T. JOCHUM[2], Y. HUANG[3], Y. SHIN[3], H. FANG[3], J. VIVENTI[2]; [2]Biomed. Engin., [1]Duke Univ., Durham, NC; [3]Dartmouth Col., Hanover, NH

Abstract: Neural interfaces are a critical part of brain computer interfaces (BCIs) and serve to bridge the gap between the brain and electronics. A tradeoff ubiquitous across neural interfaces is that of spatial coverage and spatial resolution as the number of recording channels is limited by connector sizes and backend electronics. An approach to overcome this limitation is to embed active electronics at the electrode site, which enables multiple electrodes to share the same output wire through time division multiplexing (TDM), thus increasing the number of recording channels without increasing the number of output wires. However, a drawback of TDM is increased noise due noise aliasing, and fabrication-dependent physical characteristics, which contribute to transistor noise. The goal of this work is to design a low-noise, front-end recording system small enough to fit at the electrode site using commercial complementary-metal-oxide-semiconductor (CMOS) fabrication combined with post-fabrication processing to create a flexible, low-noise, TDM neural interface. To achieve this goal, we designed a front-end recording system beneath the electrode (termed "pixel") that enables low-noise multiplexing by 1) adding filters, 2) providing modest gain, and 3) buffering the output signal while consuming low-enough power to be implanted in the brain (< 40 mW/cm^2, or < 1 μW in 50 μm x 50 μm). The electrodes are arranged in a single column with 32 channels spanning an intracortical depth of 1.6 mm, to span the cortical thickness of a rat, and a width of 70 μm to minimize tissue damage (termed "shank"). Using this shank we designed a proof-of-concept 12-shank, 384-channel intracortical multiplexed array and sent the design to a CMOS foundry for fabrication. Our design high pass filters the signal from the electrode followed by differential amplification, low pass filtering, and buffering before multiplexing. An innovation of this work is creating a tunable high pass filter which allowed the filter to also fit within the area constraints. The design achieves a 28 dB gain over a band of 0.1 Hz - 10 kHz with noise < 10 μV rms while consuming 0.7 μW/channel, which enables both local field potential (LFP) and action potential (AP) recording with 6× lower noise and 25× smaller area than previous active arrays. Future work will focus on quantifying *in vitro* and *in vivo* recording performance. This work can be applied broadly across neural interfaces to create high-channel-count arrays and ultimately improve BCIs.

Title: Detecting analog to digital conversion artifacts in electrophysiological recordings using Intan Technologies integrated circuits

Authors: *K. BARTH, C. SCHMITZ, T. JOCHUM, J. VIVENTI;
Dept. of Biomed. Engin., Duke Univ., Durham, NC

Abstract: Intan Technologies offers amplifier integrated circuits that are widely used by neurotechnology companies and research labs for acquiring neurophysiological data from many channels (up to 64 channels / chip) at high sampling rates (up to 30 kSPS). Intan Technologies RHD chips contain miniaturized front-end circuitry that perform signal amplification, filtering, and digitization, which enable compact recording systems. However, we found that the analog-to-digital converter (ADC) in the RHD2000 series amplifier chips can introduce digital artifacts in the recorded data. The digital artifacts manifest as: 1) jumps, where the ADC rapidly switches to an incorrect output code, and 2) flatlines, where the ADC maintains the same output code over time. We developed an approach for detecting these digital artifacts by recording a variety of in-vitro and in-vivo signals using Intan RHD amplifier chips. With the chips' digital-signal-processing mode disabled, we detected the occurrence of digital artifacts in a recording by examining the distribution of ADC output codes. We detected jumps at ADC output codes with successive zero occurrences and flatlines at ADC output codes with higher probability occurrences. Further, we developed an artifact-correction strategy of re-running the ADC calibration phase in the Intan RHX software based on these detections from ADC output codes. Our findings are of great relevance to many in the neuroscience community who use Intan Technologies amplifier chips for neurophysiological experiments. These results provide a methodology to detect these digital artifacts and trigger ADC recalibration to preserve neurophysiological signal integrity.

Title: Advantages of current sensing circuit architecture for highly multiplexed neural interfaces

Authors: *M. HILL[1], J. VIVENTI[2];
[2]Duke Univ., [1]Duke Univ., Durham, NC

Abstract: Interfacing with the brain at a large spatial scale with fine resolution is key to understanding and treating neurological disorders. For example, the performance of motor and speech prosthetic systems can be improved with high-density micro-electrocorticography (μECoG) recordings. As the number of electrodes increases, conventional electrode array wiring becomes unwieldy and prone to mechanical failure, as each electrode requires an individual external wire connection. Time division multiplexing using integrated flexible transistors allows

many electrodes to share a single output wire. However, as the multiplexing ratio increases, the signal to noise ratio (SNR) of the device decreases due to increases in aliased noise. Prior results show current sensing can achieve high SNRs across frequencies of interest (32 dB at 10 Hz; 42 dB at 100 Hz, and 59 dB at 1000 Hz), specifically showing large increases in SNR in the High Gamma band (70 - 150 Hz) compared to voltage sensing strategies (22 dB at 100 Hz). In this poster, we investigate the circuit architecture needed for high-speed time division multiplexing with current sensing. In addition, we compare in vitro performance of current sensing against traditional voltage sensing while varying the multiplexing ratio. This current sensing strategy (i) decreases aliased noise, (ii) reduces the footprint of each pixel, and (iii) removes the need for a voltage offset. These results demonstrate the enhanced scalability of current sensing strategies over voltage sensing when utilizing active time division multiplexing.

Title: Open-source platform for wireless characterization of neural electrode impedance and reliability

Authors: *J. E. SMITH, I. RACHINSKIY, T. JOCHUM, J. VIVENTI;
Biomed. Engin., Duke Univ., Durham, NC

Abstract: Fully implanted neural prosthetic systems require wireless interfaces to reduce infection risk and enable long-term use. Conventional approaches to enable implanted electronics with wireless telemetry rely on hermetically-sealed packages that are large enough to perform helium leak testing. However, the ceramic feedthroughs that are typically used in these devices limit the number of electrodes that can be implemented. New approaches for encapsulating electronics are needed to enable scaling to thousands of channels. We propose a method of encapsulation wherein both an electrode array and the requisite electronics for signal acquisition and wireless communication are fully enveloped by liquid crystal polymer (LCP), which is well regarded for its biocompatibility, low water transmission, and reduced risk of delamination. While there are commercially available solutions to conduct long-term reliability studies of electrodes using wired connections, the connectors add failure modes to the test that are not representative of the failures electrodes would encounter when implanted. This work presents an open-source platform (electrical design, software) for wireless characterization of electrode impedance and, to quantify the reliability of the polymer encapsulation, the conductance of

interdigitated electrodes (IDEs) positioned within inner layers. Measurements are requested of an encapsulated microcontroller wirelessly using near field communication (NFC) and are logged automatically. Firmware can be flashed to the embedded controller over-the-air. Power is provided through an inductive link. Calibration, array multiplexing, user-defined waveforms, and service interruption notifications are supported. Key metrics of performance (impedance accuracy and precision at 1 kHz) are comparable to existing, wired solutions. This work is significant in that it: (a) inherently resolves former limitations of soak testing related to chamber and connector leakage, allowing for very long-term evaluation using a fixed volume of saline solution and (b) may serve as an open-source reference for the rapid development of related wireless characterization applications. In future work, we will use this platform to evaluate the stability of LCP encapsulation through accelerated aging to quantify the viability of chronic applications and predict expected lifetimes.

Abstract: Freezing of gait (FoG) is the most disabling gait disorder in Parkinson's disease (PD). Closed-loop deep brain stimulation (DBS) in the subthalamic nucleus (STN) is used for PD treatment. To provide appropriate stimulation parameters based on the clinical state of patients with PD, there is an increasing need for equipment capable of continuously monitoring neural activity in deep brain regions during unrestricted movement. However, there are few studies on long-term continuous monitoring of deep brain neural activity in freely behaving states. Therefore, we developed a fully implantable wireless system that can continuously record neural activity in the STN and amygdala regions, and we confirmed its long-term stability in a freely moving primate. The proposed fully implantable wireless system consists of a recording part that utilizes an Intan chip with an 8,192 sampling rate and implanted electrodes with 50 kohm impedance at 1 kHz for neural recording. It also includes a wireless data transmission part that

employs the Nordic Bluetooth Low Energy protocol with a data rate of 720 kbps at a range of more than 2.0 m away from the primate. Furthermore, a power management part with sleep on mode in process and a high capacity of 2,550 mAh primary battery ensure more than 120 days of operation. An adult (14-year-old) cynomolgus macaque (Macaca fascicularis) is prepared. The procedure was performed on the custom-built CT/MRI-compatible stereotaxic frame under general anesthesia. The deep brain recording electrodes were inserted vertically into the right STN and the right amygdala, and fixed to the skull using dental cement. We wirelessly recorded local field potentials (LFP) activity in the STN and amygdala regions of the primate during freely moving and fearful states. While he was walking, beta power in the STN were reduced compared to resting state. The amygdala beta and gamma power were increased when he felt scared compared to resting state. The consistent spectral changes were observed over a period of more than 4 weeks, confirming long-term stability of our fully implantable system. Our system will be particularly useful in continuous monitoring of deep brain signals in freely moving primates. As well, it will be used to study social behavior in freely moving monkeys and to investigate appropriate stimulation parameters in clinical studies.

Title: A Neural Interface system for an Osseointegrated Prosthetic Control

Authors: L. A. SEARS[1], A. DESHMUKH[2], N. ARMSTRONG[3], A. FERNANDO[3], D. LASEGA[3], V. GO[3], A. J. SUMINSKI[4], J. C. MORIZIO[3], S. O. POORE[1], *A. M. DINGLE[1]; [1]Surgery, [2]Biomed. Engin., Univ. of Wisconsin, Madison, Madison, WI; [3]Electrical and Computer Engin., Duke Univ., Durham, NC; [4]Dept. of Neurolog. Surgery, Univ. of Wisconsin-Madison, Madison, WI

Abstract: State-of-the-art neural prosthetic systems must be capable of high-fidelity stimulation and recording of nervous tissue, imposing stringent performance demands on the telemetry of high-bandwidth neural information. We present an ovine model for the Osseointegrated Neural Interface (ONI) for bi-directional prosthetic control, which appeases these demands via novel surgical methodology and a sophisticated neural interface system. Our surgical procedure saw one mature non-lactating female sheep undergo amputation and reaming of the thoracic limb at the distal metacarpus. Subsequently, the surgical team utilized a slap-hammer to secure an osseointegrated abutment. We followed osseointegration by coupling a stimulation electrode

with the distal end of the target nerve and transposing it into the freshly reamed medullary canal with recording electrodes attached proximally to the corticotomy. Finally, we implanted the transmitter and receiver capsule into the sheep's shoulder. Now intact, the ONI system could receive programmed electrical stimulation patterns and transmit continuous recordings of the stimulated major nerve and EMGs from nearby muscles. We generated neural recording data by remotely triggering preprogrammed stimulation patterns which were delivered to the coupled nerve. The transmission of said stimulation patterns along the nerve could then be validated by analyzing the recording output in NeuroExplorer for activity mirroring the stimulation parameters. The presence of stimulation artifacts in our recording data demonstrating the programmed frequency and pulse width of 60 Hz and 200 μs, respectively, verifies our neural interface system can remotely stimulate and continuously record from a major nerve. Our poster showcases the transmitter and receiver implantable capsule technology and surgical approach that forms the backbone of the ONI device. We will present the functional specifications, benchtop test results, and 3D printing and coating processing steps for the capsule, as well as the surgical specifications of electrode and capsule placement. In addition, we will cover electrophysiology data with various *in-vivo* stimulation patterns and post-processing data analysis used to validate the ONI.

Title: A general-purpose software platform for closed-loop neuromodulation

Authors: *W. ENGELHARDT[1,2,3], J. MELLINGER[3], A. BELSTEN[1,3], J. R. SWIFT[1,3], P. BRUNNER[1,2,3];
[1]Dept. of Neurosurg., Washington Univ. Sch. of Med., St. Louis, MO; [2]Dept. of Biomed. Engin., Washington Univ. in St. Louis, St. Louis, MO; [3]Natl. Ctr. for Adaptive Neurotechnologies, St. Louis, MO

Abstract: Implementing closed-loop neuromodulation therapies is a challenging and expensive endeavor. It requires developing software capable of acquiring signals from a bio-signal amplifier, analysis of these signals, and initiation of precisely timed stimulation, all of which need to be accomplished in real time with very low latency. Developing this software is difficult, as it requires a wide range of expertise ranging from interfacing with hardware to real-time signal processing. Even when successfully implementing such a system for one set of hardware, it often then only works within the laboratory that conceived it. This is because of the inherent heterogeneity in the devices that interact with the nervous system and the lack of standardized interfaces to access and control them. Collaboration thus often necessitates acquiring the same hardware (i.e., amplifier and stimulator) across all sites, which can sometimes be cost-prohibitive. Implementing software that uses these amplifiers and stimulators within a real-time acquisition and feedback software platform, such as BCI2000, would eradicate these obstacles. Multiple stimulators, amplifiers, and peripheral devices have been implemented in BCI2000 to provide a maximum amount of real-time feedback and to make the configuration effortless. The abstraction of BCI2000 experiments from the underlying hardware allows for seamless collaboration between institutions. To best configure the stimulation parameters, a stimulation configuration tool has been created to assist users in specifying their desired parameters, visualizing them, and exporting them directly into BCI2000. A cortico-cortical evoked response BCI2000 filter visualizes the time-locked stimulation response at each electrode in real time. With these improvements, BCI2000 successfully facilitates closed-loop neuromodulation experiments across multiple institutions and heterogeneous underlying hardware platforms.

Abstract: Arrays of individual wireless chips are an emerging architecture for neural interfacing. These chips could improve brain machine interfaces by removing the wired connection through the scalp, increasing biocompatibility with their submillimeter size, and improving implant targeting with their modular placement. While several approaches using this architecture are in development, little is known regarding their implantation into the brain, such as the required pitch between chips, insertion rate, and how many can be implanted at once. In particular, a minimally invasive method to swiftly insert many individual chips floating on the brain with penetrating subcellular-scale electrodes remains to be demonstrated. Our group has proposed two such electrode designs integrating a highly biocompatible (Patel, *JNE*, 2016) 8.4 µm diameter carbon fiber electrode with a wireless chip: the ReMote and StiMote. We previously validated chip components for recording electrophysiology (Lim, *ISSCC*, 2020; Lim, *VLSI*, 2021; Lim *JSSC*, 2022), stimulation (Lee, *VLSI*, 2023), optical power harvesting (Sun, *PVSC*, 2022) and wireless uplink (Atzeni, *VLSI*, 2022). To test the implantation and develop fabrication methods for the proposed designs, we made and implanted non-functional (NF) carbon fiber mote analogs. Silicon chip bases were micromachined to have dimensions (240 x 240 x 300 µm, L x W x H) similar to our proposed functional designs and with a 20-30 µm diameter hole. Fibers were manually placed into these holes, secured with epoxy, and cut to lengths targeting 0.5 or 1.0 mm. NF motes with 1 mm fiber lengths were suspended via excess fiber and encapsulated with Parylene-C and blowtorch sharpened (Welle, *TNSRE*, 2021) to enable unsupported insertion into the brain. The bases of completed NF motes were fixed to the end of a shaft with polyethylene glycol (PEG) in 3x3 or 4x4 grid patterns. As motes aggregated in molten PEG, the grid pitch was limited to the chips' own dimensions. Implantation required dissolving this PEG in saline once the silicon bases reached the brain's surface to release the devices. To validate this method *in vivo*, we inserted into rat cortex (male, Long-Evans) five 3x3 grids of NF motes with 0.5 mm fiber length in N=3 rats and two 4x4 grids with 1 mm fiber length in N=2 rats. Of the 3x3 mote grids, 37 of 45 motes inserted successfully (82%), where six of the failures were part of the second insertion trial . Of the 4x4 grids, 31 of 32 motes inserted successfully (96%). These insertions suggest that grids with a higher chip count are possible, and motivates further investigation of the biocompatibility of this insertion method during implantation and for months afterward.

Abstract: Electrical interfacing with the brain is undergoing a transformation. High-density microelectrode arrays, such as the Neuropixels array, oversample action potentials from individual neurons enabling high fidelity and reliable unit recording (Jun *et al.*, 2017). Other reports show that ultra-microelectrodes arrays (UMEAs) with subcellular substrate cross-sectional dimensions lead to increased recording lifetimes (*e.g.*, Guitchounts *et al.*, 2013; Luan *et al.*, 2017). Clinical and research applications of microstimulation (µStim) would presumably benefit from these approaches; yet the technology is not optimized for usage by the community. Our goal is to optimize CNS microelectrode array (MEA) and UMEA µStim usage by 1) testing the separate hypotheses that *MEAs and UMEAs can deliver safe, effective levels of cortical electrical stimulation* and then 2) distributing optimized software and hardware to collaborators for assessment.
To achieve this goal, we are working on three projects: 1) *In Vitro* Testing, 2) Acute *In Vivo* experiments, and 3) Chronic *In Vivo* Experiments. First, our group has developed models to characterize the Electrochemical Impedance Spectroscopy of MEAs and UMEAs which have allowed us to better understand the degradation of UMEAs and their coatings over time. We have also developed finite element models (FEM) of MEA and UMEA stimulation in the rat cortex to model the effects of electrode size, electrode material, electrode spacing, anatomical location, and stimulation intensity on the neuronal activation in the cortex to inform our *in vivo* experiments. Second, acute rat experiments are being performed in which we are stimulating and recording through UMEAs and are gathering neural activation data throughout the layers of the cortex to verify the EIS and FEM models developed in the first part of this project. These experiments also provide information on safe stimulation parameters to reduce tissue damage and extend the life of the UMEAs and their coatings. Third, as this project progresses, we will continue into chronic studies with rats which will provide information on the long-term stability and effectiveness of UMEAs over time.

Title: Recording data from the 16-channel NeuroNexus Neurotrophic Electrode

Authors: *P. KENNEDY[1], D. FURMAN[2], J. HETKE[3], D. S. ANDREASEN[4];
[1]Neural Signals Inc, Duluth, GA; [2]Arctop Inc, San Francisco, CA; [3]Neuronexus Inc., Ann Arbor, MI; [4]Georgia Tech. Res. Inst., Smyrna, GA

Abstract: The 2 wire (single channel) Neurotrophic Electrode records about 20 identified single units that are functionally active. In an attempt to improve the harvesting of more single units, the NXNE 16-channel thin-film electrode array has been designed and implemented by NeuroneXus Inc. It has been implanted in rat vibrissa cortices. In two rats, 260 and 240 spikes have been recorded, with inter-spike interval histograms, cross correlation analyses and event-related firings suggesting the presence of 80 single units in one rat and 60 single units in the other rat. Preliminary decoding results produced by connecting NXNE data to Arctop Inc. software for real-time analysis demonstrate viability of the signal for complex pattern recognition tasks and dictionary creation. The pattern of single unit firings between different vibrissa deflections being different, for example, allows words or phrases to be associated with different firing patterns, thus allowing the audible production of different phrases by deflecting different vibrissa. Studies are ongoing.

Title: Ultrathin Amorphous Silicon Carbide Microelectrode Arrays for Chronic Recording in Rat Motor Cortex

Authors: *E. N. PAUL, J. R. ABBOTT, J. O. USORO, P. HAGHIGHI, N. GERAMIFARD, Y. WU, T. J. SMITH, B. S. STURGILL, S. PATNAIK, A. G. HERNANDEZ-REYNOSO, J. J. PANCRAZIO, S. F. COGAN;
Bioengineering, Univ. of Texas at Dallas, Richardson, TX

Abstract: Brain-machine interfaces use neural activity to control external devices like tablets and neuroprosthetics. Microelectrode arrays (MEAs) can record neural activity but signal quality tends to decline after implantation due in part to glial scarring, which leads to neuronal loss. For example, the active electrode yield (AEY), the proportion of working channels recording single units, has been shown to fall below 30% as soon as 16 weeks post-implantation and the signal-to-noise ratio (SNR) to fall from 8.6 right after implantation to 6. Previous work shows that reducing the cross-sectional area of MEAs can reduce glial scarring. Because of this, our goal here is to develop an ultra-thin MEA that can improve long-term neural recordings. We fabricated 4 shank amorphous silicon carbide (a-SiC) - a biocompatible, chemically inert, and electrically insulating material - MEAs with 4 electrode sites per shank (16 channels total) with a 160 μm^2 shank cross-sectional area. We implanted our MEAs in the left motor cortex of 7 female rats and performed weekly anesthetized neural recordings for 16 weeks. Signals were filtered using a band pass filter (300-3000 Hz) and common median reference to reduce noise and artifacts. We isolated spikes with a threshold of -4σ from the mean, then used k-means clustering followed by manual verification to identify single units. We computed the AEY and single units' average waveforms. We divided the voltage peak-to-peak (Vpp) by the root-mean square (RMS) value of the noise to compute SNR. We used linear regression followed by an F test between calculated slope and a null hypothesis of slope=0 to determine if Vpp, noise, or SNR changed significantly over 16 weeks. The day of implantation we observed an AEY over 90% which declined to 50% over 16 weeks. Vpp and SNR also declined. At the time of implantation, mean values were as follows: Vpp = 141.4±11.2 µV, noise = 8.7±0.35 µV, SNR = 15.7±0.92. Regression slopes for each value were: Vpp = -2.07 µV/week ($p<0.0001$), noise = 0.03 µV/week ($p=0.08$), SNR = -0.24/week, ($p<0.0001$). These results show a 23% decline in Vpp, 5% increase in noise, and 24% decline in SNR after 16 weeks post-implantation. The stability of noise shown in this research suggest that using ultra-thin a-SiC devices can minimize glial scarring that result in only 5% increase of noise values. This will be verified in future studies by assessing the histological response. However, preliminary neurophysiological results from a-SiC MEAs suggest that the quality of signal over time, represented by the SNR, is higher than the reported values in literature for commercial silicon MEAs, supporting the long-term use of these ultra-thin devices.

Title: Flexible and Hydrophylic Carbon Nanotube Fibers as Microelectrodes for Neural Stimulation and Recording

Authors: *N. ALVAREZ, C. RUHUNAGE;
Univ. of Cincinnati, Cincinnati, OH

Abstract: Implantable micro electrodes are generally employed to record and stimulate electrical activity of neurons in the nervous system. Most of the electrodes available today are made of metals and silicon that lack required flexibility resulting on a mechanical mismatch between soft tissues and rigid metals which induces faster biofouling and inconsistent performance for long-term applications. Biofouling triggered by inflammatory responses dramatically affect the performance of neural electrodes, resulting in decreased signal sensitivity and consistency over time. Thus, long-term clinical applications require electrically conducting flexible electrode materials with reduced dimensions and antibiofouling properties. These characteristics reduce the degree of inflammatory reactions and increase lifetime of neural electrodes. Carbon nanotubes (CNTs) are well known for their flexibility, electrical conductivity and chemical inertness. This talk will report the use of CNT fibers for neural stimulation and recording, and subsequent covalent functionalization of CNT fibers and films surfaces with hydrophilic, antibiofouling phosphorylcholine (PC) molecules. The electrochemical and spectroscopic characteristics, impedance properties, hydrophilicity, and in vitro antifouling nature of the functionalized CNT surfaces will be presented. The hydrophilicity of the functionalized CNT films was demonstrated by a decrease in the static contact angle from 134.4° ± 3.9° before to 15.7° ± 1.5° after one, and fully wetting after three functionalization cycles respectively. In addition, the extent of protein absorption on the functionalized CNT films were significantly lower than that on the non-functionalized CNT film. Surprisingly, the faradic charge-transfer properties and impedance of the CNT assemblies were preserved after functionalization with PC molecules. These functionalized CNT assemblies are promising for the development of low-impedance neural electrodes with higher hydrophilicity and protein-fouling resistance to inhibit inflammatory responses.

Title: Design and fabrication of a novel neural interface for selective peripheral nerve stimulation comprising 2-photon polymerized penetrating structures integrated on a flexible polyimide-parylene substrate

Authors: *F. CIOTTI[1], A. CIMOLATO[1], P. PALOPOLI[2], J. WEICHART[3], S. RASPOPOVIC[1];
[1]Dept. of Hlth. Sci. and Technol., [3]Dept. of Mechanical and Process Engin., [2]ETH Zürich, Zürich, Switzerland

Abstract: The potential of peripheral nerve stimulation in the treatment of clinical conditions is strongly limited by the currently available electrode technology. The high selectivity necessary to obtain desired clinical outcomes with minimal adverse effects implies the use of highly invasive multielectrode arrays and complex surgeries, which restrict their viability in chronic human implants. Through highly detailed computational models of target peripheral nerves (sacral, pudendal, and vagus nerves), we developed a novel neural interface design comprising both intrafascicular and extraneural electrodes, i.e., spikes radially penetrating the nerve and flat electrodes arranged on the nerve surface. We optimized configuration of electrodes and design parameters for highest selectivity through automatic optimization methods, and compared its selectivity, repeatability, and invasivity with respect to state of the art interfaces. The promising results obtained in-silico prompted the actual realization of the device. To guarantee the conformity of the substrate to the nerve surface, the backing of the device is made of a thin polyimide layer (< 10 μm). The penetrating spikes are fabricated with a 2-photon polymerization process with a biocompatible resin. This allows for extremely high aspect ratios, 3D resolution (< 1 μm), and design flexibility. We exploited this technique to optimize the shape of the spikes for mechanical resistance. Moreover it allowed us to micro-texture their surface to increase the effective surface area and therefore the charge injection capacity, simultaneously reducing the foreign body response of the body to the implanted device. A conductive layer made of titanium and gold is then sputtered on substrate and spikes and patterned by wet etching with ultra-thick photoresist. A conformal, biocompatible insulative layer of Parylene-C is then deposited by chemical vapor deposition, and finally the surface electrode, spike tips, and connector pads are exposed by patterning the parylene with highly anisotropic ICP-RIE, simultaneously releasing the device by etching through both parylene and polyimide layers along its contours. Lastly, we evaluated its performance by electrochemical testing, showing promise for future in-vivo studies to achieve the predicted functional improvements, possibly contributing to making more advanced neurostimulation therapies clinically viable.

Title: Scalable Wireless Neuromorphic Microsensor Network with Dynamic Spike Sensing for Implantable Brain-Machine Interface

Authors: *J. LEE[1], A.-H. LEE[1], V. LEUNG[2], L. LARSON[1], A. NURMIKKO[1];
[1]Brown Univ., providence, RI; [2]Baylor Univ., Waco, TX

Abstract: As the main currency of neuronal signaling, action potential events occur sparsely in brain circuits due to efficient spike encoding which allows cells to effectively utilize limited resources such as bandwidth and energy. However, recording and reporting these sparse events at fixed sampling frequency can lead to inefficient sampling and communication, especially in ultra-miniaturized wireless neural sensor implants with tightly constrained energy and RF bandwidth. To address this challenge, we have developed dynamic spike sensing (DSS) strategy for wireless "neuromorphic" microsensors in the context of Brain-machine interfaces (BMI), drawing inspiration from dynamic vision optical imaging sensors (DVS). In our system, each wireless sensor employs sophisticated spike-encoding algorithms to convert spike band neural signals into binary spikes and transmits only the encoded spike events through an RF link. Distinct from DVS cameras, however, our spike encoder incorporates an adaptive threshold to account for electrode-specific noise and encodes the magnitude of the change in spike temporal coding which enables spike sorting in subsequent analysis. The implementation of DSS is realized in the form of a silicon microchip, a "Neurograin". The chip with a size of only 400 µm × 400 µm, is equipped with a neural amplifier, analog-to-digital converter, DSS encoder, and circuitry for wireless energy harvesting and data communication operating at 915 MHz. While the microchip samples spike band signals at a nominal rate of 4.6 kHz, the DSS encoder achieves a significant compression ratio of 3.5% while preserving essential waveform features necessary for spike sorting. Through simulations, we have determined that up to a thousand wireless microsensors can collectively record spike signals within our nominal RF bandwidth of 10 MHz. The compression capability is made possible by the dynamic adjustment of the sampling rate in the DSS engine, allowing for an increase in the sampling rate in the presence of spike events. We have successfully demonstrated the fully wireless functionality of the DSS Neurograin in

benchtop and small animal experiments, showing its ability to accurately report spike events and form a network. The proposed dynamic event sensing approach is scalable to large-scale wireless neuromorphic sensor networks with broad applications.

Title: Network of Implantable Wireless Microchip Stimulators for Spatially Distributed Intracortical Patterned Neuromodulation

Authors: *A.-H. LEE[1], J. LEE[1], V. LEUNG[2], L. LARSON[1], A. NURMIKKO[1];
[1]Brown Univ., Providence, RI; [2]Baylor Univ., Waco, TX

Abstract: While prior research suggests the viability of free-floating implanted wireless cortical microstimulators [Khalifa, A., et al. 2018, Piech, D.K., et al. 2020], scalability remains a challenge to achieve patterned stimulation with a limited number of stimulation channels achieved, typically from a single multielectrode device. What is desired is an approach to generate complex stimulation patterns such as to evoke a sensory percept or correct abnormal neural activity. Here, we present an ultra-miniaturized ASIC measuring 300 μm × 300 μm operating at 915 MHz, a silicon microchip capable of programmable intracortical stimulation, RF energy harvesting, and bidirectional data communication. Given the small volume of the ASIC, this device is developed to enable intracortical stimulation at high spatial resolution. The distinct feature of the prospect of a neuromodulation scheme where many spatially distributed stimulators can be wirelessly networked to achieve large scale neural stimulation at multiple points across the brain. The system leverages a wireless daisy chain communication scheme capable of delivering remote commands up to a thousand microchips as a program of patterned stimulation within 300 μs using a 1 MHz downlink interface. We also report on the addition of an energy storage capacitor for keeping the required incident RF power within regulatory limits, to be integrated directly on the silicon substrate of the chip. Using microfabrication techniques for post-processing, we have monolithically integrated intracortical penetrating electrodes or planar PEDOT: PSS electrodes on the microchips which were fabricated in TSMC 65 nm CMOS process. We demonstrate the stimulation and wireless networking capabilities of microchips in a conductive medium as well as in-vivo rodent experiments. In the animal experiment, fully implanted cortical microstimulator delivers focal electrical current pulses up to 100 μA to evoke neural and behavioral modulation. The results suggest the potential of this type of wireless,

spatially distributed network of microstimulator system as a tool for advanced neuromodulation applications such as patterned electrical stimulation for use in the sensory neural prosthesis.

Title: Balance reactions to visual displacements in a virtual reality environment.

Authors: ***J. E. MISIASZEK**[1,2], R. N. CHANDRA[1], S. G. HEMAKUMARA[1], J. FORERO[1]; [1]Fac. of Rehabil. Med., [2]Neurosci. and Mental Hlth. Inst., Univ. of Alberta, Edmonton, AB, Canada

Abstract: The potency of visual feedback in the control of standing balance is highlighted by the entrainment of postural sway to the continuously oscillating motion of a visual surround in the "moving room" paradigm. We recently demonstrated that small amplitude, transient moving room displacements induced brief, balance corrective responses, indicating that visual feedback may play a role in correcting for unexpected balance disturbances. Visual motion within virtual reality (VR) is also known to induce lean and postural adjustments in relation to the perceived movement. However, it is not known if small amplitude, transient visual stimuli in VR are similarly effective in generating balance corrective responses. Here, we recreated the "moving room" paradigm with VR. We hypothesized that forward motion of the virtual surround would induce a forward sway reaction and that light touch of a stable reference would reduce the response. Additionally, we tested if seeing the motionless support surface (floor) influenced the response evoked. To test this, participants wore VR goggles that generated a virtual enclosure with either 3 walls and ceiling that moved relative to a stable floor (F), or an enclosure that included a shelf that obscured the floor (O), and either asked to touch (T) or not touch (NT) a stable reference. The virtual enclosure was programmed to create a forward linear displacement (1.25 cm, 124 mm/s peak velocity). A total of 20 naïve participants were allocated to 1 of 4 groups (ONT, OT, FNT, FT) and were unexpectedly exposed to 10 visual displacements. All ONT participants reacted by swaying forward, whereas 3/5 OT participants swayed forward but with a smaller amplitude, and the remaining 2/5 swayed backward resulting in an unpaired Hedge's g between ONT and OT of -2.31. In contrast, 2/4 FNT participants swayed forwards while 2/4 swayed backwards, with absolute amplitudes comparable to the forwards sways of the ONT group. 4/5 participants in the FT group swayed forwards, but the absolute amplitudes of the responses were smaller than the FNT group. Overall, small amplitude, forward virtual surround

displacements evoke forward balance corrections, consistent with previous natural world findings. However, seeing a stationary floor or touching a stable reference while in the moving virtual surround often resulted in an atypical backward sway response not observed previously in natural world studies, suggesting that sensory information from virtual environments can lead to conflict in standing balance control.

Title: Control of balance under varying odds of a postural perturbation

Authors: *R. SHARMA, D. GOKANI, N. KANEKAR;
Dept. of Biosci. and Bioengineering, Indian Inst. of Technol. Bombay, Mumbai, India

Abstract: Perturbations to balance such as hit or push are often experienced in everyday life. When exposed to external predictable perturbations, the central nervous system (CNS) uses anticipatory and compensatory postural adjustments (APAs and CPAs, respectively) to maintain balance. APAs are changes in muscle activity that occur prior to the onset of an expected perturbation and are followed by CPAs (corrective changes post-perturbation). CNS uses several key features of a perturbation to make predictions about the upcoming impact for generation of optimal APAs and CPAs. While the effect of predictability on APAs has been studied in terms of varying perturbation magnitudes (low/high) and timing (self-paced/reaction time); in all such cases, to begin with, the occurrence of the perturbation on a given trial was always certain. However, the odds of occurrence of a perturbation may itself influence postural planning; yet this factor has not been studied. To investigate how the odds of occurrence of a predictable perturbation affects APAs and CPAs, 7 healthy adults (24.86 ± 2.54 years; 4 males) were exposed to external predictable perturbations/hits via a pendulum at shoulder level while standing barefoot. The probability of occurrence of hits was varied across 7 conditions such that 100, 80, 60, 50, 40, 20, and 0 percent of the total trials were hits while remaining were non-hits (pendulum stopped just before subject contact); the order of conditions and of hits within conditions across subjects was pseudo-randomized. Prior to each condition, subjects were told about the total number of trials (10) and the percentage of hits. Integrated electromyographic (IEMG) activity over 4 epochs (APA1, APA2, CPA1, and CPA2) for several muscles and peak center of pressure (COP) displacements were computed. Repeated measures ANOVAs with post-hoc comparisons were conducted. In hit trials, for IEMG, while no main effect of interaction

(epoch x condition) was observed for tibialis anterior, rectus femoris, and biceps femoris muscles, a significant main effect was seen for gastrocnemius *(p = 0.014)*; post-hoc comparisons showed a larger inhibition during the APA2 phase in condition with 100% hits (-0.47 ± 0.33) than that in 50% hits (-0.19 ± 0.27) *(p = 0.005)*. Peak COP displacements did not differ across conditions. The preliminary findings suggest that even when the odds of occurrence of hits were less than 100%, the CNS seemed to largely use similar patterns of APA and CPA activity as seen in 100% hit condition. Maintaining the highest level of motor planning even when the odds of being hit are very low seems to reflect a prudent decision-making that enables maintaining postural stability at all times.

Title: Hindlimb musculoskeletal structure and mechanical demands of locomotion determine basic organization of spinal locomotor networks in the cat

Authors: S. RAHMATI[1], A. N. KLISHKO[1], S. N. MARKIN[2], N. SHEVTSOVA[2], A. FRIGON[3], I. A. RYBAK[2], *B. PRILUTSKY[1];

Abstract: Assuming that the hindlimb musculoskeletal system and its neural control have evolved in parallel to satisfy behavioral demands, locomotor demands can be used to determine the required muscle activation patterns and propose the corresponding organization of hindlimb spinal locomotor networks. We defined hindlimb locomotor demands as (i) the required muscle moments of force produced at the ankle, knee and hip leading to the observed kinematics of walking and (ii) the necessity to maximize walking time at a given speed (or to minimize muscle fatigue). We considered that the spinal locomotor network controlling each hindlimb includes (i) a half-center rhythm generator (RG), (ii) a pattern formation network (PF), receiving RG input and sensory feedback to control the activity of synergistic muscle groups, and (iii) reflex pathways projecting to motoneurons of agonist and antagonist muscles. To quantify mechanical demands, we recorded hindlimb kinematics and ground reaction forces of 9 cats during overground walking (duty cycle > 0.6, speeds of 0.5 - 0.7 m/s) and computed the resultant muscle moments at hindlimb joints. Using these data, we then computed activations of 12 major

hindlimb muscles during each recorded walking cycle based on minimizing the cost function characterizing muscle fatigue (Crowninshield, Brand, 1981) and constrained by hindlimb musculoskeletal properties and the requirement to produce the obtained moments at hindlimb joints. Potential organization of the PF network was determined by extracting muscle synergies (groups of muscles receiving the same time-dependent input; Klishko et al., 2021) from the muscle activations. We then compared the predicted synergies with the synergies obtained from actual activation patterns recorded in the same muscles and in the same walking cycles. In both cases, the number of identified synergies was the same (n=5), they contained essentially the same muscles and had highly correlated activation patterns. The computed and recorded muscle activations had the following features: (i) reciprocal activity of one-joint antagonists, (ii) concurrent activity of joint agonists, and (iii) dependence of two-joint muscle activity on moments at both joints. We incorporated the revealed muscle synergies and features of muscle activity in a neuromechanical model of spinal locomotor control of a single hindlimb. The model generated realistic walking and muscle activity patterns. The results support the idea that the structure of the hindlimb musculoskeletal system and locomotor demands predefine and shape the organization of spinal locomotor networks.

Title: Modeling perception of leg speed differences during walking through drift-diffusion models

Authors: *M. GONZALEZ-RUBIO[1], P. A. ITURRALDE[3], G. TORRES-OVIEDO[2];
[1]Bioengineering, [2]Univ. of Pittsburgh, Pittsburgh, PA; [3]Univ. de la Católica, Montevideo, Uruguay

Abstract: Sensation plays a crucial role in the planning, execution, and adaptation of movements. For example, people adapt their movements based on the difference between predicted and actual sensory consequences from our actions. However, quantifying human sensation is challenging because it does not have observable consequences like motor outputs. To measure perception of somatosensation during walking (e.g., leg speed differences), psychophysics tasks known as the 2-alternative forced-choice (2AFC) task have been used in the past. Additionally, from the recording of the task it is possible to apply computational modeling

through a variation of the drift-diffusion model to characterize the relation between accuracy and reaction times across different sensory stimulus magnitudes in this active task (Iturralde et al., 2023). This model differs from the traditional formulation of DDM (Bogacz et al., 2006) given that both the rate (drift) as well as the noise (diffusion) in the evidence accumulation process are scaled by the stimulus magnitude. Here, we wanted to assess model performance in a 2AFC task assessing sensitivity to speed differences during walking on a split-belt treadmill. Specifically, we used data from 26 participants who had mean walking speeds of 0.7, 1.05, or 1.4 m/s. We hypothesized that the new DDM formulation (drift and diffusion are stimulus-dependent) will outperform the traditional formulation in this broad dataset. To test this hypothesis, we fitted the models and computed the residual sum of squares (RSS) and Mallow's Cp (James et al., 2021) to compare between the two models. We expected that the new formulation will have a superior performance at explaining the relationship between accuracy, reaction time, and stimulus magnitude simultaneously, which would be indicated by smaller values of RSS and Cp. Consistently, the RSS for the reaction times was 42.92 for the traditional formulation vs. the 14.9445 in our proposed stimulus-dependent noise model. Likewise, Mallow's Cp had values of 0.373 vs. 0.127, respectively. Qualitatively, differences between the two models are not as striking as what was reported before (Iturralde ref). A possible explanation are the differences in protocol: 1) we limited the response window in our 2AFC task 2) we included an auditory cue warning participants when time was running up, 3) we included more repetitions per stimulus magnitude, and 4) we have a reduce set of stimulus magnitude tested. Taken together, our results indicate the parameters relevant to the evidence accumulation process leading to the perception of a difference in leg speed can be explained by magnitude-dependent noise.

Title: A role for vestibular lateral translation cues in postural control

Authors: *K. LOVE[1], A. D. GOODWORTH[2], F. KARMALI[3];
[1]Massachusetts Eye and Ear Infirmary, Boston, MA; [2]Westmont Col., Santa Barbra, CA;
[3]Otolaryngology, Harvard Med. Sch., Boston, MA

Abstract: Imbalance and falls pose significant health risks, especially as people age, leading to hospitalizations and serious injuries. While many factors contribute to postural control, a key factor is sensory feedback from the vestibular, visual, and proprioceptive systems. In most prior

work, the predominant vestibular cue for postural control is presumed to be feedback about tilt orientation relative to gravity. In fact, postural control models, which have been used to further understanding about sensory contributors, typically include vestibular feedback about tilt orientation relative to gravity. However, the vestibular system provides crucial information about head tilt, translation, and rotation. In a recent experimental study (Karmali et al. 2021), we measured postural sway and vestibular function using vestibular perceptual thresholds. These vestibular thresholds are robust measures of vestibular function, and measure the smallest motion that can be reliably perceived. We measured thresholds for lateral translation, vertical translation, tilt relative to gravity, and yaw rotation. We found that lateral translation thresholds were correlated with postural sway across subjects, and not other thresholds. This supports a role for vestibular lateral translation cues in postural control. This finding is further supported because the typical tilt of the body during quiet stance is much less than roll tilt thresholds. To further support these findings, we developed a closed-loop postural control model that includes independent feedback channels for vestibular tilt and translation, using a single-link inverted pendulum. Since thresholds are related to neural variability/noise via signal detection theory, we implemented thresholds for each pathway as low-pass filtered white noise. Notably, when both tilt and translation cues are available in the model, the predicted postural sway is significantly reduced compared to using only tilt cues. This finding provides support for the hypothesis that translation cues play a role in postural control. Future modeling will include proprioceptive and visual feedback.

Title: Similarity across walking contexts improves the generalization of adapted locomotor patterns.

Authors: *A. AWUAH, K. FJELD, G. TORRES-OVIEDO;
Bioengineering, Univ. of Pittsburgh, Pittsburgh, PA

Abstract: Generalization in motor control is the ability to transfer motor patterns from a training context, where patterns are developed, to a testing context, where patterns are tested. This ability is critical for rehabilitation because it is important that motor corrections with training devices

generalize to movements without them. However, device-induced training, for example, split-belt treadmill walking, in which one leg walks faster than the other, has limited generalization to walking without the training device. This limitation may be attributed to incongruent contextual cues, specifically, natural visual flow and the ability to self-regulate step initiation typically found in overground walking is absent in split-belt walking. To address this question, we manipulated the contextual similarity between devices inducing locomotor adaptation and overground walking. We hypothesized that devices with more contextual similarity to overground walking would improve the generalization of adapted patterns to walking without the device. To test this hypothesis, we adapted twenty young adults on either the split-belt treadmill (i.e., low contextual similarity group; n=10) or a pair of motorized shoes (i.e., high contextual similarity group; n=10) which can induce the same adaptation as the split-belt treadmill while walking overground. Following adaptation, we further divided the groups to test the generalization of adapted locomotor patterns (i.e., aftereffects) under two conditions: tested **with the training device** (i.e., treadmill or motorized shoes) or during overground walking **without the training device.** We anticipated to observe an interaction such that contextual similarity would regulate the reduction in aftereffects tested without the device relative to those tested with the device. Consistently, we found a trending interaction effect between contextual similarity and testing conditions ($p=0.054$). More specifically, we observed that groups with low contextual similarity exhibited less aftereffects without the training device than with the training device, whereas groups with high contextual similarity showed the opposite pattern (larger aftereffects without the device than with the device). Overall, due to large aftereffects observed in the groups with high contextual similarity (i.e., motorized shoe groups), our results suggest that increasing contextual similarity between training and testing contexts enhances the generalization of locomotor adapted patterns. This finding could be exploited to design rehabilitation devices that improve motor patterns in clinical populations during unassisted walking.

Title: Exploring body configurations of mice during treadmill locomotion

Authors: *L. I. SWAMINATHAN[1], B. M. IGNATOWSKA-JANKOWSKA[1], A. G. OZER[1], M. Y. UUSISAARI[1], G. J. STEPHENS[2];

Abstract: Animal locomotion comprises rhythmic spatio-temporal modules that are inherently variable. Quantifying animal movement and its variability can provide insight into underlying processes of the central nervous system. Previous studies on mouse locomotion focused on quantifying individual limb movement and inter-limb coordination using central metrics such as step-length, speed, angular excursions, and phase differences, despite locomotion being a whole-body movement. The aim of this study is to move beyond the classic metrics by describing whole-body mouse movements as body configurations changing through time. We utilized a novel marker-based 3D motion capture system comprised of 7 high-speed, high-resolution cameras and 10 custom-made retroreflective markers permanently attached to the skin of the mice (adult male, C57bl/6, n=9) at the shoulders, hips, knees and ankles. The 10 markers were tracked in 3D to obtain highly resolved (300 Hz, 200 micrometers) kinematic data that is a 30-dimensional readout of the body configurations (BCs) of the mouse as it locomoted, without restraints, on a treadmill set at different speeds. Principal component analysis (PCA) was used to decompose the trajectories into modes of deformation (MDs) around the mean BC. The analysis revealed 6 significant MDs explaining over 85% of the data variance; the remaining modes had contributions comparable to noise and were discarded. The 6 MDs form a basis set of deformations to the mean BC during treadmill locomotion, expressing the BCs during the task as a combination of these MDs. The MDs were classified into two main types: hopping and leg-alternation, each further divided into three subtypes based on differences in joint coordination. The number of significant MDs decreased from 6 to 3 at treadmill speeds above 24 m/min (associated with bounding and galloping), indicating that mice utilize only a subset of BCs seen with treadmill locomotion at lower speeds. At the highest speed, this subset could be expressed as a combination of only leg-alternation MDs with no hopping MDs. In this study, we obtained a description of whole-body mouse movements built of BCs and MDs. The space of BCs resulting from distinct leg-alternation and hopping modes can be further explored using delay-embedding techniques to unveil distinct classes of recurrent BC patterns (analogous to step-cycles) during mouse locomotion. Furthermore, this tractable representation allows the quantification of the variability of locomotory movements by assessing the spread of trajectories in recurrent BC patterns.

Title: The Effects of Variability in the Relative Arrangement of Mechanotransducive Sensors on Strain Processing

Authors: *G. F. DINGES, N. S. SZCZECINSKI;
West Virginia Univ., Morgantown, WV

Abstract: A common aspect of locomotive coordination is the integration of sensory information to modify or reinforce motor patterns while the organism is adapting to its variable environment. Sensory information is measured and monitored by sensory organs that can be found on and within various limb segments. In the legs of insects, there are multiple sensory organs monitoring key phases of cyclic movements, such as stepping. One class of sensory organ in insects whose phasic inputs has been shown to influence locomotion is the Campaniform sensilla (CS). These measure forces that arise within the exoskeleton. Investigations have shown that the general locations of CS along the leg are consistent between individuals in *Drosophila melanogaster*. However, the precise arrangement of sensilla within fields and groups show interindividual differences. Recently, a mechanical approach was used to 3-D model *Drosophila* field CS using information from nano-computed tomography segmentation. This work showed that polymer resin exhibits viscoelastic properties, much like those shown to be present within the insect cuticle. This viscoelasticity affects CS firing within the animal. This experimental design enables circumventing the experimental restrictions currently limiting the investigation of CS within the animal itself. The limited availability of sparse leg-CS labelling Gal4 lines as well as the occurrence of movement artifacts that may arise during leg calcium imaging, makes this mechanical modeling approach useful for investigating the mechanical aspects of strain sensing. We used this setup to investigate the effects of field rotation and individual cap rotation on strain induced cap compression in simplified models of the femoral *Drosophila* CS field. Using these 3-D mechanical models allows the modulation of attributes, such as rotation, while capturing viscoelastic properties. In different test samples we rotated the whole field or two individual CS. While applying different tensile forces to the field, the strain each cap experienced was monitored using strain gauges. Our findings show that the rotation of the whole field affects which loading scenario can compress the most CS. Further, the rotation of individual CS by 30° can decrease the monitored strain but does not necessarily lead to tension instead of compression, suggesting that difference in arrangement may not lead to altered firing. Further, there are distal to proximal, and coherently large to small cap, gradients in monitored strain. Our findings underline that interindividual variability in sensilla orientation can affect which strains are monitored on a purely mechanical level.

Title: Cortical brain dynamics associated with unanticipated changes in exoskeleton walking assistance

Authors: *J. BRADFORD[1], S. SONG[2], C. A. HAYNES[1];
[1]Humans in Complex Systems, US Army Res. Lab., APG, MD; [2]Texas A&M Univ., College Station, TX

Abstract: Little research has been performed to understand how the human brain and body respond and adapt to active exoskeleton assistance during walking. The goal of this study was to uncover cortical brain signals related to the user's adaptation to an autonomous, bilateral ankle exoskeleton. 22 subjects walked on a treadmill while wearing a powered bilateral ankle exoskeleton that assisted with plantarflexion at toe off. We measured EEG, EMG, kinematics, and ground reaction forces. During walking with exoskeleton assistance, we intermittently turned the exoskeleton power on and off without notifying the participant to determine the timescale of how the brain and body adapt to the new gait dynamics. We found increased theta band power in prefrontal brain areas only during the first stride when augmentation was turned on. We found decreased beta band power in the right primary sensorimotor cortex after the augmentation was turned on that persisted for many strides after the transition

Title: Gait characteristics in young adults during dual-task conditions.

Authors: *C. CHAU, T. COUGHLIN, K. DOWDALL, M. GELDER;
Nazareth Col. of Rochester, Rochester, NY

Abstract: This study investigates the gait characteristics of young adults while performing a concurrent cognitive task. Nine healthy young adults ages 18-25 years old were recruited from Rochester, NY. Participants performed two cognitive tests, serial subtraction (S) and an auditory Stroop test (A). Walking was recorded by the Vicon 3D motion capture system (Nexus) using eight cameras. Twenty-two 14 mm retro-reflective markers were placed on the skin of predetermined anatomical landmarks of the lower extremities, and seven body segments were reconstructed (CGM 1.1). Anatomical joint angles were calculated. Each participant completed 4 trials of walking (20 ft) without a concurrent task (Single-Task (ST)) or with a concurrent cognitive task (Dual-Task (DT)), either DTS or DTA, in a randomized order. The only constraint for all walking tasks is that the participant may not stop during walking trials. Spatiotemporal and kinematic gait parameters were processed by Visual3D software (C-Motion). Joint angular excursion for the pelvis, hip, knee, and ankle joints was calculated. Angle-angle diagrams were

plotted to examine intralimb coordination. A one-way repeated measures ANOVA was used to compare the gait difference between the three walking conditions. A paired t-test was used to compare the dual-task locomotor cost between DTS and DTA. The effect size between dual and single tasks was calculated using Cohen's D statistics. As compared to ST-walking, results showed a significant decrease in velocity (-0.15 m/s, -0.15 m/s), cadence (-6.9 steps/min, -5 steps/min), and stride length (-0.08 m, -0.1m) during DT-walking for both DTS and DTA, respectively. A significant increase in stance duration (+5.0 ms, +4.3 ms), double limb support (+3.9 ms, +3.4 ms), and step cycle duration (+6.9 ms, +5.5 ms) was found during DT-walking for both DTS and DTA, respectively, as compared to ST-walking. A significant decrease in joint angular excursion of the hip (-2º, -1.8º) and ankle (-2.3º, -1.9º) was found during DT-walking for both DTS and DTA, respectively. Hip-Knee and Knee-Ankle cyclogram were similar in shape between ST- and DT-walking suggesting the intralimb coordination remains robust. Cognitive errors during dual-task locomotion were comparable between DTS and DTA but with marked variability between participants. Our results suggest a decrease in gait stability in adults during both DTS and DTA walking compared to ST-walking support literature that suggests a decrease in attentional resources during dual-task conditions. A decrease in joint angular excursion may contribute to the decrease in spatiotemporal parameters.

Title: Neck muscle-specific modulation for head stabilization by vestibular reflex during locomotion

Authors: *R. WEI, O. STANLEY, K. E. CULLEN;
Dept. of Biomed. Engin., Johns Hopkins Univ., Baltimore, MD

Abstract: Locomotion is a continuous, rhythmic oscillatory motor behavior. Vestibulospinal reflexes are believed to make an essential contribution to locomotion by controlling balance, especially in activating the neck musculature for head stabilization. However, the contribution of neck muscles to head stabilization and how this contribution is influenced by locomotion velocity remains unclear. To date, it had not been possible to directly assess the contribution of vestibular pathways from that of extra-vestibular pathways to head stability. Accordingly, we studied the head stabilization and motor unit activity in neck muscles using 3D motion capture and EMG recording during treadmill and ground walking in both intact and bilateral vestibular loss (BVL) monkeys. A head-mounted 6D sensor and a marker-based tracking system was used

to extract the animals' head rotation and position. The marker-based tracking system was also used to track trunk position, while 4 high-speed cameras captured synchronized limb motion. Motor unit activity was measured through acute intramuscular EMG recordings in the splenius capitis (SPL) and sternocleidomastoid (SCM) muscles. Overall, we observed that the head was well-stabilized in normal monkeys, as the head-on-body movement compensated for the body's movements. Both the head and body exhibited increased movement as speed increased. Single motor unit activity of SPL and SCM muscles showed antagonistic phase-dependent activity. Additionally, as speed increased, there was an accompanying increase in EMG activity in the neck muscles. In contrast, poor stabilization was observed after BVL. Pronounced head oscillations were observed, which failed to compensate for the body's movements, especially in the roll rotation. Furthermore, neck muscle activity revealed minimal modulation across all speeds, leading to limited phase-locked activity or antagonism. Taken together, our findings establish that vestibular sensory inputs play a crucial role in organizing neck motor activity to ensure compensatory head movement during locomotion. Furthermore, our study highlights the distinct phasic patterns and speed modulation of muscle activity generated by vestibular pathways, which contribute to enhanced head stability during locomotion.

Title: Robotic Model of Carausius morosus Middle Leg Used to Predict Sensory Discharge During Walking

Authors: *W. P. ZYHOWSKI[1], S. N. ZILL[2], N. S. SZCZECINSKI[1];
[1]Mechanical and Aerospace Engin., West Virginia Univ., Morgantown, WV; [2]Dept. of Biomed. Sci., J.C. Edwards Sch. Med., Huntington, WV

Abstract: Animals adapt their motion by means of a variety of sensory organs and neural systems. The campaniform sensilla (CS), sensory organs located in groups in high-stress areas of the exoskeleton of the leg, is one such organ. Extracellular recordings of these sensors' discharge in response to exoskeleton strain have improved our understanding of how they encode forces acting on the body. However, due to interference from muscle potentials and other limitations, these recordings are challenging to collect in walking animals. In order to further our comprehension of the insect nervous system during walking we built a dynamically scaled robotic middle leg of the stick insect *Carausius morosus* (*C. morosus*). We attached strain

gauges to the leg in morphologically correct locations and orientations, namely CS groups 3, 4, 6A, and 6B. The robotic leg stepped on a treadmill to mimic walking. To ensure the leg supports the weight of the body, it was attached to a vertically-oriented linear guide. A computational model of CS discharge that was previously published was used to process data from the strain gauges. Our research indicates that the CS sensory discharges 1) strongly and selectively signal the beginning and end of the stance phase and 2) are sustained at lower levels during stance. Such signals would be essential for a robot or insect to maintain intra- and inter-leg coordination while traversing terrain.

Title: Identifying the naked mole-rat behavioral fingerprint using machine vision approaches

Authors: ***R. SCHWARK**[1], S. OGUNDARE[2], P. CHANG[3], P. SHENG[4], I. ABDUS-SABOOR[5];
[1]Zuckerman Inst., [2]Columbia Univ., New York, NY; [3]Columbia Univ., New York City, NY; [4]Home Address, Columbia Univ., New York, NY; [5]Columbia Univ., Univ. of Pennsylvania, NEW YORK, NY

Abstract: The naked mole-rat (*Heterocephalus glaber*) is a eusocial species of rodent which lives in large subterranean colonies in arid regions of east Africa. Colonies consist of a single breeding female, 1-3 breeding males, and dozens of non-reproductive drones organized in a dominance hierarchy. These animals have evolved an endless variety of adaptations and behaviors, including an exquisitely sensitive somatosensory system, abilities tunes to social dominance interactions, and unique navigation behaviors suited to an underground lifestyle in pitch-darkness. Despite decades of work, these behaviors have not been examined in a rigorously quantitative fashion. Here we use machine learning—specifically markerless tracking via SLEAP and unsupervised behavioral classification via MoSeq—to assay behavior in these animals for the first time. We show that naked mole-rats exhibit a wide variety of behavioral syllables that reflect their subterranean lifestyle, including fast locomotory movements (in both the forward and reverse directions) and robust digging behaviors. Isolated animals engage in certain syllables to a lesser extent than when placed in a social context with other mole-rats. We also demonstrate their highly social nature by showing that they exhibit a robust place preference for interacting with another conspecific compared to inanimate objects in the environment. MoSeq reveals that the nature of this social interaction is based heavily on snout-to-snout interactions, and that mole-rats show highly motivated digging towards conspecifics if separated. Furthermore, the queen mole-rat appears to exhibit an upregulation in locomotory behaviors and

appears to have a more hyperactive phenotype than the sterile workers in the colony. The behavioral fingerprint of a given worker furthermore appears to be modulated in the presence of a queen vs. in the presence of another worker. This data illustrates that the naked mole-rat behavioral suite is more nuanced than previously described, is divergent from that of mice, and is highly dependent on social context and caste.

Title: Corrective stepping responses and motor adaptations in young healthy adults in response to mediolateral and anteroposterior treadmill perturbations

Authors: *M. ADAM, A. HYNGSTROM, B. SCHMIT;
Marquette Univ., Milwaukee, WI

Abstract: Motivation: Individuals with neurologic disorders often fall because of external balance perturbations and an impaired corrective stepping (CS) response. Training CS strategies through repeated exposure to external perturbations has shown promise in neurologic and aging populations, yet the impact of block versus randomized protocols on CS modifications is not known and is needed to guide accurate exercise prescription. For the purposes of future comparisons to clinical populations, we aimed to quantify how neurologically intact participants adapt their CS response to random external balance perturbations during treadmill walking within a session. We hypothesized that participants would increase their CS length and velocity following exposure to a randomized perturbation protocol. **Methods:** Twenty participants (10F/10M), aged 25.7 (4.31), ambulated on a treadmill at a self-selected speed. During mid right or left single limb stance, the base of the treadmill moved anteriorly, posteriorly, or in a destabilizing mediolateral direction. 4 perturbation intensities were provided for each condition in which the amplitude and velocity of the treadmill movement increased linearly. Perturbation conditions were repeated 5 times throughout the trial, and intensity, limb, and direction were randomized. Perturbations occurred every 7-13 seconds for 20 minutes, totaling 120 perturbations. 40 reflective markers were recorded via a 16-camera optical motion capture system to quantify the biomechanical CS response. **Results:** By comparing the first to last CS response to the most intense perturbation condition during the randomized perturbation protocol using paired t-tests, it was noted that participants did not increase their CS length or velocity following mediolateral (Width: -0.033m (0.046), -0.039m (0.044), $p = 0.58$; Velocity: -0.067m/s

(0.098), -0.078m/s (0.092), p = 0.62) or posterior (Length: 0.57m (0.055), 0.59m (0.065), p = 0.17; Velocity: 1.34m/s (0.24), 1.38m/s (0.21), p = 0.38) perturbations. Participants did lengthen and quicken their CS response following anterior perturbations (Length: 0.29m (0.19), 0.44m (0.10), p = 0.005; Velocity: 0.61m/s (0.34), 0.88m/s (0.20), p = 0.002). **Conclusion:** Young neurologically intact adults adapt to a single session of randomized external perturbation gait training by lengthening their CS and increasing their CS velocity after anteriorly, but not mediolaterally or posteriorly, directed perturbations. External perturbation paradigms may benefit from a combination of block and randomized protocols to limit contextual interference and ensure sufficient motor learning.

Title: Acute intermittent hypoxia mediates the reduction of net metabolic power during motor learning and motor savings

Authors: *A. BOGARD[1], M. HEMMERLE[1], G. MARZLOFF[2], S. RYDER[2], A. SMITH[3], A. Q. TAN[1];

Abstract: Breathing mild bouts of low oxygen air (i.e., acute intermittent hypoxia, AIH) has been shown to improve walking performance after a spinal cord injury. Evidence in spinally injured rodents suggest walking improvements after AIH result from increased synthesis of the plasticity-promoting neural substrate, brain-derived neurotrophic factor (BDNF). Importantly, elevated BDNF is paralleled by improvements in motor learning in humans. Thus, gains in walking performance after AIH may be partially driven by enhancements in motor learning. To test this hypothesis, we investigated the effects of repetitive AIH on sensorimotor adaptation during a split-belt walking task. It is well documented that healthy individuals adapt spatial and temporal parameters of step symmetry in response to novel belt speed perturbations. Given that spatiotemporal adaptation is associated with reductions in metabolic cost, we investigated whether AIH would reduce net metabolic power during split-belt walking. Study participants

were randomly assigned to an AIH or control group. Participants in the AIH group received treatments for five consecutive days. A single AIH treatment consisted of breathing 90-second bouts of hypoxic air (9% O_2) alternated with 60 seconds of normoxic air (21% O_2) for 15 episodes. On the fifth day, participants adapted their walking to an unexpected, belt speed perturbation for four conditions in the following order: (1) baseline with a 1:1 speed ratio, (2) adapt 1 with a 1:1.5 ratio, (3) washout with a 1:1 ratio, and (4) adapt 2 with a 1:1.5 ratio. Step length asymmetry (SLA), step time asymmetry (STA), and double support time asymmetry (DSA) were calculated for each condition. Expired gas was collected through open circuit spirometry and used to quantify net metabolic power. In this study, the AIH group achieved greater reductions in net metabolic power that was retained upon subsequent exposure to split-belt walking. Consistent with previous work, we found that both groups adapted their walking to minimize SLA and DSA while STA remained elevated. Interestingly, the AIH group had significantly greater STA and lower DSA during each adaptation condition. These preliminary results indicate that AIH-induced enhancements in motor learning leads to the selection of more energetically favorable temporal coordination strategies. Discerning changes in motor learning may clarify how AIH modulates walking recovery after neurological injury and is important for the translation of AIH to walking rehabilitation paradigms.

Abstract: Optoelectronic 3D motion capture systems, such as the Vicon kinematic system, are widely utilized in biomedical research to track joint motion. These systems are considered

powerful and accurate measurement tools with <2 mm average error. However, these systems are costly and may be difficult to implement and utilize in a clinical setting. 3D virtual reality (VR) is gaining popularity as an affordable and accessible tool to investigate motor control and perception in a controlled, immersive environment. The HTC Vive VR system includes puck-style trackers that seamlessly integrate into its VR environments. These affordable, wireless, lightweight trackers may be more feasible for clinical kinematic data collection. However, the accuracy of HTC Vive Trackers (3.0) when compared to optoelectronic 3D motion capture systems, remains unclear. In this preliminary study, we compared the HTC Vive Tracker system to a Vicon kinematic system in a simulated lumbar flexion task. A 6-DOF robot arm (SCORBOT ER VII, Eshed Robotec/RoboGroup, Rosh Ha'Ayin, Israel) completed various reaching movements to mimic increasing levels of hip flexion (15°, 30°, 45°). Light reflective markers, along with one HTC Vive Tracker (3.0) were placed on the rigid segment separating the elbow and shoulder of the robot. We compared position measures simultaneously collected from both systems. Our preliminary analysis shows no significant differences between the Vicon motion capture system and the HTC Vive tracker in the Z axis, regardless of hip flexion. In the X axis, we found no significant differences between the two systems at 15 degrees of hip flexion but minimal differences at 30 and 45 degrees, ranging from .047 cm ± .02 SE ($p = .03$) at 30 degrees hip flexion to .194 cm ± .024 SE ($p < .0001$) at 45 degrees of hip flexion. In the Y axis, we found a minimal difference for 15 degrees of hip flexion only (.743 cm ± .275 SE; $p = .007$). This preliminary analysis shows that the HTC Vive Tracker may be an appropriate, affordable option for gross motor motion capture when the Vicon system is not available, such as in clinical settings. Further research is needed to compare these two motion capture systems in different body poses and for different body segments.

Title: Modulation of leg trajectory by transcranial magnetic stimulation during walking in human.

Authors: *H. BOURGEOIS[1], R. GUAY HOTTIN[2], H. TONKOV[3], E.-M. MEFTAH[3], M. MARTINEZ[4], M. BONIZZATO[4,2], D. BARTHELEMY[5,3];

Abstract: ln a recent study, using a rat model of incomplete spinal cord injury, we demonstrated that by delivering intracortical microstimulation during locomotion, at specific timings during the swing phase of gait, we were able to achieve precise control of leg trajectories and effectively alleviate gait deficits associated with incomplete paraplegia. Expanding on these findings, we here investigate whether cortical stimulation could similarly modulate human locomotion. ln this study, we used Transcranial magnetic stimulation (TMS), a non-invasive brain stimulation technique, to achieve this goal and determined the effect of TMS applied over the leg representation of the left motor cortex at different timings during the swing phase of the right leg in healthy subjects. Our goal was to characterize the varying effects that the timing of stimulation delivery during the swing phase may have. For a comprehensive characterization, we applied stimulation at random delays that encompassed the entirety of the right swing phase. These were done at intervals of 0, 100, 200, 300, and 400 ms after toe off. The stimulation intensity used was 120% of the movement threshold, which was defined as the minimum intensity required to elicit a dorsiflexion at the ankle during rest for at least 5 out of 10 stimuli. We found that stimulation delivered during the swing phase led to increased leg swing movement, particularly when administered early in the swing phase. lndeed, both the toe and knee excursion during walking significantly increased for four out of the five participants tested. On average, the maximum vertical toe position increased by 36.5 mm (54%,+/-30%) compared to the position during a spontaneous step, while the knee position increased by 45.4 mm (64.5%,+/-36%). However, it is noteworthy that in some subjects, stimulation delivered in the late swing phase altered foot placement moments before landing, leading to minor loss of balance. Our findings indicate that transcranial magnetic stimulation (TMS) can modulate leg trajectory during walking and highlight the potential of TMS as a valuable tool to investigate cortical control of locomotion. This can inform development of more invasive and specific neuromodulation intervention that may improve exercise-mediated recovery in gait rehabilitation therapy.

Title: Momenta control during each phase of gait reveals a common strategy between straight-line gait and 90-degree turns.

Authors: *M. TILLMAN, A. ZAFERIOU;
Biomed. Engin., Stevens Inst. of Technol., Hoboken, NJ

Abstract: Transverse-plane linear and angular momentum must be managed simultaneously to accomplish a turn. We recently uncovered that young adults leverage existing control strategies used to change momentum (and the average values of the momentum derivatives, force and moment) during each phase of gait during straight-line gait to perform a left turn. In straight-line gait and left turns, right single support generated the largest change in leftward linear momentum, while left double support generated the largest change in leftward angular momentum (Tillman et al., 2023). The purpose of this study is to determine if older adults use the same phases of gait as young adults to generate transverse-plane linear and angular momentum – and force and moment – during straight-line gait and turns.Nine healthy and active older adults (2 m 7 f; 71±6 yrs) performed two tasks. First, they walked 10 m straight 10 times along the lab's +Y axis. Next, they performed 10 90° left turns (+Y axis for 5 m, then -X axis for 4 m). Whole-body kinematics were recorded via reflective markers attached to 13 segments (250fps, Optitrack). We identified four phases of gait (left and right single and double support) using the method from (Zeni et al., 2008) modified for turning gait (Ulrich et al., 2019). We computed the change in linear momentum in the global X direction (dP_x) and the change in angular momentum about the Z axis (dH_z) during each phase of gait. The average force (Fx_{avg}) and moment (Mz_{avg}) were computed by dividing dP_x and dH_z, respectively, by the gait phase durations. Sign tests were used to compare each metric at a group level between gait phases for straight-line gait and turns (α=0.05). During straight-line gait and turns, the largest dP_x and dH_z were generated during right single support and left double support phases, respectively (all comparisons $p<0.04$). The largest Mz_{avg} occurred during left double support (all $p=0.004$). During straight-line gait, Fx_{avg} of right single support was greatest (all $p<0.04$). During turns, right single support Fx_{avg} was greater than it was during left single support ($p=0.004$), but not other gait phases (all $p>0.18$). Sex has not yet been assessed as a biological variable.Older adults generated momenta during straight-line gait and turns during the same phases of gait, suggesting a common control strategy. Further, these results mimic those found in young adults (Tillman et al., 2023). Understanding momenta control within each gait phase could lead to targeted interventions applicable to various types of turns and potentially other nonlinear gait such as side-stepping. Future work will include studying a wider range of older adults, including those with a history of falls.

Title: Characterization of locomotor adaptation and generalization dynamics from high-dimensional neuromuscular data

Authors: *D. MARISCAL, K. FJELD, G. TORRES-OVIEDO;
Bioengineering, Univ. of Pittsburgh, Pittsburgh, PA

Abstract: Humans can adapt their gait to compensate for changes in environmental demands and generalize learned movements from one situation to another. One way to study the processes that underlie locomotor adaptation is by exposing participants to split-belt treadmill walking; this paradigm induces robust changes in gait kinematics and muscle activation patterns. Additionally, we can study generalization by contrasting the adaptation effects (i.e., aftereffects) that participants exhibit in the same (treadmill) or different (overground) contexts from the adaptation. Here, we propose a novel approach for characterizing locomotor adaptation by analyzing individual muscle activation patterns. We ask what processes underly the adaptation of muscle activation patterns and what aspects are observed during generalization (overground). We hypothesize that at least two processes with distinct dynamics underlie the changes in muscle activity during locomotor adaptation and generalization. Specifically, we posit that a fast reactive process will recruit a neuromuscular pattern to maintain balance at each transition between walking environments. Whereas a slow adaptive process will forge a contextual pattern meeting the demands of the novel split environment, this pattern will be slowly disengaged during post-adaptation (tied walking) on the treadmill and will not be used during overground post-adaptation due to environmental differences. We recorded the activity of 28 leg muscles of twenty-four young adults (<40 yrs. old) who experienced split belt walking during their adaptation, and their de-adaptation was measured on either the treadmill (n=12) or overground (n=12) walking. We used a data-driven approach to measure individual muscles' reactive and contextual patterns to reproduce the evolution of muscle activity during the split-belt walking paradigm. Our analysis showed that the reactive and contextual processes contribute to the adaptation and post-adaptation of muscle activity on the treadmill. However, during overground post-adaptation, 2 out of the 28 muscles generalized the contextual pattern and all other muscles exhibit the reactive pattern, suggesting that the kinematic effects previously reported overground are mostly induced by reactive processes in response to a small number of muscles generalizing the split pattern. These findings provide insights into locomotor adaptation features beyond those drawn from traditional kinetic or kinematic analyses, which can be leveraged to study the effect of aging and brain lesions on the carryover of muscle activity.

Title: Embodying synthetic nervous system control in biomimetic robots with passive viscoelastic joints

Authors: *F. O. HOLMQUIST[1], C. GOLDSMITH[1], G. SUTTON[2], N. S. SZCZECINSKI[1]; [1]Mechanical and Aerospace Engin., West Virginia Univ., Morgantown, WV; [2]Univ. of Lincoln, Univ. of Lincoln, LINCOLN, United Kingdom

Abstract: Each nervous system is tuned to control and is constrained by the unique mechanics of its body. Understanding this harmony is necessary to understand and model how animals move their bodies. For example, while animals walk, mechanical energy delivered to the skeleton by the muscles is converted into kinetic energy of moving body parts, converted into gravitational potential energy of raised body parts, converted into elastic potential energy within muscles and tendons, and/or dissipated as heat due to viscosity within the body. To stabilize motion or reject perturbations, the nervous system monitors whether the body's mechanics can passively absorb energy and will activate muscles if they cannot. Prior modelling work suggests that the dominant form of energy is dictated by the size of an animal and speed of its stepping cycle. Because of this, we hypothesize that the nervous system's control strategies similarly depend on its size and speed. We use biomimetic legged robots modelled after insects to test this hypothesis in a real-world system. Stabilizing motion and rejecting perturbations is further complicated by sensorimotor delays due to synaptic transmission along sensory feedback pathways, muscle recruitment, and axon length and myelination. Legged robots face similar challenges regarding delays (although from different sources), and may struggle to maintain stability when subjected to perturbations and harsh impacts. Recent simulations suggest that mimicking the passive viscoelasticity within robots' joints increase stability in the face of such delays. Such delays may also increase animals' reliance on feedforward control strategies in which the passive viscoelasticity within their joints is largely responsible for stabilizing motions. To test the effect of passive viscoelastic joints on sensorimotor control and scale-driven nervous system strategies in a real-world system, we developed a device that introduces stiffness and damping to the motorized joints of robots. The device is a torsional spring infused with silicone whose viscoelastic properties mimic energy storage and dissipation an insect's joint. The device decreases the relative importance of the limb's kinetic energy by increasing the elastic potential energy stored and viscous energy dissipated during walking. The resulting dynamically-scaled insect-like robot may increase understanding of how scale and passive dynamics affect the nervous system.

Title: Using a hexapod robotic model of Drosophila to investigate walking forces and strains

Authors: *C. GOLDSMITH[1], W. P. ZYHOWSKI[1], M. HAUSTEIN[2], G. F. DINGES[1], A. BÜSCHGES[2], N. S. SZCZECINSKI[1];
[1]Mechanical and Aerospace Engin., West Virginia Univ., Morgantown, WV; [2]Inst. of Zoology, Univ. of Cologne, Cologne, Germany

Abstract: Sensory feedback is an important part of how the nervous system controls adaptive walking. Feedback from sense organs continually tunes activity throughout the nervous system, which in turn shapes limb movements. Campaniform sensilla (CS), receptors located in high stress areas of the exoskeleton that measure load, are one such type of sensory organ in insects. Leg CS have been found to have effects on walking behaviors in several species of insect. However, electrophysiological recording from CS in free-walking animals poses technical challenges, particularly in smaller insects like the fruit fly, *Drosophila melanogaster.* Biomimetic robotic models of insect legs can circumvent these constraints by facilitating strain recordings during biomimetic stepping. Affixing strain gauges in leg CS locations produces data that increases our understanding of the load feedback signaled by CS in freely moving animals. We have previously developed physical robotic models of stick insect and fruit fly middle legs with biomimetic strain sensing. These legs were used to compare CS discharge between insects and the role of tarsal morphology in strain the during stepping on a treadmill.We have also developed Drosophibot II, a 140:1 robotic model of an adult fruit fly. The proportions and degrees of freedom in each leg of Drosophibot II have been modeled after *Drosophila* 3D motion capture data, producing a robot that is kinematically similar to the animal. We developed a program to solve the inverse kinematics necessary for walking and solve the inverse dynamics necessary for mechatronic design. By applying this solver to a fly-scale body structure, we have demonstrated that the robot mimics the animal's dynamics and can hypothesize insect joint torques, internal limb forces, and ground reaction forces. The robot has been validated for straight-line forward and backward walking with biologically inspired foot trajectories. Including strain sensing on Drosophibot II allows us to make hypotheses about CS discharge in all six legs for a variety of walking directions. This data can then be used to investigate how the sensory

discharge in each leg pair may differ depending on their role in stepping, and how this discharge may change with walking direction.

Title: Faster walking speeds are retained after experiencing discrete mediolateral perturbations

Authors: *L. LEE[1], C. R. CASTANO[1], H. J. HUANG[2];
[2]Mechanical and Aerospace Engin. Dept., [1]Univ. of Central Florida, Orlando, FL

Abstract: Locomotor adaptation is a motor learning process that can be used to alter ones gait. Uncertain environments, such as perturbations to disrupt ones walking pattern, are a common approach to induce locomotor adaptation processes. Previous locomotor adaptation studies used fixed speed treadmills that do not allow subjects to change their walking speed, which is not reflective of a real-world response. Perturbations can be applied on a self-paced treadmill, which allows participants to experience uncertain environments without constraining walking speed. In a previous study, we implemented discrete mediolateral perturbations on a self-paced treadmill with varying levels of predictability and found walking speed increased compared to a self-paced walking condition. However, we did not analyze if the faster walking speeds were retained after the perturbations were removed. The purpose of this study is to conduct follow up analyses from a locomotor adaptation perspective. We can explore adaptation because our perturbation conditions contained periods of self-paced walking before and after the perturbations. We hypothesized that young and older adults would retain faster walking speeds after the perturbations were removed and that these speeds would carry over to later conditions.Young (n=10) and older adults (n=9) walked on a self-paced treadmill as we recorded lower limb movements using motion capture. There were 4 perturbation conditions randomized across subjects that were combinations of magnitudes (1, 3 or 5cm) of the mediolateral treadmill shifts and timings during the gait cycle (loading response, terminal stance, or mid-swing). Each condition was in self-paced mode for 80 strides before (PRE) and after (POST) the 200 perturbations were applied every other stride (PERT). Conditions were analysed in chronological order to determine if faster speeds were retained from one condition to the next. Walking speed was also compared within a condition between PRE, PERT and POST phases.
Walking speed generally increased with conditions in chronological order such that the walking speeds PRE and POST of the final condition were the fastest. Comparing walking speed between

PRE and PERT, young adults walked faster during PERT compared to PRE whereas older adults walked slower during PERT. In young adults, POST speeds were slower than PERT but faster than PRE. In older adults, POST speeds were faster than PERT and either as fast or faster than PRE. Our results show that when given the freedom to change walking speeds, subjects opted to walk faster after perturbations were removed and these faster walking speeds were retained and carried over to later conditions.

Title: Is Micro-Doppler radar effective as a standalone measure of gait kinematics?

Authors: *E. I. JONES[1], V. VENEZIA[1], B. SIMONE[2], M. YANKELLO[2], C. ONKS[3], J. NYLAND[4], R. NARAYANAN[2], R. CREATH[1];
[1]Exercise Sci., Lebanon Valley Col., Annville, PA; [2]Electrical Engin., The Pennsylvania State Univ., University Park, PA; [3]Family Med. and Orthopaedics, Penn State Col. of Med., Hershey, PA; [4]Neural and Behavioral Sci., Penn State Neurosci. Inst., Hershey, PA

Abstract: Introduction: Micro-Doppler radar (MDR) has emerged as a cost-effective method for human gait analysis. Combined with machine learning, MDR can discern subtle movement differences making it a potentially valuable tool for assessing neuromechanical gait conditions associated with disease or injury. MDR works the same as “police” radar. Movements create modulations in the reflected MDR signal known as the micro-Doppler effect. By analyzing frequency modulations, one can infer movement characteristics. While several studies have demonstrated MDR capabilities, radar signal consistency has not been assessed. Since inconsistencies can alter signal magnitude or cause frequency shifts, variation would affect movement characterization. The purpose of this study is to compare MDR signal consistency between a mechanical pendulum (Pd) and subjects performing a step-in-place task (STP) to determine differences in signal strength and Doppler frequency shift.
Methods: 6 adults (2f; 21.8 yrs) performed a STP task (60 sec @ 60 spm) at 6 locations on a radial grid. The Pd (height 44 cm) rotated from horizontal to vertical in 1.4 sec. Antennae were 3m above the floor facing 45 deg downward. The MDR consisted of a horn antenna emitting a 10 GHz signal at 1 watt. The reflected signal was received by an identical antenna with a sample rate of 20 KHz. Data were collected at 44.1 KHz. Radial grid locations (6) relative to the antennae were at 2 distances (4.2 and 5.0m) and 3 radial angles (0 deg, 10 deg right and left of center). Fast Fourier transforms (FFTs) of the time series were calculated which were normalized

to the maximum FFT amplitude of location 4.2m and 0 deg. The integrals of the amplitude spectra were compared to determine amplitude and frequency changes for the Pd and STP conditions for all 6 locations.
Results: For the Pd trials, MDR amplitude decreased 27% for 10 deg left, 78% for 10 deg right, and 4% from 4.2m to 5.0m. For the STP trials, the MDR signal decreased 51% for 10 deg left and 71% for 10 deg right, but increased 11% from 4.2m to 5.0m. The Pd FFT integrals showed a shift towards lower frequencies while the STP FFT integrals were similar between higher and lower frequencies.
Conclusions: The MDR signal is most consistent along the 0-deg radial path. Angular deviations of ±10 deg produce changes in signal amplitude. Frequency shifts are likely specific to the type of task. Given the narrow path of the strongest signal (0 deg), gait studies could be affected by deviations from the 0-deg path. Slight shifts ±10 deg could place one side of a subject's body in a zone of weaker signal, creating an asymmetrical Doppler shift that appears as an artifact of signal strength rather than a movement component.

Title: Heterogeneous and flexible control of triceps surae during standing balance in humans

Authors: *M. ZABACK, M. TOPLEY, C. K. THOMPSON;
Temple Univ., Philadelphia, PA

Abstract: During bipedal standing, the triceps surae modulate their activity considerably with anteroposterior oscillations of the center of mass. This has led to the assumption that the triceps surae act primarily to generate of antigravity plantarflexion torques during standing balance. The heterogeneous architecture of the triceps surae suggests each constituent muscle can contribute to ankle torques outside of the sagittal plane, but is not necessary during bipedal standing since mediolateral control of sway is accomplished largely by loading and unloading the hips. However, during tasks that challenged mediolateral stability, the triceps surae may be controlled independently to generate corrective torques in the mediolateral plane. This study examined how the muscles of the triceps surae tuned their activity to centre of pressure (COP) movement about 360 degrees during one- and two-legged standing. Ten healthy young adults completed a total of 16 one- and two-legged standing trials lasting 30 and 120-s, respectively. Muscle activity was recorded from high-density electrode arrays (64 channels) adhered to the skin overlying the right

soleus (SOL) and medial (MG) and lateral (LG) gastrocnemii, while COP was recorded from independent force plates. A rotation matrix was iteratively applied to the 2-dimensional COP data, generating 360, 1-D timeseries corresponding to COP movement about 360 degrees. Prominent peaks were identified in each COP timeseries. EMG were then triggered-averaged to each peak and the amplitude of event-related EMG was calculated to construct EMG tuning curves. During two-legged standing, all muscles of the triceps surae showed uniform EMG tuning curves, with maximal activity oriented primarily in the anteroposterior plane. During one-legged standing, significant deviation of the tuning curves were observed, with LG showing a near-opposite pattern of activation compared to SOL and MG. In particular, LG was maximally activated during COP deflections that were consistent with eversion, but inhibited during inversion, while SOL and MG were maximally activated during COP deflections consistent with inversion, but inhibited during eversion. These results demonstrate that, depending on the nature of the balance task, muscles of the triceps surae can contribute to corrective ankle torques outside of the sagittal plane. The triceps surae act as a functional unit during bipedal standing, but remarkably independent during unipedal standing, such that muscles that normally behave as synergists behave as antagonists. Future work will examine if this flexible neural control of postural musculature is modulated through training and disease.

Title: Non-contractive tissue is an important component in regulating the degree of freedom of fingers during the tapping task

Authors: *T. ITO[1], T. KOKUBUN[2,3];
[1]Grad. Sch. of Health, Medicine, and Welfare, Saitama Prefectural Univ., Koshigaya, Saitama, Japan; [2]Grad. Sch. of Health, Medicine, and Welfare, Saitama Prefectural Univ., Saitama, Japan; [3]Dept. of Physical Therapy, Sch. of Hlth. and Social Services, Saitama Prefectural Univ., Saitama, Japan

Abstract: 1. Motivation
The central nervous system constrains the degree of freedom of joint to simplify the regulating for accurate performance. Previous studies have revealed the role of muscle contraction, which is the coordination of multiple muscles or motor units, in evaluating movement stability (Ting+, 2005; Madarshahian+, 2022). However, focusing on only muscle contraction does not fully explain the control of joint movements. Joints are also composed with non-contractive tissues;

ligament, meniscus, and joint capsule. These contribute to regulating a joint degree of freedom. Here we aimed to clarify the relationship between the stability of finger movements and non-contractive tissues, collateral ligament, to constrain the motion of the metacarpophalangeal (MP) joint when the MP joint is flexed during tapping.
2. Methods
Eight healthy adults provided informed consent after a detailed explanation of the purpose and risks of the study based on the Declaration of Helsinki. 3D motion capture system was used to obtain the position of the markers attached to the right hand. We measured two tasks; (Exp. A) the subjects placed their right hand on a desk and moved the index finger as widely as possible; (Exp. B) the subjects repeatedly tapped 7 and 9 on a keypad with the index finger in time to a metronome at 180 bpm. The marker trajectories, joint angles, and tapping times were analyzed using Python 3.7. This study was approved by the Ethical Review Committee.
3. Results
In Exp. A, the fingertip trajectories of all subjects showed an elliptical shape with a long vertical direction. As the flexion angle of the MP joint increased, the abduction angle of the MP joint showed a decreased ($r = -0.65$ to -0.98). In Exp. 2, which focused on the lateral movements, subjects were classified into two groups: a group that moved the MP joint dominantly (MPD, $n = 4$) and a group that moved the MP joint and the wrist joint (MPW, $n = 4$). The variation in tapping times of the MPW was less than that of the MPD.
4. Conclusion
The collateral ligaments of the MP joint have the role of constraining lateral motion when the MP joint is flexed. This property of ligament was selected to constrain the degree of freedom of the MP and wrist joint. This function contributed to accomplishing the temporal accuracy of task performance with the low cost of central nervous systems. Analyzing each joint's movement pattern depending on the role of contractive and non-contractive tissues, which exploits the effect of the ligament, may facilitate the learning of efficient movements.

Title: Studying the Negotiated Equilibrium Between the Substrate of a New Motor Skill and the Substrate of an Old One: Protocol Design and Testing

Authors: *J. R. WOLPAW[1], R. L. HARDESTY, Jr.[2], H. MOJTABAVI[3];
[1]Natl. Ctr. for Adaptive Neurotechnologies, Delmar, NY; [2]Natl. Ctr. for Adaptive Neurotechnologies, Sauquoit, NY; [3]Natl. Ctr. for Adaptive Neurotechnologies, Albany, NY

Abstract: The substrate of a motor skill is a distributed network of neurons and synapses that produces the skill and changes continually to maintain the key features of the skill, the attributes that make it satisfactory (Neuroscientist 16:532-549, 2010; JPhysiol 596:3469-3491, 2018; JPhysiol 2022, DOI:10.1113/JP283291). This network has recently been given the name *heksor* from the Greek *hexis*. Because heksors share the CNS, their concurrent changes constitute a negotiation; they negotiate the properties of neurons and synapses they all use. They keep the CNS in a state of negotiated equilibrium that allows each heksor to maintain its skill. We hypothesize that the negotiated equilibrium between a new skill and an old skill that share spinal motoneurons; (1) comprises plasticity at many sites from cortex to spinal cord; (2) entails EMG/kinematic changes in the old skill; (3) maintains key features of the old skill. To test this hypothesis, we are studying the impact on normal locomotion of learning to walk on a splitbelt treadmill with belts going in opposite directions. Participants are healthy adults. Each of the 12 study sessions (2-3/wk) has three parts. First, the person walks on the treadmill for 2 min with both belts going in the same direction at 80% of a self-selected speed. Second, right-belt speed is gradually decreased and then reversed until is equal but opposite to left-belt speed. The person walks on these opposing belts for four 5-min periods separated by 1-min breaks. Third, the participant again walks on the treadmill for 2 min with both belts going in the same direction. Before, after, and/or during the sessions, we collect: locomotor EMG and kinematics; soleus and tibialis anterior H-reflexes and motor evoked potentials to transcranial magnetic stimulation; and somatosensory evoked potentials to tibial and common peroneal nerve stimulation. The protocol has functioned well in 6 initial participants. Each arrived over the first split-belt period at a satisfactory locomotor pattern. Two companion abstracts present initial data analyses.

Title: Aftereffects of Locomotor Adaptation to Split-belt Training in Opposing Directions: Initial Results

Authors: *R. L. HARDESTY, Jr.[1], H. MOJTABAVI[1], J. R. WOLPAW[2];
[1]Natl. Ctr. for Adaptive Neurotechnologies, Albany, NY; [2]Natl. Ctr. for Adaptive Neurotechnologies, Delmar, NY

Abstract: Locomotion is a highly adaptive behavior, allowing us to traverse new environments and accommodate changing demands. Split-belt protocols are widely used to study adaptation to asymmetric walking conditions; they have frequently found aftereffects with return to symmetrical walking (e.g., Choi & Bastian Nat NS 2007). The existing literature focuses on single-session studies. We plan multi-session studies to define the long-term impact of asymmetric split-belt training (see Wolpaw et al. abstract). This initial report examines, for our first session, the aftereffects of training with the belts moving in opposite directions. We recruit healthy adults. First, they walk for 2 min on a Bertec split-belt treadmill with both belts at 80% of their self-selected speed to define baseline gait. Then, they walk for four 5-min Training blocks separated by 1-min breaks while left-belt movement is the same as baseline but right-belt movement is in the opposite direction at equal speed. Finally, they walk again for 2 min with both belts in the same direction. We track movement with 41 reflective markers and motion capture (Qualysis). We record ground reaction forces, center-of-pressure, and soleus and tibialis anterior EMG activity in both legs. We compare symmetrical walking during baseline and post-training to assess whether adaptations adopted in the Training block persist. The 6 initial participants performed the training blocks well. Preliminary analyses show kinematic and EMG changes that enabled the training walk (see Mojtabavi et al abstract). With return to symmetric locomotion, most of these adaptations disappeared; stride length and inter-step variability quickly returned to their pre-training values. In contrast, double-stance time (% of the step cycle in which both feet touch the ground), which showed a participant-specific change in the Training blocks, remained altered after return to symmetric locomotion. This is our first clear indication of an aftereffect. Further analyses and data collection are underway.

Title: Locomotor Adaptation to Split-belt Training in opposing Directions: Initial Kinematic Analyses

Authors: *H. MOJTABAVI[1], J. R. WOLPAW[2], R. HARDESTY[3];
[1]Natl. Ctr. for Adaptive Neurotechnologies, Albany, NY; [2]Natl. Ctr. for Adaptive Neurotechnologies, Natl. Ctr. for Adaptive Neurotechnologies, Delmar, NY; [3]Natl. Ctr. for Adaptive Neurotechnologies, Sauquoit, NY

Abstract: Humans can readily adapt their gait to different environments. Split-belt treadmill protocols have helped to elucidate these adaptations and their underlying neural correlates. Studies to date have focused on adaptations that occur in a single session. We are developing a protocol to examine long-term plasticity induced by multi-session walking on a treadmill with belts moving in opposing directions (Wolpaw et al. abstract). This initial report assesses, for our first session, the kinematic adaptations to the belts moving in opposing directions. We are studying healthy adults. First, they walk for 2 min on a Bertec split-belt treadmill with both belts at 80% of their self-selected speed. This defines baseline gait. They then walk for four 5-min Training blocks separated by 1-min breaks with left-belt movement the same as baseline but right-belt movement in the opposing direction at equal speed. Lastly, they again walk for 2 min with both belts in the same direction. We record: movement using 41 reflective markers and motion capture (Qualysis); ground reaction forces; center-of-pressure; and soleus and tibialis anterior EMG activity in both legs.During the Training blocks, our initial 6 participants maintained coordination and balance with minimal difficulty. Each adopted a cyclical gait pattern within the first Training block. At the same time, inter-step variability in both kinematics and EMG was greater than in the baseline and post-training blocks, presumably due to the novelty and challenge of walking with the belts opposed. Stride length was shorter than during baseline. Double-stance (% of step cycle with both feet on the ground), was significantly altered compared to the pre-training block. Interestingly, this change in double-stance time varied across participants; it increased in some and decreased in others. This suggests that different people reach different solutions for walking with the belts moving oppositely. Current analyses seek to delineate the strategy adopted by each participant.

Title: Head motion kinematics in pre-surgical superior canal dehiscence syndrome patients

Authors: *R. ARYAN[1], J. L. MILLAR[2], J. P. CAREY[3], M. C. SCHUBERT[3], K. E. CULLEN[1,3,4];
[1]Dept. of Biomed. Engin., [2]Dept. of Physical Med. and Rehabil., [3]Dept. of Otolaryngology – Head and Neck Surgery, [4]Dept. of Neurosci., Sch. of Medicine, The Johns Hopkins Univ., Baltimore, MD

Abstract: Introduction: Superior Canal Dehiscence Syndrome (SCDS) is characterized by the abnormal thinning or formation of an opening on the bony structure of the superior semicircular canal. It is well-documented that SCDS causes sound/pressure-induced dizziness and nystagmus, resulting in chronic balance difficulties. Here we asked whether impaired function of the superior canal alters head motion generation in these patients. Specifically, we hypothesized that head kinematics in the pitch axis would be the most altered, since this axis corresponds to that which is maximally activated by stimulation of the superior semicircular canal. Accordingly, we measured head kinematics between healthy controls and pre-surgery SCDS patients while performing gaze stabilization exercises. **Methods:** Using an inertial measurement unit, 6D head movements of SCDS patients (n=17) were measured and compared with healthy controls (n=14). Participants performed standard of care gaze stabilization exercises in yaw and pitch planes with far and near earth-fixed targets. We then computed range, standard deviation, and asymmetry of linear and rotational kinematics for each exercise. **Results:** No significant between-group differences were found during pitch gaze stabilization exercises. However interestingly, our results revealed significant between-group differences in pitch velocity during yaw gaze stabilization exercises. Notably, while performing yaw gaze stabilization using a near target, our SCDS group showed higher variability and asymmetry in head pitch velocity. Furthermore, in the same task, these SCDS patients showed reduced range of yaw velocity. Additionally, correlational analysis showed significant correlations between the head kinematics and clinical measures, including logMAR (logarithm of the minimum angle of resolution, which measures visual acuity) and Beck anxiety scores. **Conclusion:** Our results confirmed that head kinematics alter in pitch axis in pre-surgery SCDS, but surprisingly during yaw head movements. Furthermore, our study suggests that impaired visual acuity and high level of anxiety are associated with more variable head kinematics in SCDS. Overall, we conclude that an objective and multiplanar examination of head kinematics in SCDS is necessary, which can ultimately lead to more effective treatment interventions.

Title: Mechanisms underlying generation of episodic bursting activity in a half-center oscillator

Authors: *M. FOMENKO[1], E. SMITH[2], Y. SHAMS[3], G. CYMBALYUK[2];
[1]Georgia State Univ., Decatur, GA; [2]Georgia State Univ., Atlanta, GA; [3]Georgia State Univ., decature, GA

Abstract: Repertoire of animal locomotor behaviors includes episodic locomotion, where episodes of movement are separated by periods with no movement. Recent experimental and modeling studies in vertebrates like mouse and fish spinal cords suggest that spinal circuits, called central pattern generators (CPGs), can produce episodic locomotor rhythm (Sharples et al., 2021). Invertebrate preparations like the leech heart CPG offer a cellular-level understanding of circuit dynamics and a biophysical model that has a high predictive capacity. This model is capable of representing experimental recordings and suggesting new hypotheses that are testable in experiments (Ellingson et al., 2021). The rhythm of this CPG is based on two pairs of mutually inhibitory bursting neurons, half-center oscillators (HCOs). Here, we found the episodic bursting regime in the model of the leech heart HCO. Relatively to the canonical parameter set (Ellingson et al., 2021), the new regime exists in the domain with upregulated h-current (Ih) and downregulated persistent sodium current (INaP) and Na+/K+ pump current (IPump). We found that the episodic bursting generation is based on slow oscillations of reversal potential of Na+ (ENa). During a bursting phase, ENa decreases due to increase in intracellular Na+ concentration, [Na+]i, reducing all the Na+ inward currents, and eventually terminates an episode. During the interepisode interval, when inward Na+ currents are small, but IPump is active, ENa increases due to decrease in [Na+]i which eventually leads to the start of new episode. The episodic bursting is affected by parameters determining [Na+]i. The episode duration and the number of bursts per episode positively correlate with the parameter of intracellular Na+ diffusion (Naidiff) and maximal conductance of h-current (Gh), and negatively correlates with conductances of leak current (gleak), maximal conductance of INaP (GNaP) and maximal pump current (IPumpMax). The interepisode interval positively correlates with gleak and Gh and negatively correlates with Naidiff and IPumpMax. Both burst duration and interburst interval notably positively correlate with GP and negatively with gleak. Importantly, manipulations of the Naidiff parameter allowed us to have an arbitrary number of bursts per episode and, therefore, episode duration. Manipulations of the IPumpMax parameter allowed us to have interepisode interval of an arbitrary long time.

Sci. Program, Univ. of Minnesota, Minneapolis, MN; [6]Univ. Calgary, Calgary, AB, Canada

Abstract: Animals employ a range of motor behaviors to survive amidst changing environmental conditions. Among these behaviors, episodic locomotion, which is characterized by alternating periods of movement and pauses with no motion, is the least understood. Central pattern generators (CPGs) are capable of generating diverse rhythmic patterns, one of which is the episodic locomotor rhythm. Recent experimental and modeling studies indicate that different ion channels produce degenerate mechanisms which can support episodic bursting patterns (Sharples et al., 2021). We developed biophysical models that reproduce temporal properties of locomotor episodic bursting rhythms in postnatal mice and in zebrafish larvae. The models predict that the interaction of the small conductance calcium-activated potassium current (I_{SK}) and the NMDAR current (I_{NMDA}) could support fictive locomotor activity at the burst and episode time scales. We tested these predictions in two animal models: dopamine (DA)-evoked episodic activity in the *in vitro* spinal cord preparation of postnatal mice and optogenetically-evoked fictive locomotor activity in spinalized transgenic (*Tg(vglut2a:Gal4;UAS:ChR2)*) larval zebrafish. Two pharmacological agents were tested; apamin (5 μM) was used to block I_{SK} alone or in combination with APV to block I_{NMDA}. In mice, application of apamin alone, after DA-evoked episodic activity was stable, led to a decrease of the interepisode interval and an increase of the episode cycle period coefficient of variation. In zebrafish, the application of apamin alone resulted in a decrease in episode duration, a decrease in the number of bursts per stimulus, and an increase in the burst duration. Subsequent application of APV in combination with apamin resulted in a decrease in the burst duration. Our biophysical models recapitulate these results. Overall, our results suggest that I_{SK} plays a key role in the generation of locomotion at the bursting and episodic scales in both mouse and zebrafish models.

Title: Co-existence of a high spike-frequency and low spike-frequency bursting regimes in a Central Pattern Generator: the special role of interaction of the Na^+/K^+pump current and persistent Na^+current

Authors: *Y. SHAMS[1], M. FOMENKO[2], P. ELLINGSON[4], J. PARKER[5], R. L. CALABRESE[6], G. S. CYMBALYUK[3];
[1]Georgia State Univ., decature, GA; [3]Neurosci. Inst., [2]Georgia State Univ., Atlanta, GA; [4]Georgia Inst. of Technol., Stone Mountain, GA; [5]Georgia State Univ. Neurosci. Inst., Stone Mountain, GA; [6]Dept. of Biol., Emory Univ., Atlanta, GA

Abstract: Essential rhythmic motor functions, such as heartbeat in invertebrates require a persistent generation of a functional pattern by Central Pattern Generators (CPGs). Neuromodulation regulates the dynamics of CPGs in order to align with environmental constraints. The CPG controlling leech heartbeat is based on two pairs of mutually inhibitory interneurons, half-center oscillators (HCO). Using our biophysical model, we showed that, through coordinated adjustments, neuromodulation guides HN-HCOs to avoid dysfunctional states by decreasing the Na^+/K^+ pump current (I_{pump}) and enhancing the h-current (I_h) (Ellingson et al., 2021). Under a condition of a high state of neuromodulation, we found a domain of coexistence of two functional bursting patterns. They have almost the same cycle periods but are distinct in terms of the intra-burst spike frequency: one has a high frequency (HF) above 17 Hz, and the other has significantly lower frequency (LF). Here, we investigated the properties of short perturbations of the HCO by pulses of conductance of inhibitory current and identified domains of phase and amplitude of the pulses leading to the switch from LF to HF bursting and vice versa. We showed that HF bursting requires dynamic interaction of I_{pump} and persistent Na^+ current, I_{NaP}. I_{NaP} is a low-voltage-activated Na^+ current, that does not inactivate and is the major source of Na^+ influx. I_{pump} is an outward current activated by $[Na^+]_i$ and is the main source of Na^+ efflux. Both currents are active and counteract each other between and during bursts. Here, we explored the role of I_{NaP} by investigating comodulation maps of HCO stationary and oscillatory regimes under variation of maximal pump activity and maximal conductance of I_h (G_h) similar to (Ellingson et al., 2021) but with smaller values of G_{NaP} . We found a large domain exhibiting the silent regime where previously we recorded functional and dysfunctional regimes. This emphasizes the necessity of an increase of G_h for the generation of bursting. The domain of

the functional activity shifted down at smaller values of maximal pump activity compared to (Ellingson et al., 2021). We also found a domain of coexistence of functional HF bursting with LF bursting. We further apply this approach to investigate the emergence of the HF bursting along comodulation of I_{pump} and I_{NaP}. We show that the dynamic interaction of I_{pump} and I_{NaP} offers a mechanism for the robust generation and flexible control of the two functional bursting patterns. We highlight the significance of multistability and this control over regime switching is vital for the effectiveness of neuromodulation and coordination of rhythmic motor programs.

Title: Neuromodulation of sodium potassium ATPase pumps dynamically regulate mammalian spinal networks

Authors: *S. J. NISBET[1], S. A. SHARPLES[2], G. B. MILES[3];
[1]Sch. of Psychology and Neurosci., Univ. of St Andrews, St. Andrews, United Kingdom; [3]Sch. of Psychology and Neurosci., [2]Univ. of St Andrews, St Andrews, United Kingdom

Abstract: Mammalian spinal motor networks are sensitive to descending neuromodulatory input, which can fine tune and adapt motor output. Neuromodulators often act by targeting, either directly or indirectly, ion channels and pumps to change membrane potentials and thus affect the likelihood or rate of action potential generation. One potential target, the sodium/potassium pump, has recently been suggested to be linked to an afterhyperpolarisation termed the ultra-slow after-hyperpolarisation (usAHP). Recent work has also highlighted a potential role for the neuromodulator dopamine in modulating this usAHP. The presented work utilises whole cord electrophysiology to interrogate the effect of Na/K pump activation and dopaminergic signalling on network activity. Lumbar ventral root recordings were taken of evoked rhythmic activity in neonatal mice both with and without the presence of dopamine. The sodium ionophore monensin was used to cause electroneutral influx of Na ions and maximally activate the pumps. This caused a strong inhibition of network activity which appeared to be enhanced by the presence of dopamine. Additionally a mutant mouse model carrying a mutation on the ATP1A3 gene was used to investigate if this relationship between dopamine and pump activity was associated with the more dynamically activated alpha3 Na/K pump which may be tied to the usAHP. The presence of the mutation, which caused a 50% reduction in functional ATP1A3 expression, appeared to disrupt the dopamine induced enhancement of pump related network inhibition. The mutation also appeared to disrupt some of the rhythmic stabilisation effect observed with application of dopamine. Work is ongoing using whole cell patch clamp

techniques to interrogate underlying components of the network. The single cell work is aimed at creating a heatmap of usAHP behaviour in lumbar spinal interneurons. Currently of 16 cells studied 7 (43.8%) displayed the usAHP behaviour in response to 10 second high frequency stimulus. The application of dopamine is also studied for effect on the usAHP and of 6 cells studied before and after addition of dopamine 4 either lost previously displayed usAHPs or had reduced afterhyperpolarisation behaviour, 1 appeared to have a usAHP unchanged, and 1 appeared to gain a usAHP after addition of dopamine. Other conductances such as Ih and PICs are also being recorded to investigate for potential correlations with the usAHP. Altogether the current data highlights that the presence of dopamine can have heterogenous effect on usAHPs but appears to have an enhancing effect of inhibitory pump currents involved in excitatory network output as a whole in a manner tied to the alpha 3 Na/K pump.

Title: Hormonal tuning of a specific circuit state

Authors: L. J. FICKLING[1], A. P. COOK[1], W. WU[2], L. LI[3], *M. P. NUSBAUM[1]; [1]Neurosci., Perelman SOM, Univ. Pennsylvania, Philadelphia, PA; [2]Chem., [3]Sch. of Pharmacy, Chem., Univ. of Wisconsin-Madison, Madison, WI

Abstract: We aim to establish how feeding state-specific hormonal milieux influence the activity patterns of feeding-related circuit states. Here, we focus on the gastric mill (chewing) circuit state configured by Gly[1]-SIFamide [G-SIF: 1 µM] in the isolated stomatogastric ganglion (STG) of the crab *Cancer borealis*. G-SIF is a peptide cotransmitter in two STG innervating projection neurons. The STG is dissected from a crab not fed for ≥24 hr [‘unfed’], with recordings done during 15 min incubations with G-SIF in saline vs. hemolymph [hemo] obtained from a different, unfed or 1 hr post-fed [‘fed’] crab. Neither saline, unfed hemo or fed hemo alone activated the gastric mill rhythm (n=8-24) but when co-applied with G-SIF a consistently coordinated gastric mill rhythm was elicited for the entire 15 min incubation in fed hemo (n=9/9), and for all (n=5/15) or some (n=6/15) of that time with unfed hemo. In the remaining G-SIF plus unfed hemo incubations (n=4/15) coordination was incomplete due to one or more neurons generating tonic instead of rhythmic activity. These rhythms included repeated bursting in the IC, LG, DG, AM and LPG neurons, plus IC-timed interruptions in the pyloric rhythm. The rhythm cycle period was similar in both hemo conditions (Unfed, 18.7±8.2s, n=24; Fed, 18.5±12.3s, n=9; p=0.45, Mann-Whitney U Rank Test). This rhythm was elicited less often in

saline plus G-SIF (7/15), with only two lasting 15 min. The greater effectiveness of fed than unfed hemo suggests it contains more of the relevant hormone(s). Notably, G-SIF is not detected in unfed or fed hemo (DeLaney et al, 2022 Analyt Bioanalyt Chem). As a first step to identify the effective hormone(s), we used HPLC to separate unfed hemo into three Fractions (F1, F2, F3). F2 alone did not activate the gastric mill rhythm but when paired with G-SIF it elicited this rhythm for the entire 15 min incubation (n=4/4), with a comparable cycle period to unfed hemo plus G-SIF (18.0±8.6s, n=4). Neither F1 nor F3 consistently mimicked the effect of unfed hemo plus G-SIF. G-SIF plus unfed or fed hemo also often prevented gastric mill rhythm activation by subsequent G-SIF applications, even after saline washes of 1-3 hr (n=24/30). No such effect occurred after most single Fractions plus G-SIF (n=1/12), suggesting the source of this effect spans HPLC fractions and is different from the hormone(s) that enhance the gastric mill rhythm response. Because there were no qualitative changes to the gastric mill rhythm in hemo plus G-SIF, and G-SIF is not detected in unfed or fed hemo, we hypothesize that the hemo effect results from a hormone-mediated increase in the local G-SIF concentration (e.g. by preventing its enzymatic degradation).

Title: Flexibility vs. consistency of circuit output: a push-pull mechanism through diverging and converging comodulation

Authors: N. DAUR, E. CRONIN, F. NADIM, ***D. BUCHER**;
New Jersey Inst. of Technol., Newark, NJ

Abstract: Neuromodulation lends flexibility to neural circuits, as different neuromodulators can sculpt circuit activity into different patterns, allowing adaptation to different behavioral contexts. Comodulation potentially increases the number of possible output patterns. However, in a single neuron, overlapping effects of two modulators on ion channels or synaptic release may either be divergent or convergent. If comodulators converge on the same signaling pathway, their effects may be occluding and therefore potentially redundant. In the crustacean stomatogastric nervous system, amine neuromodulators have divergent actions on neuronal excitability and synaptic function, whereas neuropeptide and muscarinic cellular actions are predominantly convergent. However, different neuropeptides act on different subsets of circuit neurons and therefore have divergent actions at the circuit level. If convergence at the cellular level is predominantly

additive, increasing numbers of comodulators could eventually activate all circuit neurons in the same way, rendering the identity of the modulator unimportant.
We used recordings of the pyloric rhythm of the crab, *Cancer borealis*, to test whether different combinations of convergent neuromodulators at tonic non-saturating levels produce progressively similar circuit outputs. We applied three converging modulators as a singlet, doublet, and triplet (A, A+B, A+B+C), then washed and applied a second set of modulators (D, D+E, D+E+F). We quantified a range of circuit output attributes (cycle frequency, burst phases, spike numbers and spike frequencies) under each condition. We then determined the Euclidean distance in the multidimensional space of normalized output attributes to obtain a single measure of difference between the singlet applications (A vs. D), the doublet applications (A+B vs. D+E), and the triplet applications (A+B+C vs. D+E+F). Circuit outputs became increasingly similar from singlet to triplet applications, independent of the order of modulators. We then tested non-converging neuromodulators. We started with neuropeptide applications and added one and then two different amine modulators. Comodulation with non-converging modulators did not increase circuit output similarity, and in some cases decreased it.
Our results suggest that complex comodulation can either pull circuits towards some common baseline output activity that may correspond to a baseline state or push it towards different output patterns that reflect circuit flexibility. The actual circuit output then depends on the balance of converging and diverging modulatory actions.

Title: Modulation of the stretch feedback pathway by neuropeptides in the heart of the American lobster, Homarus americanus

Authors: *K. VAN HASSEL[1], M. P. THIES[2], M. A. PADILLA SOTO[2], G. G. GRIESMAN[2], D. J. POWELL[2], E. S. DICKINSON[3], X. QU[2], P. S. DICKINSON[2];

Abstract: The cardiac ganglion (CG), a central pattern generator, is a neural network that produces the patterned motor output of the cardiac muscle in the American lobster, *Homarus americanus*. The CG in the lobster is made up of nine electrochemically coupled neurons: four premotor neurons that send signals to five motor neurons, causing bursts of action potentials from the motor neurons. These bursts cause cardiac muscle contractions that vary in strength based on the burst duration and burst frequency. Underlying these bursts of action potentials are driver potentials (DPs), which are slow and sustained Ca2+ based depolarizations that allow for the patterned motor output from the CG. We have established a generally excitatory response to cardiac muscle stretch that is mediated by stretch-sensitive dendrites that respond to hemolymph entering the heart. Experimentally, we induce this response by isolating the CG along with the surrounding muscle and applying ramp shaped stretches. These stretches have three phases: the rising phase when the muscle is stretched and the bursting phase is delayed, the hold phase when the stretch length is held constant and the bursts become shorter and more frequent, and the release phase when the stretch length returns to the baseline and the bursts increase in duration. Previous research has established that numerous neuropeptides modulate the cardiac neuromuscular system by acting directly on the CG and peripheral sites such as the neuromuscular junction and cardiac muscle. We have found that GYSNRNYLRFamide and SGRNFLRFamide, two neuropeptides with similar effects on the cardiac muscle activity, suppress the excitatory stretch response. Myosuppressin, an endogenous neuropeptide, decreases the cardiac muscle contraction and CG burst frequency and increases the contraction amplitude. Myosuppressin modulates the stretch feedback pathway by increasing the phase delay during the rising phase, suppressing the stretch response during the hold phase, and inducing no changes in burst parameters during the release phase. Additionally, myosuppressin seems to increase the time in between DPs during the rising phase, increase the DP duration during the hold phase, and induce no changes in DP parameters during the release phase. The rate of depolarization between DPs tends to decrease from saline to myosuppressin during the rising and hold phases. We are currently continuing to work on understanding how myosuppressin modulates the driver potentials underlying the stretch response and whether changes in membrane resistance may mediate the stretch response.

Title: Differential role of I_h in the Cancer borealis pyloric rhythm across temperature

Authors: *K. SCHAPIRO[1], J. RITTENBERG[3], M. KENNGOTT[2], E. E. MARDER[4];
[1]Brandeis Univ., Waltham, MA; [2]Physics, Brandeis Univ., Somerville, MA; [3]Brandeis, Waltham, MA; [4]Volen Ctr. and Biol. Dept., Volen Ctr., Waltham, MA

Abstract: Neural circuits must maintain their functions across a variety of environmental challenges, but the mechanisms underlying the execution of these functions may differ to compensate for specific challenges. We studied the role of the hyperpolarization-activated inward current, I_h, in maintaining the pyloric rhythm of the stomatogastric ganglion of male *Cancer borealis* crabs across temperature. The lab has previously shown that the firing phases of pyloric neurons are maintained across temperature, though the overall frequency of the triphasic rhythm increases (Tang et al, 2010). We asked whether, across temperature, the slowly activating I_h plays a different role in maintaining frequency or phase and/or whether the properties of this current change to allow the circuit to operate at different frequencies. Using a combination of extracellular and intracellular recordings, we assessed pyloric frequency as well as phase and membrane waveform of constituent pyloric neurons at temperatures ranging from 11°C to 21°C in both control and I_h-blocked (Cs^+ or ZD 7288) conditions. We repeated these investigations in picrotoxin to isolate the pyloric pacemaker to determine the dependence of temperature-sensitive, I_h-dependent activity on inhibitory synaptic feedback from follower neurons. We found that while the phase of each pyloric neuron's firing differed between control and I_h-blocked conditions, these differences did not change with temperature, suggesting a constant role of I_h in controlling the relative timing of each neuron regardless of temperature. However, we found that I_h blocking agents slowed the pyloric rhythm more high temperatures. This differential slowing suggests that I_h plays a larger role in maintaining pyloric frequency at high temperatures than low temperatures. This finding is particularly intriguing because I_h is canonically slowly-activating, yet it seems to be playing a more critical role in maintaining fast activity. Preliminary results suggest that this effect persists in picrotoxin.

Title: The modulatory role of the NO-cGMP signalling pathway on spinal neuronal properties and locomotor output in Xenopus laevis tadpoles

Authors: *L. HACHOUMI, N. MCLAUGHLIN, M. KUEHNER, K. T. SILLAR;
Sch. of Psychology and Neurosci., Univ. of St Andrews, St. Andrews, United Kingdom

Abstract: Rhythmic locomotor behaviours, such as swimming in *Xenopus laevis* tadpoles, are flexible to allow organisms to adapt their movements. This flexibility is partly mediated by neuromodulators that alter intrinsic properties of locomotor central pattern generator (CPG) neurons and network output. In tadpoles, nitric oxide (NO) is an important neuromodulator that exerts an overall inhibitory effect on swimming (McLean and Sillar, 2002) and impairs short-term motor memory (STMM; Hachoumi et al., 2022). STMM is a mechanism that influences future swimming behaviour based on past network activity and is mediated by dynamic Na^+/K^+ pumps that produce an ultra-slow afterhyperpolarisation (usAHP) in spinal CPG neurons (Zhang and Sillar, 2012). In this investigation, the NO-cGMP pathway was pharmacologically manipulated to elucidate its role in locomotor control. We performed ventral root recordings of fictive swimming and patch clamp recordings of spinal CPG neurons in immobilised stage 42 *Xenopus* tadpoles. The cGMP analogue, 8-Bromo-cGMP (100 μM), was utilised to examine the involvement of PKG as a downstream target of NO. 8-Bromo-cGMP did not affect swim episode duration or intra-swim parameters such as burst duration or cycle period (n=8). However, it did impair STMM (n=11) and recordings from spinal neurons indicate smaller usAHPs (n=3). Applications of the NOS substrate, L-arginine (L-arg; 2 mM) were conducted to increase NOS activity. If L-arg levels were below saturation, it should increase NO generation and consequently decrease swimming. Contrary to expectations, L-arg increased swim episode duration (n=10) and induced a slow modulation of swimming in which ventral root frequency and burst intensity waxed and waned. These rhythmic oscillations in swimming occurred with a cycle period of ~1-6 sec, reminiscent of NMDA receptor-mediated oscillations reported previously in tadpoles (Reith and Sillar, 1998). L-arg also depolarised the resting membrane potential of spinal neurons and decreased input resistance (n=7). Interestingly, L-arg did not alter STMM or the usAHP (n=7) suggesting its actions do not involve the NO pathway. In summary, we propose that the actions of NO on tadpole swimming are partly mediated via PKG and hypothesise that L-arg, a substrate also for arginase enzymes that generate polyamines, can facilitate NMDA receptor-mediated currents (Williams et al., 1991).

Title: Cellular and molecular mechanisms underlying dopaminergic mediated maturation of locomotor activity in larval zebrafish

Authors: B. MERCIER[1], M. L. BECKMAN[2], *M. A. MASINO[3];
[1]Rehabil. Sci., Univ. of Minnesota, Twin Cities, Minneapolis, MN; [2]Biol., Augsburg Univ., Minneapolis, MN; [3]Neurosci., Univ. of Minnesota, Minneapolis, MN

Abstract: The refinement of gross motor skills, such as locomotion, during development is conserved across vertebrate species. Previously we reported, in larval zebrafish, that dopaminergic (DAergic) signaling through dopamine 4 receptors (D4Rs) was necessary for the developmental transformation of behaviorally relevant locomotor activity from an immature state (erratic, long duration swim episodes) to a mature state (goal-directed, short duration swim episodes) between 3 and 4 days post-fertilization (dpf) (Lambert et al., 2012). The primary source of spinal dopamine is a subset of ventral diencephalic DAergic neurons (DDNs), which project to the spinal cord forming the DAergic diencephalospinal tract (DDT) (Takada et al., 1988; Kastenhuber et al., 2010). Although the DDNs and the DDT are present as early as 1 dpf and the DDT projects along the rostrocaual extent of the spinal cord by 3 dpf (Kastenhuber et al., 2010) and both dopamine transporter and tyrosine hydroxylase are present in the DDNs at 3 dpf (Xi et al., 2011), the cellular and molecular mechanisms underlying the developmental change in locomotor state are not well understood. Recently, we demonstrated that exogenous application of dopamine to 3 dpf larvae produced mature-like locomotor output (unpublished), which suggests both the presence of functional dopamine receptors and a lack of dopamine release in the spinal cord at this developmental stage. Thus, we hypothesized that the developmental transformation of locomotor activity may be due to increased DDN activity, greater release of dopamine in the spinal cord, increased spinal D4R receptor expression, or a combination of these. To measure and compare DDN activity and spinal dopamine release at different developmental stages, calcium or dopamine transients were recorded from larvae that expressed calcium indicator in DDNs (*Tg(th1:Gal4;UAS:GCaMP6s)*) or dopamine sensor pan-neuronally (*Tg(elavl3:Gal4;UAS:GRAB$_{DA}$)*), respectively. The calcium (n=8) and dopamine (n=3) signals were more frequent and larger in amplitude in 5 dpf larvae than in 3 dpf larvae. In addition, the calcium signals were more periodic and synchronous in 5 dpf larvae than in 3 dpf larvae (n=8). Finally, qRT-PCR demonstrated that D4Rs were expressed in the spinal cords of 3 dpf larvae (N=1); however, whether D4Rs were functional and whether their expression levels changed during development have not been determined. In summary, these data support the hypotheses that differences in DDN activity, dopamine release, and D4R expression between 3 dpf (immature) and 5 dpf (mature) larvae are correlated to the DAergic-mediated transformation of locomotor activity during development.

Title: Early, but not late, epidural stimulation alters spinal cord injury-induced plasticity of serotonergic modulation of lumbar Shox2 interneurons

Authors: *D. GARCIA-RAMIREZ, J. R. MCGRATH, N. J. STACHOWSKI, S. J. ATOCHE, L. YAO, S. F. GISZTER, K. DOUGHERTY;
Drexel Univ. Col. of Med., Philadelphia, PA

Abstract: The spinal locomotor circuitry, located in the thoracolumbar spinal cord, is able to produce the rhythm and the patterning of locomotion even in the absence of brain descending inputs. However, supraspinal control is necessary to initiate and adapt the locomotion. Spinal cord injury (SCI) disrupts the supraspinal descending control, including the pro-locomotor serotonergic modulation of the spinal circuitry. Current promising clinical therapies to recover motor control, such as epidural stimulation (ES), aim to activate the spinal locomotor circuitry by targeting proprioceptive afferents. However, chronic SCI induces plasticity, and the state of the spinal locomotor circuits after SCI and further plasticity following rehabilitation is poorly understood. Interneurons (INs) expressing the transcription factor Shox2 are part of the locomotor circuitry. Previously, we showed that Shox2 INs are modulated by serotonin producing inhibitory and excitatory actions, depending on the concentration. However, in mice that received a complete T8/9 transection 7-weeks before the terminal experiment, serotonin only increased the excitability of Shox2 INs. Furthermore, Shox2 INs from SCI mice that received 6 weeks of sub-motor threshold ES, starting one week after the injury, did not display the SCI-induced changes. The aim of this study was to determine if ES delivered early or late would prevent or reverse the SCI-induced plasticity in the serotonergic modulation of Shox2 INs. Therefore, we performed experiments on adult Shox2::Cre;R26-lsl-tdTomato mice 4 weeks after a complete spinal T8/9 transection with or without 3 weeks of ES beginning one week post-surgery. We performed whole-cell patch clamp recordings from Shox2 INs and tested serotonin modulation. Effects at 4 weeks post-SCI were similar to those observed at 7 weeks post-SCI. Next, to test if ES can reverse the SCI-induced plasticity, mice developed chronic SCI for 4 weeks, followed by 3 weeks with ES treatment. The serotonergic modulation of Shox2 INs observed from these mice was no different from the SCI mice. This result suggests that ES does not reverse the SCI-induced plasticity in chronic conditions. Finally, to test if early ES effects are maintained when ES is discontinued, mice received ES for 3 weeks, followed by 4 weeks without ES. We found that the ES prevention of the SCI-induced changes was maintained over 4 weeks following termination of ES. Our results suggest possible therapeutic implications of an early treatment with ES to preserve spinal locomotor circuitry after SCI.

Title: Contribution of non-inactivating calcium channels to the long-lasting effects of epidural polarization of afferent fibres

Authors: I. H. J. HAMMAR, ***L. I. M. M. KARLSSON SUNDBERG**, E. JANKOWSKA;
Inst. of Neurosci. & Physiol., Univ. of Gothenburg, Gothenburg, Sweden

Abstract: Epidural polarization may increase the excitability and shorten the refractory period of nerve fibres within the dorsal column. These effects are most potent at the levels of branching of afferent fibres as they enter the spinal cord. They depend on GABA but also on other factors, in particular persistent Na^+ or Ca^{2+} currents as they are long-lasting ($\geq$ one hour).
We therefore investigated the contribution of non-inactivating Ca^{2+} channels to direct current (DC) evoked changes in excitability and refractory period of fibres within the dorsal column. In one series of experiments in deeply anesthetized adult rats, changes in compound action potentials evoked in hindlimb peripheral nerves by epidural stimulation applied at lumbar segments via a thin tungsten electrode were compared in untreated animals and during local application of nifedipine, a persistent calcium current blocker.
In the presence of nifedipine, nerve fibre excitability was slightly reduced (to 85 ±10%, $p<0.01$, $n=11$). Only minor changes in the relative refractory period were observed but during epidural DC the shortening of the refractory period was somewhat counteracted.
The presence of persistent calcium current channels within the relevant spinal segments was analysed using confocal imaging and immunohistochemistry in preparations where afferents were labelled by Neurobiotin, with antibodies directed towards L-type calcium channels ($Ca_V1.3$).
Preliminary data indicate that $Ca_V1.3$-receptors are present within and ventral to the dorsal column, in the vicinity of labelled afferents but not overlapping with them.
The results suggest that L-type channels are present in the lumbar dorsal columns but are expressed in structures adjacent to the afferent fibres rather than in the fibres themselves. The weak effects of nifedipine in the dorsal column may thus be primarily indirect.

Title: Harnessing neuromodulation to prevent transneuronal degeneration of premotor interneurons after spinal cord injury

Authors: *J. PATHAN[1,2], H. SHARIF[1], T. BETHEA[1,2], J. MARTIN[1,2];
[1]Dept. of Molecular, Cellular, and Biomed. Sci., CUNY Sch. of Med., New York, NY; [2]Biol. Department, Neurosci. Program, CUNY Grad. Ctr., New York, NY

Abstract: Producing skilled movements in humans and many animals requires the corticospinal tract (CST), the direct motor pathway connecting the cerebral cortex with the spinal cord. Spinal cord injury (SCI) results in CST damage and leads to transneuronal degeneration, whereby undamaged premotor interneurons (IN) denervated of CST synaptic input are vulnerable to degeneration (J Neurosci 38:8329, 2018). Complement protein C1q triggers this process, leading microglia to phagocytose non-apoptotic cholinergic (ChAT) and glutamatergic (Chx10) INs. These INs receive direct CST inputs and synapse onto motoneurons to produce muscle contraction. In a bilateral CST lesion mouse model, we found that chemogenetic neuromodulation of motor cortex or spinal cord immediately after injury abrogates innate immune responses and mitigates IN transneuronal degeneration. However, it is unknown if abrogation of transneuronal degeneration and inflammation persists after neuromodulation ends. We hypothesize that neuromodulation will provide sustained neuroprotection, modulating microglia phagocytosis and ameliorating transneuronal degeneration after SCI. Using motor cortex intermittent theta burst stimulation (iTBS) and/or cathodal trans-spinal direct current stimulation (ts-DCS) to modulate neural activity in a C4 midline contusion SCI model in Sprague Dawley rats, we determined if ChAT and Chx10 INs are protected and if inflammation subsided during the post-stimulation period. Neuromodulation began 2 weeks post injury (wpi), daily for 10 days (30 min/day) in the following groups: 1) iTBS only, 2) ts-DCS only, and 3) combined iTBS and ts-DCS (N=18 total for all groups). Animals were perfused 8wpi to examine if neuroprotection persists after stimulation ends. After SCI, the number of ChAT and Chx10 INs decreased (ChAT 24% reduction; Chx10 40% reduction). While iTBS only or ts-DCS only provided minimal protection of ChAT INs, the dual neuromodulation protocol provided enhanced neuroprotection (3.7% ChAT reduction). For Chx10 INs, all stimulation protocols significantly reduced Chx10 IN degeneration (iTBS 1.5% reduction; ts-DCS 1.9% reduction; iTBS and ts-DCs 1.9% reduction). Intriguingly, while dual neuromodulation protected INs, there was a persistent 1.3-fold increase in activated microglia numbers. Our findings support our hypothesis and imply that electrical neuromodulation ameliorates transneuronal degeneration and modulates the inflammatory response during the post-stimulation period after SCI. Determining how augmenting activity prevents transneuronal degeneration and modulates inflammation can lead to better SCI therapeutic targets.

Abstract: During locomotion proprioceptive and cutaneous information controls amplitude and timing of the step cycle to adjust walking to the terrain and unexpected obstacles. It is known that enhancement of flexion or extension phases, resetting of the locomotor cycle or the stumbling correction responses occur through selective pathways and could provide insights on how sensory feedback modulates the different interneurons comprising the Central Pattern Generator (CPG) circuitry. This study was aimed to investigate how stimulation of proprioceptive and cutaneous afferents modulates the CPG circuitry in the neonatal mouse, considering that this approach is still suitable to disclose CPG organization. Experiments were carried out on the isolated bulbospinal neuraxis, and in some cases including one hindlimb with peripheral nerves, from C57BL/6 mice (P1-3). Fictive locomotor activity was induced by bath application of NMDA (5-7 μM), 5-HT (4 μM), DA (50 μM) and veratridine (10 nM). Stimulation strength of dorsal roots (DRs) and peripheral nerves was based on afferent volley or L5 ventral root (VR) responses, expressed in times threshold of the most excitable fibers (xT). Electroneurographic locomotor activity was recorded bilaterally on L2 and L5 ventral roots by means of glass suction electrodes. DRs, peripheral cutaneous and muscle nerves were stimulated with trains of 30 pulses at 100 Hz with strengths 2-4 xT, triggered off VR-L2 (flexor) or VR-L5 (extensor) locomotor phases every 6 cycles, in order to activate low threshold (group I muscle or group Aβ cutaneous) afferents. Preliminary results show that in general, stimulation of low threshold afferents in the ipsilateral DR-L2, triggered off the ipsilateral VR-L5 activity, evoked resetting to flexion, i.e. a shortening of the ongoing bursting and an early onset of the subsequent L2 activity. On the other hand, stimulation of ipsilateral DR-L5, triggered off the ipsilateral VR-L2 activity, evoked resetting to extension, i.e. a shortening of the ongoing bursting and an early onset of the subsequent L5 activity. As to cutaneous afferents effects, stimulation of ipsilateral Tibial and Sural nerves evoked mixed or negligible effects either in flexor or extensor phases. These data suggest that similarly to the neonatal rat, sensory information is able to modulate the CPG circuitry throughout selective pathways at early stages of development in a similar way as in adult mammals. Investigating afferent inputs on interneurons identified by molecular techniques in the mouse will disclose more thoroughly the control of the CPG circuitry by sensory feedback in mammals.

Title: Task-dependent control of coxal motor neurons in an insect leg

Authors: ***A. RUTHE**, C. MANTZIARIS, P. ROSENBAUM, A. ÖZYER, A. BÜSCHGES; Inst. of Zoology, Univ. of Cologne, Cologne, Germany

Abstract: Animal behavior needs to be highly adaptive and finely tuned to meet the ever-changing environmental demands. In terrestrial locomotion, such adaptive behaviors include straight and curve walking, climbing obstacles or changing the walking direction. The latter seems simple, but requires a number of modifications in the locomotor system. For example, in the middle legs of stick insects, forward and backward stepping differ primarily in the activity of coxal motor neurons and muscles, i.e. the retractor (Ret) and protractor (Pro) coxae: While in forward stepping Ret motor neuron activity generates leg stance and Pro motor neuron activity leg swing, the reverse is true for backward stepping. Interestingly, the activity of those muscles innervating distal leg joints, i.e. the coxa-trochanter and the femur-tibia joints are not different in principle (Rosenbaum et al. 2010). However, the underlying neuronal mechanisms are not yet understood (e.g., Tóth et al. 2011; Akay et al. 2007). In our study, we used pharmacology, extra- and intracellular recording techniques and sensory stimulation paradigms in the stick insect species *Carausius morosus* and *Cuniculina impigra* to investigate the neural mechanisms underlying the task-depend control of coxal motor neuron activity. First, we analyzed the synaptic drive underlying the rhythmic activation of the coxal motor neurons in the deafferented mesothoracic ganglion. We found that rhythmic alternating activity in those motor neurons is based on a tonic depolarization that is patterned by phasic inhibitory synaptic input from the premotor rhythm-generating networks. In the next step, we examined the role of local premotor nonspiking interneurons in reversing the activity of coxal motor neurons during backward stepping. So far, our recorded nonspiking interneurons can be classified into two groups, namely those whose activity pattern remains the same during forward and backward stepping and those that change their activity pattern depending on the stepping direction. Currently, we are analyzing whether they provide synaptic drive to coxal motor neurons during both stepping directions. Additionally, we investigate how load signals from leg load sensors contribute to the generation of forward and backward stepping.

Title: Role of haltere basalare muscles in free flight

Authors: *A. LEUNG;
Cornell Univ., Ithaca, NY

Abstract: Fruit flies have evolved the ability to execute a series of sophisticated aerial maneuvers in response to oncoming obstacles, such as gusts of wind, within milliseconds. To achieve fast and precise control of the wing muscles, the flight motor control system relies on rapid mechanosensory feedback from the halteres. Halteres are a pair of dumbbell-shaped organs that oscillate at the same frequency as the wings and are thought to encode the angular velocity resulting from Coriolis forces acting on the fly's body during rotation. Additionally, previous studies have demonstrated that haltere muscles, which are analogous to the wing steering muscles, alter the phase spike timings of the wing muscles in tethered flies. However, the resulting wing kinematics from the manipulation of the haltere motor neurons in free flight remains unclear. To answer this question, we employed split Gal4 lines to target neurons innervating the haltere basalare muscles and optogenetically activated or silenced the muscles during free flight. Our initial findings reveal that bilateral activation of the haltere basalare muscles induces a pitch up response and an increase in wing stroke amplitude. Conversely, silencing these muscles results in a pitch down response and an overall decrease in wing stroke amplitude. This suggests that the haltere basalare muscles are essential in body pitch control and maintaining stable flight. Furthermore, unilateral silencing of the muscles produces a body roll maneuver, suggesting that the haltere basalare muscles may encode multiple degrees of freedom in flies. Additionally, prior studies have shown that haltere muscle activity is also modulated by visual perturbations. To further investigate the function of the haltere basalare muscles, we propose optogenetic activation or silencing during free flight in the presence of mechanical perturbations or visual perturbations as a different testing approach. This investigation will shed light on the relationship between sensory inputs and motor control mechanisms mediated by the haltere basalare muscles.

Title: Differential force encoding in primary and secondary muscle spindle afferents

Authors: *J. D. STEPHENS[1], S. SIMHA[5], P. NARDELLI[2], T. C. COPE[3], L. H. TING[4]; [1]Biomed. Engin., Georgia Inst. of Technol., Flowery Branch, GA; [3]Applied Physiol. and Engin., [4]Biomed. Engin., [2]Georgia Inst. of Technol., Atlanta, GA; [5]Emory Univ., Atlanta, GA

Abstract: Proprioceptive signals are vital for the precise coordination of movement. However, muscle spindle feedback is considerably complex and is signalled through primary (group IA) and secondary (group II) afferents that have different stretch response properties. Thus, to better understand the role of muscle spindle feedback in movement control, it is necessary to develop models that account for the complexities of muscle spindle firing across both group IA and II pathways. The differences in firing responses have been attributed to these two afferent types terminating on different regions of the intrafusal fiber (muscle fibers within the spindle) and terminating on different intrafusal fiber types, namely the bag_1 type fiber that gives rise to the initial burst in IAs (group II afferents only terminate on bag_2 and chain type fibers). We hypothesize that IA and II afferents respond to the resistive force (F) and yank (dF/dt) on the muscle spindle during stretch, and predict that group II afferents will have reduced responses to the force on the spindle and substantially reduced responses to the yank on the spindle compared to group IA afferents.We tested this in ramp stretches (3 mm, 20 mm/s) in deeply anesthetized rats using the MTU force and yank models outlined in Blum et al 2017 and 2019. In short, we estimated the force and yank on the muscle spindle from measurements of the force on the muscle-tendon unit (MTU). We fit the force and yank to the recorded firing rate using constrained optimization, producing sensitivities to force and yank to characterize the spindle response. This analysis over 11 afferents from 3 animals showed a 25.5% lower force sensitivity and a 99.7% lower yank sensitivity of group II afferents with respect to group IA. However, this model relies on fitting forces measured from the MTU, thus it is only applicable in passive stretches when similar forces are being generated by the extrafusal skeletal muscle and intrafusal spindle fibers and offers little predictive capacity. Thus, we aim to repeat a similar analysis with the mechanistic muscle spindle model described in Blum et al 2020 and Housley et al 2023. This model uses recorded muscle stretch to simulate the force and yank in bag and chain type intrafusal fibers and generate a prediction of muscle spindle firing. By accounting for muscle fiber mechanics, this model will offer a greater mechanistic insight into the physiological differences and further our understanding of the functional differences of primary and secondary afferent pathways.

Title: Biophysical muscle spindle model predicts gamma sculpting of muscle spindle sensory signals during rhythmic behaviors

Authors: ***S. N. SIMHA**, L. H. TING;
Emory Univ., Atlanta, GA

Abstract: Current knowledge about the gamma motorneuron drive and its role in tuning the muscle spindle sensory output during behavior is limited. To understand muscle spindle function during behaviour, we developed a biophysics-based computational muscle spindle model that simulates the effects of two classes of gamma drive on muscle spindle firing. While it is hypothesized that gamma drive shapes muscle spindle Ia afferent firing differently across tasks, we know little about how it shapes the resulting information. Our model simulates the effects of gamma dynamic drive to bag1 intrafusal fibers and gamma static drive to bag2/chain fibers using cross-bridge dynamics. The muscle spindle's receptor potential that drives the Ia afferent's instantaneous firing rate is modeled as a linear sum of the force and rate change of force (yank) from bag1 fiber, and the force from chain fiber. We modelled three hypothetical tasks with the same rhythmic stretch-shorten cycles but different patterns of gamma drives. First, we simulated a postural sway task with gamma drives set to a constant low value. Similar to human spindles in Day 2017, the "posture" receptor potential showed an initial burst on the first stretch, rose sharply with each stretch, dropped slowly through the rest of the stretch, and disappeared soon after the onset of shortening. Next, we simulated an active movement task by simulating rhythmic alpha-gamma coactivation synchronized to the stretch-shorten length changes. The "voluntary" receptor potential was also rhythmic but with a slower rise and fall and no initial burst. Finally, we simulated an active locomotion task by matching the gamma drives to that measured in decerebrate cats by Taylor 2000; gamma static was synchronized to the length changes while gamma dynamic was on tonically only during lengthening. The "locomotor" receptor potential rose sharply with each stretch, continued to rise slowly for the rest of the stretch, and dropped immediately on shortening, with only the first stretch showing an initial burst. These differences in spindle firing solely from differing gamma drives suggest that we cannot estimate the muscle spindle signal during a task without understanding how neural control of gamma drive sculpts the resulting information.

Abstract: Ischemic stroke, one of the world's leading fatal diseases, has a high recurrence and incidence that can lead to severe mortality and disability. In this study, we investigated whether treadmill exercise has an important treatment for ischemic stroke to improve functional impairment. Experimental cerebral ischemia was induced by middle cerebral artery occlusion in rats and the effect of 10- or 30-minute training for two weeks was evaluated. To investigate the improvement of motor function, behavioral tests were conducted with cylinder, rota-rod, and elevated body swing tests. The region of the ischemic brain was measured by TTC staining. The expressions of the apoptosis-related genes and proteins were investigated by qPCR, western blotting analysis, TUNEL staining, and immunohistochemistry. Following cylinder, rota-rod, and elevated body swing tests, the motor function in both exercises 10- and 30-minute was improved compared to the non-exercise group. In addition, the brain infarct volume was decreased after exercise following TTC staining. Further examination of the cell signaling mechanisms involved in the improvement showed a significantly decreased expression of the pro-apoptotic proteins, Bax and caspase-9, and increased that of the anti-apoptotic proteins, Bcl-2 and Bcl-xl. Our results suggest that exercise has a beneficial effect on ischemic stroke for short- or long-term training by regulation of the signaling mechanisms such as apoptosis.

Abstract: Motor dysfunction such as gait impairment is a major disability induced by traumatic brain injury or stroke. Rehabilitation is one of the therapies for recovery of lost function after neural damage. Treadmill running is often used as a physical exercise task in clinically and experimentally for their recovery. In rodents, although several behavior experiments such as ladder waking and footprint test are performed to assess the motor function, there are no objective measurement for the motor evaluation. In rodents, although dynamic behavioral deficits can be evaluated using scoring system such as ladder waking and footprint test are performed to assess the motor function, local and minor behaviors are difficult to determine using objective measurement for the motor function. The purpose of this study is to evaluate the motor dysfunction and recovery after brain damage (BD) with/without exercise (Ex) in 8 weeks male mice using 3D kinematic analysis. To determine mild-intensity running, mice were examined an incremental running test while the pulmonary gas exchange of O_2 and CO_2 were measured. The BD was produced by aspiration of left sensorimotor cortical region, and BD with Ex mice performed mild-intensity running (10 m/min for 30 min 5 times/wk) for 4 weeks. The BD with Ex, and BD or sham-operated mice (sham) without Ex were recorded their gait by four-synchronized cameras, and gait was evaluated by 3D-kinematic analysis. The mice of BD without Ex significantly differed stride, step, and stride width in the both limbs comparing to those of sham without Ex. The BD with Ex mice were improved them. The BD without Ex mice had restricted ankle movements, and were observed impairment in dorsal/planter flexing using trajectory analysis. Consistent with the impairments, the nonaffected side also exhibited a different trajectory, suggesting compensatory movements. These results suggest that the appropriate Ex after BD recovered motor function. The present study also suggests that 3D-

kinematic analysis become a powerful tool for detecting minor behavioral alterations due to the impairment of the affected side and the compensation of the unaffected sides as well.

Title: Plasticity of cardiac vagal motoneurons to remote ischemic preconditioning

Authors: *E. HORNUNG, S. ROBBINS, A. SRIVASTAVA, J. SCHWABER, R. VADIGEPALLI;
Thomas Jefferson Univ., Philadelphia, PA

Abstract: The significance of the Dorsal Motor Nucleus of the Vagus (DMV) to the maintenance of cardiac health was previously ambiguous and underappreciated and has only recently been found to be profound (i.e. DMV activity is required for and sufficient to emulate the cardioprotection induced by physiological interventions, specifically remote ischemic preconditioning (RIPC)). Due to the recency of this evidence, little is known of the molecular, anatomical, and functional basis for the key cardioprotective role of DMV. Findings emerging from our single cell and spatial transcriptomic methods combined with heart to brain neural tracing in 12 week old male and female Sprague Dawley rats highlight pituitary adenylate cyclase-activating polypeptide (PACAP), as well as several other functionally relevant transcripts, as markers specifically of cardiac-projecting DMV neurons. We have also found several transcripts, including PACAP, to be neuroanatomically DMV-specific relative to the surrounding brainstem tissue, supporting the potential for DMV fiber-specific molecular identifiers innervating neurons of the intrinsic cardiac nervous system (ICN). Given the vast literature suggesting the cardioprotective effect of PACAP on ICN neurons, we hypothesize that RIPC increases PACAP levels in DMV. Preliminary RT-qPCR data from DMV tissue micro punches suggests differential expression of various neuromodulatory markers, including upregulation of the neurotrophic and cardioprotective neuropeptide PACAP, in response to RIPC. To build upon these preliminary RT-qPCR results, we have been collecting brainstem samples post-RIPC and post-sham surgery in an effort to validate these transcriptomic findings at the protein level with immunofluorescence staining and imaging measuring expression levels of

PACAP, and other neuromodulatory markers. This work fills a major gap in the understanding of the cellular mechanisms by which parasympathetic drive provides cardioprotection and provides a future translational path to emulating PACAP's vagal neuromodulatory effects on heart health.

Title: Investigation of mechanistic determinants of spinal segmental excitability following CST injury.

Authors: *T. BETHEA[1], T. ADEGBENRO[2], J. MARTIN[1,2];
[1]City Col. of New York- CDI, NEW YORK, NY; [2]CUNY Sch. of Med., New york, NY

Abstract: Investigation of mechanistic determinants of spinal segmental excitability following CST injury.
Authors: Thelma Bethea, Temitope Adegbenro, John Martin
SCI damages the corticospinal tract (CST), a motor pathway key to skilled movement. Selective CST injury produces aberrant proprioceptive afferent (PA) sprouting and increased spinal excitability, leading to hyperreflexia and spasticity. We have observed following a pyramidal tract lesion (PTX) an increase in PA terminals that synapse onto motoneurons. Loss of inhibitory GABAergic presynaptic (GABApre) regulation of PA afferent terminals is a second mechanism of hyperreflexia; GABApre is reduced after bilateral PTX in rats. Chloride homeostasis dysregulation is a third mechanism underlying hyperreflexia. A reduction of membrane-bound, and an increase in cytosolic, KCC2 has been observed after CST injury. In this study, we use selective CST injury to determine the individual contributions of these mechanisms to hyperreflexia.We compared naïve and PTX animals. Injury was followed by 2 weekly H-reflex assessments using rate-dependent depression (RDD). We labeled motoneurons using retrograde CTB tracing. Spinal cord sections were labeled with: VGlut1, a PA terminal marker; GAD65, a GABApre marker; and KCC2. Motoneuron 3-D reconstructions were made using Imaris, as were counts of Vglut1 and GABApre terminals. The ratio of GAD65 to Vglut1 was used to indicate the proportion of PA terminals receiving presynaptic inhibition. Pixel intensities for motoneuron membrane-bound and cytosolic KCC2 were made (ImageJ).We observed significant hyperreflexia in the cervical cord represented as increased RDD percentages (pre: 10%; post

40%), and the absence of hyperreflexia in the lumbar cord(pre: 4%; post 4%). We also see significant increases in PA synapses on motoneurons in both the cervical and lumbar cord, indicating sprouting. GAD65/Vglut1 ratios revealed a significant reduction in GABApre in the cervical, but not lumbar cord. This suggests impaired GABApre regulation in the cervical, but maintained regulation in the lumbar cord. Surprisingly, there was no significant difference between membrane-bound and cytosolic KCC2 in both spinal segments. Using the PTX model, our findings suggests that changes in KCC2 activity are disassociated from hyperreflexia. Instead, hyperreflexia can be explained by PA sprouting and associated loss of GABApre regulation in the cervical cord.

Abstract: Although organophosphates are known neurotoxicants, they remain in use as flame retardants, additives to lubricants and plasticizers, and are heavily used as pesticides. Acute exposure to organophosphates inhibits cholinesterase activity (>80%) and can lead to muscle paralysis and in some cases death. There is also evidence that low-level repeated exposures, such as those that may occur working with or around pesticides, are linked to adverse neurobehavioral effects in humans and animals even though they only impact cholinesterase levels by <10 %. Malathion is an organophosphate insecticide commonly used in the United States. Despite known neurobehavioral impacts, there are little data available as to how repeated malathion exposures impact locomotion and the structure of motoneurons and neuromuscular junctions. We hypothesized that low-level repeated exposure to malathion would result in locomotor deficits with anatomical alterations in the motor unit consistent with neurodegeneration. To test our hypothesis, we exposed male and female adult Sprague Dawley rats to 50 mg/kg of malathion

via subcutaneous injections once daily for 5 days a week for 4 weeks total. Locomotor behavior was assessed at approximately 1- and 4-weeks following exposure and included open field motor activity, rotarod/accelerod and quantitative gait analysis. Malathion exposed animals were significantly less active in the open field, with activity times for control animals of 1488 ± 150 seconds (mean ± standard deviation) while animals exposed to malathion displayed mean activity times of 1253 ± 151 seconds. Rats exposed to malathion also fell off the accelerod approximately 54 seconds earlier than control animals suggesting impairment of locomotor coordination. Consistent with this, malathion exposed rats also required a 25% increase in base of support during voluntary locomotor gait suggesting additional stability requirements. To examine neuromuscular changes that may underpin the locomotor changes, we analyzed neuromuscular junctions and found evidence of peripheral neuropathy in 50% of the endplates in the extensor digitorum longus muscle in malathion exposed animals. Altogether, our results suggest that the effects of repeated low-level exposure to malathion can cause peripheral neuropathy effects with locomotor changes.

Title: Four weeks of resistance training may improve peripheral nerve function in both young and older adults

Authors: *J. E. SHIELDS[1,2], M. L. DOS SANTOS[1,3], C. M. SMITH[1], S. M. REESE[1], J. M. DEFREITAS[1];

Abstract: It is well known that the natural progression of age can result in motor neuron degeneration. Consequently, this leads to slowing of nerve conduction, denervation, and reduced motor function. Slowing nerve speed can alter an individual's response time and could subsequently lead to increased fall risk and injury. Given the potentially detrimental effects of age-related motor axon degeneration and its role in sarcopenia, it is important to find interventions that improve peripheral nerve speed and size. Therefore, the purpose of this study is to determine if four weeks of resistance training could elicit positive adaptations in peripheral

nerves in healthy adults, with a secondary purpose of identifying the extent to which age could influence the adaptations. We hypothesized that training would result in faster nerve speed in both younger and older adults, albeit the magnitude of change would be greater in younger participants. Since larger axons are faster, we also hypothesized that any increases in nerve speed may be accompanied by axonal growth. Thirty subjects (18-71 yrs.) have completed this ongoing study so far (young training: n= 13, young control: n = 10, older training: n =7). Median nerve motor conduction velocity (NCV) was recorded before (PRE) and after (POST) four weeks of hand resistance training in both arms. Training was conducted 3×/week with the use of hand grippers, bands and rings. Cross-sectional area (CSA) measures of the median nerve from both arms were taken pre- and post-training using ultrasound imaging. Separate 3-way mixed factorial ANOVA's (limb × time × age) and (limb × time × group) were used to analyze the findings. For both NCV and nerve CSA, there were significant time (pre vs. post) × group (training vs. control) interactions ($p = 0.001$) and main effects for time ($p < 0.001$), with other comparisons being non-significant ($p > 0.05$). Our preliminary findings suggest that 4 weeks of resistance training improves nerve conduction velocity (~ 6.5%). To our surprise, age does not seem to be a factor, as the older adults improved at the same rate as the younger group. This type of training modality may be useful in counteracting diminished nerve speed with age. This study also shows that the nerve grows (~ 5.4%) with training. However, more importantly, it shows that nerve CSA, as measured by ultrasound, may be sensitive enough to identify large-scale changes in the size of motor neuron axons. Further sampling, along with the inclusion of older controls, will provide necessary insight into the efficacy of resistance training for improving nerve function, but the preliminary results are promising.

Title: Investigating the efficacy of low-gravity VR training on juggling skill improvement

Authors: *W. CHO[1], M. KOBAYASHI[1], H. KAMBARA[2], H. TANAKA[3], T. KAGAWA[4], M. SATO[1], H. KIM[5], M. MIYAKOSHI[6], S. MAKEIG[5], J. IVERSEN[7], N. YOSHIMURA[1];

Abstract: Juggling, an intricate motor skill, has garnered considerable attention in the study of motor skill acquisition mechanisms within the brain. However, the majority of investigations have relied on MRI or fMRI techniques, which are limited in their ability to directly observe neural activity during juggling. Therefore, this study aims to capture changes in brain activity associated with juggling improvement using electroencephalography (EEG) as well as fMRI, ball trajectory and arm movement, and to verify the effectiveness of slow-tempo training, which has been difficult to achieve in juggling, by realizing through a visuo-haptic virtual reality system. Participants who have never practiced juggling before were divided into two groups: the training group who practiced three-ball cascade juggling through the VR training program starting with slow tempo, and the control group who practiced it at a continuous highest speed. The participants practiced the program for 10 consecutive days. In each day, the participants also performed 3-ball juggling in the real world before and after the VR training, and 2-ball juggling with shutter-glasses in order to assess their juggling skills. As the result, behavioral data analysis showed a significant improvement in the juggling performance of the slow-tempo training group compared to the control group. Also, from EEG data acquired on days 1, 5, and 10 of the training period, it has been shown that slow-tempo VR juggling training led to changes in the event-related potential (ERP) images and event-related spectral perturbations (ERSPs) of the independent components (ICs) extracted from the EEG data. As an additional experimental approach, we conducted a comprehensive assessment of juggling experts affiliated with the juggling club at the Tokyo Institute of Technology. This assessment encompassed measurements of EEG, EMG, as well as anatomical and functional MRI data. A comparative analysis of fMRI images between juggling experts and beginners revealed a noteworthy finding: negative functional connectivity within the occipital area was observed among the juggling experts.

Title: A central mechanism for generation and maintenance of vigilance state in zebrafish and mice

Authors: *Y. ZHAO;
Tongji university, Shanghai, China

Abstract: After successfully escaping from predators into a safer space, or standing with head up in the grassland to surveil the surrounding bush for approaching predators, animals stay quietly and are alertly watchful as well as persistently attentive to avoid potential threats. Besides the behavioral phenomenon, neural signature and underpinning of vigilance state controlling generation and maintenance of vigilance state are still elusive. Here we demonstrated that in adult zebrafish conspecific alarm substance (CAS) could reliably change an actively behaving state into a quiescent vigilance state, in which neurons in the central zone of dorsal pallium (Dc) (homolog to mammalian cortex) displayed low-frequency high-amplitude synchronization, during which stage animal showed decreased threshold to aversive stimuli. The vigilance state was generated and maintained by tonic activation of raphe 5-HT neurons, which released and maintained the high concentration of 5-HT acting on the glutamatergic neurons located in the Dc zone via 5-HT7a receptors. Knockout 5-HT7a receptors diminished the synchronized state as well as vigilance behavior.
This ancestral mechanism also applies to the mammals. Persistent optogenetic activation of raphe 5-HT neurons in mice could reliably trigger the vigilance behavior state with low-frequency high-amplitude neuronal synchronization in the prefrontal cortex and decreased response threshold to aversive stimuli. This study sheds lights on understanding neural underpinning of vigilant state and may help to develop new strategies to treat with hypervigilance diseases, such as PTSD.

Title: Frequency dependent modulation of cortical excitability by peripheral nerve stimulation in patients with ataxia

Authors: *Y.-J. CHANG[1,2], M.-C. CHIANG[1], H.-C. YANG[1], M. HSU[3,4], R.-S. CHEN[2,1];
[1]Chang Gung Univ., Tao-Yuan, Taiwan; [2]Chang Gung Mem. Hosp. Linkou, Tao-Yuan, Taiwan; [3]Kaohsiung Med. Univ., Kaohsiung, Taiwan; [4]Kaohsiung Med. Univ. Hosp., Kaohsiung, Taiwan

Abstract: Previous studies demonstrated that peripheral electrical stimulation has the ability to modulate cortical excitability in individuals with spinocerebellar ataxia (SCA). The effects of stimulation frequency on facilitation/inhibition were observed in individuals without disabilities. This study aimed to investigate whether individuals with SCA could modulate their cortical excitability based on the frequency of stimulation and whether this modulation correlated with the symptoms of ataxia. Twenty individuals with SCA received median nerve stimulation at high (150Hz) and low (25Hz) frequencies in two consecutive weeks. Measurements of motor evoked potentials (MEP), intracortical inhibition (ICI), and intracortical facilitation (ICF) were conducted before and after the electrical stimulation intervention. Additionally, the clinical finger-to-nose test was used to assess coordination performance. The results revealed that after high frequency stimulation, MEP decreased, ICI decreased, and ICF increased. Conversely, after low frequency stimulation, MEP increased without any changes in ICI or ICF. Furthermore, a weak but significant correlation was observed between ICF and the timed repetition of the finger-to-nose test. In conclusion, this study demonstrates that peripheral electrical stimulation can modulate cortical excitability in individuals with ataxia, and these effects are dependent on the frequency of stimulation. High frequency peripheral electrical stimulation increases ICF, which is correlated with the symptom of ataxia. Long-term training effects should be further investigated in future studies.

Title: Role of contralesional non-primary motor areas in the recovery of proximal and distal upper-extremity muscles after stroke: A scoping review

Authors: *G. ALMALKI[1,2], A. SETHI[1];
[1]Occup. Therapy, Univ. of Pittsburgh, Pittsburgh, PA; [2]Col. of Applied Med. Sci., King Saud Bin Abdulaziz Univ. for Hlth. Sci., Jeddah, Saudi Arabia

Abstract: Targeting non-primary motor areas (NPMAs) is an alternative approach to improve upper extremity (UE) motor function after moderate-to-severe damage to the primary motor cortex (M1). Hence, determining the contribution of NPMAs to UE muscle activations is critical

to help the largest cohort of stroke survivors with moderate-to-severe stroke (65%) to improve UE function. Thus, the objective of this review was to examine the literature regarding the roles of NPMAs in proximal and distal UE muscles after stroke. We developed an a priori scoping review protocol before undertaking this review. We reviewed human and non-human primate literature using PubMed, Cochrane Library, MEDLINE, and hand-searching strategies. We initially screened 458 references, which met the eligibility criteria. One hundred forty-five studies were included for data abstraction, and 43 of the 145 studies (human studies n=16; non-human studies n=27) were included in the final review. Human studies showed that facilitating ipsilesional M1 or inhibiting contralesional M1 contributes to proximal and distal UE muscle activations after mild-to-moderate stroke. On the other hand, facilitating the contralesional dorsal premotor area (cPMd) contributes to proximal and distal UE muscles after moderate-to-severe stroke. The contralesional superior parietal lobule (cSPL) contributes to distal UE flexor muscles, while cPMd, contralesional anterior intraparietal sulcus (aIPS), contralesional posterior parietal cortex (cPPC) contribute to distal UE abductor muscles in severely impaired patients. Furthermore, human studies showed that cPMd contributes to bimanual arms coordination after moderate-to-severe stroke, while M1 contributes to bimanual arms coordination after a mild stroke. Non-human studies showed that supplementary motor area (SMA), cingulate motor areas (CMAs), and SPL have direct or indirect connections with M1 and other cortical areas and have direct or indirect projections to the spinal cord contributing to the movement of the proximal flexor and extensor UE muscles. The ventral premotor area (PMv), inferior parietal lobule (IPL), PMd, and aIPS have connections that contribute to the movement of the distal flexor and extensor UE muscles. In conclusion, the connections of the NPMAs mentioned above with M1 and other cortical areas, as well as the direct or indirect projection of these areas to the spinal cord, contribute to the movement of the proximal and distal UE muscles. These results may inform future rehabilitation protocols by laying the foundations for developing a new mechanism-based approach for proximal and distal UE recovery after moderate-to-severe stroke.

Title: Amplitude variation of motor evoked potentials with spinal cord temperature change ; rat local hypothermia model

Authors: R. MIYAGI, A. TAIRA, *K. KAMIZATO, M. KAKINOHANA;
Dept. of Anesthesiol. and Intensive care medicine, Univ. of the Ryukyus, Nakagami-Gun, Japan

Abstract: [Background] Intraoperative motor function monitoring is important for safe spine and spinal cord surgery. The motor evoked potentials (MEPs) can assess the function of corticospinal tracts, which are altered by various factors such as body temperature, anesthesia, etc. In this study, we investigated how the amplitude of motor evoked potentials changes when the spinal cord temperature is changed. [Methods] Male SD rats (300-350 g) were used. All procedures were performed under general anesthesia with intramuscular and intraperitoneal administration of ketamine. A copper perfusion plate was inserted under the dorsal thoracolumbar skin and local cooling of the spinal cord was performed until the spinal cord temperature reached 20 degrees Celsius(20℃=68℉). MEP and F waves were measured during cooling and heating.All measurements were performed in the left hindlimb. MEPs were derived in the gastrocnemius muscle by transcranial stimulation, and F waves were derived in the plantaris muscle by gastrocnemius stimulation. [Results] Spinal cord temperature was varied at 20, 23, 27, 30, 34, and 37 ℃. For MEPs, an increase in MEP amplitude was observed as spinal cord temperature decreased (Amp37℃ : Amp20℃ = 1 : 62.21); for F waves, the F/M ratio decreased as body temperature decreased (F/M37 ℃ : F/M20 ℃=21.5 : 14.7), and the frequency of appearance also decreased (P37 : P20=100 : 5). [Discussion] The present study showed that the amplitude of MEPs in the rat spinal cord increases when spinal cord temperature is decreased. Furthermore, the increase in amplitude with spinal cord temperature change was reversible, and the amplitude decreased with return of spinal cord temperature. The F-wave results also indicated that the anterior horn cell function was reduced by the decrease in spinal cord temperature.These results suggest that the increase in MEP amplitude is not due to an increase in motor nerve excitability, but that other mechanisms are involved.The amplitude of MEPs may increase even when motor nerve function is impaired, and caution should be exercised in their clinical determination, i.e., intraoperative motor function determination.

Title: A novel strategy to restore meaningful function to permanently denervated skeletal muscles

Authors: *A. YANS, V. F. RAFUSE;
Med. Neurosci., Dalhousie Univ., Halifax, NS, Canada

Abstract: Spinal cord injuries, peripheral nerve injuries and motoneuron diseases, cause permanentparalysis when the affected skeletal muscles are completely and permanently denervated due to motor neuron death. Even with advances in neuroprosthetics, functional movement of completely denervated muscles is extremely difficult to achieve because non-innervated muscle fibers cannot be efficiently activated via electrical stimulation. To circumvent this problem, we previously showed that permanently denervated muscles can be functionally activated with blue if the muscles are genetically engineered to express channelrhodopsin 2 (ChR2). Here, we are developing a novel strategy to express genes in denervated skeletal muscles without the use of transgenic technology. Briefly, shank muscles in adult C57/B6 mice were subjected to a high dose of gamma irradiation (18Gy). Days later, snake venom was then injected into the irradiated soleus muscles. Analysis of these muscles, up to one month later, showed that this procedure kills all the soleus muscle fibers and resident satellite cells. In another cohort of animals, the irradiated and venom injected soleus muscles were injected with cultured mouse embryonic stem cell-derived myoblasts (ESCMs) expressing a gene of our choice. To date, our results show that injected ESCMs expressing Td-Tomato survive the transplant procedure, fused to form multinucleated muscle fibers, and restored muscle mass as well as whole muscle cross-sectional area. Interestingly, the injected soleus muscles contained significantly more muscle fibers compared to non-operated muscles because the Td-Tomato expressing muscle fibers were significantly smaller than normal. Finally, we showed that transplanted ESCMs can become functionally innervated when endogenous motor nerve regeneration is permitted. Together, these findings indicate that ESCMs can repopulate irradiated/venom-injected mouse soleus muscles with new, exogenously derived fibers that are capable of functional reinnervation. We are currently conducting a similar series of transplant studies with ESCMs expressing ChR2. We anticipate that the exogenously formed ChR2 muscle fibers will functionally contract when illuminated with blue light. Ultimately, we hope that these preliminary studies will form the basis of using this technology to restore meaningful function to permanently and completely denervated muscles.

Title: Motion and signal analysis of the Paw Withdrawal Learning paradigm

Authors: F. MORENO[1], E. ALDANA[2], J. ARAIZA[3], M. JOSEPH[2], *C. WANG[1];
[1]Electrical and Computer Engin., [2]Kinesiology, [3]Biol., California State University, Los Angeles, Los Angeles, CA

Abstract: Following spinal cord injury (SCI), sensory and motor functions are severely disrupted yet the spinal circuitry below the injury site continues to maintain active and functional neuronal properties (Edgerton, 2004). The spinal cord is endogenously capable of several forms of adaptive plasticity, including functional re-training with exercise, instrumental, and Pavlovian learning. The paw withdrawal learning (PaWL) paradigm represents a simple spinal instrumental learning model (Jindrich 2019). In this study, we utilize high-speed, high-resolution cameras (Basler AG, Ahrensburg, Germany) to capture the motion and electromyography (EMG) to capture tibialis anterior (TA) muscle activity during the paw withdrawal learning paradigm in mice and rats. Our hypothesis is that the motion patterns from the contingent stimulation (CS) group differs greatly from non-contingent simulation (non-CS) group, especially once the learning has occurred. Joint angles of the hind leg form the raw motion data. Power spectra, acceleration/deceleration speed, and other features of the motion data of pre-stimulation, post-stimulation, and post-learning sequences were compared between the CS and Non-CS group. We successfully recreated the PaWL paradigm using a high-framerate camera and achieved synchronized data collection between the CS and Non-CS groups with EMG at the tibialis anterior muscle. Preliminary data shows successful EMG activity corresponding to the hindlimb activity throughout the length PaWL training. The successful formulation of the paradigm using improved technology will validate the instrumental learning model. The CS group successfully learned to paw dorsiflexes while the non-CS group failed to dorsiflex above the imposed threshold. Development of this spinal learning paradigm will help answer physiological and molecular mechanism of plasticity in simple neuromuscular preparation in an isolated spinal cord from any input from the brain.

Title: Variability in motor unit activity for a functional stationary cycling task

Authors: *A. M. WIGGINS, G. R. EVANS, V. VENEZIA, S. DARDZINSKI, E. FILBERT, R. CREATH;
Exercise Sci., Lebanon Valley Col., Annville, PA

Abstract: Introduction: Under isometric conditions, the orderly recruitment of motor units (MUs) occurs by motoneuron size. By comparison, functional recruitment sequences display variation suggesting an alternative mechanism that depends on muscle and task mechanics. Previously, observed EMG frequency spectra displayed seemingly random correlations between consecutive pedal power strokes (PPS) during stationary cycling at constant effort and cadence (rpm). We expected a dominant subset of motor units to emerge by time-averaging many PPS under constant rpm conditions which would serve to identify the average MU requirements for the task. Instead, averages of increasing numbers of PPS failed to converge on a dominant subset of MUs suggesting a random component to selection. The purpose of this preliminary study was to characterize the random characteristics of MU recruitment for stationary cycling at constant effort and rpm.
Methods: 6 subjects (4m; 21.3 yrs) performed 70-sec trials on a Concept2 bike for 2 conditions: 1) 60 rpm at low effort (bike setting 2); and 2) 80 rpm at low effort. Rpm and watts were recorded to ensure cycling consistency. EMG was recorded for Vastus lateralis at 2K Hz using a Delsys EMG system. Data was resampled at 20K Hz and band-pass filtered between 20 and 1K Hz. Fourier transforms (FFTs) were calculated for each PPS. PPS Spectra were normalized to the maximum amplitude. Spectra were averaged for N=5, 10, 20, and 50 PPS. Pairwise correlations of frequency spectra were calculated for all unique pair combinations for 50 PPS from each trial.
Results: Coefficients for the pairwise correlations varied between -0.99 and 0.98 with the majority between 0.0-0.5 regardless of rpm. The correlation distribution results suggested that each PPS produced a unique frequency spectrum. For averages of 5 spectra, each trial contained frequency elements between 20 - 200 Hz, but without dominant frequencies. Averaging greater numbers of PPS spectra (10, 20, & 50) produced seemingly random MU frequencies in the 20-200 Hz range. Greater PPS time-averaging produced progressively smoother distributions as variable frequency elements between 20-200 Hz filled gaps to create a continuous spectrum with fixed limits. For larger averages, a peak activity level emerged between 100 - 120 Hz for the otherwise seemingly random MU spectra.
Conclusions: The absence of consistently high pairwise correlations between PPS suggests that MU recruitment varies randomly within a fixed distribution during cycling at constant effort and rpm. It appears that MUs for individual PPS are selected from a larger distribution that is task specific but can only be identified through repeated PPS.

Title: Spinal cord stimulation in stroke patients shows suppression of cooperative movement circuitry recruited for compensatory action during movement

Authors: *R. FAKHREDDINE[1], D. M. GRIFFIN[2], N. VERMA[3], E. SORENSEN[4], E. CARRANZA[5], A. BOOS[6], G. F. WITTENBERG[6], P. GERSZTEN[4], E. PIRONDINI[7], M. CAPOGROSSO[7], D. J. WEBER[2];
[2]Carnegie Mellon Univ., [3]Mechanical Engin., [1]Carnegie Mellon Univ., Pittsburgh, PA; [4]Neurolog. Surgery, [5]Bioengineering, [6]Neurol., [7]Univ. of Pittsburgh, Univ. of Pittsburgh, Pittsburgh, PA

Abstract: Despite stroke being a leading cause of serious long-term disability, post-stroke rehabilitation is often unable to promote recovery of arm and hand function. Patients with chronic hemiplegia often use compensatory strategies in the unaffected limb to augment function in the affected limb. These strategies can be in the form of mirror movements (unaffected hand displays a scaled version of affected hand activity) or cooperative movements (antagonist-agonist pattern of activity between both hands) to better perform a task. Recently, we demonstrated that cervical epidural spinal cord stimulation (SCS) targeting the dorsal root entry zone improves upper extremity function in people with stroke related hemiplegia. The effects of SCS are attributed to activation of primary afferent neurons that provide excitatory input to motor neurons. This may compensate for the loss of descending input after stroke and reduce the need for compensatory strategies. To test this hypothesis, we examined EMG and reach-related kinematics in a patient with chronic stroke related hemiplegia during cervical epidural SCS. We instructed the subject to perform a point-to-point reaching task in a 2-D plane with their affected limb. A session consisted of trials with (stim on) and without (stim off) SCS. Although the task required only movement of the affected limb, we recorded EMG and kinematics from both limbs. Our analysis focused on the biceps and triceps of both arms, revealing consistent patterns of muscle activation in the unaffected arm while reaching with the affected arm. However, we found no signs of mirroring or coherence in the EMG, but rather an antagonist-agonist pattern of muscle activation between limbs during stim off trials. Averages of EMG activity revealed that activation of the tricep in the affected limb was paired with activation of the bicep in the unaffected limb with ~100ms latency during the reach phase of the task. During stim off trials, the participant often failed to reach the left and right targets. Motor performance of the affected limb improved with stim on, as seen by smoother kinematic traces and increase in the number of targets reached. As motor behavior improved, the need for compensatory action decreased, revealed by consistent reduction of average EMG in biceps and triceps on the unaffected side during stim on trials. EMG traces in individual trials also revealed lower levels of muscle activity in the unaffected limb with SCS, while in the affected limb EMG activity became more closely locked to reach onset with clearer activation peaks. Our analysis further reveals that SCS improves motor performance and reduces the need for compensatory behavior.

Title: Vibro-tactile Stimulation of the Neck as a Non-invasive Treatment for Cervical Dystonia

Authors: *J. KONCZAK[1], J. XU[2], J. OH[4], S. STANDAL[3], P. SALEHI[3], D. MARTINO[5], L. AVANZINO[6], A. CONTE[7];
[2]Kinesiology, [3]Physical Med. and Rehabil., [1]Univ. of Minnesota, Minneapolis, MN; [4]Children's Hosp., Los Angeles, CA; [5]Neurol., Univ. of Calgary, Calgary, AB, Canada; [6]Exptl. Med., Univ. of Genoa, Genoa, Italy; [7]Neurol., Univ. of Rome, Rome, Italy

Abstract: Cervical dystonia (CD) is a form of focal dystonia associated with involuntary cervical muscle contractions that lead to sustained or intermittent abnormal, painful head movements or postures, which severely affect a CD patient’s daily life. Current treatment opportunities for CD are limited and mainly consist of Botulinum toxin injections (Botox) in the dystonic muscles or deep brain stimulation. Both methods are invasive, and Botox is not tolerated by all CD patients. This multi-center clinical trial examined if superficial, vibro-tactile stimulation (VTS) of the cervical muscles can be an alternative, non-invasive method to provide temporary symptom relief for people with CD. **Method:** A total of 67 patients with CD (44 females) participated. The mean age was 61.1 ± SD 12.5 years. All participants were seen within two weeks before or one week after their new BoNT injection (i.e., their symptomatic period). The most often affected cervical muscles, sternocleidomastoid and trapezius, were stimulated. Participants completed up to 9 stimulations under different conditions (stimulating a single muscle or the combination of two muscles) in randomized order and based on their clinical manifestations (e.g., torticollis, laterocollis). Under each stimulation condition, VTS was applied continuously for 5 minutes. A head angle index (HAI), a composite measure reflecting the head deviation across the three head axes was and a self-reported pain score (100-point scales) were the primary outcome measures. **Results:** First, 82% (55/67) of participants showed an

improvement in head righting by at least 10% as measured by HAI in one or more stimulation condition. Second, of those experiencing pain, 66% (29/44) showed at least 10% relative improvement in pain score with 39% (17/44) of participants achieved a relative improvement in pain score of at least 50% during VTS-ON for the best stimulation condition. Retention of pain relief was observed after the cessation of VTS. Third, several stimulation conditions could either induce larger relative improvement in dystonic symptoms or higher responding rate than the other conditions for each CD manifestation. **Conclusion:** In summary, the findings of this study provide evidence that VTS can be used as a potential new treatment method for CD. Improvements in abnormal head posture and pain were observed among large portion of participants during the application of VTS.

Title: Benefits of regular physical activity and polyphenol supplementation on locomotor function and lifespan in Drosophila melanogaster

Authors: *M. MORGAN[1], G. CELAYA[1], Z. LOPEZ[2], R. E. HARTMAN[2];
[2]Psychology, [1]Loma Linda Univ., Loma Linda, CA

Abstract: Physical exercise and dietary adjustments are non-pharmacological interventions that have been shown to protect against cognitive decline. Regular participation in physically demanding activities positively influences cognitive health compared to a sedentary lifestyle. Regular consumption of a healthy, polyphenol-rich diet can likewise positively influence cognitive health compared to unhealthy diets. Several human and animal studies have demonstrated that adopting these lifestyle factors can safeguard against cognitive and motor deficits associated with neurodegenerative disorders. This study aims to explore the exercise-mimetic effects of EA dietary supplementation, investigate EA's neuroprotective potential, and provide insights into the combined use of a polyphenol-rich diet and induced exercise to enhance cognitive outcomes against the deleterious effects of neurodegeneration. Adult fruit flies were exposed to ellagic acid via diet while engaging in regular exercise three times a week. Exercise was induced in the flies through repetitive movement of their vials. Control flies were not exposed to the repetitive movement. Flies were fed either a control diet consisting of instant Drosophila medium mixed with water or 10% ellagic acid solution throughout their lifetime. Climbing performance was assessed using the negative geotaxis assay, and longevity was evaluated as a measure of survival rate. Results demonstrated that, on average, flies with a

polyphenol-rich diet climbed higher and lived longer compared to flies on a control diet. The findings provide support for the use of ellagic acid in improving longevity outcomes and its potential neuroprotective qualities against motor function decline associated with aging and neurodegeneration. Further research will look at the effects of ellagic acid and exercise on other measures of cognitive function, such as learning and memory, and the use of different doses of these two interventions.

Title: Does song preference formation in female zebra finches require mTOR signaling?

Authors: *K. V MAHESHWAR, O. CLARKE, S. E. LONDON;
Univ. of Chicago, Univ. of Chicago, Chicago, IL

Abstract: Song learning in zebra finches during development influences their social behavior in adulthood. The song structure of adult male zebra finches reflects their tutor experiences during a critical period; song preference formation and mate choice in females are shaped by song exposure during development. Overlaps in developmental learning timelines and brain regions involved in auditory processing suggest that males and females might share molecular mechanisms important for formation of song memories in juveniles as in adults. However, there are molecular data indicating the potential for sex differences in learning mechanisms. Constitutive activation and selective inhibition of the mechanistic Target of Rapamycin (mTOR) signaling cascade in the auditory forebrain of juvenile males during tutor experience disrupts tutor song copying. Interestingly, while the mTOR machinery is present in both sexes, song playback induces mTOR signaling in males, but not females, at ages when song experience influences adult behaviors in both sexes. To functionally test if formation of sensory song memories in juvenile females depends on mTOR signaling, we selectively inhibited or constitutively activated mTOR signaling in the auditory forebrain during tutor experiences, as we have done previously in males. We assayed the effect of these manipulations on adult song preference with an operant conditioning perch-trigger assay where perches were assigned to play either the tutor song or a novel song when the bird hopped on them. Preliminary results suggest that bidirectional manipulation of mTOR signaling in juvenile female zebra finches does not abolish their preference to the tutor song. These results may then add to the evidence that the

molecular mechanisms underlying sensory song learning in juvenile female zebra finches are distinct from those known to be essential for tutor song memorization in juvenile males.

Title: Developmental shifts in epigenetically-defined regulatory regions reveal putative controllers of critical period learning

Authors: *G. KUNZELMAN[1,2], S. E. LONDON[2,1];
[2]Psychology, [1]Univ. of Chicago, Chicago, IL

Abstract: In zebra finches, juvenile song experience has meaningful and lasting consequences on adult behavior. Evidence suggests that molecular mechanisms underlying sensory song learning in males and females developmentally differ. During development, maturation- and experience-dependent mechanisms of plasticity intersect to regulate neural properties (e.g., cell number, subtype, functionality, connectivity) that temporally constrain sensory song learning. These properties are largely determined by the complement of protein-coding and noncoding RNAs transcribed from the genome. Transcription is regulated by transcription factors (TFs), proteins that coordinate the expression of gene sets that orchestrate shifts in functional and structural cell properties through binding transcription factor binding sites (TFBSs) in regulatory regions of the genome (i.e., enhancers, promoters, repressors). To determine the properties that influence juvenile song learning, we performed chromatin immunoprecipitation for H3K27ac, a histone modification that denotes accessible regulatory regions, and high-throughput DNA sequencing (ChIP-Seq) on auditory forebrains (AL) of males and females spanning developmental time points at which song experience has differing influence on adult behavior. To parse the roles of maturation, experience, and sex in establishing regulatory region accessibility, we compared birds differing in developmental state of receptivity (i.e. capable and incapable of learning) and age-matched birds of the opposite sex. We identify TFBSs enriched in differentially accessible regions, identified their putative genes of regulation, and performed GO ontology analysis to examine how enriched TFBSs and putatively regulated genes may influence AL properties. Our data suggest that male and female regulatory region accessibility profiles differently shift across development to support overlapping and distinct cellular and molecular processes of brain development and function. Comparisons of age-matched males and females revealed that sexually-dimorphic regions were largely located on sex chromosomes and more accessible in males. GO terms enriched in genes annotated to regions of greater accessibility in

males suggest increase regulatory potential for upstream initiators of the ERK and mTOR signaling cascades, each of which developmentally differ in song responsivity between males and females. Together, our evaluation of epigenetically-defined regulatory region profiles promotes further insight into the emergence of neural learning circuits in a brain area required for the developmental learning of complex behavior.

Title: Call-evoked activity in the zebra finch vocal premotor nucleus HVC

Authors: *C. GOMEZ-GUZMAN, D. VALLENTIN, J. BENICHOV;
Max Planck Inst. for Biol. Intelligence, Starnberg, Germany

Abstract: Zebra finches are highly vocal and engage in vocal turn-taking when interacting with social partners. The cortical premotor nucleus HVC has been associated with the context-dependent control of vocal timing during these interactions. Additionally, zebra finches are capable of differentiating calls from multiple individuals, and vocal exchanges most often occur between bonded partners, even within a group of calling birds. To regulate call production with respect to the heard calls of particular conspecifics, the vocal motor pathway must integrate relevant information about incoming auditory signals. We have previously reported that HVC interneurons in particular exhibit a variety of auditory-evoked activity patterns in response to call stimuli. However, it is unclear whether HVC activity is differentially affected by the calls of different birds. Here, we investigate the auditory influences on neural activity in HVC by performing high density Neuropixels probe recordings while awake birds listen to playbacks of calls from a cage mate and an unfamiliar conspecific. The study aims to characterize the patterns of HVC neural activity in response to acoustically similar stimuli that differ in behavioral relevance. To achieve a fine-grained temporal decomposition of auditory evoked neural patterns, clustering algorithms were used, and the activity during the presentation of different stimuli was compared. Results demonstrate various characteristic firing patterns of HVC neurons when calls are heard. These patterns are often shared for similar call types, produced by different individuals, however some neurons exhibit caller-specific activity, evidencing two different

coding strategies in HVC. These results suggest a mechanism by which caller-specific and caller-invariant representations can influence vocal responses during interactions. In sum, heterogeneous call-evoked activity patterns in HVC demonstrate the integration of behaviorally relevant auditory information in this premotor vocal area. The identification of these patterns will enable further investigation into how they influence premotor activity in the vocal-motor pathway and subsequent vocal responses.

Title: Inter-individual differences in linked vocal phenotypes

Authors: *E. SCHUPPE[1,2], D. METS[3], K. J. LI[2], M. BRAINARD[2];
[1]Ctr. for Integrative Neurosci., UCSF, San Francisco, CA; [2]UCSF/HHMI, San Francisco, CA; [3]UCSF/HHMI, Berkeley, CA

Abstract: Many organisms use suites of tightly linked behaviors to navigate diverse social interactions, with individuals often exhibiting different behavioral tendencies. Although it is increasingly appreciated that phenotypes are organized as suites of behaviors that change together, the genetic and neural mechanisms that shape linked behavioral phenotypes remains unknown. Here, we use the Bengalese finch (BF; *Lonchura striata domestica*) to investigate whether multiple vocal traits exhibit such linked co-variation across individuals. Songbirds have been widely studied because they learn to produce songs in a way that is similar to how humans acquire speech. However, they also exhibit other distinct vocal phenotypes, including both learned and innate ‘calls’, that can be produced in vocal exchanges resembling conversations. While song is flexibly learned during development, heritable inter-individual differences can shape and constrain the structure of learned song, including the tempo at which syllables are produced (Mets & Brainard, 2018). Since neural circuitry for song and other vocalizations overlaps, and because genetic variation contributing to differences in song tempo might also influence other phenotypes (pleiotropy), we investigated whether inter-individual differences in song tempo were linked to variation in other vocal and behavioral phenotypes.
We found that birds with faster versus slower song tempos also generate call trains with shorter gaps between calls, and respond with shorter reaction times during vocal turn-taking. Moreover, through computer tutoring and cross-fostering, we demonstrated that these linked phenotypes have a strong heritable component. To investigate molecular mechanisms that might contribute

to these differences, we used bulk RNA-seq and spatial transcriptomics to determine whether pre-motor vocal control regions, including HVC and RA, exhibit a transcriptional signature correlated with inter-individual differences in vocal performance. Our preliminary results identified differential expression of genes associated with GABAergic signaling between birds with faster and slower vocal phenotypes. Given that modulation of inhibitory dynamics within pre-motor regions can influence song timing (Isola et al., 2020) and call precision (Benichov et al., 2020), we suggest that genetically driven differences in GABAergic signaling may serve as a pleiotropic mechanism to promote inter-individual differences in multiple aspects of vocal behavior. Together, our findings provide insight into the mechanisms whereby genetic and experiential influences give rise to linked behavioral phenotypes.

Title: Coordination of breathing and calls in Bengalese finches

Authors: *E. KISH, W. H. MEHAFFEY, K. YACKLE, M. S. BRAINARD;
UCSF, San Francisco, CA

Abstract: Vocal communication is crucial for successful social interactions. Vocal turn-taking is an important form of vocal communication in which vocal partners engage in collaboratively coordinated vocal exchanges, such as human conversations. Although conversational response times are usually quite precise, deviations outside of the expected response window can be used to convey nuanced and salient information about the speaker's internal world, whereas unintended deviations lead to miscommunication and social awkwardness. Our ability to exert such temporal control and flexibility in conversations is impressive considering that vocal production relies on patterning respiratory machinery vital for sustaining life that is otherwise controlled by autonomous mechanisms in the medulla. Songbird calls, brief and discrete vocalizations, are also employed with great temporal precision and flexibility during vocal exchanges, providing us with a tractable model system to study how vocal precision is coordinated with breathing. To address this question, we simultaneously recorded audio and respiratory pressure in freely moving male Bengalese finches during spontaneous and antiphonal calling, as well as in head-fixed bird where calls were evoked by electrical stimulation of the midbrain calling nucleus DM. We found that while sound is only produced during expiration,

calls are always preceded by a brief and silent inspiration. Correspondingly, DM stimulation evoked calls were always preceded by a brief inspiration, demonstrating that the call motor pattern begins with an inspiration. Although this initial inspiration can interrupt breathing at any phase, spontaneous calls are more likely to be initiated during inspirations. Congruent with the temporal precision that has been observed during vocal turn-taking, this respiratory gating is overcome during antiphonal calling. Since the vocal forebrain has been shown to shape the timing of response calls, we wanted to test if manipulation of the vocal forebrain could shape calls initiated by DM, which can continue to drive calls even in the absence of input from the vocal forebrain. Pharmacological manipulation of the vocal forebrain could bidirectionally shape the efficacy of DM stimulation in evoking calls, demonstrating the ability of the forebrain to shape and gate reflexive brainstem circuits, which may be crucial for successfully navigating complex and nuanced social environments.

Title: Low-threshold and calcium-dependent potassium currents regulate the intrinsic firing properties of forebrain-projecting HVCRA neurons in zebra finches

Authors: *A. DAOU[1,2], D. MARGOLIASH[2];
[1]Biomed. Engin., American Univ. of Beirut, Beirut, Lebanon; [2]Dept. of Organismal Biol. and Anat., Univ. of Chicago, Chicago, IL

Abstract: In zebra finch, the song system nucleus HVC produces stereotyped instructions leading to precise, learned vocalizations. The HVC contains multiple neural populations, including neurons that project to nucleus RA (robust nucleus of arcopallium; primary motor cortex analog), to Area X (of the avian basal ganglia), to nucleus Avalanche (higher order auditory structure), and interneurons. These four populations exhibit complex patterns of excitatory and inhibitory connectivity, yielding characteristic patterns of neuronal activity both *in vivo* and *in vitro*. Premotor HVC_{RA} neurons play a critical role in orchestrating the neural circuitry that guides the bird's song production. We performed whole cell current-clamp recordings on zebra finch HVC_{RA} neurons in brain slices to examine their intrinsic firing properties, determine which ionic currents are responsible for their characteristic firing patterns, and characterize firing properties of any observed classes of neurons. We show that HVC_{RA} neurons exhibit diversity in their spiking activity when stimulated with current pulses in slices, ranging from transient to stuttering patterns. Simple features of the raw data clearly subdivide the

neurons into two major classes, and a third. Morphological analysis of filled cells independently confirms these categorical distinctions. We developed conductance-based models for the different neurons in each subtype and calibrated the models using data from the slice recordings, yielding mechanistic descriptions of how the interplay of ion currents gives rise to the response properties of each neuronal class. These predictions were then tested and verified in the slice with pharmacological manipulations. The models and the pharmacology highlighted low-threshold potassium currents (D-type Kv1 channel and M-type Kv7 channel) as well as the Ca^{2+}-dependent K^+ current in driving the characteristic neural patterns observed in HVC_{RA}. The relative strengths of different currents give rise to the physiological features observed across the three classes of HVC_{RA} neurons. The data suggest that the intrinsic properties for one of the HVC_{RA} subtypes exhibit a within-bird homogeneity and across-birds heterogeneity, suggesting a role of learning in shaping the firing properties of this class of neurons. These results begin to establish a mechanistic basis for examining much debated circuit and network properties of HVC_{RA} neurons.

Title: Emergence of crystallized neural patterns during vocal learning

Authors: L. M. PASCUAL, S. J. SOBER;
Biol., Emory Univ., Atlanta, GA

Abstract: Learned motor skills are essential to everyday function. Skill learning involves repeated practice of motor acts, a process which requires the brain to integrate sensorimotor feedback to refine behavior until consistent high levels of performance is achieved. Young songbirds undergo this process whereby its undifferentiated, babbling-like vocalizations develop into categorical vocalizations (syllables) which form a highly precise and stereotyped crystallized song that mimics the song of its adult “tutor”. During this long period of motor skill acquisition, neural activity patterns are reshaped; however, it remains poorly understood how

changes in neural activity patterns enable skill learning. To examine whether and how the neural control of song vocal behavior changes during the process of song acquisition, we recorded spiking activity from individual units in the premotor nucleus of the arcopallium (RA) in Bengalese finches across song development and quantified changes in the neural vocabulary (the unique spike patterns produced) as well as in the motor code (how spike patterns influence behavior). Our chronic neural recordings span multiple weeks of vocal learning in individual animals, which we then examine with novel mathematical tools. This unique approach advantages us with new insights into the individuality of motor codes used across animals as well as changes in motor codes within animals during skill learning. Our preliminary results show changes in the statistics of spike pattern vocabularies as song syllables mature and diverge into acoustically distinct syllables. We also ask whether and how the timescale of motor coding changes during learning -that is, whether developing song is impacted by variations in spike patterns on the scale of 1-millisecond, as it has been demonstrated in adult song, or by variations on slower timescales. Furthermore, we examine whether changes in the motor code is dissociable, even at the level of a single neuron's activity, into factors like age and amount of sensorimotor practice. Broadly, our study provides a framework for investigating how transformations in spike patterns drive learning across different species.

Title: Lesions of pallial nucleus mMAN increase variability in birdsong syntax

Authors: *A. KOPARKAR[1], T. L. WARREN[2], J. D. CHARLESWORTH[2], S. SHIN[2], M. S. BRAINARD[2], L. VEIT[1];
[1]Inst. for Neurobiology, Univ. of Tuebingen, Tuebingen, Germany; [2]Dept Physiol., UCSF Ctr. For Integrative Neurosci, San Francisco, CA

Abstract: Complex motor skills such as speech and dance are composed of ordered sequences of simpler elements, but the neuronal basis for syntactic ordering of individual actions into sequences is poorly understood. Birdsong is a learned vocal behavior composed of syntactically ordered sequences of individual elements called syllables. Song premotor nucleus HVC has been linked to the control of syllable sequencing, but its role has primarily been studied in the zebra finch (ZF), a species with highly stereotyped syllable sequencing (Vu et al. 1994, Long & Fee

2008), and little is known about how the complex and variable sequencing of syllables in other species is controlled. In Bengalese finches (BFs) and canaries, unique patterns of HVC neural activity can encode the variable sequential context of syllables (Fujimoto et al. 2011, Cohen et al. 2020), but the extent to which the sequencing of these patterns reflects the internal neural dynamics of HVC (Zhang et al. 2017) or is shaped by recurrent inputs to HVC (Hosino & Okanoya 2000) is poorly understood. One major recurrent input to HVC is nucleus mMAN, which is thus well-positioned to influence patterned activity in HVC and syllable sequencing. Previous studies found that lesions of mMAN had little effect on the stereotyped sequencing of adult ZF song (Foster & Bottjer 2001, Horita et al., 2008), but we reasoned that any contributions of mMAN to sequencing might be better revealed in birds with more complex syntax. We therefore assessed the effects of bilateral mMAN lesions on the variable songs of adult BFs (Lonchura striata domestica). The syntax of BF song includes several patterns: 1) chunks, where syllables follow stereotypical order 2) branch points, where a given syllable can be followed by two or more different syllables in a probabilistic manner and 3) repeat phrases, where an individual syllable is repeated a variable number of times. We found that after lesions of mMAN, the acoustic structure of syllables remained intact, but sequencing became more variable for each of these patterns; chunks developed 'breaks' in which previously stereotyped sequences could be interrupted by novel transitions, branch points exhibited increased variability, quantified as increased transition entropy, and repeat phrases became more variable in the number of syllable repetitions. These results demonstrate that mMAN contributes to variability of syllable sequencing in the BF and highlight the potential importance of regions projecting to HVC in the ordering of vocal elements. More broadly, they indicate the utility of species with more complex song syntax in investigating neural control of motor sequences.

Title: Transformation of premotor neural activity and respiratory pressure during the repetition of introductory notes in the male zebra finch

Authors: D. RAO[1], R. P R[2], S. KALRA[1], S. CHOROL[2], M. UPADHYAYA[2], A. DUTTA[2], S. CHITNIS[3], ***R. RAJAN**[2];

Abstract: The song of the adult male zebra finch is a well-studied example of a learned movement sequence. Song consists of a stereotyped sequence of sounds interleaved by silent gaps and is controlled by the sequential and precise bursting of premotor neurons. This bursting activates vocal and respiratory muscles ensuring perfect coordination between respiration and vocalization during song production. Song bouts begin with the repetition of a variable number of short sounds, called introductory notes (INs), before actual song production. Compared to song syllables, INs have more variable gaps between them and more variable acoustic properties. This variability reduces as song approaches, with the last IN representing a more stereotyped "state" compared to the first IN in a song bout. This suggests the possibility that INs reflect a "preparatory" phase that drives respiratory and vocal coordination. To test this hypothesis, we first characterized neural activity in awake, singing zebra finches. In premotor nucleus HVC, putative interneurons (n=13 from 2 birds) and HVCX-projecting neurons (n=12 from 2 birds) showed complex IN-related activity patterns. Some neurons were active only before the last IN, while others were active for combinations of INs (all but the first or all but the last). As a population, this data suggests that different overlapping subsets of HVC neurons are active for each of the INs. Activity during the silent gaps between INs did not show correlations with the length of the gap. In a separate set of birds, multi-unit recordings (n=15 sites from 3 birds) from downstream motor nucleus RA showed equal activity for each IN. Finally, to determine whether the coordination between respiration and vocal production changes, as INs repeat, we are currently recording respiratory pressure changes in awake, singing, male zebra finches. Overall, our preliminary results suggest a reconfiguration of the HVC network during INs, possibly reflecting a switch towards the sequential and precise bursting that is necessary for song production.

Title: Female vocal feedback promotes song learning in juvenile zebra finches

Authors: *L. BISTERE[1], C. M. GOMEZ-GUZMAN[1], Y. XIONG[2], S. WILCZEK[1], D. VALLENTIN[1];
[1]MPI For Biol. Intelligence, Seewiesen, Germany; [2]Univ. of Tübingen, Tübingen, Germany

Abstract: Social interactions promote vocal learning but little is known about how social feedback affects the vocal learning process and its underlying neural circuitry. To address this issue, we explored song imitation in juvenile zebra finches raised either in the presence or absence of females providing vocal feedback. We found that male zebra finches raised with a female copied the spectral and temporal features of the tutor song more accurately than compared to birds, that were raised socially isolated. To explore whether female zebra finches provide juvenile males with vocal feedback during song practice, we tracked vocalizations emitted by female birds with a small microphone attached to the back of the female. Females emitted more calls as young birds improved their song performance, indicating that females can provide practice-specific feedback. To decipher whether female vocal feedback has an impact on the neural activity within the song learning pathway, we performed intracellular recordings in HVC, a premotor area involved in song learning and production, in singing and listening zebra finches. In juvenile zebra finches, we found that female vocalizations can modulate neural activity in HVC during passively listening and singing. In contrast, in singing adult zebra finches female calls do not have an impact on the song-related neural activity pattern. Interestingly, we found female call-evoked responses outside of the context of singing to persist after development suggesting an age-independent mechanism for the representation of behaviorally relevant vocal feedback. These results highlight the contribution of female vocal feedback to developmental song learning and how vocal input other than the tutor song can influence the neural circuit involved in song learning and production.

Title: Characterizing auditory responsivity in female zebra finch HVC

Authors: *A. SAVOY[1], D. MARGOLIASH[2];
[1]Univ. of Chicago, Chicago, IL; [2]Organismal Biol. and Anat., Univ. of Chicago Dept. of Organismal Biol. and Anat., Chicago, IL

Abstract: The zebra finch is a champion species of vocal learning and production, with males producing highly precise songs and females evaluating individual differences in male singing. The foundation of male song includes auditory learning early in development and auditory

feedback-mediated sensorimotor learning during development that extends into adulthood. Studies in females, who do not sing, have demonstrated their extraordinary auditory perception abilities as adults, as well as their sensitivity to developmental auditory experience and social context. Many studies in males have focused on sensorimotor area HVC, which expresses state-dependent higher-order song-related auditory responses. Despite the much smaller volume of female zebra finch HVC as compared to males, recent evidence shows robust anatomical connectivity between HVC and other "song system" areas in females. We hypothesize that this circuitry is involved in female auditory processing, song evaluation, and call interactions, which has been investigated only in very few studies. Our study aims to characterize the auditory responsivity of HVC in female zebra finches when exposed to male vocalizations. To date we have used Neuropixels probes for high-density extracellular recordings in HVC of awake female zebra finches. Birds were exposed to a variety of male vocalizations, as well as to artificial sounds such as noise bursts and other stimuli. Our data indicate that female HVC exhibits distinct neural responses to specific male songs or calls. Preliminary data indicate that the response patterns implicate involvement of HVC in the nuanced perceptual discrimination capability that female zebra finches are known to possess, with varying responsivity depending on her familiarity with the stimulus and relationship to the male. These findings potentially offer new insights into the role of HVC in female auditory perception and contribute to our understanding of the neural bases of social communication and mate choice.

Title: Vocal representation of acoustic features in a budgerigar forebrain motor area

Authors: *Z. YANG[1], M. A. LONG[2];
[1]New York Univ. Langone Med. Ctr., New York, NY; [2]NYU Sch. of Med., New York, NY

Abstract: Parrots have extraordinary vocal mimicry abilities, yet the neural mechanisms responsible for effectively reproducing sounds with diverse acoustic qualities remain unclear. Here we investigate neural dynamics underlying vocal production in the budgerigar, a highly social parrot species. We use high-density silicon probes to record vocalization-related activity from neuronal populations in the central nucleus of the anterior arcopallium (AAC), a forebrain motor region that directly projects to brainstem phonatory motoneurons. We found that AAC neurons demonstrate robust and consistent network activity associated with both stereotyped contact calls and flexible warble songs produced during social interactions. Furthermore, AAC

activity exhibits a distinct neural signature that aligns with the complex acoustic structure presented in warble songs. Budgerigar songs are characterized by large variations in fundamental frequency (i.e., pitch) and spectral entropy (i.e., the level of "noisiness"). We found a substantial proportion of AAC neurons that were strongly tuned to these parameters. We observed a high degree of heterogeneity across the population, with individual neurons exhibiting maximal responses to different values of these features. We used a principal component analysis to examine population activity and found a strong gradient of fundamental frequency and spectral entropy along the axes corresponding to the first and second principal components, respectively. These results indicate that AAC encodes acoustic features controlling vocalization quality, resembling the representation of vocal articulation and pitch in the human speech motor cortex and potentially contributing to their exceptional vocal mimicry abilities.

Title: Transient connection from tutor-song-responding neurons in NCM to HVC disappears at the end of the critical period

Authors: *J. A. KOMOROWSKA-MULLER, Y. MOROHASHI, Y. YAZAKI-SUGIYAMA; Neuronal Mechanism for Critical Period Unit, Okinawa Inst. of Sci. and Technol., Tancha, Japan

Abstract: Similarly to human infants, juvenile zebra finches learn to vocalize by memorizing their tutor's song and then matching their own vocalizations to the memorized template via auditory feedback during the developmental critical period. We previously identified neuronal substrate of tutor song memory in the avian analog of secondary auditory cortex, the caudomedial nidopallium (NCM)(Yanagihara and Yazaki-Sugiyama, 2016). Recently, we uncovered a developmentally transient projection from the tutor song-responding cells in NCM to the song premotor area, HVC. We labeled the tutor song-responding cells with GFP using the neuronal activity-dependent AAV (AAV9-cFos-TetON-EGFP) and tutor song playback. The NCM-HVC projection was present in juvenile birds, but not in adult birds suggesting its potential role in song learning (Louder et al., in submission). Here, we further investigated the developmental timeline of NCM-HVC projection and disconnection. We found a decrease in the density of projections to HVC in juveniles at the end of sensorimotor learning (80 days post hatch (dph)) in comparison to the juveniles within sensorimotor learning (60 and 70 dph). In contrast, we found no difference in the number of projections to other brain areas, such as HVC

shelf, AIV, CMM and Area X. Furthermore, we found that the timing of the decrease in NCM-HVC projections coincided with song maturation. Taken together, the dynamic interareal neuronal disconnection between zebra finch auditory and motor cortex is potentially shaping the developmental auditory memory-guided song learning.

Title: Molecular profiles of auditory tutor song memory neurons, transiently projecting to song premotor area in zebra finches

Authors: Y. MOROHASHI[1], N. TOJI[2], Y. GO[3], K. WADA[2], *Y. YAZAKI-SUGIYAMA[1]; [1]Okinawa Inst. of Sci. and Technol. (OIST) Grad. Univ., Okinawa, Japan; [2]Biol. Sci., Hokkaido Univ., Sapporo, Japan; [3]Grad. Sch. of Information Sci., Univ. of Hyogo, Kobe, Japan

Abstract: Like human infants learning to speak, juvenile male zebra finches learn to sing by forming auditory tutor's song memories and then vocally matching to establish their stereotyped own song in sequentially well-orchestrated auditory then sensorimotor developmental learning periods. However, neural mechanisms supporting auditory memory-guided sensorimotor learning have remained elusive. Recently, we revealed neuronal projections into the song premotor region, HVC from distinct neuronal memory ensembles of a tutor's song in the auditory forebrain area, caudomedial nidopallium (NCM) during (~60 days post hatch (DPH)), but not after (> 100 DPH) the sensorimotor learning period by employing a novel activity-dependent adeno-associated viral expression system in zebra finches, implying roles of transient NCM-HVC projections for developmental song learning and subsequent crystallization. Here, we performed single-nucleus RNA sequencing (snRNA-seq) analysis to elucidate underlying molecular mechanism of transient projections of auditory memory NCM neurons to HVC. Tutor-song responding NCM neurons were labelled by using the AAV vector AAV-cFos-TetON-EYFP-PEST, which express EYFP with an activity dependent cFos promoter combined with a tutor song stimulation, and their nuclei were collected from male zebra finches at different developmental stages. Gene expression profiles were compared between YFP-positive tutor-song

responding neurons and other EYFP-negative neurons in the NCM. Post mRNA-sequencing analysis using Seurat revealed EYFP mRNA positive tutor song responsive neurons within 2/2 neuronal clusters expressing VGLUT2 mRNA and 3~5/8 neuronal clusters expressing GAD1 mRNA both in zebra finches at 60 DPH and > 100 DPH. We further found synaptic adhesion and vesicle trafficking molecules, such as NRCAM, ADGRB3/Bai3, Rab33B, TBC1D22B and DENND2A, from the list of differentially expressed genes (DEGs) in VGLUT2 positive excitatory neurons in zebra finches at 60 DPH. Taken together, these results suggest that expression changes in synaptic connection and membrane trafficking molecules mediate dynamic remodeling of intercortical auditory-motor projections in the developmental sensorimotor learning period.

Title: A generative model of neuron migration in adult songbird HVC

Authors: *S. ANALOUI[1], N. R. SHVEDOV[2], B. B. SCOTT[1];
[1]Psychological and Brain Sci., Boston Univ., Boston, MA; [2]Boston Univ., Boston Univ. Grad. Program For Neurosci., Boston, MA

Abstract: Songbirds add new neurons to brain circuits, such as the song nucleus HVC, throughout their lifetimes. New neurons are born in the ventricular zone (VZ) and migrate hundreds of microns to their integration targets throughout the forebrain, including HVC, over the span of weeks. Previous in vivo imaging studies have revealed that adult-born neurons in HVC exhibit a form of diffusive migration where cells move in all directions and make frequent turns. Here we design a computational model of neuron migration in the HVC to assess the consequences of this type of motion. Our model assumes an independent stochastic migration process wherein 3D movement is generated in a series of steps each representing 10 minutes. Cells are born in random locations along a 2D plane representing the VZ and have their migration simulated via random draws from probability distributions derived from in vivo tracking data. HVC is represented as a 1 mm diameter sphere intersected by the VZ plane. We ran our simulation for up to 40 days, the maximum duration of migration identified in previous literature (Alvarez-Buylla & Nottebohm 1988). This model successfully recapitulated multiple features of in vivo cell migration with simulated cells having highly similar tortuosities and levels of disorderedness as tracked cells. After 21 days cells migrated an average of 365 μm, covering the distance between the VZ and the center of HVC. After 40 days of migration, simulated cells traveled an average of 530 μm and up to 1.96 mm away from the VZ. These

results suggest that this form of diffusive migration is sufficient to fill the entirety of HVC but insufficient to generate regions that lie farther than ~2 mm from the VZ. These results are consistent with a potential model in which alternative forms of migration exist outside of HVC that enable cells to travel long distances and reach integration sites far from the VZ that diffusive migration alone cannot achieve. Furthermore, this model can be used to make specific quantitative predictions regarding the outcomes of migration of newborn cells that can be tested experimentally.

Title: Benchmarking neural network models for acoustic behavior with vak and VocalPy

Authors: *D. A. NICHOLSON[1], Y. COHEN[2];
[1]Emory Univ., Baltimore, MD; [2]Weizmann Inst. of Sci., Weizmann Inst. of Sci., Rehovot, Israel

Abstract: To understand the neural bases of how animals communicate with sound, we need detailed quantification of this behavior. Recently, deep neural network models have emerged as promising tools for quantifying behavior. We previously presented TweetyNet, a neural network that automates segmentation and annotation of birdsong for downstream analyses, such as fitting statistical models of motor learning or song syntax. To enable researchers to easily work with TweetyNet and other deep neural network models for acoustic behavior, we developed a framework in Python, vak (https://github.com/vocalpy/vak). Additionally we have developed a core Python package for this research community, VocalPy (https://github.com/vocalpy/vocalpy) with the goal of making code more readable and reusable. Here we report on further studies of TweetyNet and other neural network models, using these Python libraries. We show that we can reduce the segment error rate of TweetyNet by an average 3.13% on a benchmark dataset of Bengalese finch song (https://nickledave.github.io/bfsongrepo/), without post-processing steps for clean up. (Segment error rate is analogous to the word error rate used in automatic speech recognition.) We achieve this by training TweetyNet on entire bouts of song instead of random time windows. We also extend previous work from others that used TweetyNet to segment birdsong into two classes, syllables and silent gaps, without assigning labels to the different syllables types. In this binary classification setting, models trained on 900 seconds of song from the same benchmark dataset achieve a 1.9% average segment error rate. We compare this result to off-the-shelf algorithms for segmenting audio, using VocalPy. Additionally we will present results from experiments in progress benchmarking other neural network models for audio segmentation, and demonstrating how vak can speed up training using transfer learning methods.

These results show how vak and VocalPy can support the research community investigating how the brain controls acoustic behavior.

Title: High frequency vocalizations of black jacobin hummingbirds show annual shifts suggestive of learning

Authors: *C. OLSON[1], C. V. MELLO[3], C. DUCA[4], M. DA SILVA[5], S. RODRIGUES SILVA[4], M.-Q. TRAN[2];
[1]Dept. of Physiol., [2]Midwestern Univ., Glendale, AZ; [3]Dept. of Behavioral Neurosci., Oregon Hlth. and Sci. Univ. Sch. of Med., Portland, OR; [4]Pontifícia Univ. Católica de Minas Gerais, Belo Horizonte, Brazil; [5]Univ. Federal do Pará, Belém, Brazil

Abstract: Black jacobins are a basal lineage hummingbird species of the Topaz clade from the Brazilian Atlantic Forest. This species coexists with 40 other species/subspecies of hummingbird, as well as a rich community of songbirds and vocalizing mammals. We previously reported on black jacobin's high frequency vocalizations of a mean fundamental frequency of 11.5 kHz, with oscillations up to 14 kHz and no sounds below 10 kHz (Olson et al., Curr Biol, 2016). This vocal range is well above the known limit of avian hearing (up to 8-9 KHz),

challenging a conventional belief that avian communication is limited to low frequencies. Analysis of recent recordings and behavioral observations at our field site (Sta. Teresa, ES, Brazil) in 2019 and 2022, in comparison with the published data from 2015/16, now provide further insights into the behavioral ecology context and variations of this unique avian vocalization. We found that these vocalizations are predominantly directed to other black jacobins at short distances during inflight displays, and not towards other hummingbird species, but black jacobins will also produce them while perched in a non-directed manner. Interestingly, a 3-syllable utterance with a characteristic syllable duration and acoustic structure was the predominant vocalization in the population at our study site in 2015, occurring ~71% of the time. By 2016 we noted an increase in a 2-syllable vocalization type. In 2019 the 3-syllable type occurred in only ~15% of the recordings, and by 2023 they were completely absent, replaced by the 2-syllable song type. In addition to this shift from 3 syllables to 2 syllables, the mean syllable durations increased by 20% from 2015 to 2022. Sample recordings from several birds in captivity in 2022 revealed that that individual birds have a single song type with consistent within-individual acoustic features, allowing for the possibility of individual recognition. We also found conclusive evidence that vocalizations are produced by both sexes and juveniles. These observations support the notion that the black jacobin's high-frequency vocalizations evolved as an exclusive communication channel, and provide strong suggestive evidence that these vocalizations are learned. They also set the stage for more extensive investigation of the acoustic biology of this species, and present a valuable tool for future research on vocal communication in complex environments.

Title: A neural circuit model of reinforcement learning in songbird

Authors: *Y. WANG[1], J. KORNFELD[2], M. S. FEE[3], M. S. GOLDMAN[4];
[1]UC Davis, Davis, CA; [2]Max Planck Inst. for Biol. Intelligence, Martinsried, Germany; [3]Brain & Cog Sci. / McGovern Inst., Massachusetts Inst. Tech., Cambridge, MA; [4]Ctr. for Neurosci., Davis, CA

Abstract: Reinforcement learning is widely recognized as a biological learning paradigm, but the underlying neural mechanisms are largely unknown. We propose a neural circuit model in songbird that employs policy-based reinforcement learning to guide song learning at a

millisecond timescale. We map the song learning process to a classical reinforcement learning problem known as the two-arm-bandit problem, where the neural circuit makes a sequence of binary action selections directly controlled by neuronal spikes. Our model learns the behavior policy by combining cortico-striatal activity representing action selection and midbrain dopamine signal representing behavior evaluation. During song learning, dopamine has been found to resemble a reward prediction error (RPE) signal. We demonstrate in our model how the RPE-like dopamine signal can be computed in a simple neural circuit and guides direct policy learning. Besides RPE, we propose that an action prediction error (APE) signal, stored as a molecular trace in the cortico-striatal synapse, also supports reinforcement learning in the brain. APE and RPE can be combined to avoid incorrect learning and enhance learning speed. Meanwhile, the sparseness of exploratory actions, a property often overlooked in most reinforcement learning models, plays an important role under accuracy constraints. Furthermore, the biologically motivated APE and RPE learning rules may inspire novel computational algorithms in reinforcement learning.

Title: Weight transfer in the reinforcement learning model of songbird learning

Authors: *K. H. TRAN[1,2], A. KOULAKOV[2];
[1]Neurobio. and Behavior, Stony Brook Univ., Stony Brook, NY; [2]Cold Spring Harbor Lab., Cold Spg Hbr, NY

Abstract: Song learning behavior observed in the songbird system provides a notable example of learning through trial-and-error. We present a computational model of song learning that integrates reinforcement learning (RL) and unsupervised learning (UL) and agrees with known songbird circuitry. The song circuit outputs activity from the nucleus RA, which receives two primary inputs: timing information from area HVC and stochastic activity from the nucleus LMAN. Additionally, song learning relies on Area X, a basal ganglia area that receives dopaminergic inputs from VTA. In our model, song learning begins with the HVC-to-Area X connectivity, employing an RL mechanism that involves node perturbation. This acquired information is then consolidated in the HVC-to-RA weight matrix through a UL mechanism. The transfer of weights from Area X to RA takes place via the thalamus, employing a specific form of spike-timing-dependent plasticity. Thus, we present a computational model in which the optimal policy is initially guided by reinforcement and subsequently transferred to another circuit through Hebbian plasticity.

Title: Growth and Splitting of Sequences in Neural Activity in a Computational Model of Songbird HVC

Authors: *D. SEDERMAN, D. Z. JIN;
Penn State Univ., University Park, PA

Abstract: Zebra finches sing a stereotyped sequence of syllables, with each syllable driven by a distinct sequence of bursting neurons in the premotor nucleus HVC. During development, a single ‘protosyllable’ sequence initially forms before a zebra finch produces multiple syllable types (Okubo et al., 2015). This sequence splits into multiple syllable-specific sequences as the juvenile matures and listens to an adult tutor. The mechanism underlying this splitting is not well characterized. Here we simulated the growth and splitting of sequences in an HVC network as a juvenile zebra finch learns its song. Our computational model has a realistic HVC-sized scale

with over 20,000 HVC neurons simulated using a GPU implementation. Model input from nuclei Uva and Nif spontaneously activates a group of HVC "seed neurons". Immature HVC neurons are recruited to form a feedforward chain network starting from the seed neurons through spontaneous activity, burst-timing dependent synaptic plasticity and axon remodeling. As the immature neurons fire more consistently, they mature and burst with precise trial-to-trial timing. Consistent with previous work, a large single sequence forms among HVC neurons (Tupikov and Jin, 2021). However, as the simulation continues, this sequence splits and distinct burst sequences form within HVC. This occurs with unstructured inputs to HVC neurons that lack any timing or sequence information. As development progresses, neurons belonging to each sequence more strongly inhibit one another via feedback inhibition through interneurons in HVC. This results in the sequences that initially fire simultaneously consistently firing sequentially later in the simulation. We propose this as a model for the formation of distinct neural sequences during songbird development that does not require external timing inputs. Unstructured input is sufficient to trigger networking wiring and splitting into neural sequences within HVC.

Title: Songbird motor cortex analogue neurons utilize specialized Nav and Kv3 channels to generate fast spiking: Computational modeling of ultra-narrow and energy-efficient action potentials

Authors: *L. E. S. TAVARES[1], B. ZEMEL[1], H. VON GERSDORFF[1,2];
[1]Vollum Institute, OHSU, Portland, OR; [2]Oregon Hearing Res. Center, OHSU, Portland, OR

Abstract: In songbirds, the robust nucleus of the arcopallium (RA) is a distinctive brain area of the song system dedicated to vocal motor control during singing behavior. Projection neurons in RA (RAPNs) provide the sole descending vocal-motor output to the brainstem and orchestrate moment by moment complex acoustic features of the song. RAPNs exhibit continuous and spontaneous firing of spikes during periods of silence (~40 Hz) and high-frequency burst-pause firing during song production. Being essential for courtship behavior, birdsong imposes significant temporal and energetic constraints on RAPNs. For instance, in whole cell recordings in slices at physiological temperatures (40o Celsius in birds), RAPNs fire ultranarrow action potentials (APs) of 0.16 ms halfwidth and can sustain high frequency firing with little adaptation during current injection. These properties are supported in part by the high expression of fast-

gating, high-threshold Kv3 channels in conjunction with fast-gating Nav1.6, which contribute, respectively, to high depolarization and repolarization rates during AP generation (Zemel et al, 2021, 2023). Based on these observations, we developed a detailed Hodgkin-Huxley conductance-based model of RAPNs in slices at 40oC. In our model, fast transient Na+ and high-threshold K+ gating coordinate to drive ultranarrow and fast APs. We observe that the fast kinetics of activation and inactivation of Na currents and the fast activation and deactivation kinetics of Kv3 channels also helps in diminishing the excess of Na+ influx during APs by reducing the temporal overlap between voltage-gated K+ and Na+ currents. We propose that this property may be used by RAPNs to reduce the metabolic cost of fast spiking. Indeed, the RA of adult male zebra finches is marked by high expression of cytochrome oxidase, an enzyme involved in ATP production in the mitochondria (Adret & Margoliash, 2002). Our RAPN computer model represents a new tool for understanding how RA supports birdsong behavior and provides insights for future experiments.

Title: Decision-making mechanism of songs in zebra finches by using song as a reward.

Authors: *M. IWASAKI[1], S. NOGUCHI[3], M. INDA[4], K. HOTTA[3], K. OKA[2,5];
[2]Dept Biosci. & Informatics, [1]Keio Univ., Yokohama-city, Japan; [3]Keio Univercity, Yokohama-city, Japan; [4]Fakultät für Psychologie, Ruhr-Universität Bochum, Fakultät für Psychologie, AE Biopsychologie, Bochum, Germany; [5]Kitasato Univ., Sagamihara-city, Japan

Abstract: The male zebra finches (Taeniopygia guttata) sing courtship songs to the females. The courtship song differs among individuals; females identify each song and make a pair with the male singing their preferred song. The song preferences of females have been investigated in many previous studies (Riebel, 2000; Riebel et al., 2002; Le Maguer et al., 2021), and in operant conditioning behavioral experiments, females were observed to repeatedly listen to their favorite songs (Rodríguez-Saltos et al., 2023). This indicates that listening to songs is rewarding. Previous studies on song discrimination have also shown that when females are asked to discriminate between two songs, they showed as high as 80% of the responses correct (Nagel et al., 2010; Paul et al., 2021). However, the remaining 20% were found to be incorrect, because of hearing and responding to only the beginning part of the song. We hypothesize that songbirds listen to only the first part of a song, and it can lead to misidentification of the song. Based on the above facts, we constructed an experimental system to measure preference by song rewards, and analyzed the order of songs heard with a Markov chain model in female zebra finches. We considered three types of states in the state transition diagram. The single Markov model shows

the bird selects the next song according to the only previous one, the dual model is the type of song selection it had heard on the two previous trials, and the triple model is the type of song selection it had heard on the three previous trials. By comparing the goodness of fit to the results of simulations with these three models to the raw data, we revealed differences among the models. We also examined the possibility that birds' song discrimination may include a prediction by mixing two courtship songs in the measurement of preference at the top of discrimination and by using stimuli that change in steps. If there is the prediction, the bird's behavior should initially be the same as when it heard the original song, but as the song stimulus changes and gradually resembles to the mixed song, it should behave the same as when it heard the mixed song. We tested this hypothesis in a preference experiment.

Title: Sensorimotor development in rodent neonates exposed to the clinically relevant synthetic progestin, 17-α-hydroxyprogesterone caproate (17-OHPC)

Authors: ***P. L. GRANEY**, J. MILLER, E. SARNO, C. K. WAGNER;
Univ. At Albany, Albany, NY

Abstract: 17-OHPC is commonly prescribed to individuals at risk for recurrent preterm birth. 17-OHPC was detectable within cord plasma of neonates up to 44 days after the maternal treatment, suggesting that the fetus is exposed to 17-OHPC in utero. Yet, little is known regarding the long-term effects of 17-OHPC on neural and behavioral development in children. The timing of 17-OHPC administration coincides with a period of cortical maturation. In rodents, neural maturity during the first postnatal week is comparable with human fetal neural development at term. Thus, administration of 17-OHPC in rodents during the first postnatal week can be used to model the effects of 17-O HPC on cortical development in humans. Progesterone receptor (PR) is expressed in virtually all functional regions of developing cortex including within subplate (SP) of somatosensory and motor cortex (E18-P10). Disruption to thalamocortical innervation of SP of somatosensory cortex is associated with deficits in sensorimotor behavior. PR knock-out mice (PRKO) demonstrated irregular loss of a sensorimotor-dependent behavior, rooting reflex. These data suggest that cortical development and behavioral indicators of normal nervous system development, such as sensorimotor behavior, may be sensitive to neonatal exposure to 17-OHPC. Therefore, it was hypothesized

that 17-OHPC exposure during development alters sensorimotor behavior development. There was a significant main effect of treatment, sex, age, and a day by treatment interaction ($p = 0.003$) on body weight with 17-OHPC exposed rats weighing significantly more than control rats of the same sex. Preliminary data also suggest a significant effect of treatment at postnatal days 3 and 4 on surface righting (P3: $\chi^2 = 30.392$, P4: $\chi^2 = 7.799$) and forelimb grasping (P3: $\chi^2 = 14.545$, P4: $\chi^2 = 9.468$) with a greater proportion of 17-OHPC-exposed rats successfully righting and successfully grasping with the forelimbs. 17-OHPC exposed rats has a shorter latency to surface right at P3. However, on P5 a greater proportion of oil-treated rats demonstrated successful righting ($\chi^2 = 9.013$). There was also a significant effect of treatment on hindlimb grasping at P5 ($\chi^2 = 8.720$), P7 ($\chi^2 = 16.707$), P8 ($\chi^2 = 12.029$), P10 ($\chi^2 = 18.357$), and P11 ($\chi^2 = 7.292$) with a greater proportion of oil-treated rats demonstrating partial or successful hindlimb grasping when compared to 17-OHPC-exposed animals. Results from this study demonstrate a novel effect of neonatal 17-OHPC exposure on behavior dependent on sensorimotor development and suggest that neonatal PR activity may regulate aspects of cortical development necessary for the expression of normal sensorimotor behaviors.

Title: Hunting a chimera: In pursuit of an elusive Nsmf transcript

Authors: *H. BOW[1], ***H. BOW**[2], D. C. JACOBS[2], J. SHORT[2], S. M. FARMER[2], S. WRAY[2]; [1]NINDS, Washington, DC; [2]NINDS, Bethesda, MD

Abstract: Gonadotropin-releasing hormone (GnRH) is essential for neuroendocrine control of reproduction. During embryogenesis, GnRH neurons migrate from nasal areas to the forebrain along olfactory sensory/vomeronasal axons. This migration is guided by many cues, and mutations in associated genes have been shown to prevent successful migration of GnRH neurons into the forebrain, resulting in reproductive disorders. NMDA receptor synaptonuclear signaling and neuronal migration factor (Nsmf) is one potential migratory factor. Nsmf is expressed by migrating GnRH neurons, and mutations in the Nsmf gene have been implicated in idiopathic hypogonadotropic hypogonadism (IHH). However, since its discovery in 2000, the expression and role of Nsmf have been the subject of conflicting reports. It was initially described as a membrane-bound migration cue but has since been well-documented as a synaptonuclear transcription factor. The latter role is supported by a nuclear localization signal and lack of a transmembrane domain on the Nsmf transcript. Additionally, discrepancies have been reported in knockout mice. One line showed decreased numbers of GnRH cells postnatally, pubertal delay, and subfertility, while another line exhibited normal fertility and no change in

GnRH cell number. Searching mammalian protein databases, we identified a novel chimeric protein that incorporated amino acids from Nsmf and a neighboring gene, ENTP8. We found that this novel chimeric gene product (Nsmf/Entpd8) is present in cDNA made from E11.5 mouse embryo nasal tissue, and we are currently investigating the expression of this transcript in migrating GnRH neurons. This chimeric transcript lacks a nuclear localization signal but has a transmembrane domain that accounts for the membrane localization initially observed. In addition, an alternative transcription start site has been identified. As such, this chimeric transcript may underlie the discrepancies reported in the two knockout mice lines. These results highlight the complexities of unraveling the role of genes in physiological processes and the importance of deciphering the genetic basis of variants in human disorders.

Title: Head color morph and sex-specific differences in follistatin gene expression in the Gouldian finch brain

Authors: *C. ZHAO[1], F. MADISON[2];
[2]Integrative Biol., [1]Univ. of Wisconsin-Madison, Madison, WI

Abstract: Simple genetic variation and differential gene expression have been tightly linked to differences in behavioral phenotypes, endocrine physiology, and reproduction. The Gouldian finch (*Erythrura gouldiae*) demonstrates a head color polymorphism that is tightly coupled to marked differences in aggression, parental care, immune, and stress responses. Red-headed males are neophobic, aggressive, and exhibit higher levels of testosterone (T) and corticosterone (CORT) in socially competitive environments, while black-headed males are neophilic, passive, but T and CORT remain unaltered. This head color polymorphism has been associated with genetic variation in a small non-coding region upstream of the follistatin (FST) gene. FST is a single-chain gonadal protein that is implicated in a variety of endocrine, physiological, and behavioral processes, including regulation of energy metabolism, gonadal function, stress response and anxiety-related behavior. We hypothesized that the FST gene would be differentially expressed in association with morph and sex-specific differences in the brain between male and female red-headed and black-headed morphs. To test this hypothesis, we examined FST gene expression in brain regions known to be involved in aggression, stress responses, and parental care using RNAscope in situ hybridization assay. We found that FST

mRNA was heterogeneously distributed in the Gouldian finch brain with the most abundant expression in the ventromedial hypothalamic nucleus (VMH) and the lateral part of the hypothalamic paraventricular nucleus (PVNL). Importantly, we observed that FST gene expression differed significantly between morphs and sex. Specifically, mRNA levels of FST were higher in the VMH, PVNL, medial bed nucleus of stria terminalis (BSTM), lateral bed nucleus of the stria terminalis (BSTL) and nucleus of the hippocampal commissure (nHpC) in black-headed males and females than those in red-headed males and females. Furthermore, in all these regions within the same morph type, male finches displayed greater levels of FST mRNA relative to females. Taken together, our findings suggest that head color morph and sex-specific differences in FST gene expression in the Gouldian finch brain may contribute to the morph and sex-specific differences in aggression, stress responses, and parental care.

Title: Kisspeptin cell-type and fiber projection analysis reveals its potential role on central sensorial processing and behavioral state control

Authors: *L. ZHANG[1], V. S. HERNÁNDEZ[1], M. A. ZETTER[1], L. E. EIDEN[2];
[1]Natl. Autonomous Univ. of Mexico, Mexico City, Mexico; [2]Section on Mol. Neurosci., NIH, NIMH-IRP, Bethesda, MD

Abstract: Previous chemoanatomical studies on kisspeptin (KP) distribution in rodent brain have focused on hypothalamic regulation of the hypophysial-gonad axis. Here, we examined the chemoanatomical phenotype and fiber distribution of KP neurons in mouse and rat, comparing male and female, and with and without gonadectomy, in order to extend our current knowledge of kisspeptin chemical neuroanatomy, and potential function, to extra-hypothalamic structures. Serial immunohistochemistry sampling and assessment, dual in situ hybridization (DISH), combining mRNA probes for kisspeptin with VGAT, VGLUT2, neurokinin, dynorphin, and tyrosine hydroxylase were used. Eighty-one among the 107 brain regions observed with KP fiber and terminal presence, were identified as extra-hypothalamic, including telencephalic septal, ventral striatal, amygdaloid nuclei and bed nucleus of stria terminalis; diencephalic habenular complex; mesencephalic superior and inferior colliculi, and periaqueductal grey; metencephalic parabrachial nucleus and locus coeruleus; myelencephalic nucleus tractus solitarii (NTS),

reticular formation and the gelatinous layer of spinal sensorial trigeminal nucleus. All of these regions are closely involved in central sensorial processing and behavioral state control. KP glutamatergic (VGLUT2 mRNA-expressing) neurons are mainly located in arcuate nucleus and scattered in the dorsal hypothalamic region from anterior to posterior hypothalamus; KP GABAergic (VGAT mRNA-expressing) neurons are found in the rostral periventricular region, the medial amygdala and the NTS. Some targets of these KP populations were determined based on correlation of anatomical analysis with sensitivity to gonadectomy. This study provides an anatomical basis for further hypothesis generation and testing on KP's role in a wider scope of brain function beyond endocrine regulation located to the hypothalamus. In particular, it draws attention to the remarkable presence of KP projections in central sensory and behavioral state control structures that suggest additional physiological/regulatory roles for kisspeptin.

Title: An excitatory pathway from arcuate Kiss1 neurons to the dorsomedial hypothalamus mediates the melanocortin action on energy expenditure in the male mouse

Authors: *R. TALBI[1,2], T. L. STINCIC[3], E. MEDVE[1,2], K. FERRARI[1,2], C. J. HAE[1,2], K. WALEC[1,2], O. K. RØNNEKLEIV[3,4], M. J. KELLY[3,4], V. M. NAVARRO[1,2];

Abstract: Hypothalamic Kiss1 neurons are essential regulators of reproduction through the direct release of gonadotropin-releasing hormone (GnRH) secretagogue kisspeptin onto GnRH neurons. Kiss1 neurons also control metabolism, as documented by the anorexigenic effect of

kisspeptin in rodents and the obese phenotype of kisspeptin receptor knockout (Kiss1rKO) mice. In the control of energy balance, arcuate (ARC) proopiomelanocortin (*Pomc*) neurons induce satiety and increase energy expenditure (EE) through the direct action on the melanocortin receptor 4 (MC4R). Since POMC neurons have been described to project to Kiss1 neurons, we set out to characterize the role of Kiss1 neurons in the metabolic action of melanocortins. Using RNAscope, we found that *Mc4r* co-expresses with 84% of $Kiss1^{ARC}$ neurons, suggesting that these neurons are direct targets for melanocortins. Indeed, high frequency optogenetic stimulation of $POMC^{ARC}$ neurons elicited a slow inward (excitatory) current in $Kiss1^{ARC}$ neurons that was attenuated in the presence of a MC4R antagonist in both sexes. To assess the role of $Kiss1^{ARC}$ neurons in the metabolic action of melanocortins, we generated a conditional mouse model with a specific deletion of *Mc4r* from Kiss1 neurons ($Kiss1^{cre}$:$Mc4r^{fl/fl}$ mice). $Kiss1^{cre}$:$Mc4r^{fl/fl}$ male mice, but not females, developed obesity under regular chow and high fat diet. Metabolic assessment revealed that $Kiss1^{cre}$:$Mc4r^{fl/fl}$ mice had reduced EE, without changes in overall food intake or activity. The decrease in EE correlated with significantly lower expression of the uncoupling protein 1 (*Ucp1*) gene in the interscapular pad of brown adipose tissue (BAT), suggesting impaired BAT thermogenesis in mutant mice. To further test the role of $Kiss1^{ARC}$ neurons in EE, we chemogenetically activated these neurons in $Kiss1^{Cre}$ het and Kiss1KO males, which led to increased BAT temperature in both models, suggesting that this is a kisspeptin-independent effect. Moreover, we documented that this action is mediated, at least in part, by the dorsomedial hypothalamus (DMH) based on the following evidence: a) Viral tracing revealed that $Kiss1^{ARC}$ neurons innervate leptin receptor (Lepr) expressing neurons of the DMH ($Lepr^{DMH}$); b) the chemogenetic activation of $Kiss1^{ARC}$ neurons induced cfos expression in $Lepr^{DMH}$ neurons; and c) a retrograde tracing approach revealed that these neurons project to the raphe pallidus nucleus (RPa), which is known to regulate BAT activity.
In summary, we have documented that $Kiss1^{ARC}$ neurons mediate the action of melanocortins on EE in male mice through the activation of the dorsomedial pathway that controls BAT thermogenesis.

Title: Lateral septum as a melanocortin downstream site for integrative control feeding behaviors and emotional states

Authors: *Y. XU[1,2], Z. JIANG[3], H. LI[3], J. CAI[3], Y. JIANG[3], J. ORTIZ-GUZMAN[4], Y. XU[4], B. ARENKIEL[4], Q. TONG[3];

Abstract: The melanocortin pathway is well established to be critical for body weight regulation in both rodents and humans. Despite extensive studies focusing on this pathway, the downstream brain sites and underlying mechanisms that mediating melanocortin action on the regulation of feeding and obesity development are still incompletely understood. By using multidisciplinary approaches, we hereby found that, among the known paraventricular hypothalamic (PVH) neuron groups, those expressing melanocortin receptors 4 (PVH^{Mc4R}) preferably project to the ventral part of lateral septum (LSv), a brain region known to be involved in integrating feeding behaviors and the associated emotional status in the state incorporating a choice to get food while exposure to a stressful context. Photostimulation of PVH^{Mc4R} neuron terminals in the LSv reduces feeding and causes aversion, whereas deletion of Mc4Rs or disruption of glutamate release from LSv-projecting PVH neurons both causes obesity. In addition, specific disruption of AMPA receptor but not the NMDA receptor function in PVH-projected LSv neurons causes obesity, and target deletion of GABA release from PVH-projected LSv neurons leads to the rapid development of diet-induced obesity. Importantly, chronic inhibition of PVH- or PVH^{Mc4R}-projected LSv neurons results in the alleviated anxiety-like behaviors and causes obesity associated with reduced energy expenditure. Altogether, our data indicated that the LSv functions as an important downstream node to mediate melanocortin action on feeding/body weight regulation and the integrated emotional states.

Title: Identification of hypothalamic tuberoinfundibular dopamine (TIDA) neurons in the rat by electron microscopy

Authors: *J. FERRARIS[1], V. JUAREZ[2], C. LEIMGRUBER[2], N. SABOUNE[1], J. P. PETITI[2], C. BROBERGER[1];
[1]Stockholm Univ., Stockholm, Sweden; [2]Ctr. de Microscopia Electrónica, Inst. de Investigaciones en Ciencias de la Salud (INICSA-CONI, Facultad de Ciencias Médicas, Univ. Nacional de Córdoba, Cordoba, Argentina

Abstract: The neuroendocrine TIDA neurons in the dorsomedial arcuate nucleus (dmArc) of the hypothalamus play a central role in reproduction as an inhibitory gatekeeper of pituitary secretion of the hormone, prolactin. In rats, TIDA neurons exhibit a stereotyped, slow, and synchronized network oscillation (Lyons et al., 2010). Recent work has shown that key features of this oscillation are dictated by strong TIDA-TIDA electrical synapses, the expression of the gap junction protein, Connexin-36 (Cx36) (Stagkourakis et al., 2018) and that the rhythm itself is pivotal to shaping prolactin levels (Stagkourakis et al., 2020). These new insights into TIDA physiology generate new questions about cellular and intercellular structure that we are addressing using electron microscopy (EM) on male Sprague Dawley rats (P21-35). As TIDA neurons form a small, discrete population with a restricted localization, we developed a strategy to dissect the dmArc, obtaining a sample sufficiently small for EM, but preserving anatomical references, such as the third ventricle (3V) and the median eminence. In parallel, by immunofluorescence (IF), we identified the spatial coordinates for TIDA, using tyrosine hydroxylase (TH) as a marker. TIDA neurons, identified by IF were located in a rage of ≈30-60 µm from the 3V wall (*x*-axis), and dorsoventrally (*y*-axis), from ≈180 -590 µm from the 3V ventral limit. TIDA soma length was ≈ 20 µm (n=28 cells, 6 rats).TH- immunogold staining confirmed TIDA cell location and size. TH+ cells exhibited a prominent nucleus (1:3 Nucleus: Cytoplasm ratio), a bulbous and characteristic nucleolus (n=11/12 TH+ cells, n=1/7 TH negative cells, $p<0.05$ χ^2, n= 4 rats) with nuclear-membrane invaginations (9/12 TH+ cells, n= 4 rats). The neurons with these ultrastructural features were Cx36+, present also on other structures than somata, possibly dendrites.Next, samples containing the dmArc were processed for detailed ultrastructural analysis. TIDA-TIDA somata distance (1.8 ± 0.2 µm n= 8 cells, 3 animals) indicate that the proximity may not be sufficient for electrical synapse formation. However, electron-dense gap junctions were observed in appositions between vesicle containing-dendrites segments in the dmArc, and in apposition to TIDA neuron's proximal dendrite, yet to be identified as TIDA- TIDA contact. In conclusion, we developed a reliable method for localization of TIDA neurons for EM imaging. Also, we confirm the presence of Cx36 in dopamine neurons in the dmArc and describe their main ultrastructural characteristics, opening the door to further exploration and understanding of the structural basis of network dynamics in this population.

Title: Postnatal development of Tuberoinfundibular Dopamine (TIDA) neurons in the mouse

Authors: *A. LOCARNO, C. BROBERGER;
Dept. of Biochem. and Biophysics, Stockholm Univ., Stockholm, Sweden

Abstract: Neuroendocrine tuberoinfundibular dopamine (TIDA) neurons of the dorsomedial arcuate nucleus (dmArc) control secretion of the pituitary hormone, prolactin (Prl), via inhibitory dopamine D2-type receptors. Prolactin is a key hormone regulating parental physiology and behaviour and shows considerable serum level fluctuations across reproductive states, sex, and species. Importantly, TIDA neuron activity, characterized by stereotyped membrane potential oscillations, also shows notable diversity between these states, in some cases causally implicated in Prl status. Despite this dynamic nature, it remains to be determined if TIDA features are preprogrammed at birth, or undergo maturation during the early postnatal period, and, if so, which factors shape this process. In this study, we combine slice patch clamp electrophysiology, Ca^{2+} imaging, immunohistochemistry, and pharmacology to elucidate the neurodevelopmental changes occurring within the TIDA network during the first postnatal month. To identify TIDA neurons in brain slices, we crossed a dopamine transporter (DAT) Cre driver mouse line with a Cre-dependent tdTomato mouse line ("DAT-tdT mice"). In DAT-tdT mice, the number of fluorescent cells in the Arc was sparse in the early postnatal period (p 5-8; n=6) in both sexes. This is in line with observations in the midbrain and striatum showing that DAT mRNA levels increase between the first and the second postnatal week. From the second postnatal onwards, the expression of tdT in the Arc was more substantial. In this time window, we found TIDA neuron activity to be more autocorrelated in younger mice compared to older ones. This was accompanied by an increase in the frequency of oscillation, measured by brain slice Ca^{2+} imaging through the genetically encoded indicator, GCaMP6s. These changes in the activity pattern of TIDA neurons were paralleled by an age-dependent increase in circulating Prl levels. Overall, our preliminary results show a plastic maturation of the TIDA system during the first postnatal weeks suggesting a possible crosstalk between the TIDA network and the anterior pituitary during this crucial time window.

Title: Mouse beta klotho receptor expression at glutamatergic neurons in the bed nucleus of the stria terminalis

Authors: *B. S. BONO, M. J. CHEE;
Carleton Univ., Ottawa, ON, Canada

Abstract: Fibroblast growth factor 21 (FGF21) is a metabolic hormone that stimulates the paraventricular hypothalamic nucleus (PVH) to increase sympathetic tone. FGF21 signalling requires its obligate co-receptor beta-klotho (KLB), which is only sparsely expressed within PVH, thus it is necessary to consider that FGF21 may act via cells upstream of the PVH to drive sympathetic tone. FGF21 actions are thought to be excitatory, thus we hypothesize that FGF21 increases sympathetic output via glutamatergic cells that innervate the PVH. One such glutamatergic candidate is the bed nucleus of the stria terminalis (BST), particularly the anteromedial region, which densely innervates the PVH and whose electrical stimulation increases sympathetic tone. We assessed if the BST may underlie FGF21-mediated actions by determining the spatial distribution of *Klb* mRNA in the BST and whether *Klb* mRNA colocalized with glutamatergic cells marked by mRNA expression of vesicular glutamate transporters (*Vglut1*, *Vglut2*, *Vglut3*). We performed *in situ* hybridization in male and female wildtype brain tissues to determine if *Klb* and/or *Vglut1-3* hybridization that localized to a 4',6-diamidino-2-phenylindole (DAPI)-labelled soma was low (1-3 dots/cell), medium (4-9 dots/cell), or high (10+ dots/cell) and mapped their distribution onto *Allen Reference Atlas* brain templates. *Klb* hybridization was abundant throughout the BST but was highly concentrated within the anteromedial BST. In contrast, *Vglut1-3* hybridization was differentially expressed in the BST, as *Vglut2* mRNA was concentrated in the posterior portion and *Vglut3* mRNA was concentrated in the anterior portion. Notably, more than half of all *Vglut3*-positive cells expressed *Klb* mRNA and were most prevalent within the anteromedial BST. Only 37% of *Vglut2* BST cells expressed *Klb* mRNA, which were predominantly found within the principle nucleus of the BST. Finally, *Vglut1* hybridization within the BST was mostly low-expressing and only a few *Vglut1*-positive cells contained *Klb* mRNA. Taken together, *Klb* hybridization was abundant within the anterior BST at glutamatergic neurons marked by the expression of *Vglut3* mRNA. Future work will determine if activation of *Vglut3* BST cells innervating the PVH can increase sympathetic tone and whether FGF21 can regulate BST output.

Abstract: The stress response necessitates an immediate boost in vital physiological functions from their homeostatic operation to elevated emergency response. However, neural mechanisms underlying this state-dependent change remain largely unknown. Using a combination of *in vivo* and *ex vivo* electrophysiology with computational modeling, we report that corticotropin releasing hormone (CRH) neurons in the paraventricular nucleus of the hypothalamus (PVN), the effector neurons of hormonal stress response, rapidly transition between distinct activity states through recurrent inhibition. Specifically, *in vivo* optrode recordings in anesthetized mice show that under non-stress conditions, CRHPVN neurons often fire with rhythmic brief bursts (RB), which, somewhat counterintuitively, constrains firing rate due to long (~2 s) inter-burst intervals. In the same anesthetized mice, sciatic nerve stimulation, a pain-mimicking stressful stimuli, rapidly switched RB to continuous single spiking (SS), permitting a large increase in firing rate. A spiking network model shows that recurrent inhibition can control this activity-state switch, and consequently the gain of spiking responses to excitatory inputs. In biological CRHPVN neurons *ex vivo*, the injection of whole-cell currents derived from our computational model recreates the in vivo-like switch between RB and SS, providing direct evidence that physiologically relevant network inputs enable state-dependent computation in single neurons. Moreover, *in vivo* neuropharmacology showed that local antagonism of GABAA receptors, but not activation of glutamate receptors, produced model-predicted increases in continuous single spiking underlying stress-induced high activity state. Finally, in awake head-fixed mice, we demonstrate the presence of similar firing dynamics in CRHPVN neurons and correlated firing activities between single units. Together, we present a network mechanism for state-dependent activity dynamics in CRHPVN neurons.

Title: Agouti-related protein-expressing neurons mediate enhanced saccharine intake in calorie restricted male mice

Authors: *D. A. CASSANO[1], F. BARRILE[1], M. REYNALDO[1], N. FERREIRA[2], M. CURE[1], M. CORNEJO[1], G. GARCÍA ROMERO[1], R. RORATO[2], H. SCHIOTH[3], M. PERELLO[1,3]; [1]IMBICE, La Plata, Argentina; [2]Dept. of Biophysics, Paulista Med. School, Federal Univ. of Sao Paulo, São Paulo, Brazil; [3]Dept. of Surgical Sciences, Functional Pharmacol. and Neuroscience, Univ. of Uppsala, Uppsala, Sweden

Abstract: Animals under calorie restriction (CR) display an enhancement of their reward-related behaviors towards palatable stimuli, and the molecular basis underlying such adaptations remain uncertain. Agouti-related protein-expressing neurons (AgRP neurons) are located in the arcuate nucleus (ARH), which is nearby the fenestrated capillaries of the median eminence and, consequently, able to sense circulating factors. AgRP neurons project to many brain centres, including the paraventricular hypothalamus (PVN), the lateral hypothalamic area (LHA), the paraventricular thalamus (PVT) and the bed nucleus of the stria terminalis (BNST), and they are activated under energy deficit condition, such as fasting. Several evidences have established a connection between AgRP neurons and reward-related behaviours, including food foraging and locomotor activity. Here, we studied if AgRP neurons orchestrate the enhancement of reward-related behaviours observed in mice subjected to CR. We used an experimental protocol in which male mice were fed with the 40% of their daily *ad libitum* food intake for 5 days. Additionally, they were daily exposed to a solution of the non-caloric sweetener saccharine for 4 hours before each meal. We found that C57BL6 (WT) mice under CR showed an increase of saccharine intake and an induction of the neuronal marker activation c-Fos expression in several brain regions, including the ARH-AgRP neurons, LHA, PVN, PVT and BNST. Furthermore, using an animal model in which the ARH was ablated, we found that the ARH integrity was required for CR-induced enhancement of saccharine intake and for the induction of c-Fos in most ARH-targets. By utilizing loxP-Cre technology in mice, we selectively expressed inhibitory DREADDs (Designer Receptors Exclusively Activated by Designer Drugs) in the AgRP neurons, and we observed that CR-induced enhancement of saccharine intake was reduced when AgRP neurons were selectively inhibited. Moreover, employing the same technology but using excitatory DREADDs selectively in AgRP neurons, we found that the pharmacogenetic activation of AgRP neurons alone was sufficient to induce saccharine intake in *ad libitum* fed mice. Thus, we conclude that AgRP neurons' activation is required for the enhancement of saccharine intake in CR, and that AgRP neurons' activation is sufficient to induce saccharine intake in ad libitum fed mice. Of note, current studies were performed in male mice and it remains to be investigated if these findings can be extended to female mice.

Title: The D2R-SSTR5 heterodimer in pituitary neuroendocrine tumors and its functional crosstalk.

Authors: C. LI[1,2], Y. LIU[1], Y. FENG[1], Z. WU[1], ***L. XUE**[1,3];
[1]Dept. of Neurosurg., Shanghai Jiao Tong Univ. Sch. of Med., Shanghai, China; [2]Sch. of Medicine, Kunming Univ. of Sci. and Technol., Kunming, China; [3]Shanghai Ctr. for Brain Sci. and Brain-Inspired Technol., Shanghai, China

Abstract: Pituitary neuroendocrine tumors (PitNETs) are common intracranial tumors, among which prolactinoma (PRLoma) is the most common functional pituitary adenoma. Dopamine receptor agonist is the first choice for the clinical treatment of PRLoma, and the target is the dopamine type 2 receptor (D2R), which is a typical GPCR have been well studied, especially in the psychiatry field. The D2R agonist cabergoline and bromocriptine are very efficient for PRLoma but 10-25% of patients develop drug resistance. It's urgent to solve this problem. Heterodimerization is a way to regulate and integrate the GPCR downstream signal pathway. But little is known about how dimerization regulates the D2R signal in PRLoma.It was reported that the SSTR5 can form heterodimer with D2R in HEK293. In this study, initially, we assessed the expression levels of D2R and SSTR5 in a tissue chip comprising 70 PitNET samples using immunohistochemistry (IHC). Notably, we observed high expression of both GPCRs in 23 samples.Subsequently, we employed the proximity ligation assay (PLA) to detect the formation of SSTR5-D2R heterodimers in situ. The presence of these heterodimers suggests a physiological role within pituitary tumor.Further investigations were conducted using a NanoBIT-based assay to evaluate the functional crosstalk of D2R and SSTR5. We discovered that the presence of SSTR5 enhances the activation of G_o signaling pathway while suppressing beta-arrestin recruitment of D2R, which is typically induced by the clinically used agonist cabergoline. These findings provide insights into the modulatory effect of SSTR5 on D2R signaling. Moreover, our study revealed that SSTR5 can reduce the internalization of D2R induced by cabergoline, thereby promoting the stability of D2R on the cell membrane. The work mentioned above has provided valuable insights into the potential role of SSTR5 in regulating the downstream signaling and membrane stabilization of D2R. Furthermore, the detection of D2R-SSTR5 heterodimer in PitNET samples suggests that SSTR5 may play a regulatory role in the D2R signaling pathway within pituitary tumors through heterodimerization with D2R. By elucidating the interplay between SSTR5 and D2R, this research offers valuable information that can guide the design of future therapeutic interventions for PitNET.

Title: Compartmental Modeling of the Vagus Nerve Pathway that Connects the Nucleus Tractus Solitarii to the Stomach with Potential Application to Treat Gastrointestinal Disorders

Authors: *S. FERNANDES[1], R. SCLOCCO[2], M. KOTHARE[1], B. MAHMOUDI[3];
[1]Dept. of Chem. and Biomolecular Engin., Lehigh Univ., Bethlehem, PA; [2]Dept. of Physical Med. and Rehabil., Spaulding Rehabil. Hospital, Harvard Med. Sc, Boston, MA; [3]Dept. of Biomed. Informatics, Emory Univ., Atlanta, GA

Abstract: Vagus nerve stimulation (VNS) involves delivering electrical impulses to the vagus nerve. Sensory and motor aspects of gastric physiology are controlled by the vagus nerve. There are two methods of vagus nerve stimulation: invasive and non-invasive stimulation. Invasive VNS requires a surgical implantation procedure of a small pulse generator. Non-invasive stimulation is simpler as surgical device implantation is not required. Transcutaneous auricular vagus nerve stimulation (taVNS) is a non-invasive approach to vagus nerve stimulation. This stimulation targets the vagus nerve through the auricular branch of the vagus nerve that is accessible through the ear. The nucleus tractus solitarii (NTS) in the brainstem, targeted by taVNS, also regulates gastric motility and emptying via efference from the dorsal motor nucleus of the vagus. Therefore, taVNS can be used to treat gastric disorders like functional dyspepsia by controlling the peristaltic movement in the stomach (Sclocco et al., 2022). In prior work (SFN 2021), a compartmental model (CM) of the stomach was derived to simulate gastric motility. The CM modeling approach is computationally cheap as compared to complex finite element methods (FEM) models since the compartments only contain Ordinary Differential Equations (ODE). However, to date, no model of the vagus nerve has been established that links the NTS to the gut. In this study, a CM model will be derived to model the vagus nerve pathway of the NTS to the stomach, so the stomach motility can be modulated by VNS. In the vagus nerve pathway, three groups of neurons have been reported in the literature: myelinated afferents forming two distinct groups (A-type and Ah-type) with different functional profiles, and unmyelinated afferents forming a separate group (C-type). The myelinated neurons showed higher conduction velocity than unmyelinated neurons. The action potential of A-type, Ah-type and C-type neurons are simulated using Hodgkin-Huxley gated channel equations. The propagation of the action potential along the vagus nerve pathway is simulated using cable theory equation where the spatial variable of the equation is compartmentalized. The system is solved with ODE solvers in MATLAB. The model is compared with experimental data (1) Action potential shape and amplitude (Schild et al., 1994) (2) Action potential propagation velocity (Arcilla et al., 2020). By combining the vagus nerve and stomach motility compartmental model, a model is developed

where the stomach motility can be controlled using taVNS. This study will ultimately facilitate the development of closed-loop controllers as neurostimulation-based therapy for treating GI disorders.

Title: Perineal and rectal nerve recruitment order varies during pudendal neurostimulator implant surgery

Authors: ***P.-J. CHEN**[1,2], A. C. LAGUNAS[1,2], V. SORIANO[2,3], P. GUPTA[4], T. M. BRUNS[1,2]; [1]Biomed. Engin., [2]Biointerfaces Inst., [3]Neurosci. Program, [4]Urology, Univ. of Michigan, Ann Arbor, MI

Abstract: Pudendal nerve stimulation (PNS) is an off-label use of sacral neuromodulation (SNM) for pelvic pain and bladder symptoms, including urinary retention, overactive bladder, and incontinence. These symptoms bother millions of Americans, especially elderly women. This study collected data from the PNS implant surgery in 13 female cases to investigate the nerve recruitment order.

The pudendal nerve has three primary branches: genital nerve (GEN), perineal nerve (PER), and inferior rectal nerve (REC). GEN is sensory only, and PER and REC have mixed sensory and motor functions. PER innervates muscles in the urethra, perineum, and pelvic floor, and REC innervates the external anal sphincter (EAS) and levator ani. The standard PNS implant surgery uses EAS electromyography to guide placement of the 4-electrode lead, omitting PER responses. We placed a multi-sensor pressure catheter in the urethra during PNS implant surgery to monitor PER activation patterns. Eleven participants had PNS-driven urethral responses. Six of these participants had urethral responses at the threshold for EAS activation, suggesting that the PER can be recruited before the REC. Across participants, there were 45 electrodes which evoked EAS responses (86.5%) and 35 electrodes that drove urethral pressure increases (67.3%). Seventeen electrodes had PER responses before REC responses, and one electrode only had a PER response. These results suggest that urethral responses are substantial during PNS.

The multi-sensor catheter also allowed us to distinguish PNS-driven responses between the proximal and distal urethra. Among participants with urethra responses, four had distal urethral responses first, four had proximal urethral responses first, and three had concurrent proximal and distal urethra pressure onset during PNS.

The varied perineal and rectal nerve recruitment indicates that each surgery and participant are unique. The activation patterns may provide insights for personalized programming. Within our study group, a majority of participants (11/13, 84.6%) have had successful outcomes with their PNS implant. The two explanted participants had urethral responses and improved bladder symptoms, but did not have sufficient pelvic pain relief. Our analysis of urethral recruitment extends the current perspective on PNS and may contribute to expanded use of PNS for bladder and pelvic dysfunctions.

Title: The role of TRPV1 in repeated variate stress (RVS)-induced bladder dysfunction in adult female mice

Authors: *A. SIDWELL, C. MCCLINTOCK, B. M. GIRARD, S. CAMPBELL, M. A. VIZZARD;
Neurolog. Sci., Univ. of Vermont, Burlington, VT

Abstract: Psychological stress is associated with urinary bladder dysfunction (e.g., increased voiding frequency, urgency and pelvic pain); however, the mechanisms underlying the effects of stress on urinary bladder function are unknown. Transient receptor potential (TRP) channels (vanilloid family) may be potential targets for intervention due to their distribution in the lower urinary tract (LUT) and role in pain. Specifically, the TRPV1 channel has been implicated in LUT disorders, but its role in stress-induced bladder dysfunction remains unclear. As recently shown, a 2-week RVS paradigm in adult female mice negatively impacts bladder function. Using continuous infusion, open-outlet cystometry in conscious mice, RVS significantly ($p \leq 0.05$) decreased infused volume (IV) and intermicturition interval (IMI). Bladder pressures (threshold, average, minimum, and maximum pressures) were unchanged with RVS. Anxiety-like behavior, as measured by an open field test, showed a significant ($p \leq 0.05$) decrease in time spent in the open area of the arena in RVS mice compared to control. TRPV1 mRNA levels were upregulated in spinal cord levels L6 and S1 following RVS. Here, we used a specific TRPV1 receptor antagonist, capsazepine (CPZ) (50 μM), to determine the role of TRPV1 in RVS-induced bladder dysfunction. Intravesical infusion of CPZ during cystometry significantly ($p \leq 0.05$) improved bladder function in RVS mice. Specifically, the IMI and maximum IV before voiding

significantly ($p \leq 0.05$) increased. CPZ infusion did not affect bladder function in control mice. Fecal pellets, collected on each day of RVS, were used to measure corticosterone expression as a quantifiable measure of HPA axis activation. RVS mice exhibited significantly ($p \leq 0.05$) greater corticosterone expression compared to controls, suggesting that mice did not habituate to stressors. In conclusion, CPZ (50 μM) improves bladder function following 2-week RVS suggesting the involvement of TRPV1 in RVS-induced bladder dysfunction. Current studies are quantifying TRPV1 protein expression in the lumbosacral spinal cord and associated dorsal root ganglia following RVS and CPZ. Future studies will examine changes in anxiety-like behaviors and corticosterone levels following CPZ administration.

Title: The vagus nerve controls the circadian clock-independent liver transcriptome and relays hepatic signals to regulate rhythmic feeding behaviors

Authors: *L. N. WOODIE[1], M. MIDHA[1], A. DE ARAUJO[3], L. C. MELINK[1], A. J. ALBERTO[1], G. DE LARTIGUE[3], M. R. HAYES[2], M. A. LAZAR[1];
[1]Endocrinology, Diabetes, and Metabolism, [2]Psychiatry, Univ. of Pennsylvania, Philadelphia, PA; [3]Monell Chem. Senses Ctr., Philadelphia, PA

Abstract: Many mammalian behaviors and metabolic processes exhibit circadian rhythmicity. Synchrony among these is critical for organismal health as desyncrhony has been shown to exacerbate obesity and metabolic disease. How synchrony/desynchrony are transmitted and detected within an organism is a major unanswered question in the field of chronobiology. Parasympathetic innervation via the vagus nerve has been shown to transmit metabolic signals between the brain and liver, but its role in relaying circadian signals has not been established. We hypothesized that signaling between the brain and liver via the hepatic vagus (HV) nerve regulates chrono-metabolic homeostasis and gene expression. To test this, we surgically interrupted the HV (HVx) in mice and collected their tissues at multiple times for transcriptomic analysis. We found that HV efferents regulate the rhythmic expression of the clock-independent

transcriptome in the liver as HVx rendered a large portion of the rhythmic hepatic transcriptome arrhythmic without impacting the endogenous liver clock. HVx did not alter feeding on its own, but remarkably protected against aberrant feeding behaviors observed in mice with disrupted hepatocyte clocks. This was due to altered signals sent via HV afferents that changed the rhythmic expression of orexigenic genes in the arcuate nucleus (Arc). These trancriptomic changes were then attenuated by HVx. In sum, HV signaling serves to maintain chrono-metabolic synchrony by orchestrating clock-independent rhythms between the brain and liver and this homeostatic mechanism becomes deleterious under metabolic stress. Since obesity and metabolic disease are known to be exacerbated by chrono-disruption, it is likely that parasympathetic relay between the brain and liver plays an important role in normal metabolic physiology, as well as the disturbances caused by overnutrition and circadian disruption.

Title: The modulation of sympathetic activity by GABA in the sympathetic ganglion.

Authors: *H. KANDA[1,2], H. YAMANAKA[3,2], Y. DAI[4,2], K. NOGUCHI[2];
[2]Lab. of Basic Pain Res., [3]Sch. of Pharm., [1]Hyogo Med. Univ., Kobe, Japan; [4]Dept. of Anat. and Neurosci., Hyogo Med. Univ., Nishinomiya, Japan

Abstract: The sympathetic activity is controlled primarily in the hypothalamus. While the central regulatory mechanisms of sympathetic activity have been well studied, the regulatory mechanisms in the peripheral nervous system remain unclear. The celiac ganglion (CG) is the site of neurotransmission between pre-sympathetic nerve terminals and post-sympathetic ganglionic neurons. The presence of small neural circuits in the CG has been suggested before, but the details of these circuits are still unclear. Here, we determined the intra-ganglionic regulation of sympathetic activity in the peripheral nervous system. In addition, we determined the role of Gamma-aminobutyric acid (GABA) on synaptic activity in the CG. To evaluate the synaptic activities in the CG, we established a rat whole-mount CG preparation, and applied *in situ* patch-clamp technique combined with high-speed pressure-clamp device. The synaptic activities were successfully detected from CG neurons under the voltage-clamp configuration. The results of perforated patch-clamp showed that the CG neurons have relatively higher concentration of intracellular chloride than that in CNS neurons. The bath application of GABA induced the GABAA-mediated inward currents under the voltage-clamp configuration, and

depolarized the membrane potential under the current-clamp mode. On the other hand, GABA suppressed the cell excitability above the chloride reversal potential of -45mV. Immunohistochemistry revealed that the GABAergic nerve terminals were scattered within the CG. We performed the comprehensive analysis of GABAA receptor by real time PCR, and the alpha1 and alpha2 subunits were expressed in the CG. Collectively, we successfully established the *in situ* whole-cell patch-clamp recording on the CG neurons, and directly measured the peripheral synaptic activity by analyzing synaptic transmission in the peripheral nervous system. We revealed that GABA has a bidirectional action for regulating cell excitability on post-sympathetic neurons. Our findings may provide new insights into the mechanism of regulation for sympathetic nerve activities in the peripheral nervous system.

Title: Subdiaphragmatic organization of the right and left vagus nerves, a region of neural connections with the enteric system, ganglia, and ovaries

Authors: *M. RIVERA CASTRO[1,2], C. PASTELÍN[3], J. BRAVO BENÍTEZ[2], C. MORÁN[2]; [1]Univ. Veracruzana, Puebla, Mexico; [2]Inst. de Ciencias, Benemérita Univ. Autónoma de Puebla, Puebla, Mexico; [3]Facultad de Medicina Veterinaria y Zootecnia, Benemérita Univ. Autónoma de Puebla, PUEBLA, Mexico

Abstract: The vagus nerve in the subdiaphragmatic region has been described as an important way in the control of different autonomic functions in the body. In the female rat, the vagal communication in the ovaries is associated with the control of the estrous cycle, ovulation, and physiological response, however, is not clear the neural pathway through the vagus nerve is connected. In this study, we proposed to determine the neuroanatomical pathway that links the subdiaphragmatic vagus with the ovaries and describe the organs, ganglia and branches involved. Adult female rats (Long Evans CII-ZV strain) were used during the estrous cycle (240 -350 g) and were divided into three groups, 1) gross anatomy, 2) neuroanatomy by acetylcholinesterasetechniqueand 3) immunofluorescence analysis for tyrosine hydroxylase (TH), choline acetyltransferase (ChAT), and tryptophan hydroxylase 2 (TPH) antibodiesin the right vagal plexus. The results obtained indicates that right vagus nerve (RVN) travels parallel and caudal to the esophagus, where three nerve branches were identifiedthat form a plexus

described as aRVP, examining it, we found that it is formed by some neurons, axons that cross it and glial cells. The left vagus nerve (LVN) travels over the esophagus, bifurcates before its insertion into the stomach and arrives to the celiac plexus.The immunoanalysis of RVP showed it was reactive for TH mainly, accumulating the enzyme in vesicles but without finding positive neuronsto TH.Nevertheless,were found some serotoninergic and cholinergic neurons but not vesicles in the RVP. This neuroanatomical and biochemical description of the RVN and LVN in the female rat, suggests the RVP is formed by presynaptic catecholaminergic terminals and cholinergic and serotoninergic neurons. With this, we suggest that in the rat, vagalinnervation in the subdiaphragmatic region plays a role in the physiological response of the abdominal organs including the ovaries.

Title: Sympathetic innervation in islet plasticity during pregnancy

Authors: *J. S. YAMAMOTO[1], R. KURUVILLA[2];
[2]Biol., [1]Johns Hopkins Univ., Baltimore, MD

Abstract: Pancreatic islets of Langerhans are essential for glucose homeostasis, and the loss of insulin-producing beta-cells in islets or their dysfunction causes diabetes. Pregnancy is a unique physiological condition when islets show striking morphological and functional plasticity during adulthood. During pregnancy, there is an increase in islet mass and proliferation of insulin producing beta-cells, as well as enhanced insulin secretion to compensate for increased insulin resistance. Failure of normal islet adaptive responses to an increased metabolic demand during pregnancy has been proposed to contribute to gestational diabetes. Thus, it is critical to understand the molecular mechanisms that underlie islet plasticity during pregnancy. Pancreatic islets receive neuronal input from sympathetic nerves, which is important to control hormone secretion and maintain glucose homeostasis. Whether sympathetic nerves contribute to islet plasticity during pregnancy remains unknown.Using iDISCO-based tissue clearing and 3D imaging, I found that sympathetic nerves undergo structural changes as the islet mass expands during pregnancy in mice. To assess if sympathetic innervation contributes to islet plasticity during pregnancy, I chemically ablated nerves using 6-OHDA injections. After confirming loss of innervation, I observed that denervation results in increased islet area in pregnant mice compared to pregnant mice with intact nerves. Pregnant mice injected with 6-OHDA also exhibit

slightly increased insulin secretion in response to a glucose challenge, and improved glucose tolerance at gestational day 16, compared to vehicle-treated pregnant mice. Islet plasticity during pregnancy is a tightly regulated process, where negative regulatory pathways are likely to be as important as positive regulatory pathways to prevent un-restricted beta-cell proliferation, islet expansion, and insulin secretion. My results suggest a previously uncharacterized role for sympathetic nerves in acting as a 'brake' to prevent excessive islet growth and insulin secretion during pregnancy.

Title: Analysis of adrenergic and cholinergic system in the functional structures of the ovary in the rat senescence process

Authors: *J. BRAVO[1], M. RIVERA CASTRO[2], I. SARMIENTO GARCIA[3], A. HERNÁNDEZ SILVA[3], V. BOHORQUEZ[3], C. MORAN[4];
[1]BENEMERITA UNIVERSIDAD AUTONOMA DE PUEBLA, PUEBLA, Mexico; [2]Univ. Veracruzana, Puebla, Mexico; [3]RedOSMO, Oaxaca, Mexico; [4]Benemérita Univ. Autonoma de Puebla, Puebla, Mexico

Abstract: In the rat ovary, has been demonstrated the presence and distribution of autonomic nerves, these arrive to the ovary by the ovarian plexus nerve and the superior ovarian nerve. This neural pathway is related to the release of norepinephrine from nerve endings that inhibit testosterone production via R1A (α1-adrenergic receptor), located on testosterone-producing cells in the ovary. Also, was found acetylcholine (ACh), which participates in the regulation of cellular proliferation in the follicles and corpus lutea. The presence of ACh receptors in the rat ovary, such as M1R (μ1-muscarinic Receptor) has been found in young rats, however, ovarian innervation increases their activity at the end of the lifespan. The aim was to analyze the presence of M1R and R1A and their relationship with steroid hormone receptors such as 17β estradiol receptor and α1-progesterone receptor. In this study adult and senescent female rats were used and assigned to the following groups: young adult rats aged 3-5 months (3M, n=4), middle-aged rats aged 12 months (12M, n=4), and senescence rats (15M; n=4). The ovaries were removed and fixed, then were cut at 10 μm sections and were analyzed to the primary antibodies for the 17β-estradiol receptor, α1-adrenergic receptor, μ1-muscarinic receptor, and progesterone receptor. The results obtained from the analysis of the immunoreactivity in the ovarian stroma

and cells surrounding functional structures of the ovary such as the corpus luteum, ovarian cysts, and follicles. The results obtained for the combination **R1A/ER** receptors were a significant difference between the three ages in the quantitative analysis of the number of immunoreactive cells showed (3M: 181.3±18.3; 12M: 1677± 0.89; 15M: 884.5± 0.91 SEM) finding the major difference for the group of 12M. Also, in the measure of the area of the cells was found a difference too (3M: 65.88±0.75; 12M: 61.74±0.27; 15M: 52.99±0.38 SEM). In the case of the number of cells that expressed for the combination of **M1R/PR** the results showed a significant difference between three different ages (3M: 1565.3±21.3; 12M: 1766± 23.89; 15M: 371.4± 0.4 SEM) and this difference was also significative for the area of the cells (3M: 67.99±0.41; 12M: 75.08±0.34; 15M: 78.81±0.78 SEM). In this combination, many cells reactive were at 12M too. The stroma cells and the cell surrounding functional structures of the ovary such as the follicles, the corpus luteum, and cysts express α1-adrenergic and μ1-muscarinic receptors, which confirms the influence of the autonomic nervous system. However, in the 12M age animals, the adrenergic system is the most active in the senescence process in the rat ovary.

Title: Understanding micturition reflex control by manipulating bladder volume through time in rat

Authors: *D. J. JASKOWAK[1], Z. C. DANZIGER[2];
[1]Florida Intl. Univ., MIAMI, FL; [2]Florida Intl. Univ., Florida Intl. Univ., Miami, FL

Abstract: It remains unclear exactly what sensory criteria the nervous system uses to trigger the micturition reflex for voiding. Bladder afferent activity is tightly correlated with global bladder tension; however, hypotheses of a possible dependence on bladder volume have also been proposed. In typical cystometry fluid volume is added to the bladder at a constant rate until a void occurs. Introducing infusion nonlinearities may help distinguish which aspects of the bladder sensorium are most responsible for activating the micturition reflex. Here we explored whether the volume-time integral (TI) or a sudden change in bladder volume increased the likelihood of evoking the micturition reflex, in urethane anesthetized female Sprague-Dawley rats. To achieve this, we filled the bladder via transurethral catheter at typical cystometric rates but superimposed temporary large or small volume fluid boluses for either long or short

durations (before removing the bolus volume from the bladder) to control volume-TI and volume derivative independently. We quantified the presence of reflex bladder contractions after each bolus with pressure-TI. Fluid boluses were added when the bladder reached 70 or 80% of the rat's bladder capacity (BC) estimate so that the total volume in the bladder after the addition of the bolus was between 80 and 100% BC. When fluid boluses were added at 70% BC, the evoked pressure-TI was less than when fluid boluses were added at 80% BC, indicating that background bladder volume increases the chance of activating the micturition reflex (e.g., to enter micturition mode). Adding fluid boluses of 20% BC (large bolus) at 80% BC increased the evoked pressure-TI compared to when the bolus was 10% BC (small bolus). The same effect was not observed when the fluid boluses were added at 70% BC. Volume-TI was varied by increasing the time between infusion and withdrawal of the fluid bolus such that one of the 20% BC boluses had an equivalent volume-TI to a 10% BC bolus. When the fluid boluses were added at 80% BC, larger volume-TI increased the evoked pressure-TI and EUS EMG-TI. Group differences were assessed with a three-way ANOVA. Taken together these data suggest that the nervous system integrates volume to activate the micturition reflex.

Title: Location of Sensory neurons of the clitoris in the rat

Authors: P. GÓMEZ HERNÁNDEZ[1], *N. MIRTO AGUILAR[2,3], A. ALBARADO-IBAÑEZ[3], C. MORAN[3];
[1]Facultad de Ciencias Biológicas, Benemérita Univ. Autónoma de Puebla, Puebla, Mexico; [2]Benemérita Univ. Autónoma de Puebla, Xalapa-Enriquez, Mexico; [3]Ctr. de Investigación en Fisicoquímica de Materiales, Benemérita Univ. Autónoma de Puebla, Puebla, Mexico

Abstract: The clitoris is an external sexual organ located anterior to the urethral wall. In rats, the nerve innervating the external genitalia is the dorsal nerve of the clitoris, but we lack a thorough description of the sensory neuron distribution of the organ. This study aims to determine the location and number of sensory neurons in the clitoris in rats. The rats were deeply anesthetized with ketamine and xylazine, then placed in a supine position. Under a stereoscopic microscope, a retrograde axonal transport fluorescent dye (True blue, TB; 6-7 µl) was injected into three different regions of the clitoris. At each injection site, the needle was kept in place for 20 s to ensure the diffusion of TB into the tissue. After seven days of survival, the animals were

anesthetized with sodium pentobarbital and transcardially perfused with a saline solution followed by 10% formalin. Thereafter, the dorsal root ganglia (DRGs), from L-4 to S-2 were bilaterally excised. Tissues were post-fixed for 12 h and cryoprotected. Then ganglia were sectioned longitudinally at a thickness of 14 μm. The slides were examined with a fluorescence microscope, and the cells labeled with TB were counted. Only labeled cells with clearly visible nuclei were counted. Cell counts were corrected by the method of Abercrombie. TB-positive neurons projecting to the clitoris were localized to L6 (94%) and S1 (6%) DRGs. No neurons were in the L4, L5, and S2 DRGs. The mean number of total TB-positive neurons from the clitoris was 565±206.4. The Somata area of L6 primary afferents ranged from 1287 to 107 μm^2 and the mean of the area was 432.1±210.4 μm^2. While the somata of the neurons in S1 ranged from 637.2 to 100 μm^2 and the mean of the area was 245.2±112.2 μm^2. In another way, we analyzed the intraganglionic distribution of the TB labeled in both DRGs, and the neurons were localized in the rostromedial and caudomedial areas of the L6 DRG. However, in S1 DRG was not observed a specific pattern of neuronal distribution. In conclusion, our results show that the clitoris of the rat receives innervations exclusively from L6-S1 DRGs. Furthermore, both the urethra and urinary bladder sensory innervation are also mainly projecting from L6 DRG. Thus, suggesting that this ganglion may be the main afferent supplier of the rat urogenital tract. Knowledge of the clitoral innervation is important for the understanding of the female genital function and proximity to the urethra, which could directly affect the urinary function and/or urogenital dysfunction.

Title: Transcriptomics of lateralized vagal sensory pathways

Authors: *H. F. WELCH, I. SANKARANARAYANAN, K. MAZHAR, T. J. PRICE, C. A. THORN;
Univ. of Texas at Dallas, Richardson, TX

Abstract: The vagus nerves mediate bidirectional communication between the gut and brain, modulating appetite, satiety, and food-seeking behaviors. However, recent studies have unveiled a remarkable lateralization of vagal signaling. Electrical activation of the right vagus nerve or

optogenetic stimulation of right nodose ganglion neurons, but not left, have been found to enhance neural activity in midbrain dopaminergic nuclei and drive reward-seeking behaviors. Expanding upon recent genetic sequencing research into the nodose ganglion's diversity of vagal sensory neuron subtypes, our study aims to investigate how gene expression differences between the right and left nodose ganglia may contribute to the distinct lateralization of reward-related signaling in the vagus nerve. Right and left nodose ganglia of young adult (8-week-old) male (n=18) and female (n=18) rats were dissected, and single-cell RNA sequencing (scRNA-seq) was performed. Our analyses focus on investigating the differential gene expression patterns of mechanosensory and chemosensory neuronal subtypes in the right versus left nodose ganglia. By classifying nodose ganglia neurons into putative subtypes based on their ability to sense mechanical or chemical stimuli, we aim to identify potential sensory pathways that contribute to the occurrence of lateralized vagal reward-related signaling. Preliminary analyses suggest that chemosensing subtypes may be more likely to contribute to the distinct encoding of these reward signals by the right versus left vagus nerves. Ultimately, gaining insights into the distinct molecular expression of neurons within the right and left nodose ganglia will advance our understanding of the mechanisms involved in appetitive signaling between the visceral organs and the brain.

Title: Assessment of viscerosensory processing in the human brain stem using 7T fMRI

Authors: *M. DE RIJK[1,2], S. PINCKAERS[1], A. KNOPS[1], J. JANSSEN[2], A. KLIJNSMA[1], G. VAN KOEVERINGE[1,2], J. VAN DEN HURK[1,3];
[1]Urology, Univ. of Maastricht, Maastricht, Netherlands; [2]Urology, Maastricht Univ. Med. Center+, Maastricht, Netherlands; [3]Scannexus Ultra-High Field Imaging Ctr., Maastricht, Netherlands

Abstract: The brain stem plays an essential role in the processing of visceroceptive information. In particular, the periaqueductal gray (PAG) and pontine micturition (Barrington's nucleus) and storage center are brainstem areas indicated to play an essential role in lower urinary tract (LUT) control. Human and animal studies have indicated that the PAG is organized in distinct columns which are involved in sympathetic or parasympathetic control of the LUT. Earlier work indicates that *in vivo* parcellation of the PAG into symmetrical clusters can be accomplished using 7T

fMRI. Here, we used fMRI to investigate changes in functional connectivity patterns between PAG clusters and voxels in the pons associated with changes in bladder sensations. We acquired fMRI data during a bladder filling protocol. First, we ran a resting-state fMRI scan while participants had an empty bladder and experienced no desire to void, followed by a full bladder resting-state fMRI while participants experienced a strong desire to void. A connectivity matrix of the PAG was created based on the full bladder data, and parcellated using the Louvain module detection algorithm. For each resulting cluster, functional connectivity was assessed with each voxel in the pons for both empty and full fMRI scans. Based on these data we computed the difference in PAG-pons functional connectivity between empty and full bladder scans for each PAG cluster per participant. We then assessed which PAG clusters show opposite connectivity changes with pontine areas. For each pair-wise PAG cluster comparison, we multiplied the pontine connectivity maps, yielding an *opposite-response (OR) map*, in which negative voxels point towards opposite connectivity directions of the PAG cluster pair. We assessed these OR-maps on pontine transversal sections covering the levels of Barrington's nucleus. The group level maps clearly show the neuroanatomical outline of the area including Barrington's nucleus. This indicates that the approach outlined here can be used to assess interaction between brain stem nuclei associated with visceroceptive processing at unprecedented resolution. The opposing interactions between different PAG clusters resulting from our parcellation procedure with the pons indicates that the observed pontine clusters may be involved in opposing functional processes associated with changes in bladder sensations. Furthermore, it may be stipulated these functional connectivity patterns indicate that parcellations of the PAG using the Louvain module detection algorithm results in meaningful clustering of the PAG into clusters that show distinct functional connectivity patterns with other brain areas.

Title: Exploring the sexually dimorphic role of proenkephalin-expressing neurons in lower urinary tract control

Authors: *N. KLYMKO[1], A. M. SARTORI[1,2], M. LEON[1], M. L. ZEIDEL[1,2], A. M. J. VERSTEGEN[1,2];
[1]Med. Res., Beth Israel Deaconess Med. Ctr., Boston, MA; [2]Harvard Med. Sch., Boston, MA

Abstract: *Background:* The understanding of the neural control of the lower urinary tract (LUT) remains limited. Barrington's nucleus (Bar) in the brainstem has been implicated in initiating voiding and consists of distinct neuron subpopulations. Through single-nuclei RNA-sequencing, our group identified a novel subpopulation within Bar characterized by the expression of the Proenkephalin (Penk) gene. In this study, we investigate the Penk-expressing neuron population and its role in LUT control. *Methods:* We utilized transgenic mice expressing Cre-recombinase specifically in Penk-expressing neurons. Stereotaxic injections of Cre-dependent viral tracers, Designer Receptors Exclusively Activated by Designer Drugs (DREADDs), Diphtheria Toxin A (DTA), or Channelrhodopsin 2 (ChR2), were performed. Voiding function and voluntarily controlled scent marking behavior were assessed using non-invasive micturition video thermography. Additionally, bladder pressure and external urethral sphincter (EUS) electromyography recordings were obtained. Appropriate controls were used, and post hoc analysis of the central nervous system confirmed injection sites and descending projections. *Results:* Penk-expressing neurons in Bar project to the lumbar-sacral level of the spinal cord, where interneurons and motor neurons that innervate the bladder and EUS reside. Activation of Bar^{Penk} neurons significantly increased voiding frequency in male mice; however, similar activation in females did not produce the same effect. Furthermore, selective ablation of Penk neurons in males revealed their pivotal role in a specific micturition behavior, scent marking. Utilizing modified rabies virus tracing, we identified a number of forebrain structures providing input to these neurons, and we continue to explore molecular and connectivity differences between sexes. *Conclusions:* Penk-expressing neurons residing in Barrington's nucleus project to the lumbosacral segment of the spinal cord, innervating specific downstream neurons responsible for distinct aspects of LUT function. This study uncovers sex-dependent differences in the functional roles of these neurons and highlights the intricate molecular and neural connectivity profiles linked to the control of the lower urinary tract.

Title: Analysis of Estrus Cycles in POMC-deficient Mice

Authors: *R. RICKS, B. MCHOES, Z. THOMPSON;
Utah Valley Univ., Orem, UT

Abstract: The pro-opiomelanocortin (POMC) gene, prominently expressed in the hypothalamus and pituitary, is pivotal in vital physiological processes. The gene product is a protein cleaved into various peptides which have important functions in regulating feeding behavior, body weight, and melanin synthesis. Mutations in the POMC gene yield either short versions of the POMC protein or no protein at all. As a result of this deficiency, individuals exhibit severe early-onset obesity, among other symptoms. Similarly to humans, mouse models with a POMC deficiency demonstrate pronounced early-onset obesity, hyperphagia, and infertility. Our research aims to elucidate the underlying cause(s) of infertility in POMC-deficient mice. As part of this work, we are analyzing the estrus cycle in POMC-deficient mice compared to wild-type mice to determine if POMC-deficient mice exhibit normal estrus cycles. Using a pipette, we collect samples of vaginal cells using a 0.9% saline wash, and the sample is examined under a microscope by a researcher blind to genotype. The ratio of three different types of cells: cornified cells, nucleated cells, and leukocytes, is used to determine which of the four stages of the estrus cycle a mouse is in each day. Female mice typically complete a cycle every 3-5 days, going through the stages of proestrus, estrus, metestrus, and diestrus generally in order. After investigating a month's worth of samples, we will determine whether POMC-deficient mice exhibit normal estrus cycles or not. Preliminary analyses indicate that POMC-deficient mice do not exhibit normal cycles, but we are collecting more data to better address this question. Anticipated outcomes from this study hold promise for a more comprehensive understanding of the mechanisms underlying infertility in POMC-deficient mice, subsequently offering insight into potential therapeutic approaches for humans who may also experience infertility due to POMC deficiency.

Title: Amygdala Control of the Emotional Motor System

Authors: *G. HOLSTEGE[1], *G. HOLSTEGE[1], H. H. SUBRAMANIAN[2];
[1]Groningen Academic Hosp., Den Haag, Netherlands; [2]Boston Scientific, Valencia, CA

Abstract: Amygdala Control of the Emotional Motor System [1]Gert Holstege and [2]Hari H. Subramanian[1]The University of Groningen, The Netherlands, [2]Boston Scientific Neuromodulation, CA, USA The amygdala regulates fear and anxiety. Expression of fear and anxiety is associated with changes in the emotional motor system control of breathing,

cardiovascular and pelvic organ function. The amygdala via its strong projections to the periaqueductal gray (PAG) could function as one of the emotional motor pathways for the modulation of fear and anxiety. In that case, stimulation of the amygdala should have a direct causal influence on breathing as well as on cardiovascular and pelvic organ functions. This was investigated by stereotaxic glutamate stimulation of different portions of the amygdala in both cats and rats. Using this technique it was possible to find out whether within the amygdala a topographical organization of emotional functions exist. **Results from the cat studies****Respiration:** In the cat, stimulation of the lateral amygdala generated hyperpnea and tachypnea, while stimulation of the central amygdala induced dyspnea, bradypnea, inspiratory apneusis and double diaphragm breathing patterns. Stimulation in the amygdala never generated apneas.**Cardiovascular effects:** Stimulation in both the lateral and central amygdala induced hyper- as well as hypotension. **Micturition:** In the cat stimulation of central amygdala generated micturition, but stimulation in the lateral amygdala did not. **Results from the rat studies**Focal stimulation of the central amygdala in the rat induced both tachypnea/hypertension as well as apnea/hypotension. Topical stimulation in the lateral portion of the central amygdala produced breath-hold. Focal glutamate stimulation in the lateral amygdala did not result in any cardiorespiratory effect. In the rat micturition was never generated in either the lateral or the central amygdala. **Conclusion**The lateral and the central amygdalar areas produce distinct modulations of the emotional motor system depending on its association with stress, fear and anxiety. Differences between the cat and rat exist in terms of modulation of the emotional motor system. Title: The impact of a high-fat, high-sugar diet on dopamine release, direct pathway medium spiny neuron activity, and satiation during naturalistic feeding

Authors: *C. E. MURPHY[1,2], D. MOURRA[3,1,2], J. A. BEELER[2,1,4];
[1]City Univ. of New York CUNY Neurosci. Collaborative, New York, NY; [2]Psychology, Queens Col. CUNY, Flushing, NY; [3]New York Univ. Grossman Sch. of Med., New York Univ. Neurosci. & Physiol., New York, NY; [4]Biol. Program, The Grad. Ctr. CUNY, New York, NY

Abstract: Obesity remains a global public health crisis. High rates of obesity are often attributed to the influence of the Western diet, characterized by processed foods that are highly palatable and energy-dense, containing substantial sugar and fat content. The hedonic properties of these foods are hypothesized to lead to compulsive eating and overconsumption behaviors present in obesity and have been suggested to 'hijack the reward system', likened to addiction. However, how highly palatable foods alter dopamine (DA) and direct pathway medium spiny neuron (dMSN) activity during a naturalistic free-feeding paradigm is unclear. We aimed to assess whether acute access to a diet containing high levels of fat and sugar alters dopaminergic signaling and satiety processes. We used automatic feeders (FED3) to track the *ad libitum* feeding patterns of lean D1-Cre expressing mice and provided the option to consume either standard, grain-based pellets or high-fat and high-sugar pellets across 5 days. We used dual-color fiber photometry with a red-shifted fluorescent DA sensor (RdLight1) and a Cre recombinase-dependent, green calcium indicator (GCaMP6f) virally expressed to measure simultaneous changes in DA and dMSN activity across a meal. We hypothesized that mice with access to the HFHS diet will exhibit increased pellet intake and prolonged consumption, leading to larger meal sizes which reflect a delay in the satiation process. We also predicted that phasic DA release would be increased in response to the HFHS diet, along with increased activity of dMSNs during food approach. We found that mice with access to a HFHS diet consumed more HFHS pellets than grain pellets and ate more meals when compared to mice fed only a grain-based diet. These mice had significantly increased dMSN activity during food approach but not consumption. DA attenuated similarly in both diets, suggesting that HFHS diet did not delay satiation. These findings may suggest that HFHS pellets increase motivation to approach food, rather than prolonging satiation, consistent with incentive theories of motivation.

Title: Natural striatal signaling dynamics during food approach at different timescales

Authors: *D. MOURRA[1,2,3], C. E. MURPHY[2,3], E. HOURANY[3], J. A. BEELER[3,2,4];
[1]New York Univ. Neurosci. & Physiol., New York, NY; [2]City Univ. of New York CUNY Neurosci. Collaborative, New York, NY; [3]Dept of Psychology, Queens Col. CUNY, Flushing, NY; [4]Biol. Program, The Grad. Ctr. CUNY, New York, NY

Abstract: Reduced dopamine (DA) signaling has been hypothesized to induce compulsive overeating in obesity. However, DA signaling facilitates food pursuit by acting on direct and indirect pathways. Why individuals compulsively overeat despite decreased DA, and the role of DA in mediating satiety signals, is unclear. In this study, we aimed to investigate the role of DA

and pathway-specific medium spiny neuron (MSN) activity in the nucleus accumbens (Core; NAcc vs. Shell; NAcSH) in regulating satiation (stopping a meal). We predicted that reduced food approach would correlate with reduced DA release and dMSN activity during satiation. We used fiber photometry with a red-shifted fluorescent DA sensor (RdLight1) and a Cre recombinase-dependent, green calcium indicator (GCaMP6f)) to test this. Both fluorescent sensors were injected into mice expressing dopamine D1 receptor (D1-Cre) or adenosine A2a receptor (Adora-Cre) (markers of direct and indirect pathway MSNs, dMSNs, and iMSNs, respectively). Using a free-feeding paradigm, we used dual color fiber photometry to measure real-time changes in DA and MSN activity in mice during natural food approach and consumption. This approach allows for the simultaneous recordings of both DA and pathway-specific MSN activity across varying degrees of satiation, from hungry to sated, and is designed so that mice directly control their eating patterns. We found that DA and d/iMSNs activity is increased during food approach in natural feeding, but only iMSNs were significantly decreased during consumption. Furthermore, on a minute-to-minute timescale, we found that DA and dMSNs activity attenuated as mice approached satiation in the NAcc, but not in the NAcSH. We find that DA release changes with hunger and satiety on different timescales ranging from seconds to minutes to hours, reflecting varying stages of food motivation across several hours of free-feeding. These studies are the first to directly measure DA and d/iMSN activity from initiation of active cycle free-feeding to satiation. These findings expand our understanding of dynamic changes in striatal signaling during the progression of satiation.

Title: Identification of a novel feeding-sensitive subtype of arcuate neurons

Authors: *R. ONOHARIGHO[1], J. CAMPBELL[2];
[2]Biol., [1]Univ. of Virginia, Charlottesville, VA

Abstract: Abstract body:Neurons in the arcuate nucleus (ARC) sense changes in caloric supply and demand toadaptively regulate feeding and metabolism. Previous research indicates that apopulation of inhibitory ARC neurons, which express vesicular inhibitory amino acidtransporter gene (*Slc32a1*) and leptin receptor gene (*Lepr*) control metabolism but notfeeding; however, the identity of these ARC neurons remains otherwise unknown. Wehypothesize that these neurons are a molecularly distinct subtype marked byexpression of the phosphoinositide interacting regulator of transient receptor potentialgene (*Pirt*), and these neurons are called Pirt^{ARC} neurons. To determine whether Pirt^{ARC}neurons are metabolically responsive, we assessed their expression of the immediate-early gene and neuronal activity marker, *Fos*, after feeding, fasting and post-

fastrefeeding in mice using RNA fluorescence *in situ* hybridization (FISH). Male and femaleC57BL/6J mice at 13 to 14 weeks of age were singly housed and fed *ad libitum*, fastedfor 18 hours, or fasted for 18 hours and then refed for 2 hours (n=4 mice per condition).We performed RNA FISH for *Pirt*, *Fos*, and *Agrp* mRNA in the ARC and assessed theirco-localization across the feeding conditions. Consistent with our previous studies, wefind that the *Agrp* and *Pirt* genes are not co-expressed, indicating that AgRP neuronsand $Pirt^{ARC}$ neurons are distinct populations in the ARC. Moreover, we find that AgRPneurons highly co-express with *Fos* in the fasted state, confirming previous findings thatAgRP neurons are particularly active in the fasted state. By contrast, our results showthat the percentage of $Pirt^{ARC}$ neurons expressing *Fos* is significantly lower in fastedmice than in *ad libitum* fed mice ($p=0.0135$; one-way ANOVA followed by Tukey'smultiple comparisons test), though neither group differed significantly from post-fast re-fed mice ($p>0.05$). Thus, $Pirt^{ARC}$ neurons appear to be more active in fed mice than infasted mice. Our results therefore identify $Pirt^{ARC}$ neurons as a novel feeding-sensitivesubtype of ARC neurons.

Title: Biological sex differentially modulates food reward in male and female mice

Authors: *A. DOFAT[1], K. RUNYON[4], M. TSYGLAKOVA[2], A. HARTLE[5], K. MARCHALKO[3], K. JACOBS[6], R. JACOB[2], G. HODES[2], W. HOWE[2];

Abstract: Recent studies have shown that the macronutrient profile of a food has a major influence on how the brain encodes its reward value, independent of calorie content and self-reported liking. The ability of macronutrients to modulate food reward is hypothesized to stem from post-ingestive signals triggered in the gut that are then relayed to midbrain dopamine (DA) systems. A long-standing literature also highlights that food reward and preference may be influenced by biological sex, potentially via the influence of steroid hormone receptors positioned along the gut brain-axis. Here, we have designed a set of studies to test the broad hypothesis that the rewarding qualities of macronutrients in food vary between male and female mice in a dopamine-dependent manner. First, we gave male (n=9) and female (n=9) mice free access to foods made of fat, carbohydrates, or a combination of fat and carbohydrates ("combo"). We found that whereas male mice overwhelmingly consumed combo, females rapidly develop an enduring preference for fat. Similarly, fat was found to induce a place preference over combo

in female mice (n=7), whereas the reverse pattern was seen in males (n=8). We next explored the link between these differences in preference and DA release. In male and female mice, food preference corresponded with the density of DA release in the nucleus accumbens (n=7; 4 female; 3 male), but not the dorsal striatum (n=6; 4 male, 2 female), as measured using fiber photometry and the DA sensor dLight1.1. Finally, because male and female mice are differentially sensitive to the effects of chronic stress, we assessed the impact of 6 days of variable stress on food reward in male and female mice (n=40; 18 male, 22 female). Again, we found that male mice a preferentially consumed the combo stimulus, though stress further biased this preference (n=8 control; n=10 stress). In contrast, whereas female control mice gravitated toward the more caloric dense fat (n=12), those exposed to stress developed a strong preference for combo (n=10). Combined, our results suggest that the macronutrient content of foods modifies its attractiveness, and that biological sex can have a major impact on the neural encoding of food reward. Our on-going experiments using intragastric infusions suggest that different macronutrients and combinations recruit different ensembles of midbrain neurons. Follow-up studies will test the hypothesis that such post-ingestive signals triggered by food in the gut recruit molecularly distinct midbrain ensembles in male and female mice.

Title: Meso-striatal dopamine systems differentially encode food preference and content

Authors: *A. HARTLE[1], C. SALLEE[1], S. BHATTACHARYYA[2], S. SENGUPTA[2], A. DIFELICEANTONIO[3,4], M. HOWE[1];
[1]Virginia Tech. Neurosci. PhD Program, Blacksburg, VA; [2]Deptarment of Statistics, NCSU, Raleigh, NC; [3]Human Food, Nutr. and Exercise, Virginia Tech., Blacksburg, VA; [4]Fbri, Virginia Tech., Roanoke, VA

Abstract: Fats and carbohydrates have been shown to recruit separate ascending pathways from the gut that converge onto midbrain dopamine (DA) cells. Recent human research suggests that these post-ingestive pathways play a causal role in food reward. Specifically, foods made of combinations of fats and carbohydrates are over-valued relative to equally liked foods of the same calorie content composed of just one macronutrient. We hypothesized that this effect of macronutrient combinations on food valuation is mediated through differential post-ingestive

effects on striatal DA release. To test this hypothesis, we first assessed preference for foods made of different macronutrients in male and female mice. We found that when foods made of fat, carbohydrate, and fat/carbohydrate combined (combo) were simultaneously available, mice consumed far more combination compared to either of the individual macronutrients (n=14). To test if post-ingestive signals have a causal influence such food preferences, next we manipulated DA release during the post-ingestive window using optogenetics (n=8). We found that stimulating DA cell bodies in the substantia nigra during the post-ingestive window was sufficient to shift future preference. To link these findings to striatal DA release, we used fiber photometry and the fluorescent DA sensor dLight1.1 to measure DA binding in dorsal (DS) and ventral striatum (VS) as mice consumed foods made of fat, carbohydrate, or combo. Interestingly, phasic DA release events in the VS were highest as mice consumed the combination food compared to either individual macronutrient alone (n=7). In contrast DS DA release events were highest while mice consumed the more calorically dense fat (n=7). These data suggest that food preference and content are differentially encoded by DA release in the VS and DS, respectively. On-going efforts are designed to identify the signature of post-ingestive signals on striatal DA release recorded during these free feeding tests. To this end, we are currently using intragastric infusions to bypass the influence of oro-sensory signals on DA release during food intake. In addition, we are developing a novel approach to control for movement-related DA dynamics in the post-ingestive signal by modeling the cross-correlation between movement (velocity, acceleration) and fluorescence in the VS and DS. Our initial analyses identify region and sex-specific signatures of movement-related DA release in the DS and VS that will be integrated into our larger model of how post-ingestive DA dynamics influence canonical “reward”-related DA signals.

Title: Ampk signaling mediates the cortical regulation of over-consumption of high-fat diet

Authors: J. XIANG[1], M. SHI[1], ***Z.-X. XU**[1,2];
[1]Shanghai Stomatological Hosp. & Sch. of Stomatology, State Key Lab. of Med. Neurobio. and MOE Frontiers Ctr. for Brain Science, Inst. of Brain Science, Fudan Univ., Shanghai, China; [2]Inst. of Brain Science, Fudan Univ., Shanghai, China

Abstract: Abstract: The growing prevalence of obesity and accompanying metabolic disorders underscores the importance of understanding the mechanisms that control overeating behaviors, especially in relation to an energy-dense diet. In this study, we investigate the complex interplay

between cortical circuit and molecular mechanism that drive context-dependent overeating. Employing food-induced conditioned place preference behavioral paradigms, coupled with in vivo calcium imaging, we probed the dynamic cortical neuronal activity in response to energy-dense food stimuli. Our results elucidate the role of cortical neurons in integrating homeostatic signals as well as hedonic cues that significantly promote context-dependent overeating of energy-dense food. Our study further uncovers the molecular mechanisms underlying overeating, highlighting the critical role of AMPK signaling in the overconsumption of high-fat diets. From a circuit perspective, we found that cortical projections to the lateral hypothalamus play an important role in mediating the overconsumption of high-fat diets. Taken together, our study emphasizes the need to comprehend the cortical regulation of context-dependent overconsumption of high-fat diets. Such understanding will inform the development of targeted interventions to mitigate obesity.

Title: Zona incerta neurons release GABA and dopamine in the superior colliculus

Authors: K. S. BAKER[1], ***P. A. MILLER**[1], D. FUSCA[2,3], H. FENSELAU[4], P. KLOPPENBURG[2,3], M. J. CHEE[1];
[1]Carleton Univ., Ottawa, ON, Canada; [2]Inst. of Zoology, [3]Cecad, Univ. of Cologne, Cologne, Germany; [4]Max Planck Inst., Cologne, Germany

Abstract: The zona incerta (ZI) is a narrow but long hypothalamic region that is seen rostrocaudally throughout the entire hypothalamus. This structure is predominantly GABAergic, but there is a small, spatially-distinct subset of ZI GABA neurons that coexpress tyrosine hydroxylase (TH), and we recently showed that these TH-ZI neurons produce dopamine. The ZI is implicated in fear, feeding, sleep, hunting, and motor control behaviors. The densest projections from TH-ZI neurons arrive at brain regions involved in motor coordination, including the midbrain motor regions, like the superior colliculus (SC). Here, we probed the functional contribution of TH-ZI neurons to regulate SC cells by GABA and/or dopamine release. We first injected a cre-dependent virus expressing channelrhodopsin-mCherry into the ZI of male or female *Th-cre* mice and determined if TH-ZI neurons can release GABA and/or dopamine in the motor-related layers of the SC (SCm), especially along the midline where mCherry-labelled fibers were most prominent. Photostimulation (470 nm, 5 ms) of channelrhodopsin-expressing

Th-cre fibers produced an optogenetically-evoked inhibitory postsynaptic current (oIPSC) in one-third of SCm cells recorded (n = 29/87 cells). These oIPSCs were abolished by bicuculline treatment but persisted in the presence of tetrodotoxin thus indicating that TH-ZI neurons innervated SCm cells by monosynaptic GABA release. To determine if TH-ZI neurons also released dopamine in the SCm, we transduced *Th-cre* neurons with a cre-dependent AAV encoding the red-shifted opsin ChrimsonR, and we additionally injected an AAV under control of the CAG promoter to express the dopamine sensor dLight1.1 and track dopamine content in the SCm. Photostimulating ChrimsonR-expressing TH-ZI neurons with 620 nm (1 ms) red light pulses produced time-locked firing of up to 20 Hz at the soma. We thus photostimulated ChrimsonR-expressing *Th-cre* fibers in the SCm with 20 Hz pulses within a 0.5 Hz pulse train delivered over 5 min and captured dLight fluorescent images at 0.2 Hz (excitation 470 nm; emission: 500–550nm). dLight fluorescence peaked within 5 minutes of TH-fiber photostimulation (0.15 ± 0.04%; n = 7; N = 4) and persisted for > 5 minutes before gradually returning to baseline levels over 20 min. SCm cells were dopamine-sensitive, as bath application of 10 μM dopamine directly hyperpolarized (−9.3 ± 1.8 mV) 42% (n = 20/48 cells) and depolarized (+7.1 ± 0.6 mV) 25% (n = 16/48 cells) of SCm cells by activating D2 and D1 receptors, respectively. Taken together, our findings revealed that TH-ZI cells released both GABA and dopamine to elicit acute or prolonged regulation of downstream targets such as in the SCm.

Title: Impact of Intrauterine Growth Restriction on Feeding Behavior and Nucleus Accumbens Dopamine Receptor Expression in Wistar Rats

Authors: *J. J. ISIDOR[1], M. NAVARRO MEZA, Sr.[3], E. BARRIOS DE TOMASI[2]; [1]Inst. de Neurociencias, Univ. de Guadalajara, Guadalajara, Mexico; [2]INSTITUTO DE NEUROCIENCIAS, Univ. de Guadalajara, GUADALAJARA, Mexico; [3]Lab. de Nutrición y Memoria, Ctr. Universitario Del Sur/ Univ. De Guad, Ciudad Guzman, Mexico

Abstract: Clinical research suggests that intrauterine growth restriction (IUGR) may lead to addiction-like behavior in offspring and persistent changes in preference for palatable foods due to fetal neural modulation. IUGR in rats from maternal malnourishment resulted in abnormal Dopamine DR2 receptor (DR2D) expression, possibly causing sex-specific programming of the mesolimbic dopamine system and impacting feeding behavior. However, the direct relationship between DR2 dopamine receptors and IUGR and the sex-specific effects on DR2D expression

remains unclear. This study compared food preferences, the role of the mesolimbic dopaminergic system, and the sex-specific effects of IUGR on feeding behavior and DR2D expression. Time-mated pregnant Wistar rats (n=13) were randomly assigned to a control group (standard chow ad libitum) or a 50% food restriction (FR) group. Pups were sexed, weighed, and the litter was standardized within 24 hours of birth. During lactation, mothers had ad-libitum diets with reduced interaction for lower stress. On the 22nd day of lactation, pups were weighed, separated by sex (male=52; female=52), and randomly divided into four groups per sex based on the adult ad-libitum access diets, palatable or control: Adlib/Chow (n=13), FR/Chow (n=13), FR/Palatable (n=13), and Adlib/Palatable (n=13). From postnatal day (PD) 66 to day 126, palatable or control diets were provided *ad-libitum*. On day 126, euthanasia was performed, preserving brain tissue at -40°C. Western blot analysis will assess DR2D expression in the nucleus accumbens. Food consumption, weight gain, anthropometric measurements, and D2 receptors will be compared. Exploratory two-way ANOVA results suggest IUGR rats had a stronger preference and higher caloric intake of palatable foods. FR/palatable females showed greater preference than controls. No weight differences were seen from day PD-43 to PD-80, but as approaching PD-126 both sexes under palatable food, exhibited weight gain differences compared to control, but males on palatable diets gained more. Our behavioral data suggest IUGR rats' preference for palatable foods may be linked to mesolimbic reward pathway alterations, possibly in a sex-specific manner which will be correlated with the D2RD quantification.

Abstract: Title: Fasting and Diet Type Influence Food Intake Independent of Insulin Infusion in the Nucleus Accumbens
AuthorsH. A. Emmons[1], S. C. Fordahl[1]
DisclosuresH.A. Emmons: None. S.C. Fordahl: None.
Abstract Introduction: The obesity epidemic is projected to affect 50% of the U.S. population by 2030. Changes in neurotransmission have been identified in obese individuals; however, the underlying mechanism(s) for disruption of dopaminergic neurons is unknown, and whether it

impacts satiety signals is unclear. The purpose of this study is to investigate if disrupted insulin signaling in the nucleus accumbens (NAc) alters a dopaminergic satiety circuit in mice fed a high-fat diet. We hypothesized that infusing insulin into the NAc would significantly reduce high sugar food intake and feeding duration in low-fat fed animals with dampened response in high-fat fed counterparts. One proposed mechanism is reduced insulin signaling in a NAc to hypothalamus circuit that aids in satiety. Dysregulated dopamine may interfere with homeostatic caloric intake.Methods: C57 male (n=42) and female (n=40) mice were separated into low-fat and high-fat groups (10% or 60% total kcals from fat, respectively). Insulin (0.2 μL of 5μU in 10% vol/vol aCSF) or artificial cerebrospinal fluid (aCSF) were infused into the NAc at 0.1 μL/min for 2 minutes. Mice then received 30-minute access to a high sugar food pellet with 45% of kcals from fat in either a fasted or sated metabolic state. Results: A three-way ANOVA was used to analyze differences between diet group, metabolic state, and treatment infused. We identified a main effect of diet group (LF vs HF) with the LF groups consuming significantly more of the high sugar food pellet under fasted (males: $p=0.0006$; females: $p=0.0002$) and sated (males: $p=0.0322$; females: $p<0.0001$) conditions. Additionally, we identified a main effect of insulin decreasing high sugar food intake for females under sated ($p=0.0359$) conditions.Conclusions: Insulin infused into the NAc did not significantly alter food intake in either sated or fasted conditions of LF or HF-fed mice. This indicates that under our conditions, insulin does not influence satiety via the NAc. Interestingly, HF-fed males and females consumed significantly less food in both sated and fasted conditions compared to controls. These data suggest a potential avoidance or reduced preference for their non-standard high sucrose treat; however, further experiments are needed to directly examine food preference. Overall, we show that diet composition (specifically percentage of fat intake) plays a role in food intake, with current metabolic state (in conjunction with sex) affecting insulin's actions.

Med., Wake Forest Univ., Winston-Salem, NC

Abstract: Fluid homeostasis and food intake are crucial life-sustaining functions maintained under behavioral control. Although many endogenous mechanisms that regulate fluid homeostasis are largely conserved across individuals, there are significant behavioral variations influenced by genetic and environmental factors. To characterize the genetic basis of these differences, we performed a genome-wide association study (GWAS) on genetically diverse N/NIH Heterogeneous Stock (HS) rats (n=826), focusing on free-intake of food and water over a 24-hour period. Rats were housed in hanging wire cages, where total food intake was measured and microstructure of water intake was measured by contact lickometers. Water intake data were collected on a variety of measures including total intake, total number of licking bursts (i.e., two or more licks with an interlick interval of less than one second), and mean interlick interval (ILI). These measures were found to have moderate single-nucleotide polymorphism-based heritability (SNP h^2 = .18-.425). GWAS identified four significant quantitative trait loci (QTLs) for this set of traits. Two of these QTLs were associated with burst number and size on the same section of chromosome 1, a region including the gene *Stx11* which encodes a SNARE protein. Burst size was also associated with an expression-QTL (eQTL) and coding variant identifying *Fuca2* in the forebrain. These results show that individual variation in a highly conserved motivated behavior is genetically influenced, and that HS rats are useful for identification of genetic variants contributing to these individual differences.

Abstract: Central opioid signaling promotes hedonic feeding through mesolimbic pathways. While endogenous opioids and their cognate receptors are widely expressed in hypothalamic feeding circuits, their role in homeostatic hunger is unresolved. In this study, we sought to understand the role of mediobasal hypothalamic opioids in appetite. We hypothesized that opioids decrease appetite through suppression of neurons that encode hunger. To assess the role of opioids on hypothalamic neurons we performed fiber photometry with a novel fluorescent opioid sensor, deltaLight, in combination with electrophysiology. We found that feeding rapidly increases mediobasal hypothalamic opioid release which directly inhibits AgRP neurons through the mu-opioid receptor (MOR). Moreover, MOR antagonists blunt AgRP inhibition caused by food and satiety hormones. Lastly, we found that selective deletion of MOR in AgRP neurons increases palatable food preference. Our findings suggest that AgRP MOR signaling may sculpt diet choice mediated by post-ingestive signals.

Title: High-resolution neurochemical characterization of the paraventricular nucleus of the thalamus

Authors: *B. A. RAMOS[1], S. B. FLAGEL[2], R. T. KENNEDY[3];
[1]Neurosci. Grad. Program, [2]Psychiatry, [3]Chem., Univ. of Michigan, Ann Arbor, MI

Abstract: Psychiatric disorders are associated with neurochemical imbalances in the brain that promote maladaptive behaviors. To-date, little research has focused on characterizing neurochemical signatures within a given brain region. The paraventricular nucleus of the thalamus (PVT) has emerged as a key neural node in the control of motivated behavior and is well-placed to integrate input pertaining to the internal state of the body as well as cognitive and emotional states. Of particular interest is the role of the PVT within the subcortical hypothalamic-thalamic-striatal motivation circuit. The PVT is composed of anterior and posterior subregions, known to play a role in arousal and valence, respectively. Our research aims to characterize the neurotransmitters, their metabolites, and energy molecule concentrations

that contribute to the role of the posterior PVT (pPVT) in this regard. While the PVT is known to be neurochemically heterogeneous, it has not yet been well characterized, likely because of its neuroanatomical location and difficulty in detecting neurochemical signals with high resolution due to various physicochemical properties and low concentration. Here we employ a liquid chromatography mass spectrometry (LC-MS) method that utilizes benzoyl chloride (BzCl) labeling to account for these difficulties. Specifically, we combined a neurochemical profiling approach with microdialysis sampling in outbred rats to characterize a panel of 24 neurochemicals in the PVT. These include dopamine, norepinephrine, serotonin, histamine, glutamate, GABA, acetylcholine, choline, adenosine, DOPAC, 3MT, HVA, normetanephrine, taurine, serine, aspartate, glycine, glutamine, epinephrine, cysteine, VMA, DOPEG, MOPEG, and glucose. We detected all the compounds from a panel of 24 neurochemicals. Glutamine was relatively high in dialysate (31000 nM) at baseline conditions, which is more than a 10-fold increase relative to the other dialysate concentrations quantified. The next tier of abundant analytes included glucose (2700 nM), taurine (1700 nM), choline (1500 nM), and GABA (160 nM), respectively. With knowledge of baseline concentrations, we can begin to study how experimental manipulations alter these concentrations. This neurochemical profile of the PVT will be further examined with respect to behavioral phenotypes of relevance to psychiatric disorders.

Title: Western diet consumption impairs hippocampal encoding of memory and energy valence

Authors: *A. M. R. HAYES[1], L. TIERNO LAUER[1], L. DECARIE-SPAIN[2], M. E. KLUG[1], L. TSAN[2], A. KAO[1], S. SUN[3], J. REA[1], K. SUBRAMANIAN[1], C. GU[1], K. N. DONOHUE[1], A. A. FODOR[3], S. E. KANOSKI[2];
[2]USC, [1]USC, Los Angeles, CA; [3]Univ. of North Carolina at Charlotte, Charlotte, NC

Abstract: Western diet (WD) consumption during early life periods is associated with impaired hippocampus (HPC)-dependent learning and memory function. Here, we developed an early life

WD model in rats to investigate the neurobiological mechanisms mediating these diet-induced effects. Male Sprague Dawley rats received either a highly palatable cafeteria-style WD (*ad libitum* access to various high-fat and/or high-sugar foods; CAF; n=12) or standard healthy chow (CTL; n=12) during the juvenile and adolescent stages (postnatal days 26-56). Behavioral and metabolic assessments were performed both before and after a 30-day healthy diet intervention period beginning at early adulthood. Results revealed HPC-dependent contextual episodic memory impairments in CAF rats that persisted despite the healthy diet intervention. These impairments were observed in the absence of effects on body weight, body composition, glucose tolerance, or anxiety-like behavior (CAF n=12; CTL n=12). Given that dysregulated HPC acetylcholine (ACh) signaling is associated with memory impairments in humans and animal models, we examined markers of ACh function via immunoblotting and found lower protein levels of vesicular ACh transporter (VAChT) in the dorsal hippocampus (HPCd) of CAF (n=8) vs. CTL (n=8) rats, indicating chronically reduced ACh tone. Using intensity-based ACh sensing fluorescent reporter (iAChSnFr) *in vivo* fiber photometry targeting the HPCd, we next observed that ACh binding during object-contextual novelty recognition was highly predictive of memory performance and was disrupted in CAF (n=6) vs. CTL (n=8) rats. The functional relevance of dysregulated HPC ACh signaling to CAF-associated memory impairments was further supported by neuropharmacological results revealing that nicotinic ACh receptor alpha 7 agonist infusion in the HPCd during training rescued memory deficits in CAF rats (n=8 agonist, n=9 vehicle). In addition to exhibiting memory impairments, CAF rats also demonstrated increased average meal size consumption following the healthy diet intervention period (CAF n=7; CTL n=6). To explore whether this outcome was associated with aberrant HPC ACh signaling, iAChSnFr photometry was performed in the HPCd in rats consuming a large meal following a fast. Relative to the fasted pre-meal state, CTL rats (n=10) showed increased ACh binding in the HPCd upon meal termination, whereas pre- vs. post-meal ACh binding levels did not differ in CAF rats (n=6). Overall, these findings reveal a functional connection linking early life Western diet intake and ACh signaling with hippocampal-dependent memory and encoding of meal-related satiation signals in the HPCd.

Abstract: Title : **Computational Framework to Temporally Dissociate Homeostatic Hypothalamic Neuronal Roles**
Physiological needs evoke motivational drives to produce specific natural behaviors for survival. However, it has been challenging to differentiate between need and motivation in classic experimental paradigms due to the temporally intertwined dynamics of need and motivation. In this study, we developed simple and intuitive experimental paradigms that enabled us to distinguish distinct roles of the subpopulations of neurons in the hypothalamus. Based on classic homeostatic theories, we derived normative computational models of neural activity and behaviors for need-encoding and motivation-encoding neurons during predicted gain and loss events. We then recorded neural activity using in vivo calcium imaging in Agouti-related peptide (AgRP) and LHLepR neurons and also monitored eating behaviors after optogenetic manipulations of the two subpopulations, respectively. In our experimental paradigm, AgRP and LHLepR neural activity was consistent with theory-driven-neural-activity-models for need and motivation respectively. Furthermore, the temporal dynamics of behavioral activity evoked by optogenetic stimulation of AgRP and LHLepR neurons was consistent with the theory-driven-behavior-activity-model for need and motivation respectively. Thus, our study provides a parsimonious understanding of how distinct hypothalamic neurons encode need and motivation separately to produce adaptive behaviors for maintaining homeostasis.

Title: Changes in ACTH and serum glucose in 21-day-old rat pups rearing by rats underfed during gestation and lactation.

Authors: *M. MENDOZA[1], I. JIMENEZ-ESTRADA[2], C. G. TORIZ[3];
[1]Fisiología, Biofísica y Neurociencias, Ctr. de Investigación y de Estudios Avanzados del I.P.N., Mexico City, Mexico; [2]Physiology, Biophysics and Neurosci., IPN Ctr. Invst & Adv Studies, Mexico City, Mexico; [3]CINVESTAV-IPN, Ciudad de Mexico, Mexico

Abstract: The purpose of the present study was to evaluate the metabolic impact in the offspring of mothers with different nutrition conditions during pregnancy and lactation. A 30% reduction in the protein-caloric supply of female adult rats before and during pregnancy, and along the lactation period. At birth the pups were placed with a foster mother and four groups were done: 1) pups from *ad libitum* fed mother during pregnancy and lactation (C-C), 2) pups from underfed mother during pregnancy and lactation (U-U), 3) pups from well fed mother but lactated by a underfed foster mother (C-U), 4) pups from a underfed mother lactated by a well fed foster mother (U-C). At the end of the lactation period the pups were weighted and obtained their body length, blood serum, and liver. Serum levels of ACTH and glucose were determined. The body mass index showed that U-C pups have the highest values than the other pup groups. Serum ACTH concentrations were statistically higher in U-U and U-C pups than C-C and C-U pups. Serum glucose levels showed differences between the four groups: the higher levels were observed in U-C pups followed by C-C pups, then C-U pups, and the lowest level were found in U-U pups. The heaviest liver was from U-C pups. These results showed that serum ACTH concentrations are impacted by the gestation under nutrition condition independently of the abundance of meal during the lactation period. The lower serum glucose levels were obtained in pups lactated by underfed foster mothers. However, the data obtained from pups gestated by underfed mothers and with full meals after birth suggest that these rats present a pre-diabetic metabolic pattern. We need to measure other metabolic hormones to reinforce this interpretation.

Title: Dopaminergic modulation of parabrachial nucleus activity and feeding behavior

Authors: *G. GABRIELSON, D. LAFFERTY, D. KERSPERN, A. LUTAS;
NIDDK, NIH, Bethesda, MD

Abstract: The acquisition and consumption of food, or feeding behavior, is a multi-system process all organisms undergo to maintain energy balance. The brain is involved in the appetitive, consummatory, and terminating phases of feeding behavior. The parabrachial nucleus (PBN) is an important node in the neural circuit that controls feeding. Recent evidence implicated dopamine in the direct modulation of PBN neuron activity and feeding behavior. Dopamine, produced in the substantia nigra and ventral tegmental area (VTA), signals through G protein-coupled receptors, which include two major types: D1 and D2. Both D1 and D2 receptor expression is found within the PBN. Our project looks to better understand how dopamine signaling in PBN modulates neuronal activity and the cessation of feeding. Using 8-10 week old male and female C57BL/J mice, we expressed channelrhodopsins via adeno-associated viral

gene delivery and implant optic fibers above the PBN. Following 4 weeks of recovery and viral expression, we test the influence of optogenetic manipulations on feeding. In Slc6a3-Cre mice(n = 6) injected with a Cre-dependent, red-shifted opsin (Chrimson) in the VTA to target expression in dopamine neurons, photostimulation of VTA axons in the PBN decreased consumption of both standard and more palatable high-fat diet. In D1-Cre mice (n = 6) injected with Chrimson in the PBN to target D1-expressing neurons, photostimulation drove even more robust decreases in standard and high-fat diet feeding. In D2-Cre mice (n = 6) injected with Chrimson in the PBN to target D2-expressing neurons, photostimulation lead to complete suppression of feeding and pronounced motor phenotypes. Utilizing combined optogenetics and fiber photometry in D1-Cre mice (n = 3) injected with Cre-dependent calcium sensor(GCaMP6s) in the PBN and Chrimson in VTA axons in PBN, we see an increase in neural activity during feeding aligning with feeding and the ability of photostimulation to drive responses in D1-expressing PBN neurons. However, we see that systemic injection of a D1receptor antagonist, which was capable of impairing feeding behavior, did not block photostimulation-evoked PBN D1 neuron activity, indicating that dopamine signaling did not mediate the increased activity. Fiber photometry recordings of the D2-expressing PBN neurons(n = 2 mice) also showed feeding evoked increases in neural activity. Systemic injections of aD2 agonist, decreased D2 PBN neuronal activity and suppressed feeding behavior. On-going fiber photometry, optogenetic stimulation, and acute brain slice two-photon imaging will continue to address the role of D1 and D2 receptor signaling on PBN activity and feeding behavior.

Abstract: Obesity is a complex disease with a multifactorial etiology and is one of the major health problems worldwide. The palatability, availability, and energy density of foods play an important role on its development. The type 2 dopamine receptor (D2R) is an inhibitory G-protein coupled receptor that is desensitized and internalized upon repeated stimulation by its ligand, dopamine. Overconsumption of palatable foods is involved in the internalization of D2R in the nucleus accumbens (NAc) by continuous dopamine release, which impairs hedonic feeding regulation. The tyrosine kinase receptor anaplastic lymphoma kinase (ALK), previously known for its role in cancer development, is involved in D2R internalization and when inhibited, it is prevented. The present study aims to evaluate the effect of ASP3026, an ALK inhibitor on accumbal D2R internalization along with feeding behavior of cafeteria-diet fed (CAFD) mice. Adult male Balb-C mice were offered a standard diet (SD) or CAFD (n=12/group) for 10 days. On days 8, 9 and 10, half of the animals of each group was subcutaneously (s.c.) administered with 30 mg/kg of ASP3026 (CAFD/ASP n=6; SD/ASP n=6) and half with vehicle (DMSO 10% and corn oil 90%) (CAFD/VEH n=6; SD/VEH n=6) 7 hours before the beginning of the dark phase. Daily food intake was registered, animals were sacrificed on day 10 and brains were extracted and frozen at -70°C. To determine the internalization of the D2R in the NAc, we performed a western blot of the membrane and cytosolic phases measuring the relative levels of D2R/B-actin. Mice in the CAFD/ASP group decreased their CAFD intake by 24.3 ± 0.9% (mean values, SE) vs CAFD/VEH during the 3 consecutive days after the s.c ASP3026 injection. ASP3026 also reduced the intake of standard diet in SD/ASP group by 20 ±1.35% vs. SD/VEH. This decrease is probably explained by the intrinsically rewarding characteristics of food. Our results support that the decrease in CAFD intake of ASP3026 injected mice was associated with accumbal DR2 internalization.

Title: Are trpv1 receptors in the supraoptic and paraventricular nucleus obligatory for osmoregulation?

Authors: *E. ALCIN, H. MOERZ, R.-D. TREEDE, W. GREFFRATH;
Neurophysiol., Mannheim Ctr. for Translational Neuroscience, Med. Fac. Mannheim, Heidelberg Univ., Mannheim, Germany

Abstract: Introduction: The hypothalamic supraoptic (SON) and paraventricular (PVN) magnocellular cells (MCs) play a crucial role in the regulation of water and salt balance by vasopressin (VP) in an osmolality-dependent manner. MCs react precisely to hypertonic stimulation with membrane depolarization. Some in vitro electrophysiological studies propose a product of TRPV1 gene commits to osmosensory transduction in hypothalamic neurons to regulate VP secretion. In contrast, in an in vivo study, it has been shown that TRPV1 channels are not obligatory for VP secretion and thirst stimulated by hypernatremia. We aimed to test the role of hyperosmolarity (Mannitol 40 mOSM), Capsaicin 10 µM, Glutamate 200 µM or high K^+ 140 mM on dissociated MCs from SON and PVN and on brain slices . **Methods:** Adult male Sprague-Dawley (SD) and TRPV1 KO rats were used in all experiments. **Calcium imaging:** For measurements of [$Ca2^+$]i, dissociated MCs were loaded with either 1 µM Fura-2 AM or 1 µM Rhod-2 for 60 min in Tyrode's solution. After washing with Tyrode's solution, cells were mounted on the stage of an inverted microscope in an open bath chamber and superfused by Tyrode's solution (1-3 ml/min) either at room temperature (RT) or 37 ºC. **Preparation and maintenance of brain slices:** 200-300 µm coronal slices containing the SON were collected and maintained in an incubation chamber at RT for at least 2 h in aCSF. Slices were placed in the recording wells with a 6×10 multi-electrode recording array. Throughout all procedure, aCSF was saturated with 95% O_2, 5% CO_2 at 32 ºC. **Results:** Dissociated MCs from SD rats; none of MCs reacted to Capsaicin, but Mannitol (23,5±2,9 %, n=16), Glutamate (136,2±13,4 %, n=33) and high K^+ (171,9±18 %, n=48) increased Ca^{2+} influx at RT. Mannitol (66,3±11,2 %, n=6) Glutamate (48,3±10,6 %, n=6) and high K^+ (101,4±11,8 %, n=14) increased Ca^{2+} influx in dissociated MCs from KO rats at RT. Dissociated 10 MCs from SD rats; Mannitol (101,8±18,1 %), Capsaicin (65,7±3,4 %) Glutamate (94,2±10,9 %,) and high K^+ (96,9±9,2 %) increased mean intensity value at 37 ºC. Additionally, Mannitol, Capsaicin and Glutamate increased spikes activity in the SON compared to aCSF treatment (number of spikes per min; 127, 127, 232 and 106). **Conclusion:** None of MCs from SD or KO rats reacted to Capsaicin but Mannitol and Glutamate at RT. Capsaicin, Mannitol and Glutamate had an effect on MCs from SD rats at 37 ºC and these chemicals also increased spikes activity in the SON. We have shown that regulatory role of TRPV1 at normal body temperature. TRPV1 channels together with other factors like glutamate receptors can contribute to network activity in SON and hence participate in regulation of water and salt balance.

Title: Fear extinction relies on ventral hippocampal safety codes shaped by the amygdala

Authors: *R. NGUYEN, K. KOUKOUTSELOS, T. FORRO, S. CIOCCHI;
Univ. of Bern, Bern, Switzerland

Abstract: Extinction memory retrieval is influenced by spatial contextual information that determines responding to conditioned stimuli (CS). Yet, it is poorly understood if contextual representations are imbued with emotional values to support memory selection. Here, we performed activity-dependent engram-tagging, and in vivo single-unit electrophysiological recordings from the ventral hippocampus (vH) while optogenetically manipulating basolateral amygdala (BLA) inputs during the formation of cued fear extinction memory. During fear extinction when CS acquire safety properties, we found that CS-related activity in the vH reactivated during sleep consolidation and was strengthened upon memory retrieval. Moreover, fear extinction memory was facilitated when the extinction context exhibited precise coding of its affective zones. Finally, these activity patterns along with the retrieval of the fear extinction memory were dependent on glutamatergic transmission from the BLA during extinction learning. Thus, fear extinction memory relies on the formation of contextual and stimulus safety representations in the vH instructed by the BLA.

Title: Multiplexed analysis of interneuron heterogeneity in the basolateral amygdala of male and cycling female rats.

Authors: *G. RAIMONDI[1], R. TRIPP[1], L. OSTROFF[2];
[1]Univ. of Connecticut, Storrs, CT; [2]Univ. of Connecticut, Univ. of Connecticut, Storrs Mansfield, CT

Abstract: The basolateral amygdala (BLA) has a central role in encoding anxiety- and fear-related memories, and inhibitory interneurons are known to be critical for these processes. Approximately 15% of neurons in the BLA are GABAergic interneurons, and these fall into an assortment of functional classes that express distinct combinations of calcium-binding proteins and neuropeptides. The distribution of molecular markers in BLA interneurons has been extensively characterized in male rats, and although some studies report sex differences in the expression patterns of individual calcium-binding proteins in the BLA, no comprehensive

mapping of interneuron markers has been performed in female subjects. Women are at higher risk of anxiety disorders than men during the reproductive years, and fear- and anxiety-related behaviors in rodent models are known to vary across the estrous cycle, which could arise from ovarian hormone effects on inhibitory circuitry. Indeed, there are some reports of sex and estrous cycle differences in parvalbumin (PV) expression in the rat BLA and in estrogen receptor expression in BLA interneurons. Here, we perform single-cell multiplexed imaging of a variety of interneuron markers and hormone receptors in the BLA of male and female rats across the estrous cycle. Using serial ultrathin (50 nanometer) sections, we analyze protein and RNA expression in individual excitatory and inhibitory neurons, and report relative abundance, distribution, and colocalization patterns of calcium binding proteins, sex hormone receptors, and structural proteins in amygdala subnuclei. Our study is the first multiplexed analysis in ultrathin sections comparing broad and fine anatomical features in the brain with an attention to sex and estrous cycle. These findings may also provide insight into mechanisms of amygdala inhibitory circuits and neuroanatomical explanations of sex differences in fear- and anxiety-related behaviors.

AbstractThe basolateral amygdala (BLA) is a key structure processing the threaten and emotional information, and plays a key role in controlling the fear memory. Previous research has suggested that the extinction procedure generates a new memory that coexists with the original fear memory, and that interneurons play an important role in extinction. However, the mechanisms that control the competing extinction and fear memories in BLA are not yet fully understood. In this study, we used a chemogenetic approach to investigate these mechanisms in mice that were genetically modified to improve the tagging specificity of active neurons. We found that silencing extinction-tagged BLA neurons, or stimulating fear acquisition-tagged BLA neurons, led to a relapse of fear memory. Additionally, we observed that silencing BLA GABAergic
neurons, or extinction-tagged BLA GABAergic neurons, restored fear expression after extinction, while inhibiting acquisition-tagged BLA GABAergic neurons did not impair fear memory retrieval. Our results indicate that specific inhibitory GABAergic BLA engrams are established during fear extinction, which interfere with existing fear memory-related neural circuits and suppress conditional fear memory. These findings provide new insights into the neural mechanisms underlying fear extinction and suggest that BLA GABAergic neurons are potential targets for therapeutic interventions in cognitive disorders such as post-traumatic stress disorder (PTSD).

Title: Dynorphin in vmPFC facilitates optimal approach/avoidance conflict resolution

Authors: *H. BRAVO[1], A. LIMOGES[3], C. T. LAGAMMA[4], H. A. TEJEDA[2];
[1]NIH, Natl. Inst. of Mental Hlth. (NIMH), Gaithersburg, MD; [2]Hugo Tejeda, NIH, Natl. Inst. of Mental Hlth. (NIMH), Bethesda, MD; [3]Lab. of Behavioral and Genomic Neurosci., NIH/NIAAA, Rockville, MD; [4]NIH, Lancaster, PA

Abstract: Survival depends on threat detection and the selection of appropriate defensive behavioral strategies to minimize aversive and maximize positive outcomes. This skill is especially critical when motivations to approach rewards and avoid threats co-exist. The Prefrontal cortical (PFC) circuits provide top-down control of threat reactivity. Specifically, the ventromedial PFC (vmPFC) plays a role in suppressing conditioned fear responses after extinction. Furthermore, dynorphin (Dyn) is widely expressed in the limbic circuits, including vmPFC. These findings highlight Dyn as a potential candidate for the adaptive selection of defensive behaviors critical in conflict conditions. To assess the role of Dyn in vmPFC in conflict resolution, we developed a novel approach/avoidance task in which mice are presented with the choice of seeking rewards vs. avoiding a footshock by stepping onto a safe platform. Mice first learn that sucrose availability is signaled by a 30s light cue, whereas a 30s tone co-terminates with a 2s footshock. These two stimuli are also presented simultaneously in some trials, generating a conflict between approaching the food or avoiding the shock. An essential feature of this task is that mice can develop an optimal strategy to retrieve rewards and avoid shocks during conflict trials by nose-poking early and avoiding later when the shock becomes imminent. Here we report that Conditional knockdown of Dyn in vmPFC (with PDyn-shRNA) impaired adaptive conflict resolution by favoring the maladaptive selection of passive over active avoidance. PDyn-shRNA mice also showed delayed learning of avoidance (increased shocks) and a suboptimal conflict strategy that prioritized passive avoidance at the expense of rewards. Fiber photometry recordings of Dyn neurons in vmPFC revealed increased activity in conflict trials where mice retrieved rewards in contrast with trials where they displayed passive avoidance at the expense of rewards. We did not observe this contrast during the reward phase of training in agreement with our previous experiment, where conditional knockdown of Dyn did not affect reward-seeking in the absence of conflict. Together these findings suggest that DYN signaling by vmPFC contributes to adaptive conflict resolution by suppressing passive and allowing/promoting active defensive behaviors.

Title: Innate fear responses to distal and proximal predator threats

Authors: J. N. CARROLL[1], B. MYERS[2], I. M. RAMAN[3], *C. E. VAAGA[2,3];
[1]Dept. of Biomed. Sci., Colorado State Univ. Molecular, Cell. & Integrative Neurosciences, Fort Collins, CO; [2]Dept. of Biomed. Sci., Colorado State Univ., Fort Collins, CO; [3]Dept. of Neurobio., Northwestern Univ., Evanston, IL

Abstract: To survive predation, animals must be able to detect and appropriately respond to predator threats in their environment. Such defensive behaviors are innate: suggesting dedicated neural circuits for the detection, sensorimotor integration, and execution of appropriate behaviors. Ethologically, distal threats (i.e., sweeping visual stimuli) trigger 'passive' avoidance strategies, such as freezing to avoid predator detection. Conversely, more proximal threats (i.e., looming visual stimuli) trigger 'active' avoidance strategies, such as fleeing. The goal of the present study is to examine innate fear responses when the behavioral strategy is determined by extrinsic factors. Specifically, we investigate how environmental and physiological conditions modulate innate freezing responses in mice, with a particular emphasis on understanding the conditions that alter behavioral responses to repeated stimuli. We demonstrate that in both male and female mice looming and sweeping visual stimuli elicit freezing in the absence of a nest to flee towards. However, looming stimuli triggered comparatively prolonged freezing bouts. Furthermore, when looming visual stimuli were repeated at intervals as short as 5 minutes, freezing responses decreased across trials in response to both looming and sweeping stimuli, suggestive of fear suppression. To begin testing whether the fear suppression represents safety learning, we tested animals at intervals of 1 hour and 24 hours, as well as testing fear recall at 1 month. Finally, to correlate fear behavior across paradigms with other physiological measures of stress, we measured circulating corticosterone levels after fear exposure. Together, our results indicate that when mice engage in passive avoidance strategies triggered by distal or proximal threats, the vigor of the response scales with threat proximity. Further, our results demonstrate that freezing responses are modified by repeated threat exposure.

Title: Context-dependent Neural Representations of Visual Stimuli in Primary Visual Cortex

Authors: *L. CUI[1], A. KEIL[2], M. DING[2];
[1]Univ. of Florida, Gainesville, FL; [2]Univ. Florida, Univ. Florida, Gainesville, FL

Abstract: It has been proposed that the cortical representations of visual stimuli are altered by experience. We tested this idea by recording fMRI data from 18 participants performing a Pavlovian fear conditioning paradigm. The paradigm consisted of three sessions. In the initial habituation session, two Gabor patches (45 and 135 degrees) were repeatedly presented in random order for a total of 120 trials. In the acquisition session, which followed the habituation session, the 45-degree Gabor patch (CS+) was paired with a loud scream (US) whereas the 135-degree Gabor patch (CS-) was never paired with the US. In the final extinction session, the CS+ and CS- was again repeatedly presented in random order (120 trials; no US). Applying the MVPA decoding method to fMRI data from the primary visual cortex in a sliding trial window fashion, we observed the following. First, the accuracy of decoding between the two Gabor patches was at the chance level (50%) early in habituation, and became progressively higher as the participant experienced more repetitions of the two stimuli, reaching ~60% at the end of habituation. Second, for extinction, the decoding accuracy started at ~60% and became progressively lower, reaching the chance level at the end of extinction. Third, MVPA classifiers trained on data from the end of habituation could not decode data from the beginning of extinction and vice versa. These results are consistent with the idea that the neural representations of visual stimuli undergo fundamental changes through learning: in habituation, repeated presentations without associative learning sharpened the sensory and perceptual distinctiveness of the two Gabor patches, whereas in extinction, the initially high representational distinctness of CS+ and CS-, reflecting the motivational quality of the CS+ and CS- (threat vs safety) acquired through associative learning, became diminished with extinction learning through potentially an active de-sharpening process.

Title: Protein phosphatases 1 and 2b mediate safety signal learning produced decreases in Hermissenda Type B cell excitability.

Authors: *J. FARLEY[1], J. B. ANDERSON[2], J. S. CAVALLO[3];
[1]Indiana Univ. Program in Neurosci., Bloomington, IN; [2]Psychological and Brain Sci., Indiana Univ. Bloomington, Bloomington, IN; [3]Indiana Univ., BLOOMINGTON, IN

Abstract: Explicitly Unpaired presentations (EU) of light (L) and rotation (R) produce behavioral changes (e.g., increased phototaxis) in the sea snail *Hermissenda crassicornis* that satisfy criteria for conditioned inhibition (CI)/safety signal learning. This is accompanied by decreased excitability of type B photoreceptors (B cells) due to increases in several somatic potassium (K^+) currents. We've previously found that protein phosphatase 1 (PP1) inhibitors

(e.g., Calyculin A, I-2): 1) depolarize Untrained B cells and reduce somatic K^+ currents, partially mimicking effects of L-R pairings, 2) attenuate excitability (spike frequency) decreases produced by extinction training (EXT), a form of learning that overlaps with EU. Conversely, injection of catalytically-active PP1 (caPP1) into Untrained B cells mimicked the excitability decreases produced by EXT and occluded further reductions in spiking by additional EXT. Thus, we hypothesize that PP1 may also contribute to EU-produced B cell excitability decreases. To test this, we measured B cell photoresponses from Untrained and EU animals (24-48 hr post training) after injection with caPP1. In Untrained B cells, caPP1 produced clear reductions (~ 20 and 25%, respectively) in steady state generator potentials (SSGPs) and light-evoked spike frequencies across five 30-sec test lights, mimicking EU. EU occluded these caPP1 effects. caPP1 also increased (~22 and 27%, respectively) both I_A and $I_{K\text{-}Ca}$ components of K^+ current in Untrained B cells that mediate EU-decreases in excitability. In contrast, caPP1 failed to increase these K^+ currents in EU B cells. We next injected Untrained and EU B cells with the core peptide fragment of the PP1 regulatory G subunit ($GM_{63\text{-}75}$), a competitive inhibitor of PP1. Iontophoresis of 25uM $GM_{63\text{-}75}$ increased B cell SSGPs from Untrained (19.5%; *n.s.*) and EU animals (52.7%; $p < 0.02$). While EU B cells showed a ~40% reduction in SSGP ($p < 0.001$), SSGPs of $GM_{63\text{-}75}$-treated EU B cells failed to differ from Untrained B cells. Thus, $GM_{63\text{-}75}$ treatment abolished the EU B cell excitability decrease. We also tested the involvement of calcineurin/PP2B (CaN) in EU-produced decreased excitability. Cyclosporin A (CsA; 20 nM, CaN inhibitor) had no obvious effect on either Untrained or EU B cell excitability. However, caPP2B injection reduced excitability of Untrained B cells. In contrast, caPP2B failed to affect EU B cell excitability. Our results suggest that: 1) upregulated PP1 activity is critical for EU decreases in B cell excitability, 2) PP1 is constitutively active in Untrained B cells, 3) (transient) activation of CaN by EU disinhibits PP1, 4) decreasing excitability through increases in K^+ currents.

Title: Deleterious cFos Activation in mPFC Associated with Fear Extinction in a Rodent Model of PTSD/AUD

Authors: *L. J. WILLS[1], B. SCHWARTZ[2], B. MCGUFFIN[2], J. PETERS[3], J. T. GASS[1];
[1]Quillen Col. of Med., Johnson City, TN; [2]East Tennessee State Univ., Johnson City, TN;
[3]Anesthesiol., Univ. of Colorado Anschutz Med. Campus, Aurora, CO

Abstract: Alcohol use disorder (AUD) and post-traumatic stress disorder (PTSD) are two of the most common mental health disorders and are highly comorbid. Additionally, maladaptive memories are implicated in disorders such as AUD and PTSD. Fear-/alcohol- related cues become disproportionally salient over non-fear-/ non-alcohol-related cues. This enhanced salience contributes to difficulty extinguishing fear/alcohol associations for people with comorbid PTSD/AUD. A number of recent studies have suggested that specific subregions of the prefrontal cortex mediate these fear/drug related behaviors. Specifically, lesion studies have demonstrated that the prelimbic (PrL) cortex is necessary for the expression of conditioned fear while the infralimbic (IfL) cortex is critical for the expression of extinction behavior. To gain a better understanding of the potential impact co-occurring PTSD/AUD has on neuronal activation in the IfL and PrL cortices we measured c-fos expression following the final day of fear extinction learning using a rodent model of PTSD/AUD.Wistar rats were grouped based on their exposure to the PTSD/AUD paradigm and fear conditioning (FC) task. The PTSD/AUD paradigm consisted of animals being exposed to 2h restraint stress (RS) followed by 2-weeks of chronic intermittent ethanol vapor exposure (CIE). Upon completion of CIE animals were given 10-days to recover from withdrawal symptoms prior to the commencement of the FC task. FC was used to assess future stress sensitivity by examining the acquisition of fear learning and extinction of fear behaviors. On the final day of extinction training animals were euthanized via transcardial perfusion and brain tissue was harvested to analyze changes in c-fos expression. Brain tissue containing IfL and PrL were stained with anti-cFos and Neurotrace Nissl and imaged to assess cell colocalization in each brain region.Our results indicated that animals exposed to RS+CIE had significantly less colocalized cells in the IfL than CTRL animals, suggesting a reduction of cFos activity in these neurons. Additionally, RS+CIE animals showed significantly more PrL colocalization than the CTRL animals, indicating that these animals had an increase in neuronal activation in this region. The current study provides fundamental knowledge on the possible cause in the difficulty for individuals with comorbid PTSD/AUD to extinguish fear memories.

Title: Modulation of Dorsolateral Prefrontal Cortex Activity through Auricular Skin Stimulation

Authors: *A. KAWASAKI[1], T. KAWADA[2], S. YAMAZAKI[3];
[1]Ritsumeikan Univ., Kyoto-Shi, Japan; [2]Tohoku Univ., Sendai-Shi, Japan; [3]Dept. of Physical Therapy, Sendai Hlth. and Welfare Professional Training Col., SENDAI, Japan

Abstract: **Introduction**Currently, there are two external approaches to modulating autonomic nervous activity: auricular electrical stimulation therapy and superficial skin stimulation using microcone patches. The cardiac sympathetic reflex is a physiological response associated with stress and emotion, and it is believed that exerting control over autonomic responses to external stimuli can influence the activity of the ventromedial prefrontal cortex. The purpose of this study was to examine how auricular skin stimulation with microcone patches consequently affects activity in the dorsolateral prefrontal cortex.
Methods We utilized the short text comprehension task (Takahashi, 2023) and executed a mixed model ANOVA with two within-subject factors. The independent variables were the condition of the task (rest for 2 minutes and task for 3 minutes), and the presence or absence of auricular skin stimulation through microcone patches. The dependent variables included the autonomic nervous response and the blood oxygen saturation levels in the bilateral prefrontal cortex. This study has undergone ethical review and has been approved by our institution's ethics committee.
ResultsMixed model ANOVA showed a significant impact of micro-cone auricular skin stimulation on the activity in the left (1ch, $p<.001$, $f=0.30$) and right dorsolateral prefrontal cortex (3ch, $p<.05$, $f=0.17$), indicating increased activity during stimulation. Conversely, activity decreased around the bilateral frontal poles (2ch, $p<.05$, $f=0.18$; 4ch, $p<.001$, $f=0.26$) with stimulation. Effect sizes were moderate to large. Regarding autonomic activity, there was a notable trend for sympathetic tone (LF/HF) based on task presence ($p=.057$, $f=0.17$), though the effect size was small. Additionally, while not significant, there was a trend towards a lower pnn50 (%), an index of vagal tension, during stimulation ($f=0.10$).
Consideration In this study, it is suggested that microcone-induced skin stimulation could influence the activity of the dorsolateral prefrontal cortex. Stimulation appears to suppress medial prefrontal functions related to autonomic activity, potentially permitting the dorsolateral prefrontal cortex to direct cognitive resources to its inherent activities. Given the study's low task difficulty and potential individual differences in response to autonomic nerve activity, future research should aim to clarify the underlying mechanism and consider
varying task difficulties.

Title: Polygenic risk for internalizing disorders predicts safety-cue learning during differential fear conditioning mediated by cerebello-frontal structural connectivity

Authors: *J. E. SCHNEIDER PENATE[1], C. A. GOMES[1,2], H. ENGLER[2], S. ELSENBRUCH[1], C. J. MERZ[1], O. T. WOLF[1], E. GENC[3], T. SPISAK[2], O. GÜNTÜRKÜN[1], H. QUICK[2], D. TIMMANN[2], N. AXMACHER[1], R. KUMSTA[1,4];

Abstract: Interindividual variation in fear learning efficiency is partly attributable to the individual genetic make-up. In turn, genetic factors might partly be linked to mental health risk through effects on fear learning. Genetic variants may impact the structural and functional connectivity of the human fear extinction network such that genetically driven alterations of network properties give in part rise to the observed individual rates of learning. Here, we aim to identify genetic risk indices that predict physiological measures of fear learning mediated by connectivity patterns in key regions within the extinction network.For this purpose, we computed polygenic risk scores (PRS) for major depressive disorder, post-traumatic stress disorder, anxiety disorders, cross-disorder risk, and neuroticism for one hundred and seventy-two human subjects that volunteered in several differential fear conditioning experiments. Using diffusion weighted imaging and resting state functional magnetic resonance imaging, we computed structural and functional connectivity measures for all possible pairs out of five key brain regions within the extinction network: amygdala, hippocampus, dorsal anterior cingulate cortex (dACC), ventromedial prefrontal cortex (vmPFC), and the cerebellar nuclei.Learning measures derived from modelled non-linear slopes of skin conductance responses to either conditioned stimuli (CS+) that predict the occurrence of an aversive unconditioned stimulus or stimuli that do not (CS-) during acquisition and extinction training of the experiments were regressed on the PRS. Exploratory mediation analysis as per Serang et al. (2017) was performed to identify relevant sets of region pairs and connectivity metrics that may mediate the association between genetic risk and fear learning.Structural connectivity between the cerebellar nuclei and the vmPFC was found to mediate the relationship between CS- learning and PRS for anxiety disorders, neuroticism, PTSD, and most consistently, for major depressive disorder during acquisition. No other predictor or mediator had a substantial predictive impact on learning for either stimulus type or experimental phase.Our results suggest that genetic predisposition for internalizing disorders explain a fraction of the observed variability in the efficiency of safety-cue learning. They further support the notion that the human cerebellum, a brain region frequently neglected in the field, is indeed involved in fear learning.

Title: Alto-100 improves pattern separation in mice through a neurogenesis-dependent mechanism

Authors: *H. CHUNG[1], K. TEGANG[1], A. ETKIN[2], K. RESSLER[3], J. HARTMANN[3], C. STUCKE[4], A. SAVITZ[2], R. HEN[1], W.-L. CHANG[1];
[1]Dept. of Psychiatry, Div. of Systems Neurosci., Columbia Univ. and New York State Psychiatric Inst., New York, NY; [2]Alto Neurosci., Los Altos, CA; [3]McLean Hospital/ Harvard Med. Sch., Belmont, MA; [4]Bates Col., Lewiston, ME

Abstract: Background: Neurogenesis, the formation of new neurons, continues to occur in the dentate gyrus of the hippocampus throughout adulthood in both mice and humans. ALTO-100 is a novel neurogenic drug that is thought to act at BDNF. Previous work from our group has demonstrated that ALTO-100 improves pattern separation in adult mice without altering fear conditioning. Here, we test whether this effect of chronic treatment with compound ALTO-100 is neurogenesis-dependent by ablating neurogenesis with X-irradiation.Methods: Young adult male c57Bl/6J mice were used for all experiments. X-irradiation was administered to hippocampal areas while mice were anesthetized. Sham mice were also anesthetized, but no X-irradiation was administered. Irradiated and sham mice were allowed to recover for 8 weeks prior to initiation of drug treatment, 30mg/kg of ALTO-100 administered daily by oral gavage. After 21 days of treatment with the active compound or the control vehicle, the mice underwent a series of behavioral tests, including the open field test, a contextual fear conditioning task, followed by 7 days of a contextual fear discrimination task. Successful fear discrimination was achieved when animals distinguished between the conditioned fear context “A” and a similar context “B” that was not paired with foot shock. After the conclusion of pattern separation, the mice were perfused and their brains were collected for histological analyses (N =6-7 mice/group).Results: Each of the four groups of mice displayed elevated levels of freezing after the initial contextual fear conditioning, with no difference between groups. Vehicle-treated sham mice showed a significant effect of context, but no significant context x day interaction. Sham-ALTO-100 mice also showed a significant effect of context, but also a context x day interaction, with significant discrimination between on the 6^{th} day of exposure to both contexts. X-irradiated vehicle-treated mice were not able to significantly discriminate between contexts, and X-irradiated ALTO-100-treated mice also were not able to significantly discriminate between the contexts. Data from the Open Field Test will be presented, along with data from immunohistology staining for markers of neurogenesis.Conclusion: We demonstrated that chronic pharmacological treatment with the compound ALTO-100 reliably improves context discrimination in non-irradiated mice, as we have previously shown.
Furthermore, this effect appears to be neurogenesis-dependent, as X-irradiation and ablation of neurogenesis was able to block the effects of ALTO-100 on pattern separation.

Title: Glucocorticoid-induced fear-like memory is associated with an increase in h current in the hippocampal CA1 neurons

Authors: J. KIM, K. POKHAREL, S. MICHAEL, A. LEE, ***C. KIM**;
Neurosci. & Regenerative Med., Augusta Univ., Augusta, GA

Abstract: Excessive or inappropriate fear reactions define maladaptive fear memory. Individuals experiencing maladaptive fear memory frequently have vivid and intrusive recollections of traumatic memories. As a result, they exhibit intense fear responses, even in situations that are objectively safe, a phenomenon known as emotional hypermnesia. In addition, they may struggle to retrieve complete narrative memories of the traumatic event, as certain contextual details may be missing (i.e., contextual amnesia). Glucocorticoids can generate abnormal fear-like memory, including emotional hypermnesia and contextual amnesia. However, there is limited understanding of the cellular mechanisms responsible for the development of glucocorticoid-induced maladaptive fear-like memory. Here, we employed a combination of contextual fear conditioning and post-training corticosterone (CORT) injection to produce the maladaptive fear-like memory in adult male mice. Corticosterone is a type of stress hormone known as a glucocorticoid in rodents. Hyperpolarization-activated cyclic nucleotide gated nonselective cation 1 (HCN1) channels are highly expressed in the hippocampus. We have previously reported that CORT reduces the neuronal excitability of dorsal CA1 neurons, which is mediated by HCN channels. In light of this, we inquired about the potential roles in HCN channels during the formation of fear-like memory induced by CORT. We demonstrated that contextual fear conditioning, when immediately followed by CORT (i.p. 2 mg/kg), resulted in emotional hypermnesia, as seen by an increased fear response to a salient but unrelated cue (i.e., tone) connected to traumatic stress. Furthermore, CORT-injected mice exposed to a cue (i.e., context) associated with traumatic stress exhibited impaired fear extinction over time. Following memory tests, dorsal and ventral hippocampal slices were prepared. In mice treated with CORT, the neurons in the dorsal and ventral CA1 regions exhibited diminished input resistance and reduced firing of action potentials both at rest and at -65 mV, without any changes in the resting membrane potential. This decrease in neuronal excitability in the dorsal and ventral CA1 regions was correlated with an elevation in h current (I_h). Based on our findings, it is plausible to propose

that an increase in I_h within the hippocampal CA1 neurons might underlie the development of fear-like memory induced by CORT.

Title: Adenosine A_{2A}receptors control the extinction of fear memories

Authors: S. G. FERREIRA[1], S. L. REIS[2], V. LOURENÇO[2], A. R. TOMÉ[2], A. SIMÕES[2], P. M. CANAS[2], ***R. A. CUNHA**[2,3];
[1]CNC–Center for Neurosci. and Cell Biol., [2]CNC-Center for Neurosci. and Cell Biol., Univ. of Coimbra, Coimbra, Portugal; [3]Fac. of Med., Univ. of Ccoimbra, Coimbra, Portugal

Abstract: Psychological trauma-related disorders involve pathological fear responses and impaired fear extinction. Polymorphisms of adenosine A_{2A} receptors (A_{2A}R) are associated with panic disorders (*Mol Psychiatry* 3:81,1998; *Neuropsychopharmacol* 29:558,2004) and A_{2A}R control the acquisition and recall of fear memories, through modulation of information processing in the basolateral amygdala (BLA) and ventral hippocampus (VH) (*Neuropsychopharmacol* 41:2862,2016; *Biol Psychiatry* 75:855,2014). However, it is not known if A_{2A}R also control fear extinction, which was now tested. Adult male mice were contextual fear conditioned (FC) and some were then re-exposed to the same context for 3 days without paired shocks (extinction-EXT) and other not (FC-CTR) to evaluate their freezing behaviour; additionally, synaptic plasticity was assessed in CA1 synapses of VH slices and in cortico-amygdalar synapses in BLA-containing slices. The role of A_{2A}R was investigated by injecting a selective antagonist, SCH58261 (0.1 mg/kg, i.p.), 1 hour before each extinction trial. To test the specific contribution of A_{2A}R in VH or BLA, guide cannulas were implanted and either SCH58261 (50 nM) or light stimulation (15 days after transfection with AAV5-CaMKIIα-optoA_{2A}R-mCherry, to allow the optogenetic activation of the transducing system operated by A_{2A}R) was bilaterally applied 1 hour before each extinction trial. FC-CTR mice maintained their freezing behaviour for 4 days, whereas EXT mice progressively decreased freezing. A_{2A}R blockade with SCH58261 i.p. accelerated fear extinction from day 2 onwards, but did not modify passive fear memory extinction, locomotion (open field) or anxiety (elevated plus maze) in FC-CTR mice. Two days after FC, FC-CTR mice displayed a decreased post-tetanic stimulation (5 trains of 100 Hz for 1s separated by 5s) in the BLA, which was normalised by SCH58261 i.p.;

EXT also increased LTD magnitude in BLA, which was larger with SCH58261. FC increased LTP in the VH after 2 days compared to EXT mice, an effect reduced by $A_{2A}R$ blockade, without alterations of depotentiation. In accordance with these alterations of synaptic plasticity, the selective blockade of either BLA-$A_{2A}R$ or VH-$A_{2A}R$ via SCH58261 direct administration in the BLA or VH was sufficient to accelerate fear extinction. Conversely, light stimulation of opto$A_{2A}R$-expressing mice in the VH attenuated fear extinction and increased VH-LTP. These results evidence a role for $A_{2A}R$ on fear extinction, namely in the BLA and in the VH, reinforcing the interest in targeting $A_{2A}R$ to manage fear-related disorders.

Title: Axo-axonic cells in the basolateral amygdala regulate fear conditioning.

Authors: *M. NAKASHIMA[1], R. HAYASHI[2], S. MORIKAWA[2,3], Y. IKEGAYA[2,4];
[1]Univ. of Tokyo, Bunkyo-ku, Japan; [2]Grad. Sch. of Pharmaceut. Sciences, Univ. of Tokyo, Bunkyo-ku, Japan; [3]Grad. Sch. of Sciences, The Univ. of Tokyo, Bunkyo-ku, Japan; [4]Inst. for AI and Beyond, The Univ. of Tokyo, Bunkyo-ku, Japan

Abstract: The activity and plasticity of excitatory neurons are regulated by local inhibitory neurons in a spatiotemporally specific manner. Axo-axonic cells (AACs) are a unique type of inhibitory neurons that predominantly form synapse onto the axon initial segment of pyramidal neurons. While their anatomical features have been identified, the functional roles of AACs remain unclear. In this study, using a specific labeling approach for AACs in the basolateral amygdala (BLA), we show that AACs play a crucial role in memory acquisition. By performing in vivo calcium imaging and functional silencing of AACs in the BLA, we demonstrated that AACs were activated by salient stimuli, such as foot shock or reward, and provided a mandatory heterogeneous inhibitory signals for associative learning. Furthermore, we found that AACs preferentially received long-range inputs from the basal forebrain and medial geniculate nucleus. These findings suggest a central role for AACs in the representation of salient stimuli, which is essential for the induction of adaptive behavior.

Title: Emotional stress reduces endocannabinoid signaling in cerebellar cortex

Authors: *M. SAYED, J. PATEL, M. FAROUK, S. LIU;
Cell Biol. & Anat., LSU Hlth. Sci. Ctr., New Orleans, LA

Abstract: The cerebellum is critical for emotional regulation. We have recently shown that fear conditioning reduces endocannabinoid signaling in the cerebellum and this is required for fear memory formation. Since emotional stress can modify subsequent fear memory, we tested whether predator odor stress could alter endocannabinoid signaling in the cerebellar cortex and thereby enhance the formation of fear memory. Male C57BL/6 mice were exposed to fox urine for 5 minutes and the cerebellum was isolated three hours later. Since endocannabinoid (eCB) signaling suppresses neurotransmitter release, we tested the effect of an endocannabinoid receptor (CB1R) antagonist on spontaneous GABA release, assessed by miniature IPSCs (mIPSCs) recorded in stellate cells. Bath application of a CB1R antagonist NESS0327 increases the frequency of mIPSCs in naive mice, indicating the presence of tonic eCB. However, NESS0327 failed to alter mIPSC frequency in mice that were exposed to predator odor, suggesting that predator odor stress reduced tonic endocannabinoid signaling in the cerebellar cortex. The decrease in eCB signaling could result from a loss of endocannabinoid receptor signaling. To test this, we applied a CB1R agonist, WIN55212-2 and found that WIN55212-2 reduced the frequency of mIPSCs in molecular layer interneurons from stressed mice by around 30%, comparable to that in naïve animals. Thus, fox urine exposure did not change the CB1R signaling, and may therefore alter eCB levels. 2-AG, the major eCB in the cerebellum, is produced by diacylglycerol lipase (DAGL) and degraded by monoacylglycerol lipase (MAGL). We quantified MAGL activity and found that predator odor stress did not alter the activity of MAGL, compared to naive mice. We next tested whether stress reduced DAGL levels in cerebellar cortex using western blotting. Our preliminary results show that fox urine exposure reduced the DAGL expression by 40% relative to naive mice. Our results suggest that predator odor stress reduces endocannabinoid signaling in cerebellar cortex by decreasing 2-AG production via DAGL. (Supported NIH R01 NS106915, VA I01 BX003893-01A1).

Title: Neural Correlates of Safety Signaling and Conditioned Inhibition of Fear in the Ventromedial Prefrontal Cortex

Authors: *M. A. VERBRUGGE;
Indiana University-Purdue Univ. Indianapolis, Indianapolis, IN

Abstract: Authors: M Verbrugge[1,3], DP Lyvers[1,3], CC Lapish[2,3], S Sangha[1,31]Department of Psychiatry, [2]Department of Anatomy, Cell Biology & Physiology, [3]Stark Neuroscience Research Institute, Indiana University School of Medicine, Indianapolis, IN
Neural Correlates of Safety Signaling and Conditioned Inhibition of Fear in the Ventromedial Prefrontal Cortex
The ability to accurately discern between safe and threatening situations is challenged in Post-Traumatic Stress Disorder (PTSD), often leading to maladaptive fear. Many PTSD individuals fail to show conditioned inhibition of fear, the downregulation of fear during the simultaneous presentation of a learned fear and safety cue (fear+safety cue). Our lab has a well-validated safety-fear-reward cue discrimination task, which was adapted for this study to produce a greater range in fear suppression in male and female Long Evans rats, such that approximately half of males and females show “good” fear suppression, while the other half do not. During this behavior we collected longitudinal single cell calcium activity within the prelimbic (PL) and infralimbic (IL) regions of the ventromedial prefrontal cortex (vmPFC) in freely behaving male and female Long Evans rats using miniscopes and GCaMP6m expressed via AAV1.GCaMP6m.WPRE.SV40 from Inscopix. These vmPFC regions play key roles in modulating fear, anxiety, and stress behaviors. We have shown in our safety task that the PL is necessary for fear expression, while the IL is necessary for conditioned inhibition of fear. Our data in the IL indicate that there is an ensemble of neurons highly correlated in its activity to the fear+safety and fear cues that is separate from an ensemble of neurons highly correlated in its activity to the fear+safety and reward cues. Preliminary results show that we can also follow these same cells for at least 12 days. Current analyses are examining cue-evoked calcium transients against expressed safety, fear and reward behaviors across the entirety of the 15 day task.

Title: Reduced top-down influence in the primate fronto-cingulo-striatal network underlying negative bias in conflict decision-making

Authors: *S. AMEMORI[1], A. M. GRAYBIEL[2], K. AMEMORI[3];
[1]ASHBi, JSPS postdoc, Kyoto Univ., Kyoto, Japan; [2]MIT, MIT, Cambridge, MA; [3]ASHBi, Kyoto Univ., Kyoto, Japan

Abstract: Major depressive disorder (MDD) affects a significant portion of the global population. The fronto-cingulo-striatal (FCS) network, including the dorsolateral prefrontal cortex (dlPFC), subgenual anterior cingulate cortex (sgACC), pregenual anterior cingulate cortex (pACC) and the striatum, is implicated in MDD. MDD patients often exhibit a negative processing bias, characterized by negative reactions to emotional stimuli. The approach-avoidance (Ap-Av) decision-making task is used to investigate this bias. Neuroimaging studies have revealed abnormalities in dlPFC activity during the Ap-Av task in MDD patients. Moreover, deep brain stimulation of the sgACC reduced MDD symptoms. In non-human primates, beta-band oscillatory activity in the striatum has been found to represent decision-related variables, and the pattern of beta oscillations has been shown to parallel stimulation-induced negative bias, suggesting a role for FCS network interactions and neuronal synchronization in negative bias. Thus, we hypothesized that beta-band activity and synchronization, particularly involving sgACC, contribute to negative bias processing. We trained two monkeys in an Ap-Av task in which they had to choose between receiving a reward and experiencing an air puff to the face. During task performance, we stimulated the sgACC and recorded simultaneously local field potentials in FCS network. Microstimulation of certain regions within the sgACC (10/38 sites tested) resulted in a significant increase in avoidance choices, indicating the involvement of the sgACC in negative bias. Notably, these negative effective sites were significantly surrounded by neurons that were activated by avoidance decision (n = 31) and airpuff delivery (n = 129). Next we analyzed task-related LFPs (n = 3942/4745) during a decision period in FCS network and extracted beta responses. Through multidimensional scaling, we categorized beta responses that represent approach and avoidance choices into positive (*P*, n = 911) and negative (*N*, n = 591) groups. Effective microstimulation

reduced the number of responses in *P* group, suggesting a bias towards negative outcomes. Furthermore, we performed granger causality analysis on alpha (5-13 Hz) and beta (13-30 Hz) responses in FCS network to assess regional interactions. Effective sessions showed reduced directional influences, particularly from dlPFC to pACC and striatum. These results suggest that the top-down signal from the dlPFC to the limbic system was mediated by the beta synchrony, and that the blunting of top-down processing may underlie the negative bias observed in decision-making, which is a hallmark symptom of MDD in humans.

Topic: G.01. Fear and Aversive Learning and Memory

Title: Model-based extinction of the fear of heights by active flight experience in VR

Authors: *M. FUJINO[1,2], M. HARUNO[2,1];
[1]Grad. Sch. of Frontier Biosci., Osaka Univ., Suita, Osaka, Japan; [2]Ctr. for Information and Neural Networks, Natl. Inst. of Information and Communications Technol., Suita, Osaka, Japan

Abstract: Many studies have shown “model-free” fear extinction in which a cue associated with a negative outcome is repeatedly exposed to participants without the negative outcome. The participants gradually construct a new association that this context is safe. In traditional exposure therapies for acrophobia, participants asked to experience insecure situations repeatedly, such as escalators. Such safety learning is based on “model-free” learning.
By contrast, “model-based” reinforcement learning explicitly considers transitions among contexts (state-transition probability) to predict future outcomes. It still remains unclear whether there exists a “model-based” extinction fear extinction which uses state transition information to predict a negative outcome.
Therefore, in this study, we tested this hypothesis using fear response to heights in VR. Specifically, we tested whether participants’ fear response to height reduces after the active VR flight experience. This is because after the VR flight experience, participants could then infer that they would be safe even if they fall. In other words, the participants will simulate the state transitions of falling -> flying -> safety by constructing a new safe state achieved by the flying action. At the beginning of the experiment, subjects felt a strong fear of heights. However, once they had the flight experience, they could predict that falling would not result in injury.
In total, 59 adults with fear of heights were randomly assigned to the flight group or a control group. Subjects in the flight group flew over the city in VR for more than 7 minutes. Subjects of the control group watched the flight video, which differed from the flight group only in that they could not control the course of the flight. Before and after tasks, participants in both groups walked on a plank in VR (plank task). Electrodermal activity (EDA) and photoplethysmography

(PPG) were recorded as physiological indicators of the fear response.The analysis data consisted of 16 subjects in the flight group and 15 subjects in the control group. Subjects with low EDA response were excluded. We compared the mean EDA for 30 seconds before and after the first and second plank tasks between groups.
In our experiment, as we expected, the flight group showed a significant decrease in mean SCR at high altitude ($t(21)=4.381$, $p=0.0001$). In contrast, there was no significant difference in the control group ($t(20)=1.194$, $p=0.123$).
These results revealed that an active flight experience using VR can reduce the automatic fear response to heights, suggesting the existence of "model-based" extinction of fear, which may lead to a novel treatment for phobias.

Title: Computational modeling revealing the role of spatiotemporally modulated serotonin in fear conditioning and extinction

Authors: *A. BADRIPOUR, T. KIM;
Korea Inst. of Sci. and Technol. (KIST), Seoul, Korea, Republic of

Abstract: Fear conditioning (FC) has been frequently used to study emotional learning and memory. The brain-wide distribution of involved neural circuits and diverse influence from neuromodulatory transmitters (NTs) make FC complex. Several computational approaches have tried to explain the complicated dynamics of involving circuits, including the role of NTs. Prior FC experiments showed phasic serotonin release during aversive stimuli like foot shock and serotonin-selective reuptake inhibitor has greatly helped depression and post-traumatic stress disorder which FC and extinction partially characterize, suggesting a substantial role of serotonin during FC. However, in previous computational models emulating FC and extinction, the dynamics of serotonergic involvement have been overlooked. Therefore, we built the computational model that captures behavioral responses and neural circuit dynamics under multiple scenarios of differentially modulated spatiotemporal serotonin levels that were categorized based on previously reported experimental evidence. First, our punishment-driven

reinforcement learning model demonstrated that serotonin controls the discounting factor and learning rate, as previously reported in reward-based reinforcement learning. Higher serotonin levels raised the discounting factor, reflecting the agent's prolonged expectation of punishment, while the reduction of serotonin level downregulated the learning rate, resulting in the reduced conditioned response during learning. Second, our rate-based circuit model incorporating the amygdala, medial prefrontal cortex (mPFC), and hippocampus (HPC) regenerated the time course of FC and extinction. In this model, phasic serotonin accompanied by unconditioned stimulus enhanced fear learning and regulated the time course of fear extinction via disinhibition of input pathway converging onto basal amygdala from mPFC and HPC, indicating the hub microcircuit for FC and extinction. Thus, further development of our model may contribute to a comprehensive understanding of fear conditioning and extinction, enabling the development of more precise intervention strategies for neuropsychiatric disorders.

Title: Hippocampal somatostatin interneurons mediate retrieval of conflicting threat and safety memories

Authors: *A. F. LACAGNINA, T. N. DONG, R. IYER, S. KHAN, M. MOHAMED, R. CLEM;
Icahn Sch. of Med. at Mount Sinai, New York, NY

Abstract: Fearful experiences create enduring negative associations with the surrounding context. Emotional responses to these contextual cues normally subside in the absence of threat, a process known as extinction. Fear and extinction memories appear to be represented by competing neural ensembles; however, very little is known about the mechanisms governing the switching between these conflicting memories. Understanding neural circuits responsible for the gating of emotional memory expression can provide crucial insights for developing novel therapeutics for treating disorders of pathological fear. We identified activity of somatostatin interneurons (SST-INs) in the ventral hippocampal CA1 area (vCA1) as uniquely correlated with extinction retrieval. An extinction-specific recruitment of vCA1 SST-INs was confirmed using an intersectional genetic tagging strategy. Optogenetically silencing vCA1 SST-INs impaired extinction retrieval, while stimulating these cells, either broadly or in an activity-dependent

manner, prevented fear relapse. In contrast, manipulations of vCA1 parvalbumin-expressing INs did not affect expression of contextual fear or extinction. We confirmed that fear and extinction retrieval reactivate orthogonal vCA1 excitatory ensembles and, additionally, silencing excitatory projections from vCA1 to the prefrontal cortex specifically impairs extinction retrieval. Our results suggest that retrieval of conflicting memories is mediated by vCA1 SST-INs. We hypothesize the vCA1 SST-INs gate the activity of orthogonal excitatory ensembles to suppress the activity of the ensemble associated with the initial contextual memory and promote the retrieval of the extinction-related ensemble.

Abstract: Neuronal circuits in the midbrain play a critical role in controlling defensive behavior. However, it is still elusive how different neuron types contribute to distinct behavioral outcomes during the presence of threat. In this study, we investigated a group of neurons in the ventral periaqueductal gray and dorsal raphe that express vasoactive intestinal polypeptide (VIP). Using viral tracing conducted in Vip-Cre mice, we observed that these VIP neurons innervated exclusively the bed nucleus of stria terminalis and central amygdala (CeA), the two main regions of the extended amygdala. Interestingly, neurons in these extended amygdala regions contributed to the innervation of midbrain VIP neurons to a large extent revealed by monosynaptic rabies tracing. In vitro electrophysiological recordings combined with optogenetics showed that light stimulation of VIP afferents activated ionotropic glutamate receptors in their postsynaptic partners in the extended amygdala. To clarify the role of the midbrain VIP neurons in fear acquisition, we inhibited their activity using chemogenetics during fear conditioning, and observed that this intervention impaired the contextual, but not cued fear memory recall on subsequent days. In line with the role of midbrain VIP neurons in fear learning, mild electrical shocks potently excited these neurons when tested by in vivo electrophysiological recordings.

Finally, using slice recordings combined with optogenetics, we found that the co-activation of ventral hippocampal and VIP-expressing PAG inputs forming synapses on CeA neurons underwent LTP, an observation that may provide a mechanistic explanation for the role of this subcortical pathway in the acquisition of contextual fear memory. These results collectively show that the excitatory midbrain-extended amygdala pathway expressing VIP contributes to contextual memory formation.

Title: Characterization of defensive coping strategy induced by electrical footshock or chemical stimulation of the dorsolateral periaqueductal gray in female rats

Authors: *L. CORREA NAKATSUKASA TAKASUMI, L. A SOARES, A. P CAROBREZ; Pharmacol., Univ. Federal de Santa Catarina, Florianópolis, Brazil

Abstract: Rodents in life-threatening situations exhibit specific behaviors according to their defensive coping strategy. These behaviors can be classified as defensive (DB) (i.e., freezing, darting, and jumping) or risk assessment (RAB) (i.e., crouch sniffing, rearing, and stretch approach). The literature indicated that electrical footshock (EF) and the N-Methyl-D-Aspartate (NMDA) stimulation of the dorsolateral periaqueductal gray matter (dlPAG) elicited DB in male rats. Contrarily, female rats in EF protocols showed less DB than males, suggesting sex differences in their coping strategy in aversive situations, which is yet to be determined. This study was designed to characterize the defensive coping strategy expressed by female rats exposed to EF or dlPAG stimulation. In Experiment 1, female Wistar rats underwent an EF protocol of five 0 (control) or 0.8 mA EF (40 s interval; n = 20/group). For experiment 2, the rats implanted with guide cannulas directed at the dlPAG underwent a microinjection protocol in which vehicle (PBS; n = 10), NMDA 25 (n = 9), or 50 pmol (n = 7) was continuously infused in freely moving rats (0.2 µl final volume). All experiments were recorded, and data were expressed as percentage of time for DB and RAB. Kruskall-Wallis followed by multiple comparisons test evaluated the groups for each experiment. The results from Experiment 1 showed that female rats predominantly expressed RAB (53%) rather than DB (25%) after EF. Also, RAB and DB values were higher in EF than in the control group (33% and 0%,

respectively) ($p < 0.05$). The results obtained in Experiment 2 showed that female rats injected with NMDA 25 expressed more DB (DB = 51%; RAB = 28%) and NMDA 50 more RAB (DB = 23%; RAB = 32%) than PBS (DB = 10%; RAB = 10%) ($p < 0.05$). Freezing was the predominant DB in NMDA 25; crouch sniffing was the predominant RAB in NMDA 50. In summary, female rats showed a marked defensive response under different aversive stimuli, but also showed that the coping strategy is not homogeneously switching between DB and RAB. The results suggest that freezing alone, as widely applied in fear learning studies, may not provide a complete view on the defensive coping strategy found in female rats. More importantly, female rats exhibiting decreased DB could be erroneously described as expressing low fear, when in fact they are engaging in RAB.

Title: Molecular determinants of long-term memory formation ability in Lymnaea stagnalis

Authors: *J. BANDURA[1], C.-H. GUO[1], C. CHAN[2], H.-S. SUN[3], A. R. WHEELER[2,4,5], Z.-P. FENG[1];
[1]Physiol., [2]Chem., [3]Surgery, [4]Donnelly Ctr. for Cell. and Biomed. Res., [5]Inst. of Biomed. Engin., Univ. of Toronto, Toronto, ON, Canada

Abstract: Long-term memory (LTM) formation is essential for survival, and involves cellular and molecular mechanisms, such as CREB-dependent gene regulation and protein synthesis, that are conserved between vertebrates and invertebrates (Kandel 2001). The freshwater pond snail, mollusc *Lymnaea stagnalis*, forms LTM following aversive operant conditioning of aerial respiratory behaviour, as defined by a significant decrease in its respiratory activity (Lukowiak et al. 1996). Blocking CNS protein synthesis prevents LTM formation (Sangha et al. 2003), and our lab has previously reported that LTM formation is contingent on the expression of proteins such as CREB1 (Guo et al. 2010) and MEN1 (Dong, Senzel, Li et al. 2018). The ability of an animal to form aversive LTM in this model further correlates with activity in the pacemaker neuron of the respiratory central pattern generator (CPG), RPeD1, and can be predicted by behavioural responses during aversive operant conditioning, dividing animals into LTM and no-LTM groups

(Dong & Feng 2017). In this study, we hypothesized that the ability of animals to form LTM is associated with protein expression of defined molecular networks which are regulated in the CNS following aversive operant conditioning. To test this hypothesis, we first characterized spontaneous and evoked activity in RPeD1 from snails exhibiting LTM or no LTM. To identify proteins associated with differential LTM formation ability, we used bottom-up shotgun proteomics via liquid chromatography-tandem mass spectrometry (LC-MS/MS) for label-free quantification of protein abundance in the CNS of snails exhibiting LTM or no LTM (n=4 per group) and identified 293 differentially-expressed proteins. To determine the interaction network of critical proteins for LTM formation ability, we generated 6xHis-tagged LTM-regulated proteins and used affinity purification followed by LC-MS/MS and coimmunoprecipitation to identify interactions. Using this combined behavioural, electrophysiological, and large-scale proteomic and interactomic approach, we have for the first time characterized the protein interaction network differentially expressed in LTM animals relative to no-LTM animals and untrained controls. Together, we report the correlation between electrophysiological characteristics and the set of proteins associated with differential LTM formation ability following aversive operant conditioning, suggesting that essential molecular networks underlie inherent differences in LTM formation ability. The signaling pathways identified may thus constitute fundamental mechanisms of LTM formation cross-species.

Title: Unit activity in the amygdalostriatal region and central nucleus of the amygdala during cue-evoked suppression of reward seeking

Authors: *K. J. ANDERSON[1], C. E. STELLY[2], A. M. HALL[1], P. STOLIN[1], J. P. FADOK[3]; [2]Cell & Mol. Biol., [3]Psychology and Tulane Brain Inst., [1]Tulane Univ., New Orleans, LA

Abstract: A common feature of many mental illnesses is dysregulated responding to different valences, yet the neural mechanisms that contribute to this are poorly understood. We have utilized a cue-evoked suppression of reward seeking paradigm designed to address both positive and negative valence using a combination of operant learning and Pavlovian conditioning. In addition, we have recorded single unit activity in awake, behaving mice during this conditioned suppression paradigm. With this work, we aim to track single unit activity in the

amygdalostriatal region (Astr) and central nucleus of the amygdala (CeA) in mice that have undergone conditioned suppression of reward seeking across three different stages of learning: naïve, conditioning, and extinction. We have found recorded single unit evidence to suggest neuronal activity in Astr is altered in response to reward, rather than the fear-associated cue presentation; further work is required in order to assess the extent of such reactivity. Additionally, we predict that single unit recordings in the CeA will demonstrate neuron reactivity in response to fear-associated cue presentation, which we have not identified as yet in such recordings from the Astr. The overall goal of this work is to identify the underlying mechanisms regarding behavior selection and valence responding.

Title: Orexin/hypocretin mediates sleep disturbances and drug seeking during initial cocaine abstinence

Authors: *U. GYAWALI, S. MERAI, A. BHAT, D. DE SA NOGUEIRA, M. JAMES; Rutgers Univ., Piscataway, NJ

Abstract: Sleep disturbances commonly occur in individuals with substance use disorders and worsens during withdrawal. Cocaine-exposed rats display disrupted sleep patterns, characterized by fragmented and reduced non rapid eye movement (NREM) and rapid eye movement (REM) sleep. Normalizing sleep during abstinence reduces drug cravings, indicating a potential relationship between these processes. The orexin neuropeptide system holds promise as a therapeutic target for medications designed to abrogate cocaine cravings and associated sleep disturbances, as orexins regulate both reward and wakefulness brain circuits. However, direct evidence linking orexin-sleep circuits with drug seeking behaviors is lacking. Here, we used conditioned place preference (CPP) to establish a contextual association with acute bolus injections of cocaine (10mg/kg). Rats then underwent 5d of drug abstinence followed by a place preference test. During abstinence, rats were treated daily with the dual orexin receptor antagonist suvorexant (0, 30 mg/kg, p.o.) immediately prior to the onset of the inactive period. In a subset of rats, electroencephalogram (EEG) and electromyogram (EMG) activity was monitored throughout the experiment. We observed sleep disturbances following cocaine

conditioning, characterized by increase in wake time, decrease in NREM and REM sleep along with sleep fragmentation (more frequent stage transitions). These changes persisted into abstinence but were abrogated by suvorexant treatment, which also facilitated extinction of cocaine seeking behavior. In a separate cohort, following the CPP expression test, we collected ventral tegmental area (VTA) and lateral hypothalamus (LH) and quantified orexin and orexin receptor 1 and 2 mRNA levels using qRT-PCR. We saw an increase in VTA orexin receptor 1 and LH orexin mRNA levels in cocaine vs. saline conditioned rats; these changes were positively correlated with cocaine preference. These data indicate that blocking orexin signaling during initial cocaine abstinence normalizes sleep and reduces drug seeking, indicating a potential causal link between these processes. Ongoing work is exploring VTA as a potential site through which orexin signaling might mediate both sleep and reward outcomes following cocaine.

Title: Administration of the dual orexin receptor antagonist suvorexant during the active vs. inactive period: Implications for cocaine behaviors

Authors: *S. L. O'CONNOR[1], U. GYAWALI[2], M. S. PALADINO[2], N. KRISHNAKUMAR[2], M. M. BILOTTI[3], D. J. BARKER[4], M. H. JAMES[2];
[1]Psychology, [2]Psychiatry, [3]Joint Grad. Program in Toxicology, Rutgers Univ., Piscataway, NJ; [4]Psychology, Rutgers Univ., Pisctaway, NJ

Abstract: Introduction: Cocaine self-administration in rats is associated with an increase in the number and activity of orexin (hypocretin) neurons. Orexin neurons are involved in reward and sleep, both of which are perturbed in cocaine use disorder. Thus, therapies that block orexin signaling might offer multifaceted therapeutic benefit. Here, we tested if the FDA-approved dual orexin receptor antagonist suvorexant, which is currently indicated to promote sleep in insomnia, can be used i) at low, non-sedating doses during the active period to reduce drug seeking, and ii) at higher doses to normalize sleep and subsequent drug seeking during cocaine abstinence. Methods: Male and female Long Evans rats were assessed for baseline economic cocaine demand using a within-session threshold procedure. Rats were then given daily intermittent access (IntA) to cocaine (5min access every 30min for 6h) for 2w. One group of rats (n=24) was treated with suvorexant (0, 3, 10, 30mg/kg; p.o., within-subjects) prior to being reassessed for

demand during the active period. To test for soporific effects of suvorexant, these rats were also tested on the rodent psychomotor vigilance task (rPVT), which requires rats to maintain attention for 30min to earn sucrose rewards; rats received suvorexant prior to testing, as above. A second group of rats (n=14) underwent extinction training for 7d; during this time, rats received suvorexant (0, 30mg/kg, p.o.) 30min prior to the onset of the inactive period. Results: Males and females both exhibited increased cocaine demand following IntA; this was reversed by suvorexant (10, 30mg/kg). Suvorexant did not impair performance on the rPVT. Repeated dosing with suvorexant during the inactive period facilitated extinction. Suvorexant efficacy in females was not affected by estrus stage. Discussion: Suvorexant can be used acutely during the active period to reduce drug motivation and during the inactive period to accelerate extinction of drug seeking. Ongoing studies will determine if the effects of suvorexant on extinction are linked with improved sleep outcomes.

Title: Sex differences in the functioning of orexin (hypocretin) neurons and behavioral outcomes following peripubertal BPA exposure

Authors: *M. M. BILOTTI[1,2], V. ISSKANDAR[3], S. ANTHONY[1], A. YASREBI[4], N. T. BELLO[4], T. A. ROEPKE[4,1], M. H. JAMES[3,2];
[1]Joint Grad. Program in Toxicology, [2]Brain Hlth. Inst., [3]Psychiatry, Rutgers Univ., Piscataway, NJ; [4]Animal Sciences, SEBS, Rutgers Univ., New Brunswick, NJ

Abstract: Introduction: Human and rodent studies indicate that early life exposure to bisphenol-A (BPA), a weak estrogen receptor agonist, alters feeding and mood outcomes in adulthood. Separate literatures indicate that orexin-producing neurons in hypothalamus are 1) sensitive to estrogen, and 2) regulate feeding and motivational processes, making them a strong candidate system mediating the effects of early-life BPA exposure. Despite this, the effect of BPA on orexin system functioning, and any implications for behavioral outcomes in later life, have not been tested. Methods: Male (n=8-10/group) and female (n=8-12/group) Long-Evans rats were exposed to BPA (0, 25, 250µg/kg/day) in their drinking water from post-natal days (PND) 28-56. After BPA exposure, rats were tested for food motivation using three different assays: 1) binge-like eating of sweetened fat, 2) economic demand for sucrose, and 3) saccharine preference.

Following behavioral testing, brains were collected to determine orexin mRNA and protein levels. Results: In females, BPA rats exhibited reduced binge-like eating, demand for sucrose, and saccharine preference, indicating decreased food motivation. These behavioral changes were associated with lower orexin mRNA and protein levels in lateral hypothalamus. In males, BPA exposure was associated with increased food motivation and higher orexin mRNA and protein levels. Conclusions: Peripubertal BPA has opposing effects on food motivated behavior in males vs females. These behavioral changes were mirrored by alterations in orexin availability, indicating differential estrogen-mediated regulation of orexin neuron function in males vs. females

Title: Binge-like eating restores hedonic tone in female rats maintained on a high fat diet via an orexin- (hypocretin) ventral tegmental area

Authors: U. GYAWALI, A. J. ARMANIOUS, J. B. MEHR, S. MERAI, ***M. H. JAMES**; Rutgers Univ., Piscataway, NJ

Abstract: *Introduction:* Binge eating has been argued to be 'self-medicating' against depressive states in persons of higher weight. Despite this, the neural systems that drive excessive food intake in the absence of caloric deficit remain to be fully characterized. Here, we tested if a diet-induced obesity model predisposes to binge-like eating in rats, and whether these binge-like episodes restore hedonic tone. We also examined whether an orexin-ventral tegmental area circuit, known to regulate other hedonic processes, governs binge-like eating in a diet-induced obesity model. *Methods:* Female Long Evans rats were maintained on a regular chow or high fat diet (HFD; 45% fat) for 8w; binge-like eating was then promoted via intermittent, restricted access to sweetened fat for 4w. Hedonic tone was measured using intracranial self-stimulation (n=6-7/group) and social preference (n=8/group) assays. Orexin release in VTA was measured using fiber photometry recordings of the OxLight1 sensor (n=5-6/group). In a separate group of rats, we also tested if binge-like eating differentially promotes 'addiction-like' food behaviors in lean (n=8) vs. HFD (n=9) rats by measuring sucrose demand, sucrose seeking during periods of signaled food non-availability, and reinstatement of extinguished sucrose seeking. *Results:* HFD

rats had higher ICSS thresholds and lower social preference compared to chow-fed controls. HFD rats exhibited greater escalation of binge-like eating, which partially normalized ICSS thresholds and social preference. In chow rats, food-associated stimuli elicited orexin release in VTA; this was blunted in HFD rats but partially restored by binge-like eating. Binge-like eating promoted higher 'food addiction' behaviors in HFD but not control rats. *Conclusions:* These data indicate that binge-like eating in obesity is i) governed by negative (rather than positive) reinforcement processes, ii) promotes 'addictive-like' eating behaviors, and iii) is mediated, at least in part, by the orexin-VTA circuit.

Title: For the sake of safety: Orexinergic modulation of VTA for avoiding threats

Authors: *C. SILLER-PEREZ[1,2], E. C. ANDRADE[1], C. K. CAIN[1,2], J. E. LEDOUX[3], R. M. SEARS[1,2];
[1]Nathan Kline Inst., Orangeburg, NY; [2]Child and Adolescent Psychiatry, NYU Langone, New York, NY; [3]Ctr. For Neural Sci., New York Univ., New York, NY

Abstract: Identifying the neuromodulatory mechanisms that orchestrate survival behaviors is of critical importance to understanding anxiety- and stress-coping in health and disease. Perifornical (PFH) and lateral hypothalamus (LH) neurons expressing orexin (hypocretin) peptides project throughout the brain and mediate functions critical for survival behaviors including vigilance, attention, and action selection. Here we assessed the role of a key hypothalamic orexin system target using a model of proactive threat-coping behavior—signaled active avoidance (SigAA). Based on appetitive studies and physiology findings, we hypothesized that orexin would invigorate safety seeking via projections to a central hub in the reward pathway, the ventral tegmental area (VTA). Sprague Dawley rats received infusions of an orexin-specific viral vector containing an inhibitory opsin (AAV1-Ple112-Arch3.0-eYFP) into the PFH/LH, and optic fibers were implanted in the VTA. Following a 6-8-week incubation, rats were trained in the SigAA task. Animals received one Pavlovian trial (60 s white noise warning signal (WS) paired with an inescapable foot-shock (1.0/0.7 mA males/females; 0.5 s)). For all remaining trials, if animals shuttled during the WS (an avoidance response), a feedback (FB) tone was delivered (5 s, 80 dB) and indicated the animals were safe from harm (a safety signal). Failures to shuttle during the

WS resulted in shock, identical to trial 1. Rats received 15 trials per day until reaching criterion (80% successful avoidance) after which they were subjected to daily shock-free avoidance tests. Orexin◊ VTA axon terminals were inhibited (green laser 532 nm, 10 mW) during FB stimulus presentations only. On the first day, latencies and avoidance responses were unimpaired. However, inhibition on subsequent days increased latencies and impaired avoidance. These results suggest that 1) the FB cue is a reinforcer, perhaps through its association with safety, and 2) orexin communication with VTA is essential for safety-reinforced avoidance. Future studies will uncover the orexin system's role in adaptive coping behaviors and provide support for novel treatments of maladaptive coping, including active coping therapy combined with drugs to target the orexin system.

Title: Blockade of orexin 1 receptor signaling impairs sustained attention in rats

Authors: *N. KRISHNAKUMAR[1], M. PALADINO[1], J. WISKERKE[2], B. GRUSZKA[1], S. L. O'CONNOR[1], U. GYAWALI[1], M. H. JAMES[1];
[1]Brain Hlth. Inst., Rutgers Univ., Piscataway, NJ; [2]Dept. of Biomed. & Clin. Sciences/ Ctr. for Soc & Affect Neurosci. (CSAN), Linköping Univ., Linkoping, Sweden

Abstract: Introduction: Preclinical studies support the utility of orexin-1 receptor (Ox1R) antagonists for the treatment of substance use disorder (SUD). However, the orexin system is also important for maintaining arousal, raising the possibility that such treatments may also interfere with cognitive functioning. Here, we tested whether the Ox1R antagonist SB334867 (SB) affects performance on the rodent psychomotor vigilance task (rPVT), an adapted version of a task used to measure cognitive fatigue and sustained attention in humans. **Methods:** Male (n=21) and female (n=11) Long Evans rats were trained to make rapid responses on a lever following presentation of a light cue that varied in onset time (3-10s after trial initiation); correct responses were rewarded with sucrose pellets and sessions ran for 30min. We first validated the task by testing the effect of two drugs with known attention-modulating properties (d-amphetamine, 0, 0.03, 0.1, 0.3 mg/kg; guanfacine, 0, 0.03, 0.1, 0.3 mg/kg i.p.). Next, all rats were tested following injections of SB (0, 3, 10, 30mg/kg; i.p.). All drugs were tested in a within-subjects design (order counterbalanced). **Results:** Across all measures, there was no effect of sex and thus data from males and females were analyzed together. At baseline,

performance (accuracy) worsened across the duration of the rPVT test session; this time-on-task effect was abrogated (accuracy was improved) by d-amphetamine and guanfacine, specifically in rats with low baseline performance. Accuracy was dose-dependently reduced by SB, however significant deficits were observed only at the highest dose tested (30mg/kg). **Conclusions:** Blockade of Ox1R tended to impair measures of sustained attention on rPVT, but meaningful changes were observed only at a relatively high dose of SB (30mg/kg). Given that SB reduces drug seeking at lower doses (5-20mg/kg), these data indicate that Ox1R antagonists might be useful for treating SUDs while having limited effect on general cognitive functioning.

Title: The effects of naloxone on learned sexual behaviors in male Japanese quail on a partial schedule of reinforcement

Authors: E. CANTY, B. GLEESON, S. LEVY, S. NEWMAN, ***K. S. HOLLOWAY**; Vassar Col., Poughkeepsie, NY

Abstract: Determining the role that opioids have in learned sexual behavior has been complicated by inconsistent methods and divergent interpretations of data. In some cases, opioid blockade, typically with the antagonist naloxone, results in sharp attenuation of sexual conditioned behaviors. In others, naloxone has no effect. A review of this literature suggests that opioids may be particularly important in the maintenance of learned sexual behaviors during periods of non-reinforcement. Previous data from this laboratory supports this conclusion. Naloxone administration facilitates the extinction of Pavlovian sexual conditioned behavior but does not affect acquisition when reinforcement is present. This does not appear to be due to state-dependent learning effects. In a recent experiment, we extended the finding that naloxone facilitates extinction to a partial reinforcement Pavlovian sexual conditioning procedure. An important related question is whether opioid blockade with naloxone would affect the acquisition of a learned sexual response under a Pavlovian partial reinforcement schedule. To explore this, male Japanese quail were presented with an arbitrary visual stimulus paired 50% of the time with copulatory access to a quail hen. One group of subjects received naloxone (30 mg/kg) injections and another vehicle injections prior to each arbitrary stimulus presentation. Unlike the case for continuous reinforcement schedules, naloxone disrupted the acquisition of sexual behavior conditioned on a partial schedule. This finding is consistent with the view that opioids play a key role in the persistence of behavior when sexual reinforcement is not available. Further, it is

functionally important because in natural settings not every encounter with a conspecific, even during the breeding season, will result in copulation.

Title: Dual Viral Approach allows Selective Expression in VTA Dopamine Neurons and Supports Optogenetic Intracranial Self Stimulation

Authors: J. C. BRENT, IV[1,2], **A. WELTER**[1], E. MITTEN[2], M. FREDERICK[1], A. SOUDERS[1], A. WICKMAN[1], K. WICKMAN[1], *E. MARRON[1];
[1]Pharmacol., [2]Neurosci., Univ. of Minnesota, Minneapolis, MN

Abstract: The use of optogenetic tools has greatly enhanced our ability to probe key neuronal populations and brain regions implicated in reward and addiction. Selective expression of these tools relies on the use of transgenic mice, viral tools, or both. Although transgenic mice have proven to be invaluable to current research, using genetically modified mice can limit experimental design and it increases costs. Th-Cre or Dat-Cre mouse lines have been used extensively in combination with optogenetic tools to study the role of VTA dopamine neurons in reward, learning, mood, motivation, etc. In this study, we propose the use of a dual viral approach that allows selective expression in VTA dopamine neurons in C57BL/6J mice (wild-type, WT mice). Specificity is provided by the expression of Cre under the mTH promoter (AAV8-mTH-Cre) and a cre dependent opsin (AAV8-EF1-DIO-ChR2(H134R)-eYFP). WT mice (n=20, 7-10 wks; 10 males /10 females) underwent stereotaxic surgery for viral injection and fiber optic implantation. Subjects then completed our optical intracranial self stimulation (oICSS) paradigm, which included an 11 days acquisition period, a single stimulation frequency preference test session, and a 5 days extinction. DATCre heterozygotes (n=21, 7-12 wks; 11 males/10 females), served as a control group. These mice underwent the same surgical and behavioral manipulations as the WT mice, however they only received the ChR2-containing virus. Negative controls in the study included WT mice (n=5, 7wks; 3 males/2 females) injected with only the ChR2-containing virus and or WT mice (n=6, 7wks; 3 males/3 females) injected with the mTH-Cre, and a Cre-dependent eYFP control virus. These groups control for the possible cre-independent expression of the opsin and the effects of UV light stimulation,

respectively. In our preliminary results, no sex differences were found in the WT group (2-way ANOVA, p = 0.696); however, they were present in the Dat-Cre group (2-way ANOVA, p = 0.006). Both WT and Dat-Cre mice acquire optical self stimulation at a similar rate, however, WT mice showed a significantly higher number of nose-pokes when compared to DATCre mice (2-way ANOVA, p = 0.001). There were no differences in stimulation frequency preference, discrimination index during the acquisition or stimulation frequency preference test sessions, or the extinction profile. These results demonstrate that this dual viral approach is sufficient to support an oICSS behavioral paradigm. In conclusion, this dual viral approach is a valid alternative to the use of Dat-Cre or TH-Cre mouse lines, and could be extended to be used in other species like rats, hamsters or non-human primates.

Title: Dopamine responses in the dorsal striatum do not support the role of reward prediction error

Authors: M. J. KIM[1], ***D. J. GIBSON**[2], D. HU[2], A. MAHAR[2], C. SCHOFIELD[3], P. SOMPOLPONG[4], T. YOSHIDA[2], K. TRAN[2], A. M. GRAYBIEL[2];

Abstract: Dopamine (DA) transmission is widely interpreted as representing a teaching signal, reward prediction error (RPE), posited by reward learning theory. We employed fiber photometry with G protein-coupled receptor-based dopamine sensors expressed in the central dorsal striatum to measure real-time dopamine release in mice as they learned a series of cue and reward associative learning tasks. Contrary to expectations based on the known RPE-like spiking patterns of DA-containing cells in the substantia nigra, we found several substantial departures from the RPE pattern in the DA release patterns in dorsal striatum. (1) Medially, there was no increased DA release in response to unexpected reward; (2) sustained DA responses developed with learning; (3) laterally, where outcome responses were strong, there was no progressive transfer of the phasic DA response from reward delivery to cue presentation. 63 head-fixed mice were successively trained in single cue conditioning (SC), then visual cue discrimination (CD)

and reversal cue discrimination (RD) based on the laterality of visual stimuli, and finally several different levels of probabilistic reward delivery. During initial SC, a brief burst of DA release was triggered by the visual stimulus at all sites probed. The strongest response occurred during the initial trial of cue presentation, gradually diminishing with training. The peak amplitude at cue onset was higher during SC than in CD and RD. A sustained plateau-like DA release response emerged in tandem with the development of cue discrimination behavior during CD and remained present through the remainder of training. The plateaus lasted throughout all or most of the cue presentation period, bridging the period between cue onset and outcome laterally, and were highest in the most successful learners, almost nil in non-learners. They were most frequently found in the more ventral regions explored. Responses to the outcome (cue off/reward) were sharply different between medial and lateral regions. DA responses to reward were absent or even slightly negative medially, but strong, phasic outcome responses occurred laterally and ventrally. The DA response at outcome remained similar across all stages of training, except for a gradual positive shift over the entire learning period, and - unlike an RPE signal - did not gradually transfer from reward presentation to cue presentation. These findings join a growing literature on heterogeneity in DA signaling during learning and performance.

Title: Assessment of food preference behaviors and orexin neuronal activation in an intermittent feeding model of chronic binge eating behavior

Authors: *H. WARREN, S. JACKSON, K. RICHARDSON;
Pharmacol., Howard Univ. Col. of Med., Washington, DC

Abstract: Binge eating disorder (BED) is characterized by the overconsumption of food over a short period of time. Various models in the literature have been noted as suitable paradigms for binge eating behavior. However, many of these models have not been substantiated over a chronic period (several months) of time as defined by the DSM-V for BED. We seek to validate the longevity and maintenance of palatable food preference across several months using the Boggiano intermittent test for identifying binge eating behavior and assess orexin neuronal activation. Orexin (or hypocretins) hypothalamic peptides are involved in the regulation of food

intake. Female Sprague Dawley rats (n=12/group, 250-300g) were given 30g of high fat/sugar pellets (PF) and the PF intake was measured at 0-hour, 1-hour, and 4-hour time increments. The median 4-hour PF intake was utilized to establish the upper, middle, and lower tertile where animals were characterized as high preference (HP), neutral preference (NP), or low preference (LP) across nine intermittent feeding tests. The HP and LP rats were also tested at 2 and 6 months after the feeding phenotypes were established. Data show that PF intake was significantly higher in HP versus LP rats and this pattern was maintained 2 and 6 months after phenotypes were established (p&lt 0.05). This finding validates the consistency of the feeding phenotypes across several months. This model provides a reliable and consistent paradigm to test preferences for high fat, high sugar diets over a chronic period and its use can help us gain a better understanding of the etiology of binge eating. Studies are underway to determine if there are differences in orexin neuronal activation within the lateral hypothalamus of the rats in each group.

Title: Neuropeptide Y neurons in nucleus accumbens promote palatable food memory

Authors: *Y.-B. KIM, D.-H. CHEON, S.-H. JUNG, L. HA, S. BAEK, H. CHOI;
Seoul Natl. Univ., Seoul, Korea, Republic of

Abstract: The nucleus accumbens (NAc) has been recognized as a prime center for the reward. However, the mechanism by which neuron in NAc controls food-specific memory, especially for palatable food, remains unknown. Neuropeptide Y (NPY) has long been considered to have a profound orexigenic influence on the entire brain. Among the diverse molecular cell types in NAc, the role of NPY-expressing neurons is not yet fully understood. Here, we demonstrated that NPY neurons in NAc promote palatable food memory. Using calcium imaging, we showed that the NAc^{NPY} neurons respond to eating behavior. This response depended on the palatability of the food. Using optogenetics, we discovered that the NAc^{NPY} neuronal activation significantly increased palatable food (high-fat food) intake. Optogenetic activation of NAc^{NPY} neurons showed food-specific positive valence in real-time place preference test with palatable food context. Furthermore, optogenetic activation of NAc^{NPY} neurons served as an unconditioned stimulus for the formation of palatable food memory. In conclusion, these experiments provide strong evidence that NAc^{NPY} encodes positive memory for palatable food. Our findings could lead to the development of novel therapeutic strategies to prevent and treat obesity and food addiction.

Title: Pavlovian trace conditioning produces devaluation-insensitive, habitual form of conditioned response in mice

Authors: *R. SUZUKI, M. KOMURA, Y. KOSAKI;
Waseda Univ., Tokyo, Japan

Abstract: Unlike instrumental behavior which can become goal-insensitive under certain conditions (i.e., habit), the conditioned responses (CRs) engendered in Pavlovian conditioning procedures are usually sensitive to outcome (US) devaluation, regardless of the amount of training (e.g., Holland, 1998; Holland et al., 2008). This is especially true when the conditioned food-cup response (magazine entry) is measured as the target CR. However, the lack of evidence for habitual CRs may reflect the relative paucity of effort to find the phenomenon, rather than its indicating a general principle. Functionally, the expressions of CRs in the absence of a clear representation of sensory-specific features of the US would still be advantageous in some situations. In the current study, we investigated whether placing a temporal gap between the CS and the US would produce devaluation-insensitive habitual CRs using an appetitive trace conditioning procedure in mice. We trained one group of mice (Group Trace; n = 16) with a 4-s auditory CS followed by a 6-s trace interval that ended with the delivery of sucrose solution US. The other group of mice (Group Delay; n = 16) was trained with a 10-s CS that co-terminated with the US. After the mice achieved the acquisition criterion, the US was devalued for half the mice in each group by means of LiCl-induced taste aversion, while the value of the US was maintained for the other half with the unpaired control procedure. The results from the extinction test showed that the magazine CRs in Group Delay were substantially reduced by the US devaluation, whereas those in Group Trace were unaffected. The result indicates that the mice in Group Trace expressed the CRs which did not involve the specific representation of the US. The development of habitual CRs in the trace conditioning parallels the facilitation of instrumental habit formation under the delayed reinforcement paradigm (Urcelay & Jonkman, 2019). The placement of temporal gap between events might generally make it difficult for animals to use the specific sensory representation of the consequent event.

Title: Deciphering Arc-dependent control of circuit dynamics underlying the consolidation of associative memories

Authors: *L. S. BREBNER[1], E. KOYAMA[1], M. OKAMURA[1], Y. KONDO[1], T. YOKOYAMA[2], R. SHIMODA[1], K. OTA[1], R. KIM[1], H. OKUNO[3], H. BITO[1];
[1]Neurochemistry, Univ. of Tokyo, Tokyo, Japan; [2]Dept. of Advanced Imaging, Kyoto Univ., Kyoto, Japan; [3]Dept. of Biochem. and Mol. Biol., Kagoshima Univ., Kagoshima, Japan

Abstract: Cortical neurons expressing immediate early genes such as Arc following learning experiences encode associative memories. However, how these neurons come to encode associative memories is poorly understood, particularly when memories require repeated learning experiences. Crucially, the activity dynamics that Arc-expressing neurons display during these learning experiences remain unclear. Furthermore, while dorsal medial prefrontal cortex (dmPFC) neurons show altered signal processing in response to associative learning, the contributions of transient and targeted Arc expression in mediating these alterations are unknown.
Aim: Thus, our goal is to characterize the activity dynamics of dmPFC Arc-expressing neurons during associative learning.
Methods: To this aim, we performed longitudinal in vivo 2-photon imaging of the dmPFC in mice as they performed a cue-reward associative learning task. Imaged mice were injected with viral constructs coding for both the calcium indicator XCaMP-G and a red fluorophore driven by the Arc ensemble-marking E-SARE promoter. This method allowed us to track dmPFC Arc-expressing neurons across associative learning sessions and observe their activity patterns at different stages of learning.
Results: We observe that Arc-expressing neurons are progressively mapped to neurons displaying strong task-related activity over learning, resulting in the emergence of an Arc-expressing population with enhanced encoding capacity in late learning. Furthermore, past high Arc expression was not associated with subsequent modulations of activity per se but instead predicted long-term stabilization of activity dynamics.
Conclusion: Together, this suggests a dynamic two-way relationship between neuronal activity and Arc expression during associative learning. Over the course of associative learning, neurons

showing task-related activity are increasingly selected as Arc-expressing ensembles which in turn predicts persistence of their activity dynamics.

Title: Acute stress before instrumental conditioning promotes habit expression in female rats

Authors: *R. J. DOUGHERTY, Z. MOHAMMED, S. VONDOEPP, E. HILTON-VANOSDALL, D. J. TOUFEXIS;
Psychological Sci., Univ. of Vermont, Burlington, VT

Abstract: Much remains unknown about how stress affects the learning and memory processes involved in instrumental conditioning. Stress has been demonstrated to impair goal-directed action, but whether it does so by altering the acquisition of the behavior, or by affecting the expression of the goal-directed or habitual components of the response, has yet to be determined. In this study our objective was to explore the influence of acute stress on action control when administered prior to a minimal amount of acquisition training (Experiment 1), or prior to the test of behavioral expression (Experiment 2). In Experiment 1, 36 young female Long Evans rats received acute restraint stress (n=18) or a control behavioral treatment (n=18) before acquiring a nose-poking response to get a sucrose reward. Following training, the reward was devalued for half of the animals in each group by pairing it with lithium chloride to induce illness. In the critical test, behavioral sensitivity to reward devaluation was assessed in extinction conditions by comparing response rates between devaluation groups in a two-way analysis of variance (ANOVA). Results indicate that exposure to acute stress prior to instrumental conditioning is sufficient to support habitual responding, while the Non-Stressed group remained goal-directed. Experiment 2 was conducted identically to Experiment 1, apart from the installment of acute stress before the extinction test rather than before training. Results from this experiment indicate that rats receiving acute stress before the test responded in a goal-directed manner, as did those who received the control treatment. These data suggest that acute stress may promote habitual control over a minimally trained behavior through an effect on the learning and memory processes engaged during acquisition, but not during retrieval of the response memory. This study extends the contemporary understanding of the interaction between stress and instrumental learning by characterizing the effect of acute stress in female rats – which has not been done

before – when administered before conditioning or before the test. Progress in understanding how and why habits form has implications for understanding how they may go awry in compulsive pathologies such as addiction, obsessive compulsive disorder, and post-traumatic stress disorder. Further research is needed to determine the mechanism by which stress disrupts this conditioning process, and whether a sex difference exists in this regard.

Title: Consumption of palatable food persists despite induced aversion during adolescence in rats

Authors: *L. RODRIGUEZ-SERRANO[1,2], M. CHAVEZ HERNANDEZ[3], A. LOPEZ-CASTILLO[4], F. LEYVA-GARCIA[2];
[1]Univ. Anáhuac México, Estado de México., Mexico; [2]Facultad de Psicología, Univ. Anáhuac México, México, Mexico; [3]Facultad de Psicología, Univ. Anáhuac México, Mexico, Mexico; [4]Univ. Anáhuac México, Facultad de Psicología, Mexico

Abstract: Palatable food (PF) intake can lead to chronic overconsumption and, subsequently, obesity. Furthermore, the classical view distinguishes that homeostatic feeding is necessary for basic metabolic processes and survival, while hedonic feeding (consumption PF) is driven by sensory perception or pleasure. In this regard, food properties have a main role in intake, in particular the palatability of food can lead to the development of obesity in susceptible individuals, produce metabolic syndrome and cognitive impairment, and enhance food intake by hedonic mechanisms that prevail over caloric necessities. The present study aims to evaluate binge-like intake of palatable food after inducing aversion during adolescence in rats. We used thirty male Sprague-Dawley rats (30 days postnatal); all animals were housed individually and had ad libitum access to a standard diet (SD) and water; animal weight and SD food intake were manually recorded every 24h. Rats were distributed on the following treatment: group 1 “CON-PF”, with PF access and no treatment; group 2 “PF-A”, with PF access and administration of LiCl to induce aversion; group 3 “PF-Veh” PF access and administration of vehicle. All groups had 1h access to PF (Oreo® Cookies Nabisco®) according to diet protocol intermittent with one-day access, one-day no-access. PF and SD caloric intake, and binge eating criterion (defined as

consuming ≥20% of total caloric intake per day during the 1h access to PF) were analyzed. Our results showed that PF-A reduced consumption of PF after inducing aversion; nevertheless, consumption increased rapidly and normalized with the other two groups. Overall, these results show that persistence in intake of PF during adolescence despite inducing aversion and that it can lead to chronic overconsumption in conditions of non-homeostatic feeding.

Title: Preliminary Assessments of Flexible Cognition and Stress Hormone Profiles in Wild Brown Mouse Lemurs (Microcebus rufus)

Authors: *K. LAMBERT[1], R. G. HUNTER[2], P. WRIGHT[3], A. RAZAFINDRAKOTO[4], H. RAVELONJANAHARY[4], H. HESSELN[5], E. TRONICK[6], M. KENT[7], B. CROCKETT[1], J. DORION[1], S. HARTVIGSEN[1];
[1]Univ. of Richmond, Richmond, VA; [2]Psychology, Univ. of Massachusetts, Boston, MA; [3]Stony Brook Univ., Stony Brook, NY; [4]Ctr. ValBio, Ranamofana, Madagascar; [5]Univ. of Saskatchewan, Saskatoon, SK, Canada; [6]Univ. of Massachusetts, Boston, Boston, MA; [7]Virginia Military Inst., Lexington, VA

Abstract: Mouse lemurs represent a valuable nonhuman primate model for Alzheimer's Disease (AD) due to shared age-related cognitive and neuropathology responses with humans (Piferri et al., 2019; Gary et al., 2018; Ho et al., 2021). Consequently, this small primate offers enhanced translational potential compared to shorter-lived rodents. In contrast to captive mouse lemurs, wild brown mouse lemurs (i.e., up to 8 years of age) failed to exhibit physical signs of senescence (Zohdy et al., 2014) suggesting that neurocognitive differences may exist between captive and wild aging mouse lemurs. In the current study, we assessed cognitive performance in wild brown mouse lemurs trapped near Madagascar's Ranomafana National Park. All animals were assumed to be young adults based on external evaluations; however, specific aging assessments were not conducted. Fecal samples were collected in male (n=9) and female mouse lemurs (n=5) to assess stress hormone profiles (cortisol and DHEA) at pre- (males and females) and post-trap time points (only males). For the flexible cognition assessment, male lemurs were

habituated to a dynamic foraging task consisting of three food wells that changed positions, each with a distinct visual pattern associated with a specific food value (i.e., specific pieces of banana). At appx 2100 hrs each evening, lemurs were assessed in habituation and test trials for three days for Group 1 (n=4 males) and one less test day for Group 2 (n=5). Preliminary results indicated significant sex differences in pre-trap DHEA/CORT ratios [x=0.18 and 0.94 for females and males, respectively; p=.04; higher ratios are correlated with resilience (Kent et al., 2018)]. Overall, 66% of the lemurs interacted with the dynamic foraging panel with minimal habituation; further, lemurs that interacted with the foraging task also solved a different grasping problem-solving task. Interestingly, the second cohort of animals failed to interact with the foraging panel during the habituation phase. This effect was likely due to relatively sparse foliage in the habitat compared to Cohort I, an effect that was reversed when sufficient foliage was added to the habitat. Hair samples are currently being assessed for integrative endocrine profiles. Although considerable variability in endocrine and behavioral responses was observed, no significant correlations were detected. These initial findings indicate that cognitive assessments can be conducted in wild mouse lemurs temporarily housed in ecologically appropriate habitats-- informing the developmental trajectory of cognitive performance in these small primates as they are evaluated for translational research opportunities.

Title: Behavioral, hormonal and neuroanatomical effects of appetitive anticipation in male and female rats.

Authors: *S. C. HARTVIGSEN[1], M. HOOPER[1], O. HARDING[1], E. WIENER[1], Y. SHATALOV[1], I. TOME[1], A. SAGE[1], L. BASTIAN[1], E. BARRINGER[1], C. OWENS[1], P. LUBY[1], B. CROCKETT[1], M. KENT[2], K. G. LAMBERT[1];
[1]Psychology, Univ. of Richmond, Richmond, VA; [2]Virginia Military Inst., Lexington, VA

Abstract: Developing more efficacious interventions for mental health disorders requires a better understanding of the long-term neural and behavioral impacts of emotionally salient events. While the effects of negative events have been widely studied, less is known regarding the effects of appetitive events on longstanding neural and behavioral changes. Our lab is interested in understanding how anticipation of positive events (“appetitive anticipation”)

influences stress resiliency, learning and memory. Prior experiments in our lab examined this by comparing stress-resilient behaviors, hormones and neuroanatomical markers in female Long Evans rats exposed to either five weeks of positive events preceded by anticipation or to five weeks of positive events that were not anticipated. Results from these experiments suggest appetitive anticipation may affect motivational and exploratory behaviors as well as receptor expression in the brain, though it remains unknown if similar effects are seen in males. Thus, the current study examines how appetitive anticipation in both male and female rats influences stress-related behaviors, hormones and receptor expression. Because optimism is associated with positive health outcomes in humans and animals, we also examined if anticipation of positive events affects optimistic cognitive bias, as determined by preference for a high-value or low-value reward in response to an ambiguous cue. We found a trend towards significance in which males exposed to appetitive anticipation chose a high-value reward more than males receiving unanticipated positive events (X^2 (1, N=11) = 3.592, p=0.0581), though future experiments are needed to examine if the high-value reward accurately reflects an optimistic cognitive bias. Comparing concentrations of corticosterone (CORT) before and after five weeks of anticipated or unanticipated positive events revealed a main effect of time (F(1,16) = 4.801 , p = 0.0436, N=24 rats total), where the direction of the effect was an increase in CORT in all groups except males exposed to appetitive anticipation, suggesting anticipatory training may blunt CORT increases in a sex-dependent manner. Because receptors can mediate effects of fluctuating stress hormones, ongoing analyses are examining glucocorticoid and mineralocorticoid receptor expression in brains of male and female rats exposed to anticipated versus unanticipated positive events. Overall, results from this study suggest increasing anticipation of positive experiences may offer a novel therapeutic avenue for improving stress resiliency and mental health.

Title: Regulation of Pavlovian conditioning by stress and amphetamine: Learning of sensory cues with no predictive value

Authors: S. KARIMIHAGHIGHI[1], B. PAHLAVAN[2], H. R. WESSEL[1], M. R. DREW[1], G. A. RUEBEN[3], *H. MORIKAWA[1];
[1]The Univ. of Texas at Austin Dept. of Neurosci., Austin, TX; [2]The Univ. of Texas at San

Antonio Dept. of Neurosci., San Antonio, TX; [3]The Univ. of Texas at Austin Col. of Pharm., Austin, TX

Abstract: The ability to associate predictive environmental events with rewarding outcomes is essential for adaptive behaviors, while excessive learning of the incentive value of environmental cues can drive maladaptive behaviors, such as addiction to drug and non-drug rewards. It is well established that sensory cues need to precede reward for effective learning of cue-driven responses. However, it is not clear how daily experience regulates the cue-reward timing-dependence of learning. In this study, we investigated the impact of stress and amphetamine on timing dependence of reward learning in male rats. We employed a Pavlovian conditioned approach paradigm, where light cue at the food cup was paired with food pellet delivery, and the temporal relationships between the cue and food delivery were varied. To examine the effect of acute stress, male rats underwent 30-min social defeat stress. After a 10-min interval, stressed rats (n=11) and handled controls (n=12) underwent a single conditioning session (30 trials). While both handled and defeated rats developed comparable cue responses (i.e., food cup entry in response to the cue) with 5 sec cue-reward delay, only defeated rats developed cue responses when the cue onset and food delivery were simultaneous during conditioning. Neither group developed cue responses if food preceded the cue onset. Overall, defeat stress caused a leftward shift in cue-reward timing-dependence of conditioning and relieved the requirement of cue-reward delay. Acute defeat stress had no effect on food consumption during conditioning. Next, we tested different doses of amphetamine (0.1, 0.3, 1, 5 mg/kg, i.p.) injected ~15 min before each simultaneous conditioning session. Although saline-injected control rats failed to develop conditioned cue responses, all doses of amphetamine enabled simultaneous conditioning after three conditioning sessions (n=7-15 in each group). Interestingly, 5 mg/kg amphetamine virtually eliminated food consumption during conditioning even though conditioned cue responses were observed, suggesting that rats can learn using the pellet delivery sound learned previously. Finally, 1 mg/kg amphetamine caused robust rise in norepinephrine levels in the ventral tegmental area (VTA) measured with microdialysis (n=4), suggesting the potential role of norepinephrine, which has been shown to regulate the timing dependence of glutamatergic synaptic plasticity in the VTA. In conclusion, our results demonstrate that acute exposure to stress or amphetamine enables learning of the valence of sensory cues presented at the same time as reward, i.e., learning of cues that do not predict reward availability.

Title: Psychophysiological Examination of Cognitive Models Interpreting User Thought Processes Leading to Product Acceptance

Authors: *N. YAMADA, K. UEDA, K. NAGATO, M. NAKAO;
The Univ. of Tokyo, Tokyo, Japan

Abstract: At a time when material wealth is saturated and a transition to a sustainable society is required, innovation is needed to create products with new functions that have never been seen before. Although there have been industrial developments that should be called innovations in the past, the process of discovery and acceptance often took a circuitous route; people did not easily accept and evaluate new functions that they had not yet encountered. In order for the value of a new feature of a product to be properly understood, its design must take into account the thought process leading to user acceptance. Models for evaluating user acceptance proposed by previous studies, such as the Technology Acceptance Model (Davis, 1989), are all static models that use subjective evaluation, and it is difficult to apply them to design in the early stages of development. When designing a product, it is necessary to include appropriate information in the product itself and its documentation that provides clues for understanding the functionality. Therefore, it is necessary to clarify the modality, presentation method, and the process of information required in the thought process leading to the user's comprehension. We aim to construct a theory that can be applied to product design based on the insights of cognitive neuroscience, and to model the thought processes that lead to a deeper comprehension and acceptance of product functions by users who are first given the product. In this study, we prepared highly professional tools or gadgets used for only a small part of daily life, and let users who used them for the first time observe the products until they understood their functions as experimental participants. We measured the EEG, eye gaze, and pupil diameter of the participants during the products observation. Whenever the participants became aware of a product feature during the observation, they were asked to write it down graphically and report it to us. These results showed that in addition to the state of "having accepted the product", which has been expressed by conventional models, we were able to capture the changes that lead to the acceptance of the product. In this presentation, we report on the characteristics of the biometric signals at each stage of the thought process, referring to the product characteristics that triggered acceptance, and show the possibility of constructing a model.

De Fisiologia Celular-UNAM, Mexico city, Mexico

Abstract: The insular cortex (IC) has been linked to the processing of interoceptive and exteroceptive signals associated with maintaining addictive behavior. However, whether the IC modulates the acquisition of affective reward states related to drugs by direct top-down connectivity with the ventral tegmental area (VTA) dopamine neurons is unknown. Our results demonstrated that photostimulation of the VTA terminals from the anterior insular cortex (aIC) pathway induced rewarding contextual memory, modulated VTA activity, and led to dopamine release within the VTA. Using neuronal recordings and neurochemical analysis, we confirmed the functional top-down organization of the circuit by transsynaptically and anterogradely tagging aIC presynaptic neuronal bodies with AAV1-Cre-dependent expression and identifying VTA recipient neurons. Furthermore, systemic administration of amphetamine altered the excitability of VTA neurons modulated by the aIC projection, enhancing contextual rewarding behavior. Our study reveals a circuit that plays a pivotal role in developing and retaining reward-related contextual memory, providing insight into the neurobiological basis of addictive behavior, and opening possibilities for developing therapeutic strategies for addiction.

Title: Temporal difference learning models explained dopamine activities during contingency degradation

Authors: *L. QIAN[1,2], M. BURRELL[1,2], J. HENNIG[2,3], V. N. MURTHY[1,2], S. GERSHMAN[2,3], N. UCHIDA[1,2];

Abstract: Studies on animal learning have shown that the efficacy of both associative learning and responding depends on contingency, the extent to which the likelihood of an outcome changes by a presentation of a stimulus. The mesolimbic dopamine (DA) system, vital in associative learning, is believed to signal reward prediction errors which resemble temporal difference (TD) errors in reinforcement learning. Yet, how DA signals are modulated by contingency remains poorly understood. We examined how contingency changes affect conditioned responding and DA responses in mice (n=15). Mice were conditioned on two odors: one probabilistically rewarded (Odor A; 75%); the other, unrewarded (Odor B). Subsequently, the cue-reward contingency was degraded by delivering uncued reward. To control for possible satiety effects, a separate group of mice received additional rewards cued by a distinct odor (Odor C; cued-US group). Anticipatory licking decreased in Odor A trials in the degradation cohort ($p < 0.001$), while no significant change was observed in the cued-US group ($p=0.25$). DA axonal signals, recorded in the ventral striatum using photometry, tracked the contingency. The response to Odor A developed quickly during conditioning sessions ($p < 0.001$), and attenuated during degradation ($p < 0.01$). In contrast, the cued-US group did not exhibit a decrease ($p=0.14$). We next examined if DA responses in contingency degradation could be explained as TD errors. We found nearly all aspects of DA responses were explained by a TD learning model that harnesses a state representation reflecting the task structure, transitioning between inter-stimulus and inter-trial intervals (ISIs and ITIs, respectively). A recently proposed retrospective learning model, which claimed to replicate DA responses during contingency degradation (ANCCR; Jeong et al., 2022; Garr et al., 2023), failed to explain these responses, incorrectly predicting DA cue responses change identically in both degradation and cue-US groups as the retrospective contingency (P(Odor A | reward)) was the same in both groups. Additionally, we found that recurrent neural networks (RNNs), trained using TD learning, recapitulated nearly all aspects of DA responses. Trained RNNs developed state transition dynamics and the value function that matched those in the TD learning model with ISI and ITI states. Both models show DA cue response drops in degradation due to heightened ITI value predictions, reducing TD error. Our findings highlight TD learning can fully account for DA responses, if task states are carefully considered, and provide insights into the neural mechanisms underlying contingency learning.

Title: Cued reward memories bias cognitive strategies: role of orbitofrontal circuits

Authors: *S. PETERSON[1], J. CHAVIRA[2], A. MAHERAS[3], R. KEIFLIN[2];
[1]Psychological & Brain Sci., Univ. of California Santa Barbara, Goleta, CA; [2]Psychological & Brain Sci., [3]Molecular, Cellular, and Developmental Biol., Univ. of California, Santa Barbara, Santa Barbara, CA

Abstract: Reward-predictive cues can influence choice behavior and promote the pursuit of specific reward outcomes. This influence of cued reward memories on choice processes is often studied using outcome-specific Pavlovian to Instrumental Transfer (PIT). In this paradigm, stimuli established as Pavlovian predictors of specific outcomes can bias/invigorate specific instrumental actions. However, traditional PIT experiments fail to account for the fact that pursuit of specific outcomes often requires specific cognitive strategies (e.g. rule selection, selective attention, flexible working memory). The influence of cued reward memories on cognitive strategy selection has received less attention, and the neural circuits mediating this effect remains largely unknown. To address this gap in knowledge, we adapted the traditional PIT paradigm in rodents. In a first phase, rats acquired different cognitive strategies for decision-making in an instrumental sequence. Specifically, in separate blocks, they learned that a delayed nonmatching to sample (dNMTS) strategy was rewarded by outcome 1 (sample lever press - nosepoke - nonsampled lever press : O1) and that a visual cue tracking strategy was rewarded by outcome 2 (sample lever press - nosepoke - cued lever press : O2). In a second phase, two distinct auditory cues were established as Pavlovian predictors of the two outcomes (S1-O1; S2-O2). Finally, in nonrewarded probe tests we measured how the presentation of these Pavlovian cues biased the selection of a cognitive strategy. We found that Pavlovian predictors promoted the adoption of the strategy that corresponded to the cued outcome. Specifically, S1 promoted dNMTS strategy while S2 promoted a visual cue tracking strategy. This new behavioral paradigm will be used in combination with chemogenetic silencing to investigate the role of the orbitofrontal cortex and its projections to the prelimbic cortex in mediating cued outcome memories and their influence on cognitive strategy selection.

Title: Frustrative nonreward: Role of the accumbens-globus pallidus connections in reward downshift

Authors: *M. R. PAPINI, C. HAGEN, P. OGALLAR;
Psychology, Texas Christian Univ., Fort Worth, TX

Abstract: Reward downshift is used as a model of frustrative nonreward, a negative valence trait related to the response to loss, psychological pain, and frustration. Most neurobiological research on reward downshift has centered on the amygdala, but recent results implicate the basal ganglia. Activation of the nucleus accumbens (NAc) and globus pallidus externus (GPe) with excitatory DREADDs (designer receptors exclusively activated by designer drugs) enhanced and reduced consummatory suppression, respectively, after a 32-to-2% sucrose downshift (Guarino et al., Neurobiol Learn Mem, 2023). We hypothesized that these effects were mediated by the direct NAc-GPe connection and tested this hypothesis using a double-infection technique to selectively excite the pathways connecting the NAcàGPe and NAc-GP internus (GPi). Male Wistar rats (90 days old at the start of surgery) were used. Viral vector constructs carrying the excitatory Cre-dependent DREADD [AAV8-hSyn-DIO-hM3Di-mCherry] containing a red fluorescent reporter (mCherry) and a DNA fragment for the engineered muscarinic receptor M3 were infused bilaterally into the NAc (departure area). Retrogradely transported viral vector constructs (AAV9-hSyn-eGFP-Cre) carrying the Cre protein and a green reporter (eGFP) were infused bilaterally into the GPe or GPi (destination areas). Thus, only projection neurons containing the Cre protein expressed the excitatory DREADDs in the NAc, as assessed by fluorescent microscopy. Groups infused with a control virus were also included. All animals received systemic injections of clozapine N-oxide or vehicle during four 32-to-2% sucrose downshift sessions. In contrast to our hypothesis, activating the NAc-GPe pathway did not affect consummatory behavior after reward downshift relative to vehicle and virus controls. However, activating the NAc-GPi pathway enhanced consummatory suppression after the downshift. Thus, the previously described effect of NAc activation was at least in part related to its direct connection with the GPi. There was no evidence that activation of these pathways had motor effects in the open field. Unlike previous studies that focused on single brain regions, our approach uncovered for the first time the importance of specific brain pathways in frustrative nonreward.

Title: Medial septum glutamate neurons play a role in strategy switching potentially via modulating nucleus accumbens dopamine responses to reward-related stimuli

Authors: *A. KESNER, S. RAMOS-MACIEL, N. WESTCOTT;
Unit on Motivation and Arousal, NIAAA, Rockville, MD

Abstract: The septum was first region discovered by Olds and colleagues to support electrical intracranial self-stimulation in the rat. Further studies by Heath in the 1970s showed humans will similarly press a button to earn intra-septal electrical stimulation. Despite these landmark studies, further interest in the septum, in particular the medial septum (MS), as a locus for reward related behaviors remained limited. We previously found that mice will lever press to earn optogenetic stimulation of the MS, and in particular MS glutamate neurons (MS-GLUn), and MS-GLUn in turn project to the VTA to influence dopamine (DA) release in the nucleus accumbens (NAc) (Kesner et al., 2021). Little else is known about the role of MS-GLU neurons during natural reward-seeking behaviors. To address this knowledge gap, we recorded MS-GLUn population activity using GCaMP7F and fiber photometry techniques while mice performed various operant and Pavlovian reward-seeking behaviors. We found that MS-GLUn indeed respond differentially to reward-related stimuli (e.g., active vs inactive lever presses, reward consumption, and reward predictive cues). We next modulated MS-GLUn activity using a chemogenetic approach (Gi and Gq DREADDs, or mCherry control), and found that enhancing MS-GLUn excitability increased the rate that mice incorporated new information to obtain goals, i.e., strategy switching. Since we know optogenetic stimulation of MS-GLUn can increase NAc-DA, we next hypothesized that the effect on strategy switching behavior from chemogenetic modulation of MS-GLUn may be driven by resultant changes in NAc-DA during these tasks. We recorded NAc-DA via fiber photometry of dLight1.3b during the same operant and Pavlovian strategy switching behaviors while MS-GLUn were chemogenetically manipulated. We observed differences in NAc-DA during these tasks dependent on chemogenetic modulation of MS-GLUn that appears to correspond to NAc-DA responses to new reward related cues/stimuli. These findings are an important step in understanding the role of this understudied population of neurons in an understudied brain region related to reward and motivational processes, and could lead to novel therapeutic interventions for treating psychiatric disorders related to maladaptation in motivated behaviors.

Title: Striatal integration of inverse dopamine and serotonin signals gates learning

Authors: *D. F. CARDOZO PINTO[1], M. B. POMRENZE[1], M. Y. GUO[1], B. S. BENTZLEY[2], N. ESHEL[1], R. C. MALENKA[1];
[1]Stanford Univ., Stanford, CA; [2]Magnus Med., Burlingame, CA

Abstract: The neuromodulators dopamine (DA) and serotonin (5-hydroxytryptamine; 5HT) are powerful regulators of associative learning. Similarities in the activity and connectivity of these neuromodulatory systems have inspired competing models of how DA and 5HT interact to drive the formation of new associations. However, these hypotheses have yet to be tested directly because it has not been possible to precisely interrogate and manipulate multiple neuromodulatory systems in a single subject. Here, we establish a double transgenic mouse model enabling simultaneous genetic access to the brain's DA and 5HT systems. Anterograde axon tracing revealed the nucleus accumbens (NAc) to be a putative hotspot for the integration of convergent DA and 5HT signals. Simultaneous recordings of DA and 5HT input activity in the NAc posterior medial shell revealed that DA axons are excited by rewards while 5HT axons are inhibited. Optogenetically blunting DA and 5HT reward responses simultaneously blocked learning about a reward-predictive cue. Optogenetically reproducing both DA and 5HT responses to reward, but not either one alone, was sufficient to drive the acquisition of new associations. Altogether, these results demonstrate that striatal integration of inverse DA and 5HT signals is a crucial mechanism gating associative learning.

Title: Parallel dopamine circuits from the VTA to Nucleus Accumbens and their response to natural rewards and opioids

Authors: *O. CULVER, IV;
Neurosciences, MUSC, Charleston, SC

Abstract: Dopamine (DA) neurons in the VTA play key roles in motivation and addiction, including addiction to opioids. However, these roles are increasingly recognized to be heterogeneous, as prior studies showed that VTA DA neurons projecting to medial vs. lateral nucleus accumbens respond differently to motivational stimuli. Prior studies also showed that medial accumbens-projecting dopamine neurons exhibit greater c-Fos activation by heroin as compared to lateral accumbens-projecting DA neurons. However, these prior studies did not examine other opioids such as fentanyl nor did they examine withdrawal effects, and also did not examine whether DA release mirrors these c-Fos patterns. Therefore, we examined fentanyl-induced (single 0.1 mg/kg sc dose) c-Fos in VTA neurons that were retrogradely labeled from the medial and lateral nucleus accumbens. We also examined fentanyl-induced DA release in medial and lateral accumbens using fluorescent DA sensors. Our c-Fos experiments extended previous findings, as medial accumbens-projecting DA neurons had significantly higher c-Fos activation as compared to lateral accumbens-projecting DA neurons after a single fentanyl dose. Fentanyl also increased accumbens DA differentially between animals, but further analysis is required to correlate these differences with anatomical location.

Title: Altered gamma oscillations in a prefrontal striatal network associated with social preference impairments after traumatic brain injury

Authors: *M. SALIMI[1,2], M. NAZARI[3], H. AFSHAR[1,2], N. LEE[1,2], K. MOKHA[1,2], T. WALKER[1,2], M. FRANCOEUR[1,2], D. RAMANATHAN[1,2];
[1]Psychiatry, Univ. of California San Diego, San Diego, CA; [2]Mental Hlth. Service, VA San Diego Healthcare Syst., San Diego, CA; [3]Dept. of Mol. Biol. and Genetics, Aarhus Univ., Åarhus, Denmark

Abstract: Background and objectives: Traumatic Brain Injury (TBI) leads to cognitive and behavioral, impairments, including social preference deficits. Physiological studies have identified the mediation of gamma frequency oscillations for social behaviors. This study aims to investigate how frontal TBI affects cortical gamma frequency activity and coordination across distributed networks resulting in chronic social preference impairments. We simultaneously recorded local field potentials (LFP) from 32 brain areas: an approach study advantageous to studying distributed brain networks and offers translational potential to human studies.
Materials and Methods: We compared social preference behavior and concurrent data across two groups of Male Long-Evans rats. One group received a severe frontal TBI (n = 12 TBI rats) and control (n=10 rats). One week after we implanted 32 electrodes in regions focal, and distal to the site of injury. 3 weeks post-injury using three-chamber social interaction maze locomotor activity and social preference were measured. LFP analysis performed offline with Matlab software included Power spectral density (PSD) and coherence connectivity calculations to assess frequency bands and brain areas supporting social preference. Histological analysis was performed to measure tissue damage and verify electrode placement.**Results:** Frontal TBI decreased social preference and increased overall locomotor activity ($F_{1,38} = 29.8$, $p < 0.0001$). TBI animals spent more time and made more visits to the non-social chamber compared to controls ($t_{(38)} = 3.23$, $p = 0.002$). TBI increased locomotor activity in the ($F_{1,38} = 5.73$, $p = 0.02$). Power Spectral Density showed a deficit in brain regions focal (prelimbic cortex), local (anterior lateral motor cortex, anterior insula), and distal (nucleus accumbens shell) to the injury site. Sham animals exhibited elevated prefrontal-ventral striatum coherence of gamma frequency oscillations (25-60 Hz) in the social chamber compared to the non-social chamber. TBI animals showed less pronounced differences in gamma coherence between the social and non-social chambers compared to sham animals.**Conclusion:** This study demonstrates that damage to the frontal cortex reduces social preference driven by alterations in gamma oscillations within frontostriatal networks. Even areas beyond the focal injury site showed gamma frequency deficits that persisted weeks after the injury. Understanding the impact of gamma oscillation disruptions on social preference deficits in TBI can provide valuable insights for developing targeted interventions to improve social outcomes in individuals with TBI.

Title: Divergence between the rewarding effect of MFB stimulation and photometric measurement of dopamine release

Authors: *J. VOISARD, Z. MOHAMMADREZAEE, A. ARVANITOGIANNIS, P. SHIZGAL;
Psychology, Concordia Univ., Montréal, QC, Canada

Abstract: Rodents work vigorously to earn electrical stimulation of the Medial Forebrain Bundle (MFB). The prevalent account attributes the highly rewarding effect of MFB stimulation predominantly, if not entirely, to activation of midbrain dopamine neurons. We challenged this widely held view by coupling fiber-photometric recording of dopamine release to behavioral measurement of reward effectiveness. At multiple pulse frequencies, stimulation current was varied to drive responding from asymptotic to negligible levels. Dopamine release in the Nucleus Accumbens (NAc) was measured using the molecular sensor, GRAB-DA2m, both during self-administered and passively received MFB stimulation. We determined the current required to hold either behavior or dopamine release constant at each pulse frequency. The resulting behavioral and chemometric trade-off functions were similar at low pulse frequencies but diverged sharply at higher ones. These results parallel those obtained previously by means of fast-scan cyclic voltammetry. Together with recent optogenetic findings, the photometric and voltammetric results support a model in which midbrain dopamine neurons and the directly activated, non-dopaminergic, MFB neurons subserving self-stimulation project in parallel to the behavioral final common path. If so, identifying the non-dopaminergic MFB neurons and their efferents is crucial to achieving a comprehensive account of brain reward circuitry.

Title: Phosphorylation of ribosomal protein S6 as a marker of reward identity and time prediction errors throughout the rat brain

Authors: *D. SIEGEL[1], N. HUSSEIN[2], A. R. DELAMATER[3];
[1]CUNY - The Grad. Ctr., Brooklyn, NY; [2]Brooklyn Collage, Brooklyn Col., Brooklyn, NY; [3]Psychology, Brooklyn Col. - CUNY, Brooklyn, NY

Abstract: The concept of a “reward prediction error (RPE)” is central to our understanding of how learning and neuroplasticity takes place. While RPEs are key to many influential models of associative learning, most neuroscientists define this in terms of a mismatch between obtained and anticipated values of reward. However, distinct sensory and temporal features of reward can also regulate learning at the behavioral level of analysis, although less neuroscience research has

focused on RPEs defined in these terms. To what extent does learning about different reward features rely on the same or different neural processes? Some data suggest that different neural systems may be required for learning about reward identity and time (e.g., Delamater et al, 2018). Here, we used immunofluorescence techniques to begin exploring the neural systems invoked by reward identity and time RPEs during a Pavlovian magazine approach task. Across two experiments, rats were trained to associate two stimuli with reward, followed by an unexpected reversal of the stimulus-outcome contingencies. During the critical test session, control groups were given stimuli and rewards without reversal of those contingencies. Brains were processed for phosphorylation of ribosomal protein S6 (p-rPS6; a cytoplasmic marker of cell activity) and tyrosine hydroxylase (dopamine precursor) 20 min after this test session, and sections were analyzed in several cortico-striato-limbic and mid-brain regions. In our first experiment, one 10 s stimulus was paired with grain pellets and another with liquid sucrose rewards at stimulus offset. In the second study, two 60 s stimuli were paired with grain pellets but for one those pellets were delivered at 15 s and for the other at 60 s after stimulus onset. The number of dopaminergic and non-dopaminergic cells activated, as well as their activation intensities, in each brain region was measured following the test session involving a switch in the stimulus-outcome contingencies or not to assess which brain regions processed reward identity and/or time RPEs. Our findings suggest that reward identity and time RPEs recruit distinct neurobiological circuits, with the nucleus accumbens playing a significant role in identity RPEs and nigrostriatal, VTA, and hypothalamic-BLA pathways playing a role in reward time RPEs.

Title: Characterizing the Interhemispheric Projections from the Pedunculopontine Tegmental Nucleus to the Substantia Nigra Pars Compacta Dopaminergic Neurons

Authors: *A. BALDWIN, H. ARIAS, N. FERNANDEZ, M. NEELALA, M. RODRIGUEZ, A. ELFEZOUATY, I. KHETARPAL, D. PENNY, C. HOFFMAN, L. MUZYKA, G. M. BEAUDOIN, III;
Dept. of Biol., Trinity Univ., San Antonio, TX

Abstract: The neurotransmitter dopamine has been shown to be involved in motivation and reward, notably in the nigrostriatal dopaminergic pathway. Within this pathway, our research focuses on the synapse between the midbrain regions pedunculopontine tegmental nucleus (PPN) and substantia nigra pars compacta (SNc). The PPN is unusual as it sends both ipsilateral and contralateral projections, unlike other brain structures that generally confine their innervations to either ipsilateral or contralateral. To understand the nature of these inputs, the current study focuses specifically on the glutamatergic excitatory projections and the GABAergic inhibitory projections within the PPN-SNc synapse using electrophysiological and confocal microscopic methods. These projections have not been previously studied due to a lack of tools. The goal of this study is to investigate how hemisphere-specific inputs differ in their synaptic strength. Optogenetics allows us to characterize the ipsilateral and contralateral PPN inputs to SNc both functionally and structurally. We use unilateral stereotaxic surgery to deliver virus expressing a depolarizing light-gated ion channel, Channelrhodopsin (ChR2), which is tagged with either a yellow or red fluorescent protein. The virus labels glutamatergic and GABAergic neurons in the PPN. Thus, we use electrophysiology to characterize the light-activated, PPN-innervated synapses to SNc dopaminergic neurons either ipsilateral or contralateral to the injection site. Finally, the PPN innervation of the SNc is further confirmed using imaging by immunostaining with markers for dopamine neurons, GABAergic synapses, and glutamatergic synapses. Confocal images were collected to quantify the macroscopic distribution of any ipsilateral and contralateral inhibitory projections in the SNc. The results of these anterograde tracing technique are being corroborated with retrograde tracing by using retrograde bead injections into the SNc to label projecting neurons in the PPN.
Current findings suggest that only the SNc ipsilateral to PPN receives GABAergic inputs, while both ipsilateral and contralateral SNc receive glutamatergic inputs from PPN. The PPN exhibits stronger glutamatergic innervations ipsilaterally to SNc DA neurons than contralaterally. Our research will permit greater clarity for future studies which seek to understand the underlying neural network and synaptic-level processes of the nigrostriatal dopaminergic pathway.

Title: Paradoxical findings concerning behavioral function of supramammillary neurons projecting to the lateral preoptic area

Authors: *Y. ARIMA, S. IKEMOTO;
NIDA/NIH, Baltimore, MD

Abstract: The supramammillary region (SuM) projects to both the septal area and the hippocampal formation. This connectivity led to investigations of the SuM with respect to hippocampal functions such as theta oscillations, spatial and episodic memories, and spatial navigation. By contrast, our group found that excitation of SuM glutamatergic neurons (GluN) projecting to the medial septum (SuM-MS GluN) reinforces approach behavior and triggers dopamine release in the nucleus accumbens (NAc). Because SuM neurons are known to respond to salient stimuli, we hypothesized that the SuM is important in coordinating approach behavior toward not only rewards but also other salient stimuli. To further understand such coordination role of the SuM and its mechanisms, first, we examined if SuM-MS GluN send collateral projections to multiple brain regions. We confirmed that about 95% of SuM-MS neurons were GluN using retrograde tracing and mRNA in situ hybridization. Then, we examined collateral projections of SuM-MS GluN by viral tracing. We found that SuM-MS neurons densely project to the lateral preoptic area (LPO). Because the LPO is known to modulate reward-seeking behavior, we then examined if optogenetic stimulation of SuM-LPO GluN instigates approach behavior using an optogenetic intracranial self-stimulation test. Mice quickly learned to press the lever that activated SuM-LPO GluN, suggesting that the stimulation of SuM-LPO GluN instigates and reinforces approach behavior. Finally, we examined if SuM-LPO neurons respond to positive and negative stimuli, we used a fiber photometry with a calcium indicator GCaMP to detect their activity in response to water in thirsty mice and aversive footshock. Intriguingly, water reward and the tone cue paired with water decreased the activity of SuM-LPO neurons, while footshock and the tone cue paired with shock increased their activity. Moreover, we found that salient sensory stimuli bright light and loud noise increased their activity. In summary, our observations together with previous findings led us to hypothesize that SuM-LPO and SuM-MS GluN respond to salient stimuli that are uncertain and require immediate attention, but not salient stimuli that are familiar, particularly consumables and that these neurons facilitate investigatory behavioral processes in stressful or uncertain conditions. In addition, we suggest that water and its conditioned cue decreased their activity because the activation of SuM-LPO neurons induces investigatory behavioral processes, which are not compatible with consuming ingestible stimuli such as water, thereby being inactivated during consumption. Future studies will test the hypotheses.

Title: Anticipatory dopamine ramps are decorrelated from acetylcholine dips

Authors: *K. M. COSTA[1], Z. ZHANG[1], Y. ZHUO[2], G. LI[2], Y. LI[2], G. SCHOENBAUM[1]; [1]Behavioral Neurophysiol. Neurosci. Section, NIH, NIDA IRP, Baltimore, MD; [2]PKU-THU Ctr. for Life Sci., Peking Univ., Beijing, China

Abstract: Striatal dopamine release, heavily implicated in learning, movement, and motivation, is regulated by cholinergic interneurons. Previous work has demonstrated that peaks in dopamine release are typically correlated with a characteristic pause in firing in cholinergic interneurons. The coordination of phasic dopamine peaks with dips in cholinergic tone is thought to create a critical plasticity window for dopamine to act as a teaching signal. Acetylcholine can also rapidly trigger dopamine release by acting directly on dopamine axons. However, dopamine dynamics are not always phasic. For example, dopamine release in the nucleus accumbens slowly ramps up as animals approach a desired goal, and there is still controversy on how these slower signals contribute to behavior. Here, we tested whether dopamine ramps in the nucleus accumbens are coincidental with dips in acetylcholine release. We used multi-channel fiber photometry and two newly developed genetically encoded optical sensors, rDA3m and gAch4h, to simultaneously record dopamine and acetylcholine release, respectively, in the nucleus accumbens of freely moving rats. These methods avoid the known confounds of measuring bulk calcium signals from neurons. Rats (male, N=4) were water restricted and trained on task that required them to attend to a light cue that indicated trial start, then perform a nose poke, hold for 0.5 seconds, and then perform a second entry into a fluid well to receive a droplet of water. We found that dopamine signals slowly ramped up prior to the initial nose poke, as expected. However, to our surprise, this dopamine ramp was not coincidental with changes in acetylcholine release. On the other hand, the initiation of the fluid well response and the receipt of rewards led to phasic dopamine peaks that were correlated with clear dips in cholinergic signals. We also found that the light cues that indicated trial start and end led to measurable phasic increases in acetylcholine release, which precludes the possibility of a ceiling effect in the fluorescence signal. Our results reveal that anticipatory dopamine ramps in the nucleus accumbens are not coincidental with major changes in acetylcholine release, and that seemingly only phasic dopamine peaks related to reward and directly rewarded actions are correlated with cholinergic dips. This finding has important implications for the understanding of the behavioral relevance of dopamine signals at different time scales, and how these are coordinated with acetylcholine signals during learning and decision making.

Title: Investigation of neural circuits underlying hedonic consumption

Authors: *S. CHOI, S. LEE, J. PYO, J.-H. KIM;
POSTECH, Pohang-si, Korea, Republic of

Abstract: Consumption is generally triggered by homeostasis due to nutritional imbalance. However, not in nutritional imbalance, people can consume palatable food to fulfill their preferences. Consumption of palatable food could be an addictive behavior. Like substance addiction, food addiction involves a compulsive and uncontrollable relationship with food, leading to negative consequences for physical health, emotional well-being, and overall quality of life. To investigate the neural circuits that mediate hedonic consumption, especially compulsive consumption, we established a mouse model behavior paradigm. We found differential activation in an epithalamus brain region in a compulsive consumption group. We tried functional approaches using optogenetics and observed neural populations.

Title: Effects of the chemogenetic lateral habenula activation on the association of CS with the nonoccurrence of US in Pavlovian appetitive conditioning

Authors: *I.-B. JIN, S.-P. PARK, J.-S. HAN;
Konkuk university, Seoul, Korea, Republic of

Abstract: The presentations of an unconditioned stimulus (US) contingent upon the occurrence of a conditioned stimulus (CS) establishes excitatory conditioning or conditioned excitation, such as approaching a food-cup area. Conversely, associating a CS with the nonoccurrence of a US generates inhibitory conditioning or conditioned inhibition, such as not approaching a food-cup area. While previous research has predominantly focused on conditioned excitation, less attention has been given to the neural mechanisms underlying conditioned inhibition. In a previous study, our objective was to demonstrate the effects of chemogenetic inactivation of the lateral habenula (LHb) on the establishment of conditioned inhibition. Inhibiting LHb activity

during unpaired training eliminated the delayed acquisition of subsequent excitatory learning following inhibitory learning. However, LHb inhibition during paired training had no effect. In the present study, we examined whether the chemogenetic LHb activation facilitates the association of CS with the nonoccurrence of US. We adapted the same experimental design described above and employed the chemogenetic method to test it. In this study, rats went 3 days of unpaired training, which did not retard the acquisition of the subsequent excitatory conditioning, along with chemogenetic LHb activation. And then paired training was followed. Rats with chemogenetic LHb activation and the 3-day unpaired training exhibited delayed acquisition of subsequent excitatory conditioning. These results suggest that LHb activation promotes inhibitory learning. These findings contribute to our understanding of the neural mechanisms underlying conditioned inhibition and shed light on the role of the LHb in this process.

Title: Chemogenetic inactivation of the lateral habenula impairs the association of a conditioned stimulus with the absence of an unconditioned stimulus, as assessed by the superconditioning task

Authors: *N.-H. KIM, S.-Y. SIM, D.-H. KIM, J.-S. HAN;
Biol. Sci., Konkuk Univ., Seoul, Korea, Republic of

Abstract: The present study aimed to explore the neural substrates involved in conditioned inhibition, which occurs when a conditioned stimulus (CS) is associated with the absence of an unconditioned stimulus (US). Recent research suggests that the lateral habenula (LHb) plays a role in the association of a CS with the nonoccurrence of a US. To investigate this further, we conducted experiments using chemogenetic inhibition of the LHb to examine its effect on the inhibitory property of a CS generated by explicitly unpaired CS and US procedures. We employed the superconditioning task to assess the inhibitory property of CS, which consisted of three phases. During the initial phase, animals underwent six days of explicitly unpaired training of a light (CS1) with food in the behavioral chamber. In the subsequent phase, the animals received six days of paired training involving a light (CS1)-tone (CS2) compound paired with food. In the final phase, food-cup responses to each CS were measured over two days, with four trials of each CS per day. A comparison group of rats only underwent the second phase of the paired training, followed by the third phase. The results revealed a significantly higher food-cup

response to the tone (CS2) was significantly higher in animals that underwent explicitly unpaired training during the first phase, compared to the comparison group. These findings demonstrate the successful generation of conditioned inhibition through explicitly unpaired training. Additionally, we investigated the effects of experimental manipulations throughout the explicitly unpaired training on the conditioned inhibitory properties. Animals with chemogenetic LHb inhibition throughout the unpaired training showed diminished conditioned inhibitory properties. These results indicate that chemogenetic LHb inhibition impairs the association of a CS with the absence of a US, thereby supporting the notion that LHb mediates a conditioned inhibition.

Title: Flow of reward prediction error signaling during appetitive Pavlovian conditioning in mice

Authors: *S. BISWAS[1], S. SHABEL[2];
[1]UT Southwestern Neurosci. Grad. Program, Dallas, TX; [2]Psychiatry, UTSW, Dallas, TX

Abstract: Reward prediction error (RPE) - the difference between the value of received reward and the expected reward value - is thought to be a computation that animals use to predict reward and change behavior accordingly. Neurons in certain brain regions, such as the globus pallidus (GPi), lateral habenula (LHb), and ventral tegmental area (VTA) encode RPE bidirectionally, i.e., these regions encode positive RPE and negative RPE in opposite directions. These regions are connected through direct and indirect projections and are key nodes in the reward system of the brain. Previous studies have examined the nature of RPE encoding in each of these regions. However, it is unclear whether and how this information changes as it flows from one region to another. To investigate this, we are analyzing data from multi-site fiber photometry during appetitive Pavlovian conditioning in mice. Data were collected from two groups of 4 mice - in one group, we recorded from the LHb and GPi terminals in the LHb, and in the other group, we recorded from the LHb, dopamine neurons in the VTA, and dopamine terminals in the nucleus accumbens. Preliminary data indicate that changes in neural activity during conditioned and/or unconditioned stimuli are sometimes distinct in different regions within the same mice. This suggests that information may not be simply passed on from one region to another but that there is additional processing in some regions of the circuit.

Title: Investigating the role of a cluster of dopaminergic neurons in the regulation of motivational state in Drosophila

Authors: *Y. PARK[1,2], D. B. BUSHEY[3], M. ITO[3], M. ENDRES[2], L. SHAO[2];
[1]Interdisciplnary Neurosci. Grad. Program - Univ. of Delaware, Newark, DE; [2]Dept. of Biol. Sci., Univ. of Delaware, Newark, DE; [3]Janelia Res. Campus, Howard Hughes Med. Inst., Ashburn, VA

Abstract: The motivation to consume rewards, including food and sex, depends on the internal state and the value of the rewarding stimuli. Understanding how motivation is represented and regulated in the nervous system is essential for understanding reward-driven behaviors as well as pathophysiology of mental disorders, such as depression and addiction. Dopaminergic neurons (DANs) have been shown to signal for reward value and motivation in various species. Yet the functions of DANs in reward processing remains to be fully explored due to the heterogeneity in their location, projection, and transcriptional profiles. Many clusters of DANs have been identified in the *Drosophila* brain that mediate distinctive aspects of reward processing. Recently, we identified a cluster of DANs that may involve in the animal's motivation to engage in reward-driven behaviors. Specifically, we identified two cell types in the paired posterior medial 3 (PPM3) cluster of DANs that projects to the fan-shaped body. We show that optogenetic activation of these PPM3 neurons is rewarding to the flies. Interestingly, these neurons also involve in the regulation of feeding and mating behaviors. Further research is in need to determine the role of PPM3 DANs in the regulation of reward-driven behaviors in *Drosophila*.

Title: Basolateral amygdala dopamine and D1 neurons track dynamic drug seeking behaviors

Authors: *M. A. BRICKNER, J. M. PROHOFSKY, A. R. WOLFF, M. J. THOMAS, B. T. SAUNDERS;
Dept. of Neurosci., Univ. of Minnesota, Minneapolis, MN

Abstract: Environmental cues can reinforce actions and evoke strong, dynamic motivational states during drug seeking and craving to prompt relapse. The basolateral amygdala (BLA) is critical for the associative learning that underlies this process, via the linking of affective valence to sensory stimuli that predict biologically relevant outcomes. Dopamine signaling is also critical for learning and cue-driven motivational states. The BLA receives dense dopaminergic projections and is enriched with D1 dopamine receptors (D1DRs). Microdialysis and electrophysiology studies indicate that cocaine-predictive stimuli increase extracellular dopamine levels and activate neurons within the amygdala, potentially via D1DRs. In recent work, we and others demonstrated that intermittent access to cocaine promotes a sensory gated, state-level control of motivation that results in binge-like seeking profiles thought to approximate human drug use. How BLA dopamine and D1DR activity functions in addiction remain largely unexplored. Here, we used fiber photometry to measure *in vivo* dopamine signaling and D1-neuron activity in the BLA during an intermittent access to cocaine self-administration (IntAc) paradigm using dLight and GCaMP, respectively, with high spatiotemporal precision. The IntAc paradigm includes periods of drug available and unavailable periods, and the shifts between the two are indicated by changes in sensory stimuli to probe whether the BLA is involved in state-level encoding associated with drug seeking. Both BLA dopamine and D1-neuron signals emerged in response to cocaine infusions and came to track the presence of dynamic, sensory-guided drug seeking motivational states during the transitions between drug availability periods. Dopamine and D1-neuron signals exhibited different temporal profiles during state transitions and cues, suggesting that they may underlie unique facets of drug-related behaviors. In ongoing studies, I am exploring the functional role of D1-containing BLA neurons in state-level control of drug seeking using inhibitory optogenetics.

Title: Superior colliculus influences Pavlovian motor learning via excitation of dopamine and GABA neurons in the VTA and SNc

Authors: *C. L. POISSON[1], A. R. WOLFF[2], B. T. SAUNDERS[2], C. R. HERUBIN[2];
[1]Neurosci., Univ. of Minnesota Twin Cities, Minneapolis, MN; [2]Dept. of Neurosci., Univ. of Minnesota, Minneapolis, MN

Abstract: Animals associate rewarding or threatening events with specific sensory stimuli (i.e. cues) through Pavlovian conditioning. It is well known that the ventral midbrain (ventral tegmental area- VTA, and substantia nigra pars compacta- SNc) are key to the formation and expression of cue-guided behaviors. However, it is unclear how these dopamine (DA) rich regions rapidly integrate sensory information about cues in order to create conditioned behavior. In addition, the ventral midbrain is noted to have a significant population of GABA neurons that influence appetitive conditioning. A candidate structure that processes sensory information and sends excitatory projections to both DA and GABA neurons is the superior colliculus (SC). Here, we use a combination of optogenetics and fiber photometry to manipulate SC projections while simultaneously recording DA and GABA neurons in the ventral midbrain. Fiber photometry recordings demonstrate that optogenetic stimulation of SC terminals in the VTA/SNc increases DA neuron activity. Interestingly, SC terminal excitation also increased activity of local inhibitory GABAergic neurons in the VTA. These results suggest that SC inputs can influence the ventral midbrain not only via excitation of dopamine neurons, but also more subtly through the recruitment of local inhibitory neurons. In order to determine how SC inputs influenced Pavlovian conditioning, we optogenetically excited SC terminals to the VTA and SNc during a cue conditioning task. Unlike direct DA neuron stimulation, optogenetic activation of SC-DA projections does not drive learning to create conditioned behavior to an otherwise neutral cue. Instead, excitation of these projections produces unique motor output - changes in head, neck, and body orientation. Stimulation of SC-DA projections does not create real time place preference or support intracranial self stimulation, suggesting that the information signaled by this projection does not have a strong positive valence. These studies suggest that excitatory input to DA and GABA neurons from the SC has a subtle role in learning, including movement invigoration and postural control during reward-seeking behaviors. In ongoing studies we are recording deep layer SC neuron activity during a visual cue-sucrose Pavlovian conditioning task with fiber photometry. These results reveal SC dynamics that are time-locked to reward consumption and are modulated by the presence of predictive sensory cues. Overall, our work implicates that deep layer SC neurons are involved in Pavlovian conditioning, and that projections to dopamine regions influence movements associated with cue-reward learning.

Title: The Role of Striosomal Inhibition on Midbrain Dopamine Neurons in the context of Reward-Seeking Behavior

Authors: *J. MANKEL[1], J. READ[2], S. LAMMEL[2], J. ROEPER[1];
[1]Goethe-University Frankfurt, Frankfurt, Germany; [2]Mol. and Cell Biol., Univ. of California Berkeley, Berkeley, CA

Abstract: Midbrain dopamine neurons (mDAN) in the substantia nigra pars compacta (SNc) receive direct synaptic input from various brain regions, including the dorso-medial (DMS) and dorso-lateral striatum (DLS) (Lerner et al., 2015). Recent research showed direct inhibitory input from the striosomal compartment to induce enhanced rebound firing in a subset of mDANs (Evans et al., 2020). However, the presence and functional role of DA rebound in vivo remains unclear. We aim to investigate the connectivity between striosomes and projection-defined mDANs to elucidate the role of dopamine rebound in the basal ganglia network. We hypothesize relevant differences between DMS and DLS-projecting DANs, since the later are intrinsically rebound ready and might thus be more susceptible to inhibition by striosomes. A deeper understanding of this circuitry might have implications for the modulatory role of dopamine during value-based decision making. To test our hypothesis, we selectively expressed channelrhodopsin in striosomes of *pdyn-cre* mice and utilized in-vitro patch-clamp recording paired with retrograde tracing to assess their connectivity to projection-defined mDANs. While optogenetic patch-terminal activation evokes $GABA_B$-mediated GIRK- currents in both mDAN-populations (DLS-proj.: 37.41 +/- 6.58 pA; DMS-proj.: 31.41 +/- 4.27 pA), striosomes in the DMS showed similar connectivity to DMS- and DLS-projecting DANs (DLS-proj.: 86%; DMS-proj.: 75%). However, DLS-striosomes preferentially innervated DLS-projecting neurons (DLS-proj.: 76%; DMS-proj.: 40%), which is in accordance with the ascending-spiral model proposed by Haber et al. (2000). Next, we tested the effect of optogenetic patch-terminal stimulation on dopamine release in vivo. By using rGrab-DA 3.0 to monitor striatal dopamine transients (Sun et al., 2020), we observed a strong inhibition of dopamine release following optogenetic patch stimulation compared to baseline (mean Z-score: -3.2). In contrast, optogenetic activation of dMSNs using *Drd1-cre* mice enhances striatal dopamine levels relative to baseline (mean Z-score: +2.3). This finding indicates that the striosomal compartment exerts a strong inhibitory control on SNc DANs, while the matrix compartment disinhibits them.To gain a better understanding of the effect of striosomal activation on reward-seeking behavior, we are chemogenetically manipulating DMS-striosomes in a probabilistic reversal-learning task.

Additionally, we intend to examine the contribution of mDANs to value-based decision making by directly recording from projection-defined mDANs in a head-fixed reversal-learning task using Neuropixel-probes.

Title: Neurotensin in the nucleus accumbens regulateshedonic feeding and obesity.

Authors: ***N. GAZIT**[1], A. TOSE[1], C. SENG[2], Y. JIN[3], H. YANG[4], J. P. VERHAREN[1], C. LIU[1], E. HU[1], L. W. TANG[1], J. READ[1], B. LIM[5], L. TIAN[3], C. FOLDY[2], S. Inst., Univ. of Zurich, Zurich, Switzerland; [3]Univ. of California, Davis, Davis, CA; [4]Neurobio., Zhejiang Univ., Hangzhou, China; [5]Biol. Sci., UCSD, La Jolla, CA

Abstract: The neuropeptide neurotensin (NTS) and its receptors are widely expressed in the mammalian brain. NTS regulates many physiological functions including sleep, feeding, blood pressure, body temperature and locomotion, but its role in the nucleus accumbens is unclear. Here, we combined patch-seq, *in vivo* and *ex vivo* electrophysiology, optogenetics and imaging to study the anatomy and function of NTS in neurons in the lateral nucleus accumbens projecting to the ventral tegmental area (NAcLat→VTA). We found that NTS is highly expressed in this pathway and optogenetic stimulation promotes NTS release. In addition, we found that neural activity of NAcLat→VTA cells is directly correlated with consumption of palatable food but not regular chow or other behaviors. Accordingly, optogenetic activation of NAcLat→VTA induced hedonic feeding in a NTS dependent manner. Furthermore, in the high fat diet (HFD) obesity mouse model, we found a diet dependent uncoupling of NAcLat→VTA activity and hedonic feeding behavior. This was accompanied by reduced NTS expression and release. Lastly, when we selectively overexpressed NTS in the NAcLat→VTA pathway of mice exposed to HFD, we observed a significant reduction in weight gain compared to control mice. Together, these data reveal an unexpected role for NTS in the NAcLat→VTA pathway for regulating hedonic feeding behavior and obesity. Our findings contrast the well-known anorexic effects of NTS in the lateral hypothalamus suggesting that circuit-specific manipulations of NTS neurons may be necessary in order to harness the translational potential of NTS in the treatment of obesity.

Title: Optogenetic stimulation of dopamine neurons disrupts the acquisition of sign-tracking behavior and cue encoding in the nucleus accumbens

Authors: E. MCLAUGHLIN, K. LEAR, S. ZENG, K. DUFFER, ***S. MORRISON**; Neurosci., Univ. of Pittsburgh, Pittsburgh, PA

Abstract: If a Pavlovian cue predicts a reward in a different location, some rats will preferentially approach and interact with the cue (sign tracking) and others will approach the site of reward delivery (goal-tracking). Sign tracking, but not goal tracking, has been shown to involve the modulation of dopamine release in the nucleus accumbens (NAc) over the course of cue-reward learning: in sign trackers, dopamine release in response to the cue strengthens over time, while dopamine release in response to reward delivery diminishes (Flagel et al., 2011). We have previously demonstrated that reward-evoked activity in the NAc reflects the different patterns of dopamine release in sign trackers vs. goal trackers (Gillis and Morrison, 2019). However, the causal relationships among dopamine release, NAc neural activity, and sign tracking have not been tested. In particular, it remains unknown whether cue- or reward-specific stimulation of dopamine neurons can alter sign-tracking behavior or NAc responses.
To address this question, we used male and female TH-Cre (tyrosine hydroxylase-Cre) rats to specifically express channelrhodopsin in dopamine neurons of the ventral tegmental area (VTA). We found that reward-concurrent stimulation of VTA dopamine neurons during early stages of cue-reward learning had little effect on sign-tracking behavior at first, but, surprisingly, disrupted the continued acquisition of sign tracking in sessions after stimulation was discontinued. Meanwhile, in another group of TH-Cre rats performing sign tracking and/or goal tracking, we recorded from individual neurons in the NAc while stimulating VTA dopamine neurons concurrent with either cue or reward. We observed complex effects of stimulation on neural activity, including enhancement of excitatory responses, but also induction of later inhibitory responses, often within the same neuron. These findings largely support the idea that NAc dopamine release enhances cue- and reward-evoked excitations, which in turn drive Pavlovian conditioned approach towards a reward-associated cue. However, they reveal additional complexity in the relationships among dopamine release, neural signaling, and behavior; this

includes a key role of the specific timing of dopamine neuron activation, on both short time scales (i.e. within a trial) and long (i.e. across sessions).

Title: Propensity for risky choices despite lower cue-reactivity in adolescent rats

Authors: *S. ZENG, E. MCLAUGHLIN, K. LEAR, S. E. MORRISON;
Neurosci., Univ. of Pittsburgh, Pittsburgh, PA

Abstract: Reward-associated cues play an important role in the development of addiction and relapse, including the development of gambling disorder. Notably, the ability of reward-related cues to elicit interaction varies widely among individuals; this may be modeled in animals using a Pavlovian conditioned approach procedure. If a cue is repeatedly predictive of reward in another location (e.g., lever extension followed by sugar pellet delivery to a food cup), some rats will present a preference for lever approach and interaction—a behavior known as sign tracking (ST)—while others will approach the site of reward delivery, a behavior known as goal tracking (GT). We recently showed (Swintosky et al., 2021) that a propensity towards sign tracking is associated with suboptimal behavior—more risky choices and fewer optimal ones—in a rodent gambling task (rGT) with win cues (modified from Barrus and Winstanley, 2016). However, we and others have shown that adolescent males exhibit less sign tracking and more goal tracking than adults (Rode et al., 2020), implying lower cue reactivity than adults. Therefore, we assessed the sign-tracking tendency of adolescent male rats (n = 48), as well as their performance on the rGT, and compared their behavior to that of adults (n = 64).
Confirming our previous report, we found that adolescents displayed markedly less sign tracking and more goal tracking than adults. At the same time, adolescents were much more likely to make risky choices, and less likely to behave optimally, on the rGT with win cues. Unlike adults, in adolescents, increased sign tracking behavior was not associated with riskier choices on the rGT; in fact, there was a tendency towards the opposite (i.e., a propensity towards goal tracking being associated with risk-taking). This implies that suboptimal behavior on the rGT may be driven by a different factor - e.g., increased reward sensitivity - in adolescents, rather than a motivational pull towards reward-associated cues. Finally, we found that adolescents who were

trained on the rGT in adolescence retained their risk-taking preferences into adulthood, resulting in a markedly different behavioral profile compared to subjects who began "gambling" as adults. This may have important implications for adolescent exposure to gambling as well as other potentially addictive behaviors.

Title: Nucleus accumbens neurons encode social reward

Authors: *J. RIMORIN[1], C. W. TSCHUMI[2], L. S. ZWEIFEL[3];
[1]Univ. of Washington Undergraduate Neurobio. Program, Seattle, WA; [3]Pharmacol., [2]Univ. of Washington, Seattle, WA

Abstract: Prosocial behavior is important to many species and its disruption is a hallmark symptom of many neurodevelopmental and neuropsychiatric disorders including autism, schizophrenia, and depression. The neurotransmitter dopamine modulates neuronal activity in the nucleus accumbens (NAc) and plays a critical role in the regulation of prosocial behavior. While the role of dopamine (DA) is well studied in the context of social behavior, little is known about neuronal activity in the NAc during social behavior. Here we used a viral vector to drive the expression of a genetically encoded fluorescent calcium sensor combined with mini-scope imaging to monitor calcium dynamics in the NAc. Calcium dynamics were recorded during an operant task in which an experimental mouse presses a lever to gain access to a conspecific social partner. We identified subpopulations of neurons within the striatum that encode for social reward, but not for other discrete cues or actions associated with the task. Findings from this study will improve our understanding of how prosocial behavior is encoded in the ventral striatum and how perturbations in these signals contribute to social behavioral disruption that will likely be relevant to disorders in which prosocial behavior is impaired.

Title: Analysis of miRNA and mRNA gene networks in Major Depression in a large postmortem brain sample

Authors: *Z. N. TAYLOR[1], J. DRAKE[1], A. DENHAM[1], S.-A. BACANU[3], J. SHIN[4], J. KLEINMAN[5], T. HYDE[6], V. I. VLADIMIROV[2];

Abstract: Major Depression (MDD) is a disorder characterized by low mood and anhedonia that affects roughly one out of every six adults worldwide. Genome-wide significant variants associated with MD have been identified in large GWAS studies but GWAS alone provides little insight into the functional impact of such variants. Analysis of MDD associated transcriptome changes in postmortem brain tissues offers a complimentary approach to uncovering the underlying neuropathology of MDD.
MicroRNA (miRNA), a class of small non-coding RNA with gene regulatory functions and high expression in the brain, has been investigated in different multiple neuropsychiatric phenotypes. Here, we used miRNA-Seq to compare the expression of over 1000 miRNAs between 150 MDD patients and 150 matched controls in the subgenual anterior cingulate cortex (sACC) and Amygdala. Our analysis includes differential expression analysis (DEA) of individual miRNAs, weighted gene co-expression analysis (WGCNA) of miRNA and mRNA expression, and miRNA/mRNA correlation-based analyses to identify miRNAs with a converging role in the etiology of MDD. We identified multiple differentially expressed miRNAs (at FDR of 5%) including several previously associated with MDD and/or associated with neurodevelopment or other psychiatric illness. Our network analyses detected both significant miRNA and mRNA modules associated with MDD at the Bonferroni corrected $p \leq 0.05$. Using correlation analysis, miRNA target site prediction, and gene enrichment analysis a number of mRNAs and their attendant gene ontologies were identified potential miRNA regulatory targets.
Ours is the largest to date postmortem brain miRNA expression study of major depression, and our ongoing analyses provides solid evidence of the importance of miRNA as a contributing factor to the development of MDD.

Title: Extracellular vesicle miRNAs from depressed brain are dysregulated in a sex-specific manner

Authors: *P. IBRAHIM[1,2], R. DENNISTON[1], H. MITSUHASHI[1,2], J. YANG[1], C. NAGY[1,2], G. TURECKI[1,2];
[1]Douglas Hosp. Res. Ctr., Verdun, QC, Canada; [2]McGill Univ., Montreal, QC, Canada

Abstract: Major Depressive Disorder (MDD) is a leading cause of disability worldwide. MicroRNA's (miRNA) are disrupted in MDD, and they can be packaged into extracellular vesicles (EVs), along with other bioactive molecules. We hypothesize that EV cargo from the anterior cingulate cortex, a brain region highly implicated in MDD, will have a disease specific profile that could mediate disease development. EVs were isolated from post-mortem human brain tissue of 40 (20M/20F) individuals who had depression and died by suicide, as well as 40 (20M/20F) individuals with no psychiatric illness, via size exclusion chromatography. The quality was assessed by western blots, transmission electron microscopy (TEM), and microfluidic resistive pulse sensing. MiRNA profiling and differential analysis were then performed. Western blots showed no contamination with cellular debris and enrichment of EV marker CD9. TEM images showed cup-shaped vesicles with sizes mostly between 30 and 200 nm and labelled with CD81, another EV marker. Differential analyses revealed sex-specific dysregulation in miRNAs, where miR-92a-3p was downregulated in depressed females, while miR-129-5p was downregulated in depressed males. MiRNA target genes were predicted *in silico*, and functional analysis suggested that these miRNAs are involved in neurotransmission and synaptic plasticity. This is the first study to profile brain-derived EV miRNA in the context of depression. This study will provide novel mechanistic insights into the pathophysiology of MDD, which could serve as a starting point for the development of targeted therapeutic strategies as well as prevention measures for depression.

Abstract: Clinical care for major depressive disorder (MDD) relies on a trial-and-error approaches to select the most effective therapy. The difficulty of studying the molecular processes of the living brain has been a limitation in advancing our understanding of the molecular mechanisms that mediate the antidepressant response. However, recent technical advances have enabled us to overcome this limitation. Brain can communicate with peripheral tissues in a quasi-endocrine manner by secreting nano-sized extracellular vesicles that can cross blood-brain barrier and carry cell-type specific molecular cargo. Thus, the levels of brain-derived extracellular vesicles (BDEVs) and their cargo composition may reflect the actual molecular state of the brain and help understand mediators of antidepressant response. In this study, we used 430 human plasma samples from CAN-BIND-1 clinical trial (clinicaltrials.gov, NCT01655706) that were collected at two time points — before and after an 8-week escitalopram treatment—from healthy controls and depressed patients who either responded or did not respond to the treatment. We isolated a population of BDEVs from plasma samples by using a combination of size exclusion chromatography and immunoprecipitation against SNAP25, a protein exclusively expressed in brain neurons and present on the surface of BDEVs. Small RNA-seq profiling followed by RT-qPCR validation revealed that the levels of miR-151a-5p in BDEVs differentiated depressed patients from healthy controls and predicted a positive response to escitalopram (interaction time x treatment response $F(2,403) = 3,623$, $p<0.05$, n=71-73/group). Before treatment, depressed patients had lower levels of miR-151a-5p in BDEVs than

controls while this levels significantly increased over time only in group of depressed patients who responded to antidepressant treatment ($q<0.05$). Further analysis showed good miR-151a-5p predictive value in discriminating groups of responders and non-responders (AUC = 0.65, $p<0.01$). *In vitro* and *in sillico* experiments showed that miR-151a-5p negatively regulates a set of genes enriched in the prefrontal cortex and being responsible for the regulation of synaptic glutamate release. Engineered BDEVs enriched with miR-151a-5p displayed antidepressant properties *in vivo* and effectively ameliorated the behavioral deficits induced by chronic social defeat stress paradigm in stress-susceptible mice when delivered to the prefrontal cortex (interaction time vs treatment: $F(3, 29) = 6{,}194$, $p<0.01$, n=6-11/group). Our observations suggest that miR-151a-5p in BDEVs may be a molecular mediator of effective antidepressant treatment response.

Title: Behavioral and neurochemical effects of increased MAO-A activity in the prefrontal cortex in mice

Authors: *R. LEBEAU[1], R. ZHOU[2], T. TOMODA[3], J. MEYER[4], E. SIBILLE[5], J.-P. GUILLOUX[1];
[1]Univ. Paris Saclay - INSERM 1018 CESP, team Moods, Orsay, France; [2]Univ. of Toronoto, Toronto, ON, Canada; [4]Dept. of Psychiatry, [3]Ctr. for Addiction and Mental Hlth., Toronto, ON, Canada; [5]CAMH - Univ. of Toronto, Toronto, ON, Canada

Abstract: The Monoamine Oxidase A (MAOA) is a mitochondrial enzyme involved in the catabolism of monoaminergic neurotransmitters, more precisely serotonin (5HT) and norepinephrine (NE). A pathological feature of major depressive disorder (MDD) that may underlay decreased monoamines, depressive symptoms, and variable response to antidepressant (AD) treatments is elevated levels of MAOA. PET imaging studies revealed a ~34% increase in MAOA brain levels in unmedicated MDD patients compared to healthy controls, with greater levels in the prefrontal cortex (PFC). MAOA levels are also correlated with the severity of MDD symptoms. This higher expression and activity of MAOA is suspected to be involved in the MDD etiology but also in the resistance to AD, an hypothesis never been formally tested.We propose to develop a murine model of human MAOA overexpression to determine whether increased MAOA activity could result in decreased 5-HT extracellular levels, change in

expression in monoamine-related genes, and impact emotional behavior.An adeno-associated viral (AAV) vector containing the human MAOA (hMAOA) gene and the fluorescent marker GFP (or GFP only for control mice) was injected in the PFC of adult CamKII-Cre mice to increase selectively hMAOA expression. The effects of increased hMAOA were tested 2-3 weeks after the AAV injection. A microdialysis probe was implanted in the same region and in vivo microdialysis in awake mice was performed. Depression and anxiety-like phenotype were tested in a second cohort, using Elevated Plus Maze, Open Field, Novelty Suppressed Feeding and Splash tests. Microdialysis experiments revealed that hMAOA overexpression decreases basal [5-HT]ext levels by 40% in the PFC. Emotional behavior analyses showed that hMAOA overexpression did not affect anxiety-related behavior, but decreased grooming behavior in the Splash test, suggesting an anhedonic effect of hMAOA overexpression. Molecular biology experiments confirmed an increase in the level of expression and activity of hMAOA but neither endogenous MAOA or SERT expressions were affected.Overall, our results confirmed that increased hMAOA activity results in lower 5-HT neurotransmission associated with changes in emotional behavior. Whether these regio-selective neurochemical changes can lead to greater susceptibility to stress and lead to AD treatment resistance remains to be tested. Moreover, overexpression of hMAOA will be tested in other brain regions related to emotional behavior.

Title: Involvement of medial prefrontal cortex in the rapid onset of antidepressant effects of acute physical exercise

Authors: *C. TONG, Y. SUK YU;
Hong Kong Polytechnic Univ., Kowloon, Hong Kong

Abstract: Major depressive disorder (MDD) is a widespread mental health disorder. Emerging clinical studies have demonstrated the rapid onset of antidepressant effects of single-bout of physical exercise. This study investigated the underlying neural mechanism of antidepressant effects of acute exercise in an animal model. We subjected the adult mice with C57BL/J to moderate-intensity acute exercise intervention and investigated the molecular mechanism of rapid antidepressant response involving the medial prefrontal cortex (mPFC). Our pilot data have shown that acute exercise elicited a rapid (30 min post-exercise) and sustained antidepressant effect (last to 24 hours post-exercise). Acute exercise also induces significant activation of

neurons in the mPFC, mainly glutamatergic neurons, and its activation lasts at least 2 hours. This study provides preliminary mechanistic insights into the novel roles of acute exercise in counteracting depression.

Title: Response to cannabidiol administration in a murine model of depression

Authors: *E. ROBLES[1], A. GONZALEZ HORTA[1], D. MONTIEL CONDADO[1], M. BERMUDEZ DE LEON[3], B. GONZALEZ HERNANDEZ[2];
[1]Univ. Autonoma de Nuevo Leon, San Nicolás de los Garza, Mexico; [2]Univ. Autonoma de Nuevo Leon, San Nicolas de Los Garza, Mexico; [3]Inst. Mexicano del Seguro Social, Monterrey, Mexico

Abstract: RESPONSE TO CANNABIDIOL ADMINISTRATION IN A MURINE MODEL OF DEPRESSION
Major depressive disorder (MDD), also known as unipolar depression, is one of the most serious and common psychiatric disorders worldwide, MDD is a condition characterized by pathological sadness accompanied by psychophysiological signs. About 30% of patients taking antidepressants are considered drug resistant, so it is necessary to study alternatives, one of which is cannabidiol (CBD), a non-psychotropic phytocannabinoid derived from the Cannabis plant. Methods: Wistar rats (200-250g) were used, the model of depression used was the forced swimming test combined with a "time-sampling" analysis: 1) pre-session of 15min. and 24hrs. later, 2) experimental session of 5min, in which behaviors are recorded. Treatments: Saline, cannabidiol (10mg/kg, 20mg/kg and 30mg/kg), imipramine (30mg/kg) and ACEA (3mg/kg). The following behaviors were analyzed: immobility (depression) as passive behavior, climbing and swimming as active behavior. Results: 1) Males, immobility decreased significantly with the five treatments, showing better effect CBD 10mg and CBD 20mg, swimming increased in all five conditions showing better effect CBD 10mg and CBD 20mg. Climbing decreased with imipramine, CBD 20mg, CBD 30mg and ACEA. 2) Females: immobility decreased significantly with the five treatments, swimming increased in all conditions showing better effect in imipramine, CBD 20mg and ACEA, but no difference was found in climbing. Conclusion: CBD shows a dose-dependent antidepressant profile, with better effects in males than in females.

Title: Signaling snapshot of cholecystokinin receptor-2 unravels G-protein coupling selectivity

Authors: *Y. LIAO, Y. DING, X. LI;
Zhejiang Univ., Hangzhou, China

Abstract: Signaling snapshot of cholecystokinin receptor-2 unravels G-protein coupling selectivity Yu-Ying Liao, Yu Ding, Xiao-Ming Li
AbstractCCK2R is primarily expressed in the brain, particularly in the cortex and the limbic structures including the amygdala, the hippocampus, and the nucleus accumbens and selected regions in the gastrointestinal tract, including gastric epithelial parietal cells, pancreatic acinar cells, myenteric neurons, and human peripheral blood mononuclear cells. In this paper, we determined two high-resolution cryo-EM structures of CCK2R signaling complexes. The analysis of structures, together with mutagenesis studies, revealed distinct features of the CCK2R selectivity for gastrin-17, and thus highlighted the basis for G-protein coupling promiscuity and ligand recognition by CCK2R.
Key Words: GPCR; Cholecystokinin; G-protein

Title: Female-specific role of progesterone-activated astrocyte focal adhesion kinase in inhibiting stress responses

Authors: *C. JIA, W. D. GILL, C. LOVINS, R. W. BROWN, T. HAGG;
East Tennessee State Univ., Johnson City, TN

Abstract: Astrocytes have been implicated in stress responses. We found that ciliary neurotrophic factor (CNTF), which is only produced and released by astrocytes in the brain, plays a sex-specific role in stress responses and that CNTF is upregulated by inhibition of focal adhesion kinase (FAK). Here, we found that inducible conditional gene deletion of FAK in astrocytes or systemic treatment with an FAK inhibitor promoted despair or passive coping behavior, i.e., immobility in an acute forced swim stress in female, but not male, mice. Strikingly, four weeks of chronic unpredictable stress did not further increase immobility in female astrocytic FAK knockout mice but exacerbated it in female wildtype mice and male mice of both genotypes. These data suggest that chronic stress might act through astrocyte FAK in females. CUS indeed reduced phospho-FAK in the female medial amygdala, an area involved in female stress responses, as we previously found. Stress reduces systemic progesterone levels, whereas progesterone attenuates ovariectomy-induced stress responses and inhibits CNTF expression in the amygdala. Here, progesterone treatment after ovariectomy activated FAK in the amygdala and alleviated ovariectomy-induced immobility in wildtype, but not astrocytic FAK knockout females. This suggests that progesterone-mediated activation of FAK in amygdala astrocytes underlies a beneficial mechanism in reducing female stress responses. Finally, astrocytic FAK knockout or FAK inhibitor treatment increased CNTF expression in the medial amygdala of both sexes, although not in the hippocampus. However, as we previously found, CNTF in the medial amygdala promotes stress responses only in females explaining the female-specific role of astrocytic FAK inhibition. Together, this study reveals a novel female-specific progesterone-astrocytic FAK pathway that inhibits stress responses and points to opportunities for developing treatments for stress-related disorders in women.

Title: Intravenous Reelin treatment in a rodent model of chronic stress: Putative implications for treatment of depression

Authors: *B. S. K. REIVE[1], R. ROMAY-TALLON[2], L. E. KALYNCHUK[1], H. J. CARUNCHO[1];

[1]Div. of Med. Sci., Univ. of Victoria, Victoria, BC, Canada; [2]Psychiatry, Univ. of Illinois at Chicago, Chicago, IL

Abstract: Major depression has been linked to inflammation and is marked by multiple depressive episodes. Our lab has shown antidepressant-like actions of intravenous Reelin in a rodent model of chronic stress, where we evaluated whether peripheral Reelin treatment impacts stress-induced alterations to immune function in brain and/or periphery. Spleens and brains were collected from male and female rats exposed to 21 days of corticosterone or vehicle injections and 2 injections of either Reelin or vehicle (delivered on days 11 and 21 of chronic stress) for analysis of spleen white pulp and hippocampal microglia morphology. To evaluate if Reelin maintains antidepressant-like effects after multiple episodes or "bouts" of depression, we incorporated Reelin treatment in a cyclic chronic stress model involving multiple episodes or bouts of depression. In this model, 1 cycle involves 21 daily corticosterone injections followed by a 21-day injection-free recovery period. Antidepressant-like effects were evaluated following both 1.3 and 2.6 cycles of chronic stress and subsequent Reelin treatment. Our results indicate chronic stress atrophied spleen white pulp, reduced lengths and complexity of microglia processes and increased microglia cell body sizes, consistent with disrupted immune regulation in brain and periphery following chronic stress. Reelin treatment was associated with recovery of white pulp atrophy and normalization of morphological alterations to hippocampal microglia induced by chronic stress. In evaluating antidepressant-like effects of Reelin in the cyclic corticosterone model, we found rats treated with Reelin after chronic stress were more mobile in the forced swim test, indicating a single peripheral injection of Reelin continues to show antidepressant-like properties following both 1.3 cycles and 2.6 cycles of chronic corticosterone injections. As Reelin treatment reversed both peripheral and central inflammatory alterations induced by chronic stress and a single peripheral injection continues to have antidepressant-like properties after multiple bouts of chronic stress induced depression-like behaviour, our results support the continued assessment of Reelin-based therapeutics in the context of major depression.

Title: Phenotypic profiling of psychedelics in mice using SmartCube to find the next generation of drug candidates to treat psychiatric disorders.

Authors: *A. PEHRSON, G. ZHOU, A. AMBESI, D. BRUNNER, D. BLEAKMAN, M. A. VARNEY;
PsychoGenics, Inc., Paramus, NJ

Abstract: SmartCube® is an artificial intelligence-enabled phenotypic screening platform that rapidly evaluates and categorizes the behavioral effects of drugs in mice. In partnership with Sunovion, this platform resulted in the discovery of ulotaront, a novel antipsychotic candidate currently in late-phase clinical trials. We have used SmartCube to screen a library of more than 7,000 behaviorally active compounds for similarity to psychedelic, dissociative, and entactogen reference compounds. Molecules similar to psilocin, ketamine, or MDMA served as starting points for discovery programs aimed at identifying novel treatments for major depressive disorder or post-traumatic stress disorder (PTSD) without producing psychedelic-like side effects. Mice were treated intraperitoneally with test or reference compounds and placed in SmartCube, which presents challenges and monitors behavior for 45 min. Behavioral features were identified using deep learning, and machine learning derived similarity scores from those features. Promising compounds were screened for functional activity at 5-HT_{2A} and NMDA receptors. Those with behavioral similarity to psilocin or ketamine (and without 5-HT_{2A} agonist or NMDA antagonist activity) were evaluated in the mouse tail suspension test (10/group) as a screen for antidepressant-like potential. MDMA-similar compounds were evaluated in the mouse extinction of conditioned fear test (15/group) as a predictive screen for PTSD. Finally, compounds were tested for the mouse head twitch response (10/group), which may predict hallucinogenic activity, and the rat prepulse inhibition model (15/group), which is disrupted by serotonergic hallucinogens, NMDA receptor antagonists, and stimulants like MDMA. Here we present results for PGI-33 and PGI-81, which had antidepressant-like and psychedelic similar behavioral signatures but no 5-HT_{2A} agonist or NMDA antagonist activities. Both molecules had favorable pharmacokinetic profiles, and reduced tail suspension immobility with a minimally effective dose of 3 mg/kg for PGI-33 and ≤ 10 mg/kg for PGI-81. PGI-33 also reduced freezing in the cued fear test. Neither compound induced head twitch up to 100 mg/kg nor did they impair prepulse inhibition at up to 30 mg/kg. Thus, these molecules may represent novel antidepressant-like compounds with limited potential for hallucinogenic or dissociative side effects.

Title: Functional in vitro Screening of 5-HT2A receptor modulators in neuronal network cultures

Authors: O. H. SCHROEDER, L. SCHULTZ, A.-M. KNOSPE, M. WINKLER, *K. JÜGELT; NeuroProof Systems GmbH, Rostock, Germany

Abstract: The 5-HT2A receptor plays a significant role in the mode of mechanisms of psychedelic drugs. Psychedelic drugs can change the treatment paradigm for deep depression and traumatic brain injury (Khan et al. 2021).
Psychedelics cause hallucinations and are therefore called hallucinogenic drugs (Lowe et al. 2021). Hallucinogenic drugs are classified into dissociative drugs, such as dextromethorphan (DXM), ketamine and phencyclidine (PCP), and classic serotonergic and dopaminergic hallucinogens.
Psilocybin and its metabolic psilocin are studied in many psychiatric diseases, especially depression.
5-HT2A agonists demonstrate fast anti-depressive actions with unknown mechanisms responsible for their anti-depressive effects.
The 5-HT2A is a GPCR of the type Gαq with the effector PLCβ; this catalyzes phosphoinositide PI into IP3, which triggers Ca2+ release (Pottie and Stove 2022). 5-HT2A agonists exhibit a rapid effect in the CNS with a strong afterward desensitization, which is challenging for in vitro modeling.
We have tested 5-HT2A modulators in our microelectrode array approach on primary frontal cortex cultures from mice cultivated 28 days in vitro, such as risperidone, DOI, DMT, MDMA, and psilocin. We tested all 5 compounds at 5 concentrations and analyzed their response in time intervals of 15 minutes for one hour. We found a significantly different behavior in these time intervals.
Our experiments showed that psychedelics show a strong variation of activity in the first hours of application. The time course of the dose responses could be a clear descriptive biomarker for assessing psychedelics and potentially anti-depressive compounds.

Title: First ^{18}F radiolabeling and PET-imaging of NLX-204 in rat brain: a 5-HT$_{1A}$ receptor biased agonist with antidepressant-like activity

Authors: *V. RICHIN[1,3], C. BOUILLOT[4], S. BOUVARD[2], P. COURAULT[2,5], F. HERBRECHT[3], A. NEWMAN-TANCREDI[3], L. ZIMMER[2,5,4], W. ZEINYEH[2];
[2]Ctr. de Recherche en Neurosciences de Lyon, [1]Univ. Claude Bernard Lyon 1, Villeurbanne, France; [3]Neurolixis SAS, Castres, France; [4]CERMEP - Imagerie du vivant, Lyon, France; [5]Hospices Civils de Lyon, Lyon, France

Abstract: The serotonin 1A receptor (5-HT$_{1A}$R) is involved in central nervous system functions such as mood, pain, and motor control and in psychiatric and neurodegenerative disorders. In particular, agonist activation of 5-HT$_{1A}$R mediates the antidepressant activity of diverse classes of antidepressant drugs. NLX-204 is a highly selective 5-HT$_{1A}$R biased agonist which preferentially activates ERK1/2 phosphorylation. This molecule presents an efficacious antidepressant-like activity in a variety of mouse and rat models (1,2,3). Positron emission tomography (PET) imaging with agonist radiotracers allows exploration of the targeted receptors in their activated coupling state. PET imaging with different radiolabeled biased agonists is therefore a promising strategy to investigate whether functional selectivity for a signaling pathway *in vitro* is associated with activation of a specific region in the brain. In this study, we radiolabeled NLX-204 and performed PET imaging to explore the brain regions involved in the antidepressant-like activity of NLX-204. To produce [^{18}F]NLX-204, we developed a nitro precursor allowing an isotopic radiolabeling with a good specific activity (>444 GBq/µmol). The radiochemical yield was 1% and the chemical and radiochemical purities were >98%. MicroPET imaging in healthy Sprague-Dawley rats showed a rapid brain penetration of [^{18}F]NLX-204 within 5 min after its IV administration, with pseudo-plateau kinetics. The reproducibility of brain labeling by [^{18}F]NLX-204 was evaluated by a Test-Retest exploratory study on 4 healthy rats. Standardized Uptake Values Ratio to cerebellum (SUVR) determinations were reproducible with a variability <8% over the different regions of interest (ROIs). Radiometabolites of [^{18}F]NLX-204 were measured in rat plasma (N=2) and revealed that 69% of [^{18}F]NLX-204 remained unchanged 1 hour after IV injection. A competition study with 8-OH-DPAT (a reference 5-HT$_{1A}$R agonist) showed that 80 to 85% of [^{18}F]NLX-204 binding was blocked (N=4). Over those two studies, SUVR values ranged from 1.1 to 1.6 depending on brain region. Notable ROI labeled by [^{18}F]NLX-204 were the dorsal raphe nucleus, brain stem, thalamus and hypothalamus, hippocampus and cortical areas. Brain regions labeled by [^{18}F]NLX-204 are associated with control of mood and cognition and are consistent with the potential antidepressant properties of the drug. Future studies will investigate the relationship between these data and the therapeutic-like effects of NLX-204.

Title: Tcb-2, a non-selective serotonin$_{2a}$ receptor agonist reduces correlative links for neurotransmitter systems across mouse brain regions

Authors: J. J. BUTLER, M. VIRGILI, *P. DE DEURWAERDERE;
Univ. of Bordeaux, Bordeaux, France

Abstract: The mechanism of action of classical psychedelics in the brain remains unknown, in particular the possible widespread influence of these compounds on the activity of neurotransmitter systems across the brain. In mice, we studied the effect of non-selective 5-HT2A receptor (5-HT2AR) agonist TCB-2 (0.3, 3, and 10mg/kg) and the combination TCB-2 (3 mg/kg) / MDL100,907 (5-HT2AR antagonist; 0.2 mg/kg) on the tissue content of neurotransmitters [GABA, glutamate, noradrenaline (NA), dopamine (DA), serotonin (5-HT) and their metabolites] 1-h after agonist administration. Post-mortem, tissue content was measured by HPLC in 30 brain regions belonging to various neurobiological networks. The neurochemical study was preceded by the behavioural measurement of head twitches in isolated cages to determine the efficacy of the treatments. Quantitatively, TCB-2 dose-dependently decreased 5-HT turnover (usually an increase in 5-HT) in all brain regions. It reduced the ratio 3-methoxytyramine/DA in the striatum, and enhanced markers of the DA system in a few cortices (cingulate, somatosensorial) and NA in the cingulate cortex and the ventral hippocampus. Despite the ability of MDL100,907 to prevent TCB-2-induced head twitches in these animals, the decrease in 5-HT turnover induced by TCB-2 was generally insensitive to MDL100,907. However, MDL100,907 blocked TCB-2-induced 5-HT increase in the cingulate and auditory cortices and the ventral hippocampus. It also blocked some DA and NA effects notably in the anterior cingulate cortex. TCB-2 alone or combined with MDL-100,907 did not modify amino acid tissue contents. Qualitatively, TCB-2 dramatically decreased the correlative links assessed by Pearson’s correlations for a neurotransmitter between brain regions, whatever the neurotransmitter system considered. Of note, MDL100,907 also reduced the correlative links. The disruptive effect of TCB-2 was partially counteracted by MDL100907 for 5-HT, glutamate,

and GABA. Irrespective of its questionable action beyond 5-HT2AR, the data indicate that TCB-2 dramatically alters the activity of 5-HT neurons in the brain and disrupts the correlative links between brain regions for all neurotransmitters.

Title: Discovery and preclinical characterization of 2,5-dimethoxy-4-thiofluoroalkyl phenethylamines as potent and long-acting serotonin 5-HT_2 receptor agonists

Authors: *G. B. VARTY[1], C. E. CANAL[3], J. A. HARTSEL[2], R. TYAGI[3], K. AVERY[2], M. E. MORGAN[2], T. A. MUELLER[2], A. C. REICHELT[2], P. PATHARE[2], E. STANG[2], M. G. PALFREYMAN[2], A. NIVOROZHKIN[2];
[1]Cybin, Annandale, NJ; [2]Cybin, Toronto, ON, Canada; [3]Mercer Univ., Atlanta, Georgia

Abstract: Novel chemical synthesis and structure-activity studies led to the discovery of 4-thiofluoroalkyl-substituted phenylalkylamine serotonin 5-HT_2 receptor ligands with varying efficacies and durations of action in the mouse head-twitch response model of 5-HT_{2A} receptor activation. Several potent 5-HT_2 receptor ligands exhibited varying degrees of 5-HT_{2A} receptor agonism in vitro and elicited robust head-twitch responses, while other compounds did not elicit an in vivo response despite binding to the 5-HT_{2A} receptor in vitro. The phenylalkylamine, 2,5-dimethoxy-4-(trifluoromethyl)thiophenethylamine (CYB210010) is an example molecule with high agonist potency at 5-HT_{2A} and 5-HT_{2C} receptors, modest agonist selectivity over 5-HT_{2B}, 5-HT_{1A}, 5-HT_6, and α_{2A} receptors, and >100-fold binding selectivity over 70+ other proteins including monoamine transporters. CYB210010 dosed either subcutaneously or orally elicited a robust, dose-dependent head-twitch response, and could be administered sub-chronically at threshold doses that occupy brain 5-HT_{2A} receptors without any behavioral tolerance. In studies measuring target engagement and gene expression, CYB210010 occupied frontal cortical 5-HT_{2A} receptors and increased the expression of genes implicated in neuroplasticity in the frontal cortex, but not the hippocampus. Pharmacokinetic studies demonstrated that CYB210010 was orally bioavailable in three species, exhibited high brain penetration, and similar pharmacokinetic profiles in three compartments; plasma, brain, and CSF. Based on these properties, CYB210010 represents an important molecule for investigating the downstream effects of serotonergic receptor activation and the therapeutic potential of serotonin 5-HT_2 receptor agonists administered via sub-psychedelic chronic dosing regimens.

Title: Novel 5-HT2A receptor agonists exhibit translational antidepressant and psychedelic drug-like profiles in a model of treatment-resistant depression

Authors: *C. A. BOWEN, I. PREMOLI, T. A. KHAN, R. PERNI, P. KLEINE, S. RAO, G. F. SHORT, III;
EntheogeniX Biosciences, Inc., Encinitas, CA

Abstract: Mood disorders, particularly treatment-resistant depression, remain a significant unmet medical need. Clinical and preclinical research suggest the potential for serotonergic psychedelic compounds, such as psilocybin, to produce rapid and lasting antidepressant activity after a single dose. Increased rapid eye movement (REM) sleep is a hallmark of depression in humans that is suppressed by antidepressant treatment. Wistar Kyoto (WKY) rats exhibit behavioral, neurobiological and endocrine phenotypes that are consistent with symptoms observed in clinical depression. In particular, this strain shows increased REM sleep that is resistant to suppression by antidepressant drugs, making it a potentially useful genetic model of treatment-resistant depression. Novel hallucinogenic 5-HT2A receptor agonists discovered using an artificial intelligence (AI)/machine learning (ML) approach were investigated for antidepressant drug-like effects using translational electroencephalography (EEG)-based measures in the WKY rat model of treatment-resistant depression. Adult male WKY rats (n=7) were implanted with epidural EEG electrodes, an electromyography (EMG) electrode and an intraperitoneal telemetry transmitter to record EEG, EMG, body temperature and locomotor activity. During weekly testing, at approximately 2 hours after light onset, rats received one of the test conditions (negative control, psilocybin positive control (10 mg/kg IP), or novel 5-HT2A agonist EGX-A (3-30 mg/kg IP) or EGX-B (1-30 mg/kg IP)) in a pseudo-randomized cross-over fashion. EEG recording continued for at least 22 hours after dosing. Automatic sleep-wake scoring was performed, and the hourly distribution of wakefulness, non-REM (NREM) and REM sleep was determined. In addition, sleep latency and spectral frequency power by vigilance state was analyzed. Compared to vehicle, significant increases in latency to REM sleep and decreases in the amount of REM sleep were found with psilocybin, EGX-A and EGX-B, indicative of antidepressant drug-like responses. Also similar to psilocybin, EGX-A and EGX-B significantly decreased NREM low-frequency delta and theta power. The profiles of EGX-A and EGX-B on high-frequency gamma power during wake, locomotor activity and body temperature were distinguished from each other and psilocybin. The data suggest that these novel 5-HT2A receptor agonists exhibit significant, dose-related antidepressant and hallucinogenic drug-like activity in a model of treatment-resistant depression and demonstrate the use of translational EEG-based measures in antidepressant drug discovery.

Title: Psilocybin: the relationship between head twitch response, locomotor activity, 5-HT2A ex vivo receptor occupancy and plasma and brain levels of psilocin

Authors: *S. CHEETHAM[1], M. ACKLEY[2], E. BILLINGHAM[1], M. BURNETT[1], A. CARTER[1], A. CHAND[1], M. CONWAY[1], I. DAVIES[1], G. LAI[2], T. PISER[2], A. PLUMB[1], D. RIAL[1], U. SHAH[2], C. TAYLOR[1], S. VICKERS[1], L. JAGGER[1];
[1]Sygnature Discovery, Nottingham, United Kingdom; [2]Onsero, Boston, MA

Abstract: The use of psychedelics, such as, psilocybin, as therapy for mental health disorders is receiving significant interest. The mode of action of psychedelics may involve 5-hydroxytryptamine$_{2A}$ (5-HT$_{2A}$) agonism. Psilocybin, a prodrug, is metabolised to psilocin which has moderate affinity for mouse frontal cortical 5-HT$_{2A}$ receptors (inhibition constant: K_i = 58 ± 7 nM; Hill slope 0.87 ± 0.03: mean ± sem, n=5). We have evaluated the effect of psilocybin on head twitches, locomotor activity, 5-HT$_{2A}$ ex vivo receptor occupancy and plasma and brain levels of psilocin in male C57BL6J mice (20 - 25g). Psilocybin (0.3 - 3 mg/kg sc) was dosed to mice and head twitches manually counted by blinded observers and locomotor activity measured using Ethovision. In a second study, mice given psilocybin (1 - 10 mg/kg ip) were terminated one hour later by a schedule 1 method and a post-mortem blood sample collected and plasma prepared by centrifugation. Frontal cortex and rest of brain were dissected and frozen on dry ice. Frontal cortex was homogenised in 50 mM Tris-HCl, pH 7.4 containing 4 mM $CaCl_2$ (3.75 mg wet weight of tissue/ml) and incubated with [^{3}H]cimbi-36 (0.075nM) for 30 minutes at room temperature. Plasma and brain levels of psilocin were measured in the rest of brain by mass spectrometry. Psilocybin (0.3 - 3 mg/kg sc) increased the number of head twitches (Vehicle 0.90 ± 0.52; psilocybin 0.3 mg/kg 13 ± 1; 1 mg/kg 18 ± 1; 3 mg/kg 19 ± 1; all $p<0.001$ vs vehicle; values are mean number of head twitches in 1 hour ± sem; n=7-8). This was associated with a significant decrease in locomotor activity at the highest dose (Vehicle 6583 ± 212; psilocybin 0.3 mg/kg 7043 ± 312; 1 mg/kg 7005 ± 436, 3 mg/kg 3503 ± 523, $p<0.001$ vs vehicle; values are distance travelled in 30 minutes in cm ± sem; n=7-8) with less time spent in the central zone of the arena (Vehicle 6583 ± 212; psilocybin 0.3 mg/kg 7043 ± 312; 1 mg/kg 7005 ± 436 $p<0.05$, 3 mg/kg 3503 ± 523 $p<0.001$; values are sum of time/pixel; n=7-8). Frontal cortical 5-HT$_{2A}$ receptor occupancy increased with increasing dose of psilocybin (Vehicle 1174 ± 24, 0%; psilocybin 1 mg/kg 1080 ± 24, 8%, $p<0.01$; 3 mg/kg 1009 ± 24, 14%; $p<0.001$; 10 mg/kg 811 ± 26, 31%, $p<0.001$ (values are mean specific binding (dpm) ± sem, mean receptor occupancy (%); n = 5-8). There was a good correlation between plasma and brain levels of psilocin and ex vivo receptor occupancy. Thus, psilocybin increases head twitch behaviour which is associated with an increase in 5-HT$_{2A}$ receptor occupancy which correlates with plasma and brain levels of psilocin. Rigorous in vitro, ex vivo and in vivo characterisation of psychedelics may prove useful in the discovery and screening of novel therapeutics acting at the 5-HT$_{2A}$ receptor.

Title: Distinct behavioral effects of a serotonergic psychedelic and a non-hallucinogenic analog

Authors: K. LUKASIEWICZ[1], ***J. LU**[2], J. BAKER[2], Y. ZUO[2];
[1]Psychiatry Clin., Med. Univ. of Bialystok, Bialystok, Poland; [2]Molecular, Cell and Developmental Biol., Univ. of California Santa Cruz, Santa Cruz, CA

Abstract: Psychedelics induce profound changes in conscious experiences and have shown promise as therapeutics for neuropsychiatric disorders. Human studies suggest long-lasting psychological impacts of psychedelics on both healthy individuals and psychiatric patients. However, it is challenging to disambiguate biological, experiential, and placebo effects due to psychedelic-induced perturbations to consciousness. Animal models may allow a clearer understanding of the biological effects of psychedelics on behaviors that are less reliant on conscious experience. Computational neuroethology approaches are uniquely advantageous for such studies as they provide a comprehensive, unbiased assessment of behavioral patterns in animals. In this study, we characterized the exploratory behavior of mice using an unsupervised machine learning algorithm and revealed distinct acute and long-term effects of a classical serotonergic psychedelic (2,5-dimethoxy-4-iodoamphetamine hydrochloride, DOI) and a recently synthesized non-hallucinogenic psychedelic analog (tabernanthalog, TBG). This approach can be applied to studies on psychedelics' effects on mouse spontaneous behaviors in the context of aging, neurodevelopmental, and neuropsychiatric disorders.

Title: Theoretical-computational study and molecular modelling of the interactions between DMT-derived psychedelic ligands as potential natural serotonergic agonist antidepressant candidates on 5-HT-type receptors in neuropharmacological systems.

Authors: *A. F. LATORRE PALOMINO;
Chem., Univ. Nacional Mayor San Marcos, Lima, Peru

Abstract: Depression, according to WHO, affects about 280 million people worldwide. This disease is characterized by altered levels of serotonin uptake in the body, the use of natural psychedelics such as serotonergic derivatives containing the Amazonian preparation ayahuasca (DMT, harmine and harmaline) has potential and promising effects against depression. However, to our knowledge, there are few theoretical-computational studies of affinity mechanisms of these derivatives for serotoninergic receptors of the 5HT type (5-HT1A, 5-HT2A, 5-HT1B, 5-HT2B, sigma 1 and the serotonin transporter SERT). Therefore, it is proposed to theoretically evaluate their chemical reactivity and to analyze, by molecular docking, DFT and molecular modeling, the natural ligands derived from the pharmacophore N,N-dimethyltryptamine (DMT): (serotonin, N-methylserotonin, psilocin, 5-MeO-DMT, bufotenin, psilocybin, baeocystin, norbaeocystin, LSD and mescaline) on the mentioned receptors to choose the ligand/receptor systems that present lower energies and interact with the residues of interest of the receptors. Subsequently, we will evaluate temporal stability, free and interaction energies for the selected systems using molecular mechanics and quantum mechanical calculations. With this we hope to estimate their efficiency as possible serotonergic agonists and propose them as antidepressant drug candidates. In addition to the molecular approach, we intend to contribute to the field of study of psychedelics by using the database of interaction of the neurotransmitter seronotonin with the receptors of interest, as well as taking advantage of the availability of data collected using psylocibin, DMT and LSD, thus giving a total-brain analysis approach to determine specific regions that respond to the use of psychedelics in depression

Title: Preclinical and translational profile of GM-1020, a novel, orally bioavailable NMDA antagonist

Authors: *Z. A. HUGHES[1], A. KLEIN[1], D. DVORAK[1], E. AUSTIN[1], M. PAPP[2], J. SPORN[1], S. GATTI[3], G. J. MAREK[1], L. KISS[1], A. KRUEGEL[1];
[1]Gilgamesh Pharmaceuticals, New York, NY; [2]Polish Acad. of Sci., Maj Inst. of Pharmacol., Krakow, Poland; [3]McArthur & Associates, Basel, Switzerland

Abstract: Despite ketamine providing rapid and sustained antidepressant efficacy, patient access is limited by poor bioavailability and sedative and dissociative side effects. Here we describe the novel NMDA receptor (NMDAR) antagonist, GM-1020 which was designed to be orally bioavailable and cause limited sedation and dissociation at therapeutic doses.
GM-1020 displaces [^{3}H]MK-801 binding in rat cortex (Ki = 3.25 μM) and is a voltage-dependent antagonist of human GRIN1/GRIN2A-containing NMDAR (IC50 = 1.19 μM at -70 mV and 265.21 μM at +60 mV). Oral bioavailability (%F) ranged from 27-43% in 4 non-clinical species which was predicted by microsomal clearance (%F=32-52%); human %F was predicted to be >60%.Antidepressant efficacy was demonstrated in Wistar Han rats exposed to the chronic mild stress paradigm (CMS). Exposure of rats to CMS produced a robust reduction in sucrose intake that was maintained throughout exposure to stress in vehicle treated rats. GM-1020 (1.5-9 mg/kg, i.p.), like ketamine (10 mg/kg, i.p.) produced a restoration of sucrose intake in stressed rats 24 h after a single administration. Efficacy was maintained through 5 weeks of once weekly dosing. After cessation of drug treatment efficacy of GM-1020 and ketamine was maintained for ≥2 weeks despite continued exposure to stressors. In a separate study GM-1020 and ketamine (both 3.2-32 mg/kg, s.c.) were evaluated for ataxia in the rotarod assay in SD rats. Both compounds produced dose-dependent ataxia (decreased latency to fall); for GM-1020 the ED50 = 17.4 mg/kg, while for ketamine ED50 = 3.4 mg/kg. A cohort of SD rats implanted with skull screw electrodes above the frontal cortex, was used to test the effects of GM-1020 (1-10 mg/kg, s.c.) on EEG spectral power. GM-1020 increased gamma and decreased theta power at exposures associated with antidepressant efficacy.
In summary, GM-1020 had rapid-onset, durable efficacy in CMS at plasma concentrations ~14-fold lower than ataxic doses. In contrast the dose of ketamine that was efficacious in CMS produced plasma concentrations ~35% lower than those that produced ataxia acutely after dosing. After dosing with GM-1020 EEG spectral power changed in a plasma concentration-dependent manner indicating that decreases in low frequency and increases in high frequency power provide translational biomarkers of NMDA receptor target engagement. Quantitative EEG can be used clinically to determine whether significant target engagement can be achieved without causing dissociation or sedation.

Title: R-ketamine enhances anterior insular cortex activity associated with social cognition

Authors: *R. YOKOYAMA[1], Y. AGO[2], M. TANUMA[1], Y. SHIMAZAKI[1], K. SEIRIKI[1], T. NAKAZAWA[3], K. HASHIMOTO[4], A. KASAI[1], H. HASHIMOTO[1];

Abstract: Recent studies have revealed that (R)-ketamine, the enantiomer of (S)-ketamine (esketamine) which is an FDA-approved antidepressant, may be effective for treating depression and the associated cognitive dysfunction. Although many studies provide insights into the neural mechanisms of racemic ketamine and (S)-ketamine, the mechanism of (R)-ketamine remains largely unclear. We have found that (R)-ketamine has more potent antidepressant-like effects than (S)-ketamine in rodent models of depression. Then, to identify brain regions that contribute to effects of (R)-ketamine, we have performed brain-wide mapping of immediate early gene Arc expression and investigated the effects of temporary suppression of neural activity by Gi-DREADD in social isolation-reared male C57BL6/J mice treated with the ketamine enantiomers. Our previous results suggest that activation of the anterior insular cortex (aIC) is necessary to exert the effects of (R)-ketamine on immobility in the forced swim test (SfN Annual Meeting: Neuroscience 2022). In this study, we aimed to clarify the roles of aIC activation in the effects of (R)-ketamine on social cognition. First, we analyzed aIC calcium activity by using fiber photometry before and after administration of the ketamine enantiomers in the three-chamber test. Isolation-reared mice treated with saline exhibited a similar aIC activity pattern after contact with an object and mouse. (R)-ketamine, but not (S)-ketamine, caused a significant increase in aIC activity after contact with a mouse compared with the activity after contact with an object, similar to group-reared mice treated with saline. We next conducted the 5-trial social memory test in social isolation-reared mice expressing Gi-DREADD in the aIC. Under a vehicle-treated normal condition, (R)-ketamine rapidly decreased the time investigating the same intruder, indicating promoting social memory formation. Under DREADD-ligand CNO-treated condition which inhibited aIC activity, there was no difference in investigation time between mice treated with saline and (R)-ketamine. Our results indicate that activation of the aIC plays an important role in mediating the effects of (R)-ketamine on social cognitive behaviors and might provide a promising mechanism for restoring cognitive dysfunction in depression.

Title: Metaplastic effects of ketamine metabolite (2R,6R)-hydroxynorketamine on hippocampal synaptic plasticity in mice

Authors: *K. A. BROWN[1], T. D. GOULD[1,2,3,4];
[1]Dept. of Psychiatry, [2]Dept. of Pharmacol., [3]Dept. of Neurobio., Univ. of Maryland Sch. of Med., Baltimore, MD; [4]Veterans Affairs Maryland Hlth. Care Syst., Baltimore, MD

Abstract: Ketamine metabolite (*2R,6R*)-hydroxynorketamine (HNK) maintains the rapid and prolonged preclinical antidepressant-like effects of ketamine without adverse effects and has completed human phase I clinical trials. Metaplasticity is an alteration in plasticity induced by previous synaptic activity that influences synaptic function and may mediate sustained antidepressant action. To study *in vitro* HNK metaplastic effects, we incubated slices collected from mice with HNK for 60 min followed by ACSF washout for 35 min. To study the sustained effects of HNK *in vivo,* mice were treated with HNK and sacrificed for electrophysiology experiments 24 h later. Primary outcomes assessed were input/output excitatory postsynaptic potential slope (fEPSP), paired-pulse facilitation (PPF), and long-term potentiation (LTP). Incubation with HNK enhanced presynaptic-mediated synaptic transmission at the Schaffer collateral-CA1 synapse in a concentration-dependent manner as indicated by enhanced basal fEPSP responses and reduced PPF while also impairing LTP magnitude. These effects were blocked by preincubation with AC or PKA inhibitors. Preincubation with the NMDAR antagonist D-APV neither blocked HNK's effects nor exerted metaplastic effects on its own, and

no effects were observed with ketamine itself. *Ex vivo* recordings revealed dose-dependent enhancement of LTP without significant alterations in basal synaptic transmission or PPF. Our *in vitro* findings suggest that rapid HNK effects are induced by a presynaptic mechanism that enhances glutamatergic transmission whereas our *ex vivo* results suggest sustained HNK effects are maintained by a postsynaptic metaplastic mechanism. These findings provide insight into HNK's rapid and sustained mechanism of action that may facilitate novel antidepressant discovery.

Title: Structural basis of ketamine action on human NMDA receptors

Authors: *Y. ZHANG[1,2], F. YE[3], T. ZHANG[1,2], S. LV[1,2], L. ZHOU[2,4], F. GUO[4], C. LUO[2,4], S. ZHU[1,2];

Abstract: Ketamine is a non-competitive channel blocker of N-methyl-d-aspartate (NMDA) receptors. A single sub-anaesthetic dose of ketamine produces rapid (within hours) and long-

lasting antidepressant effects in patients who are resistant to other antidepressants. Nevertheless, the precise mechanism by which ketamine binds to NMDA receptors remains to be elucidated. In this study, we first resolved the three-dimensional structure of the ketamine-bound human NMDA receptor by single particle cryo-electron microscopy (cryo-EM), and uncovered the binding pocket of ketamine is located within the central vestibule between the channel gate and selectivity filter in the transmembrane domain. Furthermore, combining site-directed mutagenesis and electrophysiological recordings, we found that mutations of asparagine 616 on GluN1 (N1-N616) and leucine 642 on GluN2A (2A-L642) largely reduced the potency of ketamine inhibition on NMDA receptors. Molecular dynamics simulation further revealed that two hydrophobic groups of ketamine (phenyl ring and cyclohexane) formed hydrophobic interaction with 2A-L642, while the amino-group of ketamine selectively formed hydrogen bond with N1-N616. In addition, the ketamine derivatives with modification of ketone group and chlorine still effectively inhibit the activity of NMDA receptor, indicating that ketone group and chlorine were not necessary for ketamine to bind with NMDA receptor. Altogether, we propose the mechanism of ketamine action on NMDA receptor: ketamine forms hydrophobic interaction with its hydrophobic groups facing 2A-L642 on the sides of vestibule, and hydrogen bond with its amino-group pointing to N1-N616 at the bottom of vestibule to bind in the vestibule and block ion flow. Based on our structure, we conducted high-throughput virtual screening in the chemical databases, and identified 102 candidate compounds likely to bind in the vestibule of NMDA receptor. Electrophysiological recordings validated seven compounds with inhibition potency comparable to ketamine. Preliminary behavioral tests showed that one compound elicited rapid antidepressant effects in mice with chronic restraint stress (CRS) one hour post drug administration. These findings show structurally how ketamine binds to and acts on human NMDA receptors, and pave the way for the future development of ketamine-based antidepressants.

Title: Predictors from initial ketamine administration with neuropsychiatric patients for long-term ketamine treatment utilization

Authors: A. TILLMAN[1], K. HURST[1], D. GREENSTEIN[1], *J. GILBERT[2], C. ZARATE, Jr.[1], E. BALLARD[1];
[1]Section on the Neurobio. of Mood Disorders, [2]Natl. Inst. of Mental Health, NIH, Bethesda, MD

Abstract: Depression is the leading psychiatric cause of morbidity and disability, with few rapid-onset treatments. Ketamine is a glutamatergic modulator that can produce rapid improvements in depression symptoms within hours of administration. Mixed evidence has linked the dissociative effects of ketamine with better antidepressant response. Community utilization of ketamine and esketamine has increased, but less is understood about who seeks out ketamine treatment and why. Participants from the National Institute of Mental Health (NIMH) represent some of the first individuals to receive ketamine in a controlled trial, providing a unique opportunity for long-term follow-up. We explored the association between ketamine's antidepressant and dissociative effects observed during NIMH clinical trials and patients' decision to receive ketamine post-discharge. Follow-up assessments were completed by 41 adults (65% female) with unipolar depression (n=28) or bipolar disorder (n=13) who had previously participated in NIMH ketamine trials, including two-period placebo-controlled crossover trials (n=29). All trials measured antidepressant response using the Montgomery-Asberg Depression Rating Scale (MADRS) or the Hamilton Depression Rating Scale (HAM-D); dissociation using the Clinician-Administered Dissociative States Scale (CADSS); and anhedonia using the Snaith-Hamilton Pleasure Scale (SHAPS). Logistic regression was used to determine if depressive symptoms one day post-ketamine or dissociation immediately post-ketamine was associated with ketamine and/or esketamine utilization in the years post-discharge. A separate logistic regression analysis was performed to control for placebo response in the crossover studies. Each model included time post-discharge, study, and baseline measures as covariates. We did not detect relationships between either depressive symptoms or dissociation (all p values > 0.10) post-ketamine and ketamine/esketamine utilization post-discharge. Results were similar when limited to participants from two-period crossover trials, controlling for placebo response. Leveraging data collected over 20+ years, we did not find relationships between ketamine response in inpatient clinical trials and subsequent ketamine/esketamine use in the community. Due to the length of follow-up, data are limited by the relatively low recruitment rate. Future research is needed to examine other factors that may impact patients' ketamine treatment post-discharge, including logistical/financial barriers to access and long-term symptom profiles.

Title: A simple protein biomarker may reveal a continuity of antidepressant properties, at the cellular level, for monoaminergic antidepressants, ketamine and psychedelics.

Authors: A. GUNAY[1], S. D. TARGUM[2], W. DUNN[3,4], O. A. AJILORE[5], ***M. M. RASENICK**[6,7,2];
[1]Univ. of Illinois at Chicago, Univ. of Illinois at Chicago, Chicago, IL; [2]Pax Neurosci., Glenview, IL; [3]Psychiatry, Greater Los Angeles VAMC, Los Angeles, CA; [4]UCLA, Los Angeles, CA; [5]Univ. of Illinois, Univ. of Illinois Chicago, Chicago, IL; [6]Physiology&Biophysics and Psychiatry, U. Illinois Col. of Med., Chicago, IL; [7]Jesse Brown VAMC, Chicago, IL

Abstract: The heterotrimeric G protein, Gsalpha (Gsα), when ensconced in lipid rafts shows impaired stimulation of adenylyl cyclase (AC). Both decreased Gsα-AC coupling and an increase in lipid raft Gsα are observed in MDD subjects. Antidepressants (AD) accumulate in, and trigger the translocation of Gsα out of lipid rafts resulting in the sustained cAMP elevation observed during antidepressant treatment. "Rapid-acting" ADs (e.g) ketamine, show this effect on an accelerated timescale. Clinical data suggest that psychedelics and dissociative compounds have similar properties with a variable speed of onset and variable durability of effect. We hypothesize that increased accumulation of Gsα in lipid rafts is a biomarker for depression and that the translocation of Gsα from those rafts is a biomarker for clinical response to AD. Platelets were collected from studies with depressed subjects, treated with various ADs. Activation of adenylyl cyclase by Gsα was determined by comparing activity in the presence of prostaglandin E1 (PGE1) vs no activator. Greater lipid raft localization of Gsα is reflected by less PGE1 activation of the enzyme. Statistical measures were used to compare pre- and post-treatment MDD severity (measured by HAM-D, MADRS and QIDS) with PGE-1 activation of AC. AD effects on Gsα-mediated cAMP accumulation were also measured in cultured neurons and glia, exposed to ADs and psychedelic compounds. These preclinical studies allow assessment of speed of onset and durability of AD effect. Preclinical studies on cultured neural or glial cells, with escitalopram, desipramine, ketamine, psilocin, LSD and MDMA, all showed augmented Gsα activation of AC; mood stabilizers and antipsychotics had no effect. While the monoaminergic ADs required 3 days to achieve this effect, ketamine required 15 minutes and the psychedelics, one hour. Only the psychedelics had a persistent effect. In two clinical studies, platelets from the first study showed Gsα-activated AC (but not intrinsic enzyme activity) was elevated in healthy controls vs. depressed subjects. Subjects responding to AD therapy returned to the level of PGE1 activation seen in healthy controls where non-responders were unchanged in this biomarker value. Similar results were seen in the second trial.
Lipid-raft localization of Gsα, as determined by Gsα-activated AC, is a potential biomarker for depression and therapeutic success of ADs. While the onset and durability of action differ between traditional ADs, ketamine and psychedelics, the cellular model system may be a useful tool to predict antidepressant properties of a compound.

Title: Ropanicant (SUVN-911), an α4β2 nAChR antagonist: A phase-2a study evaluating the safety and efficacy in participants with moderate to severe major depressive disorder

Authors: *V. PALACHARLA, V. BENADE, J. RAVULA, S. JETTA, V. GOYAL, A. MOHAMMED, R. SUBRAMANIAN, S. PANDEY, P. JAYARAJAN, A. SHINDE, R. NIROGI;
Suven Life Sci. Ltd, Hyderabad, India

Abstract: Ropanicant (SUVN-911) is a potent and selective α4β2 nAChR antagonist and has demonstrated more than more than 100 fold selectivity for α4β2 nAChR receptors (NovaScreen selectivity panel and closely related α3β4 nAChR receptors). Ropanicant showed good oral bioavailability in tested preclinical species (rats, mice and dogs). Upon oral administration in rats, it showed good brain exposures that translated well into dose dependent receptor occupancy at α4β2 receptors. Good oral exposures translated into robust antidepressant like effects in animal models of depression and significantly increased cortical serotonin and norepinephrine levels. It showed faster onset of antidepressant activity, enhanced cognitive function and did not induce sexual dysfunction in animal models thus, addressed major limitations of the currently used antidepressants. Ropanicant showed good margin of safety in toxicity studies and is non-mutagenic and non-clastogenic in nature. Ropanicant was well tolerated and safe up to the highest tested dose of 60 mg single dose and 45 mg once daily for 14 days in humans. Ropanicant has shorter half-life in humans following once daily (QD) dosing, and twice a day (BID) dosing could provide sufficient target coverage and maximize the therapeutic potential. An open-label parallel group study to evaluate the safety and efficacy of ropanicant in participants with moderate to severe major depressive disorder (MDD) is being initiated. The primary objective of the study is to evaluate the safety of ropanicant upon BID dosing. The secondary objectives include assessment of ropanicant treatment in reducing depressive symptoms and to evaluate pharmacokinetics. Approximately 36 participants will be randomized to receive ropanicant either 45 mg QD, 30 mg BID, or 45 mg BID in a ratio of 1:1:1. Following a screening period of up to 4 weeks, participants will be treated for 2 weeks. Safety assessments will include adverse events, physical examination, vital signs, ECG, clinical laboratory tests, and suicidal ideation/behavior evaluation by Columbia Suicidal Severity Rating Scale (C-SSRS). The

efficacy assessments will include change from baseline in Montgomery-Asberg Depression Rating Scale (MADRS) and Clinical Global Impression of severity (CGI-S). Pharmacokinetics will be evaluated on day 1 and day 14 in subjects receiving BID dosing. This open-label study will be a preface to a large double-blind placebo controlled study of ropanicant in participants with MDD.

Title: Tnf antagonism enhances motivation and dmpfc encoding of subjective value in patients with major depression and high inflammation

Authors: S. LIU[1], S. BETTERS[1], J. KUBERT[1], S. ETUK[1], J. A. COOPER[3], E. HAROON[4], J. FELGER[4], A. H. MILLER[4], *M. T. TREADWAY[2];

Abstract: Background: It has been shown that chronic inflammation may act on the cortical-striatal effort-based decision-making circuitry, namely the dorsal anterior cingulate cortex, to aggravate motivational deficits in individuals with Major Depression (MD). In our study, a single dose challenge of infliximab, a TNF antagonist that reduces inflammation, was given to patients with MD and high inflammation, to study the drug's effect on motivation deficits and dACC functioning.Methods: 37 medically stable, unmedicated, MD patients with high inflammation (C-Reactive Protein > 3.0 mg/l) participated in a double-blind, placebo-controlled randomized clinical trial (NCT03006393). A reward/effort-based decision-making task was

administered during an fMRI scan, both before infliximab/placebo infusion and 14 days post-infusion. Using a group-by-time comparison, we examined changes and correlations in (1) behavioral effort/reward choices and the effort discounting parameter from a subjective value model; (2) brain signals in the cortical-striatal network, especially the dACC; as well as (3) peripheral levels of TNF inflammation markers.Results: Compared to the placebo group, patients who received infliximab showed significant decreases, from baseline to 14-days post-infusion, in behavioral effort discounting ($p < .05$) and peripheral TNFRII ($p < .005$) levels. Increased willingness to expend effort was associated with greater reductions in TNFRII ($p = 0.017$) and anhedonia symptoms ($p = 0.083$). Decreases in effort discounting ($p < .001$) and TNF ($p = 0.017$) were additionally associated with decrease in the level of dACC encoding of the subjective value of monetary reward. Moreover, dACC subjective value encoding played a mediating role in the correlation between TNFRII and effort expenditure behavior (bootstrapped CI: [-1.7, -.01]). Finally, using gene expression maps from the Allen Brain Atlas, we found that the areas impacted by infliximab showed greater expression of TNF as compared to other inflammatory markers.Conclusion: Our results suggest that, for MD patients with high inflammation, a single dose of infliximab may lead to decreased effort discounting and increased motivation. These results may be mediated by the reduced engagement of dACC during reward/effort-based decision making.

Title: The mood-improving effects and changes in brain activity brought about by visual stimulation with images of the natural environment in patients with depressive and anxiety disorders: A near-infrared spectroscopy study

Authors: *T. MIZUMOTO[1], H. IKEI[2], K. HAGIWARA[1], T. MATSUBARA[1], F. HIGUCHI[1], M. KOBAYASHI[1], T. YAMASHINA[1], J. SASAKI[1], N. YAMADA[1], N. HIGUCHI[1], K. HARAGA[1], F. KIRIHARA[1], C. CHEN[1], Y. MIYAZAKI[2], S. NAKAGAWA[1];

Abstract: Introduction: Whereas nature therapies have been attracting much attention, few studies have examined their effects in clinical patients. Here, we aimed to examine the mood-improving effects of viewing images of nature and the accompanying brain activation changes in patients with depressive and anxiety disorders. Methods: We conducted a randomized crossover trial with sixty adult outpatients diagnosed with a depressive or anxiety disorder based on DSM-5. Subjects were randomized to view images of nature and city in a counterbalanced order. We used greenish natural images for nature and building-centered urban images for city (as control images). Each intervention had 12 images presented for 3 minutes in total. Frontal brain activity, specifically orbitofrontal cortex (OFC), was measured using 2-channel near-infrared spectroscopy device (Pocket NIRS Duo, Hamamatsu, Japan). Immediately after each intervention, participants reported their mood in the moment with a visual analog scale in term of comfortableness, relaxation, and vigor. This study was approved by the IRB of Yamaguchi University Hospital and conducted in line with the Declaration of Helsinki. All participants provided written informed consent.Results: Viewing images of nature improved mood, as shown by increased comfortableness, relaxation, and vigor, in patients with only depressive (n=26) and anxiety (n=24) disorders. In contrast, in patients with comorbid depressive and anxiety disorders (n=10), viewing images of nature increased only comfortableness. During viewing images of nature, patients with depressive disorders showed increased concentration of oxygenated hemoglobin (Oxy_Hb) in the right OFC. In patients with anxiety disorders, in contrast, whereas the trend towards a decrease in the concentration of Oxy_Hb in the OFC during viewing images of nature was nonsignificant, there was a significant negative correlation between the changes in Oxy_Hb in the left OFC and changes in mood such that the lower the concentration of Oxy_Hb, the greater the mood-improving effect. In patients with comorbid depressive and anxiety disorders, however, there was no such difference nor correlation.Discussion: To our knowledge, this is the first study to examine the effects of visual stimulation with images of nature in patients with depressive and anxiety disorders. Whereas both disorders showed mood improvement, the effect was limited when they comorbid. Furthermore, the patterns of frontal brain activity were opposite in the two disorders. These findings may advance our knowledge of the unique neuropsychopathological changes in depressive and anxiety disorders and their comorbidity.

Title: Blood biomarkers potentially exploitable to predict vulnerability and resilience to stress.

Authors: *M. RINAUDO, F. NATALE, M. SPINELLI, R. PIACENTINI, M. D'ASCENZO, S. FUSCO, C. GRASSI;
Dept. of Neurosci., Univ. Cattolica Del Sacro Cuore-Fondazione Policlinico Universitario "A. Gemelli" IRCCS, Roma, Italy

Abstract: When exposed to similar stressors, individuals' responses may largely differ, with some people developing mood alterations, including depression, while others being virtually unaffected. However, the molecular and cellular mechanisms underlying susceptibility and resilience to stress are largely unknown. Aim of the present study was to identify a molecular fingerprint of stress vulnerability to unravel biomarkers potentially allowing to predict the risk to develop mood alterations in response to stress. Experiments were performed in male C57Bl6 mice exposed to the Unpredictable Chronic Mild Stress (UCMS) paradigm for two weeks. Blood samples were collected before starting the UCMS and behavioral assessment of the depressive-like phenotype was conducted at different time points during the stressing protocol. Employing a clustering algorithm, animals were categorized into two sub-populations: one exhibiting consistent depressive-like symptoms throughout the observation period and another group never developing such phenotype. Subsequently, two -omic analyses were performed on blood samples previously collected: i) untargeted metabolomic analysis and ii) transcriptome analysis of miRNAs extracted from circulating brain-derived extracellular vesicles. Supervised and unsupervised multivariate data analysis of the -omic datasets revealed distinct metabolic and miRNome profiles associated with the identified sub-populations of vulnerable and resilient mice. Specifically, enrichment analysis indicated significant alterations in energetic pathways such as the pentose phosphate pathway, Krebs' Cycle and amino sugar and nucleotide metabolism. Furthermore, single metabolic and miRNomic variables showed strong correlation with behavioral data. In conclusion, our findings suggest the existence of specific biomarkers, both in terms of circulating metabolites and brain-derived microRNAs, which are quantifiable before stress induction and may harbor information about stress vulnerability or resilience, thus potentially providing predictive insights into stress responses of the population at risk.

Title: Network structure and gene expression patterns of sex-specific brain-behavior correlates of chronic variable stress in mice

Authors: *L. HERRERA PORTILLO[1,2], Y. YEE[1,2], D. R. GALLINO[2], R. C. BAGOT[1,3], M. CHAKRAVARTY[1,2];

Abstract: Intro: Stress is a major risk factor for depression. Female mice exposed to Chronic Variable Stress (CVS) display greater stress susceptibility. However, the sex-specific impacts of CVS on whole-brain network organization is unknown. Here, we used *in vivo* magnetic resonance imaging (MRI) and the Allen Institute's mouse connectivity and gene expression data to uncover putative mechanisms underlying sex-specific brain-behavior correlates of CVS in mice. **Methods**: We acquired T1w MRI (100 um isotropic voxels, Bruker 7T) and behavioral measures (social preference and open field; OFT) on 8 week old C57BL/6 male and female mice, pre- and post- sex-specific CVS protocols: 28 or 6 days of 1hr daily stressors (foot shocks, tail suspension, restraint), respectively (n=~10 group/sex). Brain (voxel-wise Jacobian determinants) and behavior relationships were examined with partial least squares correlation (PLSC), using 1) post- minus pre-CVS and 2) post-CVS measures. We used the spatial pattern of voxels significantly correlated with behavior (negative or positive) to examine their network structure (rich club; RC, community structure, and participation coefficient; PC), and correlation to spatial gene expression patterns.**Results:** In females, behavioral and neuroanatomical change covaried significantly (p=0.03, covariance explained=44.1%; Fig 1A). Decomposing the structural network of negative or positive voxels into 9 and 5 communities revealed the highest PC in the amygdala and cerebellum, respectively (Fig 1B). In males, CVS-induced neuroanatomical adaptations covaried with the OFT (p=0.04, cov. exp.=29.1%; Fig 1C). In the 3 communities for neg. or pos. voxels the highest PC located in the hippocampus and anterior cingulate, respectively. In both sexes, the RC involved the subcortex (neg.) and cortex (pos.). Correlated gene ontology terms are shown in Fig 1. **Conclusion:** Our results suggest different biological mechanisms related to sex-specific brain-behavior correlates of CVS, in which their networks suggest distinct key areas for inter-community communication.

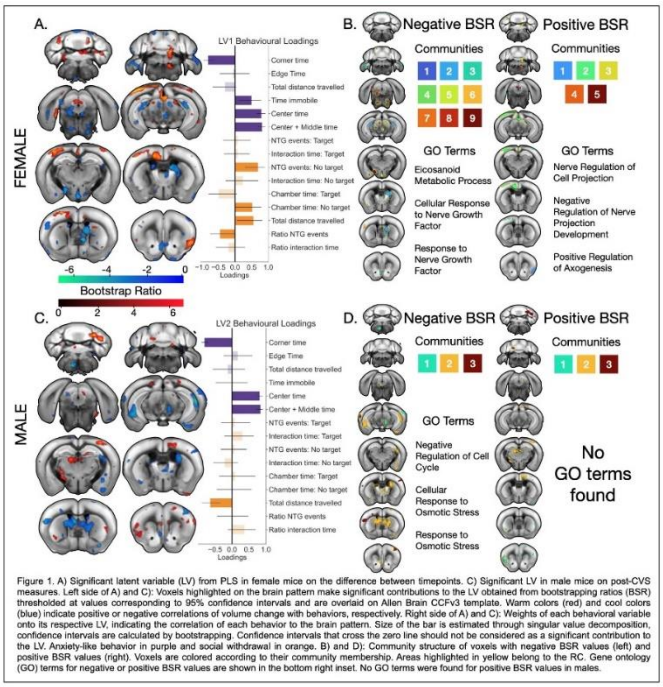

Figure 1. A) Significant latent variable (LV) from PLS in female mice on the difference between timepoints. C) Significant LV in male mice on post-CVS measures. Left side of A) and C): Voxels highlighted on the brain pattern make significant contributions to the LV obtained from bootstrapping ratios (BSR) thresholded at values corresponding to 95% confidence intervals and are overlaid on Allen Brain CCFv3 template. Warm colors (red) and cool colors (blue) indicate positive or negative correlations of volume change with behaviors, respectively. Right side of A) and C): Weights of each behavioral variable onto its respective LV, indicating the correlation of each behavior to the brain pattern. Size of the bar is estimated through singular value decomposition, confidence intervals are calculated by bootstrapping. Confidence intervals that cross the zero line should not be considered as a significant contribution to the LV. Anxiety-like behavior in purple and social withdrawal in orange. B) and D): Community structure of voxels with negative BSR values (left) and positive BSR values (right). Voxels are colored according to their community membership. Areas highlighted in yellow belong to the RC. Gene ontology (GO) terms for negative or positive BSR values are shown in the bottom right inset. No GO terms were found for positive BSR values in males.

Title: Profiling Transcriptional Maladaptations in a Mouse Model of Treatment-Resistant Depression

Authors: *A. TORRES BERRIO[1], E. M. PARISE[2], M. ESTILL[4], T. M. GYLES[3], C. J. BROWNE[5], L. SHEN[4], E. J. NESTLER[2];

Abstract: Major Depressive Disorder (MDD) is the most prevalent psychiatric disorder worldwide, representing a high level of global economic burden. Fluoxetine (FLX) and like

antidepressants have been widely used to treat MDD, nonetheless, ~50% of patients do not achieve full remission. Further, a subset of those afflicted are considered non-responsive to orally-available medications and are considered to have treatment-resistant depression (TRD). More recently, Ketamine (KET) has been shown to induce a rapid antidepressant response in ~50% of TRD patients, providing a novel therapeutic approach. However, the molecular mechanisms underlying TRD are poorly understood. This study was aimed at characterizing the transcriptional profile of successful vs. unsuccessful response to KET in chronically-stressed mice that failed to respond to an initial course of FLX as a model of TRD. We exposed adult male mice to chronic social defeat stress (CSDS), a validated mouse model of depression that identifies a spectrum of resilient vs. susceptible outcomes based on a social interaction test (SIT). Mice classified as susceptible underwent antidepressant treatment with FLX in their drinking water for 28 days or received water during the same period (water-treated). After FLX treatment, we identified a subset of mice (~35%) that continued to show reduced social interaction despite treatment (non-responders). FLX non-responders and water-treated mice were subsequently given a single injection of KET and assessed in the SIT 24 hr later. Transcriptome-wide changes in the prefrontal cortex (PFC) and nucleus accumbens (NAc) 48 hr after KET administration were profiled by RNA-sequencing. We found that ~50% of FLX-non-responder mice exhibited an antidepressant response to a single KET injection, a significantly greater response than that seen in susceptible mice treated with water (0%). We further identified a subset of treatment-resistant mice that failed to respond to consecutive FLX and KET treatment. Pattern analysis of the differentially expressed genes in the PFC and NAc revealed transcriptional profiles associated with the antidepressant-like actions of FLX and of KET as well as a series of genes that were unique to treatment resistance to both drugs. We developed a novel paradigm of treatment resistance in mice that allows the identification of potential mechanisms underlying TRD. The KET response rate in FLX-non-responders is similar to that seen in TRD patients, lending further validity to our model. Moreover, our findings suggest that prior unsuccessful antidepressant treatment induces a “priming effect” that increases the likelihood of successful response to KET.

Abstract: Stress impacts vulnerability for mental illnesses, including depression. Most behavioral paradigms attempting to model this phenomenon induce stress in manners that do not adequately reflect the human experience. Consequently, social stress models with higher ecological validity have become increasingly popular. Unfortunately, despite the higher rates of depression among females, most of these models only include male subjects. To address this deficit, we used the chronic witness defeat stress paradigm with D1-Cre- RiboTag (RT) and A2A-Cre-RT female mice. A social preference test with same-sex conspecifics was used to demonstrate a susceptible group that displays reduced social preference and a resilient group with social preference similar to controls. To obtain a more granular characterization of the behavior in this group of mice and male wildtype mice, video recordings from the social preference test were used to track animal behavior using the deep-learning based Python tool DeepLabCut. Spatiotemporal data extracted from DeepLabCut was then used to calculate kinetic variables based on mouse location, activity and interactions. Factor analysis was then employed using these variables to identify latent factors driving the observed behavior during the social preference test. To elucidate the molecular mechanisms underlying stress susceptibility and resilience in female mice, RNA-seq profiling of ribosome-associated mRNA from dopamine receptor 1 and 2 expressing medium spiny neurons (D1-MSNs and D2-MSNs) was performed. Weighted gene co-expression network analysis (WGCNA) was used to identify gene co-expression modules significantly associated with the stress groups. The susceptible and resilient mice were found significantly different in latent variables involving exploratory behavior, interaction with the cup containing the conspecific mice, surveillance behavior and chamber/cup preference. The gene co-expression networks that were differentially regulated between the stress groups involved protein synthesis and trafficking, neurite formation, synapse formation and maintenance and mitochondrial translation and activity in both D1- and D2-MSNs. Collectively, our studies are uncovering distinct behavioral characteristics and cell specific translatomes of socially stressed mice.

Title: Microglia & Neuronal Dysfunction marker, PFKFB3, in Rodent Model of Chronic Unpredictable Stress

Authors: *M. M. MIRRIONE[1], C. FORD[1], C. WHITELOCK[2], K. RONALTER[2], K. JONES[1], A. J. BETZ[3];
[1]Biomed. Sci., [2]Hlth. Sci., [3]Psychology Department, Behavioral Neurosci. Program, Quinnipiac Univ., Hamden, CT

Abstract: The hippocampus undergoes significant atrophy (cell death) during chronic stress and depression. The underlying mechanisms of neuronal dysfunction and disrupted neuronal circuits are thought to involve altered function of microglia. Neurons and glia work together seamlessly in the healthy brain and are critical for maintaining proper health and function of neurons. However, it has been postulated that glial cells become altered during stress and may be causally linked to disrupted neuronal circuits in mood disorders. Here, we further explore a potential link between microglia morphology changes and neuronal metabolic dysfunction in the hippocampus, using the widely accepted mild Chronic Unpredictable Stress (CUS) model. Male, Sprague-Dawley rats were randomized to control (n=5) and CUS (n=5) groups on post-natal day 21. CUS animals were exposed to three weeks of randomized stressors, evaluated for sucrose preference, then sacrificed on post-natal day 44, brains excised, fixed in formalin, and sectioned at 30 microns for immunofluorescence microscopy analysis. We hypothesized that increased microglia activation and proliferation would be evident in the hippocampus following CUS compared to controls, and would correlate with metabolic damage in neurons measured using the marker 6-phosphofructo-2-kinase/fructose-2,6-biphosphatase 3 (PFKFB3). PFKFB3 is glycolysis enzyme thought to accumulate with excitotoxicity, and could contribute to oxidative stress and cell death. Immunofluorescence was performed on the hippocampal tissue for microglia via an antibody for ionized calcium-binding adapter molecule 1 (Iba1) and an antibody for PFKFB3. In male rats, we quantified the amount of microglia and PFKFB3 within the dorsal and ventral hippocampus CA1, CA3, DG sub-regions using MatLab and CellProfiler. Our data reveal an increase in PFKFB3 in the ventral hippocampus CUS animals, and remained as a trend when normalizing to total number of neurons. We also measured changes in cell body size of microglia in CUS animals, across all subregions, but no change in total counts of microglia. Together our data suggests evidence of early stages of neuronal dysfunction in the hippocampus resulting from CUS exposure in adolescent animals, which may be associated with altered microglia function. Future experiments will evaluate the association between reduction in microglia soma size, and the number and complexity of processes, and altered neurotropic support for hippocampal neurons from CUS. Overall, our results may provide insight into the molecular mechanisms responsible for atrophy and neuronal dysfunction in limbic circuits related to stress and depression.

Title: Investigation of transcriptome alterations (RNAseq) in neuronal population of ventral hippocampus in mice susceptible and resilient to chronic social defeat stress

Authors: *G. ZANETTI[1], M. F. PAGLIUSI, Jr[2], A. S. VIEIRA[3];
[1]Unicamp, Campinas, Brazil; [2]Biol. Inst., State Univ. of Campínas, Campinas, Brazil; [3]IB - DBEF, Univ. Estadual De Campinas, Campinas, Brazil

Abstract: Depression is a common and recurrent mental disorder impairing the daily life and well-beingof the individual. Social stress is already well established in the literature as a model ofdepression and, in this context, we can highlight the chronic social defeat stress model(CSDS).In this model, the social interaction test is used to assess social avoidance,considered a depressive-like behavior. Not all mice submitted to CSDS develop socialavoidance behavior and are called resilient. The ventral hippocampus is a well studiedstructure in the context of depression, mainly because of its neuroplasticity and relation withother limbic system structures. In addition, the ventral hippocampal cell layers play differentroles during behavior. Ventral CA1 inactivation increases avoidance of conflict cue behavior,while CA3 inactivation increases approach behavior to conflict cue. Furthermore,neurogenesis confers resilience to chronic stress by inhibiting granular cells from ventraldentate gyrus. Litterature shows different results depending on the specific hippocampal celllayer, making their separation very important. In this study we aimed to investigate thetranscriptome alterations in distincts ventral hippocampal cell layers after CSDS. For theCSDS 12 week old C57/BL6 mice were submitted to 10 minute aggression sessions against 6month old aggressor retired breeder Swiss mice for 10 consecutive days. One day after thelast aggression session we performed the social interaction test and, after 24 hours, mice wereeuthanized and the brains were collected and fresh-frozen in isopentane. All brains weresliced in a cryostat, flushed with violet cresyl, and microdissected using a laser-capturemicrodissection apparatus to separate ventral dentate gyrus and ventral CA1 celllayers.Following the social interaction test, we could classify 7 animals as resilient to CSDSshowing social interaction ratio (SIR)average 3.02, and 11 animals showing social avoidancebehavior (susceptible)with SIR average 1,03, in addition to 10 control mice, not submittedto CSDS protocol, with SIR average 2.32. Furthermore, 5 brains of each group werecollected, processed, and microdissected, where we separated the ventral dentate gyrus andCA1 cell layers from the hippocampus for further analysis. The CSDS protocol wassuccessfully performed in the present study, once we could observe and classify the mice aspresenting either susceptible or resilient phenotype. This is an ongoing study and

themicrodissected material from each animal will be submitted to transcriptome analysis ofCA1, and Dentate Gyrus cell layers.

Abstract: Anxiety and major depressive disorders are highly prevalent worldwide, and strongly associated with exposure to stress. Individual differences in sensibility to the environment may explain why some individuals are at higher risk for the development of psychopathology. Exploring the molecular mechanisms of resilience is essential for informing targeted prevention and treatment investigations. Here, we tested whether the Environmental Enrichment (EE) paradigm promotes resilience in male mice, and we analyzed transcriptional networks involved in response to EE exposure in comparison to standard-housed animals (SD). We measured anxiety and depressive-like behaviors after exposing animals to 8 weeks of EE. We observed an anxiolytic effect of EE in comparison to SD (Novelty suppressed Feeding, $F_{1,39}= 14.34$, p=

0.001), without differences in the depressive-like phenotype between the groups (Forced Swimming Test: p>0.05). RNA sequencing of the hippocampal ventral dentate gyrus (N=9/10 group) was used to identify a functional gene network associated with EE through a weighted gene co-expression network analysis (r=0.57, p=0.01). Enrichment analysis revealed that this network is associated with mitochondrial function, and response to stress, especially oxidative. Human single nucleotide polymorphisms from these genes were weighted using the association between alleles and gene expression from GTEx hippocampus dataset, and used to compute an expression-based polygenic score (ePGS) in the UK Biobank. Variations in ePGS represent individual differences in the expression of the network. We investigated the interplay between ePGS and adult stress exposure on the development of psychopathology. The ePGS moderated the association between stress exposure and the International Classification of Disease-10 codes F40-F41, that comprise anxiety disorders (N=1240, B= -0.03, P= 0.025), in which higher stress is associated with higher risk for anxiety disorders in the low ePGS group (simple slope analysis: B= 0.25, P< 0.001). This suggests that variations in the expression of a network associated with EE in mice are also associated with mental health in humans. These findings offer insights for future research aimed at investigating the causal role of specific molecular pathways associated with the promotion of resilience.

Title: C-fos expression and gad-immunoreactivity in brains of adolescent female mice undergoing activity-based anorexia, food restriction only, wheel running only or neither

Authors: *Y. DONG[1], C. J. AOKI[2];
[1]CNS, NYU, New York, NY; [2]New York Univ., New York Univ., New York, NY

Abstract: Anorexia nervosa (AN) is a complex mental disorder characterized by significantly low body weight due to voluntary food restriction, persistent behaviors like excessive exercise that interfere with weight gain, and body dysmorphia (American Psychiatric Association, 2013). Activity-based anorexia (ABA) is an animal model that presents all critical symptoms of AN

except distorted body image. Specifically, ABA represents two main characteristics of AN: increased voluntary physical activity and increased restriction of food intake, leading to excessive body weight loss (Aoki, 2020, Animal Model of Eating Disorders). ABA animals increase wheel running activity during the dark phase and 2-3 hours before feeding time (Mistlberger, 1994, Neuroscience & Biobehavioral Reviews, 18(2), 171-195). This food anticipatory activity (FAA) has been shown to associate with anxiety levels (Wable et al., 2015, *Behav Neurosci*, 129:170), reward-seeking, and anticipation of palatable food stimuli (Mendoza et al., 2005, European Journal of Neuroscience, 22(11), 2855-2862). Many neuronal changes can lead to changes in feeding behavior and hunger-evoked hyperactivity. Altered neuroendocrine and brain reward circuit function is one hypothesized mechanism behind AN pathology. Previous study on ABA after the feeding period showed increased activation in the supraoptic nucleus, arcuate nucleus and locus coeruleus (Scharner et al., 2016, Frontiers in neuroscience, 10, 475). We addressed two questions that remained unanswered: 1) What is the brain state of ABA animals during food anticipatory activity (FAA) time, when they are hungry and running simultaneously? 2) What is the brain state of ABA animals during the re-feeding time? To answer these two questions, we created four groups of animals: food-restricted, exercising, ABA, and control with neither food restriction nor exercise. Brains were collected at two time zones: during FAA @6 pm and during re-feeding @8 pm. Brain regions we investigated included the prefrontal cortex, caudate putamen, nucleus accumbens, lateral hypothalamus, substantia nigra, VTA, dorsal raphe, habenula and insula. C-Fos marked neuronal activities, and GAD-immunoreactivity was used to identify whether they are GABAergic or not.

Title: catFISH analysis of medial preoptic area neuronal activation during maternal interactions with offspring of varying needs

Authors: *E. LOPEZ ROBINSON[1], K. COPELAS[2], A. GADEKAR[2], M. PEREIRA[2]; [1]Psychological Brain Sciences, Neurosci. and Behavior, [2]Psychological and Brain Sciences, Neurosci. and Behavior, Univ. of Massachusetts Amherst, Amherst, MA

Abstract: Maternal behavior that is sensitive to the needs of the offspring in everyday interactions is essential for healthy development and wellbeing in mammals. Postpartum depression (PPD) is a serious health problem that has a tragic impact on the mother's ability to sensitively care for her child, with life-long consequences for both the mother and her child. Our

prior work demonstrated that the medial Preoptic Area (mPOA), a critical node in the circuitry regulating maternal behavior, is required for this critical maternal ability (referred to here as maternal sensitivity). The objective of this study was to examine the contribution of mPOA cells to maternal sensitivity. To this aim, we leveraged the well-validated Wistar-Kyoto (WKY) rat model of depression and used cellular compartment analysis of temporal activity by fluorescence in situ hybridization (catFISH) technique to assess overlap between mPOA population of cells during maternal interactions with offspring with varying needs. WKY and control Sprague-Dawley (SD) mother rats experienced two 10-min interaction episodes, 20 min apart with normal vs increased needs pups. Mothers were perfused immediately after the second episode and their brains processed to quantify nuclear cfos pre-mRNA and cytoplasmic mRNA transcripts in the mPOA. Consistent with our prior results, WKY mothers exhibited similar caregiving behaviors regardless of their offspring needs, highly contrasting the sensitive parenting of SD mothers, indicative of deficits in maternal sensitivity. c-fos catFISH analysis revealed overlapping but distinct neuronal populations involved in adjustments of care that resolve the needs of the offspring. Together, this new work expands our understanding of the mPOA contribution to parenting.

Title: Characterization of Mu Opioid Receptor Expression on Dopaminergic Axons of Nucleus Accumbens Shell in Relation to Wheel Running

Authors: *M. JIMINIAN[1], I. J. PAT-OSAGIE[2], C. J. AOKI[3];
[1]New York Univ. Ctr. For Neural Sci., New York, NJ; [2]NYU/CNS, New York, NY; [3]Ctr. for Neural Sci., New York Univ., New York, NY

Abstract: Anorexia nervosa consists of primary symptoms that include excessive exercise, severe weight loss, and food restriction. Severe weight loss is a huge contributing factor to the high mortality rate of the disorder, which is the highest out of all psychiatric illnesses. My research primarily focuses on the excessive exercise component as it is the major contributor to weight loss. To study excessive exercise I work with the activity-based anorexia (ABA) model where mice are exposed to wheels, food restriction, or both within their adolescence to observe its impact on their exposure to a wheel in adulthood. The research focuses on why the mice who excessively exercise in response to food restriction do so in the first place. It could potentially be

attributed to the euphoric sensation produced during exercise known as “Runner’s High.” Endorphins and dopamine are two molecules suggested by popular press to be associated with this sensation but neurobiological verification of this idea is lacking. On the other hand, there is substantial evidence that synaptic plasticity involving dopamine in ventral striatum, also called nucleus accumbens, is associated with addiction. To determine if it's the euphoric sensation motivating this exercise symptom, I am quantifying the number of mu opioid receptors on dopaminergic axons in nucleus accumbens. Mu opioid receptors bind endorphins and suppress dopamine release. A large quantity of these receptors on dopaminergic axons would suggest the euphoric sensation is not attributed to the excessive running. In order to quantify the level of mu opioid receptors on dopaminergic axons, I’m using immune-electron microscopic staining to identify tyrosine hydroxylase-immunopositive axons and mu opioid receptors localized on them. I’m also running correlation analysis of these co-localizations and each animal’s wheel running. The same tissue will also be used to assess the extent to which mu opioid receptors occur at excitatory synapses and inhibitory synapses to learn whether mu opioid receptor-mediated modulation of these synapses correlate with the extent of wheel running.

Title: Glyoxalase I inhibitors as novel fast-acting antidepressant drugs following chronic mild stress

Authors: M. ULIVIERI[1], **H. ROSBERG**[1], X. FANG[1], C. BUI[1], A. LEE[1], E. ALCANTARA[2], *S. C. DULAWA[3];
[1]UCSD, La Jolla, CA; [2]UC San Diego Hlth., La Jolla, CA; [3]Univ. of California-San Diego, San Diego, CA

Abstract: Depression is a complex mood disorder affecting millions of people of all ages worldwide. Common antidepressants usually require weeks of treatments and are inefficient in a wide range of patients (30-40%). Ketamine is the only fast-acting antidepressant compound currently approved for clinical use, but still lacks the effectiveness in approximately 30% of patients. We recently demonstrated that subchronic Glyoxalase I (GLO1) inhibition induces antidepressant effects in mice following chronic mild stress (CMS). GLO1 is a key enzyme mediating the catabolism of methylglyoxal (MG), an endogenous $GABA_A$ partial agonist. In our study, we aimed to demonstrate the fast-acting antidepressant effects of methyl gerfylin (MeGFN), a GLO1 inhibitor, following acute systemic administration in control and CMS

animals, investigating possible gender differences in susceptibility to depressive behavior and drug response. We used adult male and female Balb/cj mice and exposed them to a 6-week CMS protocol. At the end of the 6 weeks, animals were tested in several behavioral tests assessing depression-like behavior: frustration induced by reward omission, effort-related choice (ERC), social interaction, coat state, open field, forced swim test (FST). On the test day, animals were separated into four different treatment groups: MeGFN, ketamine (fast-acting antidepressant control group) or their respective vehicles. We found that CMS induces a progressive reduction of sucrose preference across the 6 weeks. A single systemic injection of MeGFN or ketamine, exerted fast-acting antidepressant (within 24-48 hours) by improving social interaction dysfunction (with no effects on social novelty), reduction of coat deterioration, restoring reward processing alterations, and reducing immobility time and increasing swimming time in the FST, without affecting locomotor activity. Therefore, our results show the impact of CMS on frustration induced by reward omission protocol, sociability, and ERC, as well as other depressive-like behaviors, and reveal fast-acting effects of acute MeGRF treatment. Overall, our study suggests that glyoxalase system, and particularly GLO1 enzyme, is a novel suitable target for novel fast-acting antidepressant drugs.

Title: Social defeat stress in adulthood alters the Slit - Robo, but not the Netrin-1- DCC guidance cue system in the PFC of female mice

Authors: *A. MAHMUD[1], R.-G. AVRAMESCU[3], J. RESTREPO[1], C. FLORES[2];
[2]Psychiatry, [1]McGill Univ., Montreal, QC, Canada; [3]Douglas Mental Hlth. Univ. Institute, McGill Univ., Montreal, QC, Canada

Abstract: Elevated levels of the Netrin-1 guidance cue receptor gene deleted in colorectal cancer (*DCC)* in the adult prefrontal cortex (PFC) is a consistent trait of major depressive disorder (MDD) in humans and plays a causal role in susceptibility to chronic social defeat stress (CSDS) in adult male mice (Manitt, et al., 2013; Torres-Berrío et al., 2017). In contrast, the axonal guidance gene SLIT1 is downregulated in ventromedial PFCs (vmPFC) of female, but not male,

patients with MDD, and similarly, is reduced in vmPFCs of female and not male mice exposed to chronic variable stress (van der Zee et al., 2022). Although depression is twice more prevalent in women than men, the molecular mechanisms underlying this disparity remain unknown. Here we investigated if the Netrin-1/DCC and Slit/Roundabout (Robo) guidance cue systems are dysregulated in the PFC of adult female mice following CSDS. Adult (P75±15) C57BL/6J female mice were exposed to CSDS for 5 minutes each day for 10 days. To induce aggression from CD1 mice, urine of C57BL/6J male mmice was applied to the females. Control mice were housed with a different conspecific every day. Following CSDS, mice were assessed in the social interaction test (SIT) and 24h later, PFC tissue was collected to measure mRNA and miRNA expressions. Defeated females were segregated into resilient and susceptible groups based on the SIT. Compared to control mice, susceptible and resilient mice showed an increase in body weight and a deficit in the nestlet shredding test, a measure of self-care-like behaviour. In the PFC, there was no difference in mRNA levels among groups for either *Dcc* and *Netrin-1*, nor for *Unc5c*, another prominent Netrin-1 receptor gene. However, the expression of miR-218 – a microRNA which represses *Dcc*, *Robo1*, and *Robo2* and is intronically encoded in the *Slit2 and Slit3* genes – was slightly elevated in susceptible mice compared to control and resilient mice. Moreover, both susceptible and resilient mice show elevated *Slit2* and *Robo1* mRNA levels in the PFC. These data indicate that contrary to males, CSDS in females alters the Slit/Robo, but not the Netrin-1/DCC guidance cue system in the PFC, possibly via currently unidentified sexually dimorphic molecular processes involving microRNAs.

Title: Effects of Chronic Stress and Prefrontal Cortical REDD1 Overexpression on Attentional Set Shifting Behavior in Mice

Authors: *B. KURTOGLU[1], M. HEARING[2], J. MANTSCH[3];
[1]Phamacology & Toxicology, Med. Col. of Wisconsin - Neurosci. Doctoral Program, Milwaukee, WI; [2]Biomed. Sci., Marquette Univ., Milwaukee, WI; [3]Phamacology & Toxicology, Med. Col. of Wisconsin, Milwaukee, WI

Abstract: Cognitive (behavioral) flexibility, the ability to adapt behaviors in response to changes in the environment is an essential element for everyday life, with deficits commonly observed in neuropsychiatric disease states and reducing resilience to negative life events such as stress. The

rodent prelimbic cortex (PrLC) plays a critical role in processing information necessary for optimal cognitive flexibility and is known to undergo structural and functional changes following prolonged stress exposure, thus PrLC dysfunction represents a likely substrate for stress-induced deficits in cognitive control. We have recently shown that chronic unpredictable stress (CUS) produces an enduring dysfunction in PrLC physiology and impaired cognitive flexibility using an operant-based attentional set shifting in male but not female mice, however what adaptations drive these deficits remains unclear. To gain more insight into this, our studies chose to focus on the protein REDD1 (regulated in development and DNA damage responses-1) (aka DDIT4, RTP801, Dig2) as it is increased in post-mortem dorsolateral prefrontal cortex (dlPFC) tissue from individuals diagnosed with depression. In line with these findings, we find that there is an increase in REDD1 expression and a decrease in Raptor phosphorylation, one of the key elements of the mTORC1 complex, in the PrLC after CUS, suggesting disrupted mTORC1 function. To determine if REDD1 overexpression is sufficient to produce deficits in attentional set shifting, we used a viral vector to overexpress REDD1 in the PrLC of male mice. Relative to control mice, REDD1 mice required more trials to pass the extradimensional shift testing criterion that was equivalent to that produced by CUS. Notably, REDD1 overexpression did not impact acquisition of lever training, or measures of motivation for non-drug reward. Furthermore, we also examined the effects of REDD1 overexpression on PFC pyramidal neuron physiology and found that there is a reduction in miniature excitatory post synaptic current (mEPSC) signaling. The observation that CUS and REDD1 overexpression produce deficits in attentional set shifting in male mice likely has relevance for understanding a number of stress related disorders. Future research will assess the cell-type localization of REDD1 increases following stress in males, determine whether female mice are similarly affected by REDD1 overexpression and/or is upregulated in females following CUS, chronic CORT effects on attentional set shifting and examine the necessity of disrupted mTORC1 for stress effects.

Title: Critical role of mPFC layer 1 interneuron activity in stress-induced depressive-like behavior

Authors: *C. SHEN, W. CUI, D. LEE, I. SANTIAGO, H. WANG, W. ZOU, W.-C. XIONG, L. MEI;
Case Western Reserve Univ. Dept. of Neurosciences, Cleveland, OH

Abstract: The prefrontal cortex (PFC) serves as a central hub for emotional processing and stress responses; its abnormal function has been implicated in major depression disorders

(MDD). Layer 1 of the medial PFC (mPFC) consists of inhibitory interneurons (L1INs) that coordinate cerebral functions by integrating inputs from various brain regions and regulating information flow within the mPFC. However, it remains unknown how the mPFC L1INs change their activity in depressive-like behaviors. To this end, we selectively expressed the calcium indicator GCaMP6f in L1INs of the mouse mPFC (via NDNF-Cre) and recorded calcium activities during the tail suspension test (TST). We found that 24.1% of L1INs displayed a higher calcium activity during immobility in naïve mice, suggesting that these L1INs may be involved in depressive states. In agreement, this proportion rose to 48.1% after chronic restraint stress (CRS, an established paradigm to cause depressive-like behaviors). Notably, the expanded proportion mainly consisted of neurons that were previously insensitive to immobility or struggle behaviors, indicating circuit-level activity alterations. On the other hand, 51.9% of L1INs showed a higher calcium activity during struggle behavior in naïve mice, which reduced to 38.0% following CRS. These findings provide evidence that the activity of L1INs changes in association with depression levels. By retrograde tracing, we found that the nuclei of the diagonal band (NDB) and the ventromedial thalamus (vmTH) as primary inputs to NDNF+ L1INs. CRS enhanced cFos expression in NDB neurons and their vesicle release probabilities, but reduced cFos expression in vmTH neurons and their vesicle release probabilities. Experiments are underway to examine whether circuit activity imbalances of mPFC L1INs could be a possible mechanism for depressive-like behaviors.

Title: Increased adiposity due to maternal western-style diet consumption shapes serotonin innervation of the amygdala and anxiety behavior in adolescent nonhuman primate offspring

Authors: *G. DUNN[1], A. MITCHELL[2], J. GRAHAM[2], J. JACINTO-SCHREEDER[2], H. GUSTAFSSON[2], E. L. SULLIVAN[2];
[1]Psychiatry, Oregon Hlth. & Sci. Univ., Eugene, OR; [2]OHSU, Portland, OR

Abstract: Obesity is an epidemic that currently effects 40% of adults in the US. Further, about one-third of pregnant women are classified as obese. While many factors contribute to becoming obese, consumption of an obesogenic diet (e.g. high in saturated fat and sugar) is the largest predictor of increased adiposity. Previous research suggests that children born to obese mothers are at increased risk for developing neurodevelopmental and neuropsychiatric disorders. The

mechanisms underlying this increased risk are poorly understood. Utilizing a non-human primate model of maternal obesity, we hypothesized that maternal consumption of an obesogenic diet would increase anxiety-like behaviors in offspring through a reduction in serotonin innervation in the amygdala. We performed behavioral assessments in 34-month-old Japanese macaques (n=51; females = 26), born to either control or Western-style diet consuming mothers, and measured rates of anxiety-like behaviors. Further, we designed a fluorescent immunohistochemistry experiment to examine serotonin axonal projections into the amygdala in 36-month-old Japanese macaques (n=16, females = 8). In this study we utilized structural equation modeling for the simultaneous estimation of the relationship between maternal diet, metabolic state, offspring sex and offspring serotonin or behaviors measures. We found that maternal adiposity had a significant direct effect of a reduction in serotonin innervation in the amygdala ($\beta_{\text{Adiposity} \rightarrow \text{Offspring Serotonin}} = -0.482$, SE = 0.239, $p<0.05$). However, maternal diet was not found to have a significant effect on offspring serotonin outcomes ($\beta_{\text{Diet} \rightarrow \text{Offspring Serotonin}} = 0.153$, SE = 0.211, $p=0.470$). Similarly, we found an association between maternal adiposity ($\beta_{\text{Adiposity} \rightarrow \text{Offspring Serotonin}} = 0.363$, SE = 0.135, $p<0.01$), but not diet ($\beta_{\text{Diet} \rightarrow \text{Offspring Anxiety}} = -0.086$, SE = 0.120, p=0.473), on the rates of offspring anxiety behavior at 34 months. In summary, the current study provides support for reduced 5-HT innervation of the amygdala, due to maternal obesity, being a mechanism underlying the association between maternal WSD and increased anxiety behaviors in offspring.

Abstract: Background: Major depressive disorder (MDD) is a prevalent psychiatric disorder. Zinc deficiency is associated with an increased risk of MDD in humans and induces depressive-like behavior in rodents. Zinc homeostasis plays a crucial role in macromolecule synthesis,

signal transduction, redox homeostasis, DNA repair, and gene transcription. The prominent coexisting factors in depressive disorder are metabolic alterations and mitochondrial dysfunctions. In this study, we aimed to investigate the proteomic changes and mtDNA damage in the context of zinc deficiency-induced depressive disorder using a mouse model of stress. **Methods:** Male mice were fed either a standard diet (50 mg Zn/kg) or a zinc-deficient diet (3mg Zn/kg, ZnD) for 4 weeks. After one week, some mice from both groups were also subjected to chronic restraint stress (CRS) for 21 days. Bio-Plex Pro Mouse Cytokine 23-plex - Luminex multiplex technology was used to measure cytokine levels in the mouse prefrontal cortex (PFC), hippocampus (Hp), and serum. Proteomic analysis was performed using mass spectrometry to investigate protein alterations in the PFC and Hp. The LORD-Q PCR method was employed to assess mtDNA damage levels. **Results:** Our findings revealed numerous protein alterations in the PFC and Hp indicating disruptions in mitochondria and energy production, protein metabolism and translation, as well as RNA metabolism in the PFC. In the Hp, pathways related to mitochondrial function, axonal transport, mitochondria, energy production, GTPases of the Rho Family, and ATP synthesis showed differential regulation. The analysis of cytokine expression demonstrated increased levels of interleukin (IL)-5 (IL-5), granulocyte colony-stimulating factor (G-CSF), granulocyte-macrophage colony-stimulating factor (GM-CSF), and monocyte chemoattractant protein-1 (MCP-1) in the PFC of ZnD mice. In the Hp, ZnD + CRS resulted in altered expression of IL-3, IL-4, IL-6, IL-9, IL-10, IL-12p70, eotaxin, G-CSF, GM-CSF, macrophage inflammatory protein-1 beta (MIP-1B), tumor necrosis factor-alpha (TNF-alpha), and interferon-gamma (INF-gamma). Moreover, increased mtDNA damage was observed in the PFC suggesting a potential role of reactive oxygen species in ZnD-induced mitochondrial dysfunction. **Conclusions:** These findings highlight the critical role of zinc homeostasis in the pathophysiology of major depressive disorder and suggest potential implications for metabolic alterations and mitochondrial dysfunctions. Further research is necessary to elucidate the underlying mechanisms and develop targeted therapeutic interventions.

Title: Mice lacking GPR171 display alterations in mood in a sex dependent manner

Authors: *M. C. RADDATZ[1], C. PORTER[2], M. STOTT[1], E. BOBECK[1];
[2]Biol., [1]Utah State Univ., Logan, UT

Abstract: GPR171 is a recently de-orphanized G protein-coupled receptor whose biological functions are still largely unknown. Thus far, studies have revealed a positive correlation between eating behaviors and GPR171 activity, anxiolytic effects of GPR171 antagonism, and synergistic effects of morphine and GPR171 agonism in acute pain treatment. However, the research regarding GPR171 functions is incomplete, with a considerable degree of disparity and ambiguity in what is currently known. Additionally, all the research thus far completed on GPR171 has relied almost exclusively on exogenous ligands which are only relatively selective and are subject to unknown pharmacodynamics and pharmacokinetics. In order to directly determine the functions of GPR171 and its necessity in several behaviors, we conducted an extensive phenotypic characterization of a novel GPR171 knockout mouse model. GPR171 knockout (KO), heterozygous (HET), and wild-type (WT) mice of both sexes were subject to a behavioral battery assay including tests assessing physiological functions, anxiety, depression, and locomotion. GPR171 KO did not alter general feeding behaviors or feeding after fasting ($F(52,416) = 1.286$, $p = .41$) and did not significantly impact overall weight ($F(2, 52) = .56$, $p = .58$). However, GPR171 knockout did affect mood, with a significant effect of genotype on anhedonia measured in the sucrose preference test ($F(2, 52) = 6.85$, $p = .002$). Post-hoc analyses indicate that male GPR171 KO mice displayed increased anhedonia compared to HET and WT males ($p = .02$ and $p = .006$ respectively) while females were unaffected by genotype. Interestingly, the knockout of GPR171 also resulted in decreased anxiety-like behaviors as measured in the elevated plus maze ($F(2, 93) = 3.615$, $p = .03$), without affecting total locomotion ($F(2, 93) = 0.66$, $p = .5$). These results indicate that GPR171 is necessary for normal mood regulation, particularly in male mice, with much smaller effects in females, potentially representing sexually dimorphic receptor actions. While GPR171 was originally proposed to be a feeding receptor, our results indicate that it is not necessary for normal physiological functions, likely due to redundancy in feeding mechanisms. Together, our results expand on the known functions of GPR171 while exploring sex differences which have historically been overlooked. GPR171 not only serves as a viable target for pharmacological manipulation, but also as a potential biomarker for different disease states, particularly those involving mood dysregulation.

Title: Elevated MAOA and altered bioenergetics underlying elevated emotionality in depression

Authors: *R. ZHOU[1,2], R. LABEAU[3], R. C. LAISTER[4], J. H. MEYER[5,2], J.-P. GUILLOUX[3], T. TOMODA[5,2], E. SIBILLE[5,2];

Abstract: The Monoamine Oxidase A (MAOA) is an outer mitochondrial membrane protein that catalyzes the oxidative deamination of various monoamines, while producing hydrogen peroxide and electrons to fuel bioenergetic machinery in cells. In human brains, MAOA is widely expressed in both neurons and glia, and primarily responsible for metabolizing monoaminergic neurotransmitters, serotonin and norepinephrine, produced in the brain stem. Altered MAOA activity or expression levels in the brain are associated with changes in diverse behavioral traits, such as mood, cognition and personality, likely through deregulated monoaminergic neurotransmission. Notably, elevated MAOA expression in corticolimbic brain areas has been consistently reported in major depressive disorder (MDD) via positron emission tomography (PET) imaging studies. High MAOA level is thought to contribute to low brain serotonin levels and hence depressed mood, or resistance to conventional monoaminergic antidepressant treatments. However, the causal link of elevated MAOA to the pathobiology of MDD and/or treatment resistance has not been tested, and the mechanisms underlying these psychopathological conditions remain to be studied. To test this causality, we have developed a humanized model of elevated MAOA in mice, in which human *MAOA* gene is selectively expressed in relevant neuronal or glial cell types within corticolimbic areas, and studied the impacts on emotional behavior, neurochemistry and cellular functions, with particular emphasis on mitochondrial bioenergetic pathways. Current results show that the mice with increased MAOA expression in pyramidal cells of prefrontal cortex (PFC) exhibit elevated MAOA protein levels comparable to that seen in depression in PET studies, concurrent with reduced serotonin levels in PFC and altered emotional behavior. In addition, primary neurons and astrocytes with elevated hMAOA show reduced mitochondrial membrane potential, suggesting altered bioenergetics induced by MAOA expression. Studies are underway to further study the impact of elevated MAOA on mitochondrial functions (e.g., rate of ATP production, oxygen consumption rate, mitochondrial contents) using a series of functional tools, such as a redox-sensing probe, Seahorse ATP rate assays, pharmacological inhibitors for electron transfer complex components, along with the mitochondria-specific proteomic probes for proximity labeling. Through these studies, we aim to decipher the mechanisms mediating MAOA-induced bioenergetic and psychopathological consequences.

Title: Depletion of BLM-s causes decreased proliferation of adult neural progenitor cells at dentate gyrus by modulating cell cycle progression and mitochondrial dynamic

Authors: H.-R. LO[1], Y.-J. JHANG[2], C.-C. TSOU[2], H.-J. CHENG[1], ***P.-H. HUANG**[2]; [1]Inst. of Mol. Biol., Academia Sinica, Nankang, Taiwan; [2]Grad. Inst. of Pathology, Natl. Taiwan Univer, Taipei, Taiwan

Abstract: Mood disorders rank among the top ten causes of human disability and recent advances in genomic studies indicate that molecules involved in neurodevelopment are causally related to mood disorders. We have previously demonstrated that mice with null BLM-s (BCL-2 like molecule, small transcript isoform), a BH3-only apoptosis sensitizer/derepresser regulating apoptosis of postmitotic immature cortical neurons, exhibit depression and anxiety behaviors that is closely related with reduced dendritic complexity of hippocampal dentate gyrus (DG) granule cells and reduced ventral DG circuit connectivity (Huang et al. Transl Psychiatry 12:411, 2022). Our study of global *Blm-s*-KO mice and *Gli1::CreER^{T2};Blm-s$^{lox/lox}$;Rosa26R-CAG::tdTomato* mice further suggests that BLM-s deficiency results in decreased proliferation of adult DG neural stem cells (DG NSCs) in part via cell-autonomous interference with the activation and subsequent cell cycle progression of quiescent *Gli1*-responsive DG NSCs in adult mice. Via study of adult DG neurosphere cultured *in vitro*, we demonstrate that depletion of BLM-s causes prolonged G1-phase upon cell cycle progression in actively proliferating DG neurospheres. Additionally, adult *Blm-s$^{-/-}$* DG neurospheres harbor higher glycolytic flux, lower mitochondrial respiratory capability, and elevated intracellular reactive oxygen species (ROS) compared with wildtype DG neurospheres. The metabolic profile and mitochondrial morphology together suggest that BLM-s depletion confers DG NSCs in a more naïve primitive and inactivated RGL status.

Title: Mrgprb4-lineage Social Touch Somatosensory Neurons Engage a Skin-Brain Pathway Mediating Stress Resilience

Authors: *S. FULTON[1], M. SCHAFFLER[3], M. JOHNSON[5], B. W. HING[6], P. KAHLER[5], I. HULTMAN[5], S. SRIVASTAVA[5], J. ARNOLD[1], J. A. BLENDY[4], R. HULTMAN[5], I. ABDUS-SABOOR[2];

Abstract: Tactile interaction between social mammals is a naturally rewarding stimuli, motivating social bonding and other adaptive behaviors. Socially valanced touch can also have anxiolytic effects and has been shown to attenuate stress-related pathophysiology. Importantly, a lack of social tactile stimulation, particularly during early life, can induce neurobiological changes associated with mood disorders. However, the neuronal circuits by which social touch mediates stress resilience and affective states are unknown. We have previously characterized a genetically defined subpopulation of social touch-responsive somatosensory neurons in the mouse dorsal root ganglion, Mrgprb4-lineage neurons. We found that activation of Mrgprb4-lineage neurons stimulates dopamine release, promotes CPP, and facilitates normal mating behaviors in female mice. Thus, Mrgprb4-lineage neurons appear to be part of a rewarding skin-brain touch circuit, but it is still unknown if these neurons also play a role in the anxiolytic effects of social touch. Here, we use mouse genetics and targeted neuronal manipulations in combination with behavioral, electrophysiological, and molecular phenotyping to demonstrate a critical role for Mrgprb4-lineage touch neurons in stress resilience. We found that early-life ablation of Mrgprb4-lineage touch neurons increases vulnerability to subthreshold stressors in adulthood for both male and female mice, including an increase in anhedonia-like and despair-like behaviors. Multi-unit *in vivo* neurophysiological recordings across seven brain regions revealed that Mrgprb4-lineage neuron ablation induces a unique pattern of electrical activity at the network-level, characterized by altered modulatory interactions between the Basolateral Amygdala (BLA) and the mesolimbic reward pathway (e.g. NAc, VTA), as well as specific changes in VTA-NAc signaling. We next leveraged molecular profiling in these altered regions (BLA, NAc) to define the cell-type specific transcriptomic changes associated with developmental loss of Mrgprb4-lineage neuron input to the CNS. Finally, we show that Mrgprb4-lineage neuron activation attenuates HPA reactivity, highlighting the therapeutic potential of targeting this somatosensory population in stress-related psychiatric disorders. Together, our data demonstrate that Mrgprb4-lineage neurons mediate skin-brain communication pathways that are critically important to stress resilience phenotypes.

Title: Understanding the mechanisms of how a ketogenic diet might treat bipolar disorder

Authors: *M. TSYGLAKOVA, C. A. MCCLUNG;
Psychiatry, Univ. of Pittsburgh, Pittsburgh, PA

Abstract: Bipolar disorder is a common and debilitating mood disorder. It affects a person's mood, concentration and energy levels, and it is characterized by aberrant GABAergic and dopaminergic signaling, as well as mitochondrial dysfunction and oxidative stress. There is recent interest in the ketogenic diet as a treatment for bipolar disorder with small case study reports of efficacy. However, the neurobiological mechanisms by which ketone bodies might ameliorate symptoms of bipolar disorder are yet to be determined. Here we investigate whether a ketogenic diet rescues manic-like behavior in *Clock*Δ19 mice, a mouse model of bipolar mania, and whether it leads to changes in gene expression in the ventral tegmental area (VTA) of the brain. To investigate the effects of ketogenic diet on behavior, homozygous *Clock*Δ19 and wild type (WT) male and female mice (n = 8-10/treatment, sex, genotype group) were treated with regular chow or a ketogenic diet AIN-76A-Modifled (Bio-Serv S3666) for two weeks and then throughout behavioral testing. The behavior testing battery consisted of the following tests: locomotor activity, open field, dark/light box, elevated plus maze and forced swim test. Following testing, mice were sacrificed, brains were rapidly extracted and flash frozen, punches from the VTA were taken and RNA isolated for quantitative PCR analysis. Our results show that the ketogenic diet normalized the abnormally high novelty seeking behavior in female *Clock*Δ19 mice, with no effect in the males in the light dark box. In comparison the diet produced an antidepressant-like response in both males and females in the forced swim test. Interestingly ketogenic diet increased locomotor activity in female ClockΔ19 mice and male WT mice only. In addition, we found that ketogenic diet led to a significant decrease in *tyrosine hydroxylase* (a rate-limiting enzyme in dopamine synthesis) expression in *Clock*Δ19 mice, suggesting that the diet might reduce their aberrant hyper dopaminergic transmission. Our findings suggest that the ketogenic diet affects mouse behavior relevant to bipolar disorder and may reduce the hyper dopaminergic synthesis in the VTA of *Clock*Δ19 mice. Title: Divergent effects of mGlu3 receptor activation on meth-seeking and meth-induced working memory deficits in male and female rats

Authors: *R. CONRAD, C. MODRAK, P. HAMOR, L. WU, M. SCHWENDT;
Univ. of Florida, Gainesville, FL

Abstract: Chronic methamphetamine (meth) abuse is associated with a spectrum of neurobehavioral deficits, including changes to working memory (WM). Studies suggest that impaired cognition predicts a higher risk for relapse and worsens treatment outcomes in chronic meth users. Moreover, both the severity of cognitive impairment and the intensity of meth craving undergoes dynamic changes after discontinuation of meth use, bringing about a high-risk period for recovering meth users. Critically, while females tend to engage in more robust meth-seeking behavior than males, sex differences in meth-induced WM deficits are unclear, and the neurobiology underlying these behavioral deficits remains poorly understood. Here, we introduce a translational animal model that allows for the concurrent evaluation of post-meth WM performance and meth-seeking, along with the effects of mGlu3 glutamate receptor activation on these variables. mGlu3 is a viable target for intervention, as studies show that dysregulation of mGlu2/3 receptors is associated both with WM deficit and persistent drug-seeking. Male and female Sprague-Dawley rats were first trained on the operant delayed match-to-sample (DMS) task and tested for 10 days to establish baseline WM across a range of delays (0-24s). Rats then underwent 21 days of meth self-administration followed by ~7 weeks of homecage abstinence, during which DMS was re-tested. We found that a post-meth WM deficit coincided with robust meth-seeking as far as 12 days into abstinence, with females more severely impaired than males. Next, treatment of indirect mGlu3 agonist 2-PMPA (30 mg/kg, i.p) rescued WM impairment at long delays in a subgroup of the most severely-impaired rats. Conversely, acute 2-PMPA administration failed to alter cue/context-primed meth-seeking nor had any delayed effects on extinction learning or WM. Finally, under a condition of high WM demand (24s delay only), 2-PMPA treatment partially improved WM performance, motivating further investigation of acute pro-cognitive effects of mGlu3 activation and its underlying effects with respect to meth-seeking and post-meth cognitive changes while considering sex as a variable.

Title: Investigation of sex-specific and meth-seeking behaviors in rats with a history of predator scent stress.

Authors: *C. G. MODRAK, C. S. WILKINSON, L. KNACKSTEDT, M. SCHWENDT; Psychology, Univ. of Florida, Gainesville, FL

Abstract: Only a subset of trauma-exposed individuals go on to experience long-lasting behavioral impairments and receive a diagnosis of post-traumatic stress disorder (PTSD). Developing effective treatments for PTSD is complicated due to the heterogeneity of stress responses and comorbidity with other psychiatric disorders such as substance use disorder. As such, individual and sex-specific differences in stress responses have been observed in comorbid (and non-comorbid) populations, with females at a greater risk to develop PTSD after trauma exposure, and engaging in differential anxiety and fear-reactive behavior than males. Overall, PTSD patients are twice as likely to use methamphetamine (meth), and preclinical research shows that both early life stress and acute stress in adulthood augment meth-seeking, with females twice as likely to use meth with shorter abstinence periods. Unfortunately, animal research to date inadequately addresses the individual and sex-specific heterogeneity of stress responses. Thus, the present study sought to investigate the consequences of a trauma-like stressor on subsequent anxiety-like behavior and meth-seeking in male and female rats. Rats (n=40) were briefly exposed to either trimethylthiazoline (TMT) or a control scent (n=24) during the predator scent stress (PSS) task and evaluated for anxiety-like behavior one week later in the elevated plus maze (EPM) and acoustic startle response (ASR). Following re-exposure to the TMT context to assess conditioned fear response, rats underwent 21 days of meth self-administration, extinction training, and cue-primed reinstatement. Rats were perfused and evaluated for cFos expression throughout the prefrontal cortex, as prefrontal activation is linked to enhanced meth-seeking behavior. TMT-exposed rats exhibited elevated anxiety and fear behaviors as shown by increased freezing during re-exposure, hypolocomotion in EPM, and less time in the open arms during EPM compared to controls. This same group subsequently exhibited greater meth intake and significantly reinstated to meth-paired cues following extinction, suggesting elevated meth-seeking behaviors in response to stress. While there was no link between drug-seeking and cortical activity, there was a negative correlation between locomotion and time spent in the TMT quadrant during exposures and the prelimbic and infralimbic cortices, suggesting the possibility for a role of these regions in PSS-induced fear. Future directions are to use AI approaches to identify additional fear-reactive behaviors following PSS exposure.

Title: Role of the prelimbic cortex projection to the nucleus accumbens core in the reinstatement of cocaine-seeking

Authors: *J. MESA, L. KNACKSTEDT;
Univ. of Florida, Gainesville, FL

Abstract: The prelimbic (PL) cortex to nucleus accumbens core (NAc) pathway is strongly implicated in the reinstatement of cocaine-seeking. Pharmacological or optogenetic inhibition of this pathway attenuates reinstatement, and reinstatement is accompanied by release of glutamate into the NA core. The antibiotic ceftriaxone reliably reduces the reinstatement of cocaine-seeking and the release of glutamate into the NA core. However, the majority of cocaine users also consume alcohol and in a rodent model of cocaine-alcohol polysubstance use (PSU), we found that glutamate release in the NA core no longer accompanies cocaine-reinstatement and ceftriaxone is unable to attenuate reinstatement. Here we continue to probe the role of this pathway in mediating reinstatement. Expt. 1 utilized the retrograde tracer cholera toxin B in combination with c-Fos immunohistochemistry to determine whether ceftriaxone attenuates the activity of neurons projecting from the PL-NAc. Expt. 2 used chemogenetics to determine whether inhibition of the PL-NAc pathway attenuates reinstatement in PSU rats. Sprague Dawley rats underwent surgery for jugular catheterization and received either intra-NAc infusion of CTb, or AAV6-cre into the NAc and AAV2-hSyn-DIO-hM4D(Gi) into the PL cortex. Rats next underwent 12 days of cocaine intravenous self-administration (IVSA; 2 hr/day; 1 mg/kg/infusion) followed by 2 weeks of daily instrumental extinction training. A subset of rats received 2-bottle choice alcohol/water access (6 hr/day) in the home cage following daily cocaine IVSA sessions. Rats underwent a 2 hr cue-primed reinstatement test and were immediately perfused. Brains were dissected and the PL and NA core were sliced and stained for c-Fos. In Expt. 1, rats were treated with either ceftriaxone (200 mg/kg IP) or vehicle for 5-7 days prior to reinstatement testing. We found that ceftriaxone attenuated cue-induced reinstatement but did not alter c-Fos expression in prelimbic cortex neurons overall and in those that project to the NA core. Expt. 2 data analysis is ongoing. The current results indicate that inhibition of neurotransmission along the PL-NAc pathway is not necessary to attenuate cocaine seeking in rats that consume cocaine alone.

Title: Behavioral economic analysis of oxycodone-THC co-use in a rat model

Authors: *K. DRIVER[1], C. JONES-GOUCHER[1], A. SANCHEZ[1], B. SETLOW[2], M. SCHWENDT[1], L. A. KNACKSTEDT[1];
[1]Psychology, [2]Dept. of Psychiatry, Univ. of Florida, Gainesville, FL

Abstract: Opioid use disorder (OUD) lacks an effective, broad-spectrum treatment. Limited clinical evidence suggests that co-use of cannabinoids can reduce the rates of opioid dependence and severity of withdrawal, but potentially increases anxiety. Despite poor understanding of risks and benefits of opioid-cannabinoid interactions, OUD is currently considered a qualifying condition for the use of medical cannabis in several US states. Thus, well-controlled, translational animal models are necessary to investigate the neural and behavioral consequences of cannabinoid-opioid co-use. The current study investigated the effects of daily oral Δ9-tetrahydrocannabinol (THC) consumption on behavioral economic demand for intravenously self-administered (IVSA) oxycodone in male and female Sprague-Dawley rats. Rats were first trained to self-administer IV oxycodone or oral sucrose under a FR (fixed ratio)-1 schedule for 6 days followed by a FR-3 schedule for 6 days. After reaching stable intake during training, rats began economic demand procedures in which the FR requirement to earn a reinforcer was increased in quarter log unit increments on successive days until zero reinforcers were attained for a given FR. Throughout the demand procedures, rats also received access to unsweetened gelatin containing either THC or vehicle in the home cage for one hour following the oxycodone/sucrose session. Somatic signs of withdrawal were assessed, and the light-dark box test was used to assess anxiety-like behavior at 22 hr withdrawal. Following completion of economic demand procedures, self-administration at FR-3 was re-established prior to 14 days of home cage abstinence. On Day 15 of abstinence, rats underwent a cue-primed relapse test. Brains were collected to assess levels of mu opioid and CB1 cannabinoid receptor phosphorylation in select regions in response to an acute oxycodone challenge. No effects of sex were observed on oxycodone self-administration. THC consumption led to increased demand elasticity (i.e. reduced seeking upon FR increases) for oxycodone IVSA and decreased cue-primed relapse, with no effects on sucrose intake or somatic signs of withdrawal. The findings of this study provide first-ever preclinical evidence regarding the effects of THC on motivation to seek oxycodone, as well as assessment of corresponding receptor activity changes.

Title: Oxytocin reduces alcohol intake in a model of alcohol+opioid polysubstance use

Authors: *T. D. THOMPSON[1], C. S. WILKINSON[1], C. M. MODRAK[1], R. CONRAD[1], I. LEON[2], L. A. KNACKSTEDT[1];
[1]Univ. of Florida, Gainesville, FL; [2]San Diego State Univ., San Diego, CA

Abstract: Over two million Americas have both alcohol use disorder (AUD) and an illicit drug use disorder; 24.2% of those who misuse opioids report an AUD diagnosis. The neuropeptide, oxytocin, shows promise as a treatment for alcohol use disorder (AUD). Humans with AUD treated with intranasal oxytocin decrease alcohol craving, withdrawal, and intake; and preclinical research in rodents show oxytocin decreases alcohol intake. It is unknown whether oxytocin can reduce alcohol intake in the context of alcohol+opioid polysubstance use (PSU). To begin to examine this, and to determine the neurocircuitry of oxytocin's effects on alcohol intake with a focus on the basolateral amygdala (BLA), we developed a rodent model of oral alcohol+oxycodone PSU. Forty Sprague Dawley rats (half female) were assessed for baseline anxiety-like behavior on the elevated plus maze (EPM) and acoustic startle response (ASR) task, implanted with cannula in the BLA, and then divided into three groups based on future drug condition: alcohol-only (n = 16), oxycodone-only (n = 8) or PSU (n = 16). Rats that would later comprise the oxycodone-only and PSU groups were given daily 2-bottle choice (2-BC) access to an oxycodone solution (0.1 mg/ml) and water or water only for 6 hrs/day for 7 days. Next, a subset of rats that would later comprise the alcohol-only and PSU groups received intermittent access to alcohol (IAA) where rats received 2-BC access to alcohol (20% v/v) and water for five 24 hr periods separated by 24 hrs with no access. Next, PSU rats underwent 12 days of PSU sessions where they received 2-BC access to oxycodone and water for 3 hrs followed by 6 hrs 2-BC for alcohol and water. Monosubstance conditions continued to receive access to either oxycodone or alcohol according to the same timing. Oxytocin (0 or 1 mg/kg, IP or 0.6 nmol/0.25uL/side, intra-BLA) was administered 30 minutes prior to alcohol access on test day. Mean startle positively correlated with oral oxycodone intake. Oxycodone access, both prior to IAA and on the same day in PSU sessions, increased alcohol intake. Systemic oxytocin decreased alcohol consumption in single and polysubstance rats relative to basesline alcohol consumption. These results implicate baseline anxiety increases susceptibility to oxycodone and suggest oxytocin will remain effective in polysubstance users.

Title: Sex-specific effects of predator scent stress on oxycodone self-administration

Authors: *C. S. WILKINSON[1], S. BHUTANI[2], M. SCHWENDT[1], L. A. KNACKSTEDT[1]; [1]Psychology Dept., [2]Univ. of Florida, Gainesville, FL

Abstract: Post-traumatic stress disorder (PTSD) is often comorbid with substance use disorder (SUD). Animal models of psychiatric disorders are critical for the uncovering of relevant neurobiology. A widely used rat model of PTSD exposes outbred rats to predator scent stress once for 10 minutes and, weeks later, evaluates fear and anxiety-like behavior. Reliably, only a subset of rats show long-term susceptibility to such stress, and in our prior work, we found that susceptible rats displayed increased cocaine-seeking. The present study sought to use the same model to investigate the relationship between stress susceptibility and opioid-seeking. Eighty-four Sprague Dawley rats (half female) received a single 10-minute exposure to the fox pheromone 2,5-dihydro-2,4,5-triethylthiazoline (TMT) or unscented control condition in an inescapable chamber. Seven days later, rats were assessed for anxiety-like behavior using the acoustic startle response and elevated plus maze (EPM). Rats were implanted with jugular catheters and underwent self-administration of intravenous oxycodone (0.1 mg/kg/infusion) for 6 days on a fixed ratio-1 (FR-1) schedule of reinforcement followed by 6 days on an FR-3 schedule. Rats underwent extinction training and a single cue-primed reinstatement test. Tail blood was collected immediately before and after TMT/control exposure and after the reinstatement test for quantification of corticosterone (CORT) concentrations. TMT-exposed rats increased freezing during exposure and decreased time spent in the open arms of the elevated plus maze one week later. Female TMT-exposed rats decreased active lever presses for oxycodone and oxycodone intake compared to controls, while male TMT-exposed rats did not differ from controls. Corticosterone release was protective against anxiety-like behavior but was not related to the reinstatement of oxycodone-seeking. These findings indicate a sex-specific effect of stress on subsequent motivation to seek oxycodone and further analysis will elucidate the role of corticosterone and neuronal activation in these effects.

Title: Evaluation of cannabidiol’s effects on oxycodone-induced antinociception and reward-related behavior

Authors: *A. C. BRICE-TUTT[1], W. MALPHURS[1], A. BEHNOOD-ROD[1], A. S. SENETRA[2], R. M. CAUDLE[3], M. FEBO[4], A. W. BRUIJNZEEL[5], A. SHARMA[2], B. SETLOW[5], N. P. MURPHY[1], J. K. NEUBERT[1];

Abstract: We evaluated the effect of chronic treatment with cannabidiol and oxycodone, alone or in combination, on pain- and reward-related behavior in male and female rats (N = 8-10/treatment/sex). Rats were trained to consume sweetened condensed milk solution under painful (44.5°C) and non-painful (37°C) conditions in an operant pain assay. They were then treated daily for 14 days with oxycodone (0.56 mg/kg, i.p.), cannabidiol (3.2 and 10 mg/kg, i.p.), or cannabidiol + oxycodone combinations, and operant pain responding was evaluated. Rearing behavior was also recorded to assess development of behavioral sensitization. Oxycodone alone increased operant responding in a sex- and temperature-dependent manner. Neither dose of cannabidiol alone altered responding. Combined with oxycodone, however, cannabidiol dose-dependently increased the effect of oxycodone only at the nociceptive (44.5°C) temperature. Oxycodone also produced locomotor sensitization, which was neither attenuated nor potentiated by cannabidiol. In a separate study, rats conditioned with oxycodone in a conditioned place preference paradigm developed a significant preference for the oxycodone-paired chamber, an effect that was not impacted by combination with cannabidiol during conditioning. These results suggest that while devoid of inherent analgesic and rewarding effects, cannabidiol potentiates the antinociceptive effects of oxycodone without affecting its rewarding properties under these experimental conditions. As such, cannabidiol may be useful as an opioid-sparing approach to treat pain.

Title: The effects of sex and orbitofrontal cortex inhibition on cocaine-seeking in a voluntary abstinence model

Authors: *C. JONES-GOUCHER, L. A. KNACKSTEDT;
Univ. of Florida, Gainesville, FL

Abstract: Contingency management uses non-drug reinforcers to facilitate abstinence from drugs of abuse, effectively reducing drug seeking. Once discontinued, drug seeking often resumes. An animal model of contingency management is the voluntary abstinence model, in which after several weeks of intravenous drug self-administration, animals are provided a choice between drug and palatable food reinforcement in discrete trials. Voluntary abstinence produces a decrease in drug seeking that does not persist when access to palatable food is removed. Using such a model with male rats, we previously found that sucrose availability leads to a decrease in, but not cessation of, cocaine seeking and a differential relapse-induced c-Fos expression such that voluntary abstinence results in greater relapse-induced Fos expression in the ventral orbitofrontal cortex (vOFC). Here we sought to extend these findings to female rats and test the necessity of the vOFC in relapse, using intra-OFC AAV8-hSyn-hM4D(Gi)-mCherry or control AAV8-GFP vector and systemic DCZ administration. Male and Female Sprague-Dawley rats (n=50, half male) first self-administered sucrose pellets for five days and then intravenous cocaine for 12 days. Rats then underwent 14 days of voluntary abstinence during which time rats had the opportunity to choose between sucrose and cocaine reinforcement in discrete trials (20 trials/3 hr session). Next, a relapse test was conducted during which time only the cocaine-paired lever was available and delivered cocaine-paired cues. Both males and females exhibited greater choices on the cocaine lever during early abstinence than late abstinence, with the sucrose lever representing more than 50% of choices by Day 6. However, by Day 14, group-level analysis finds that male and female rats continued to choose the cocaine lever during 35% of trials. In the last five days of voluntary abstinence, 35% of females and 39% of males continued to choose the cocaine lever on the majority of trials. There were no sex differences in the number of presses on the cocaine lever during the relapse test. Analysis of vOFC inactivation and cortical c-Fos expression is ongoing. These results extend the use of the voluntary abstinence model to female rats and will potentially shed light into the role of the vOFC in relapse both sexes.

Title: Simultaneous intravenous cocaine and alcohol self-administration alters the motivation to seek cocaine and associated neurobiology

Authors: *A. SANCHEZ[1], C. JONES-GOUCHER[2], J. R. MESA[3], L. B. COTTLER[1], M. SCHWENDT[3], B. SETLOW[3], L. A. KNACKSTEDT[3];
[1]Univ. of Florida, Gainesville, FL; [2]Home, Univ. of Florida, Celebration, FL; [3]Univ. of Florida, Univ. of Florida, Gainesville, FL

Abstract: An estimated 60-90% of cocaine users also use alcohol, but animal models of such polysubstance use (PSU) are lacking. In a recent epidemiological study from our research group, cocaine users reported using the two drugs simultaneously, for several hours at a time, approximately 7 days/month. Here we back-translated this real-world pattern of human PSU into a rat model of simultaneous cocaine+alcohol self-administration, to investigate the neurobiology of drug seeking in a PSU condition. Male and female Sprague-Dawley rats underwent intravenous self-administration (IVSA) of cocaine alone (n=24) or a cocaine+alcohol solution (n=25) for 2 hr/day for 5 consecutive days, then 6 hr/day, 2 days/week, for 5 weeks. Two doses of cocaine were tested (0.25 and 0.5 mg/kg/infusion) with and without alcohol (12.5 or 25 mg/kg/infusion). Control rats received yoked-saline infusions. At the conclusion of IVSA, rats were tested on a progressive ratio schedule for 2-3 days, followed by tests for cued cocaine-seeking (relapse) at 1 and 30 days of abstinence. Brains were collected and processed for fluorescent *in situ* hybridization for c-fos and dopamine 2 (D2) receptor mRNA expression. For the low dose of cocaine, the addition of alcohol to the intravenous solution had no effect on cocaine intake during self-administration, breakpoint for self-administration, or cued relapse after 30 days of abstinence. For the high dose of cocaine, the addition of alcohol to the intravenous solution resulted in increased cocaine intake during self-administration, increased breakpoint for self-administration, and increased cued relapse after 1 day of abstinence, with no sex differences observed. C-fos mRNA expression in both D2-positive and -negative cells was increased relative to yoked controls following the cued relapse test in the cocaine-only and cocaine+alcohol condition in the nucleus accumbens core and shell. In the prelimbic (PL) cortex, however, the number of c-fos/D2-positive cells was greater in the cocaine+alcohol condition relative to the cocaine-only condition. Current work is quantifying dopamine release in the PL and nucleus accumbens following intravenous cocaine and cocaine+alcohol administration. In conclusion, simultaneous cocaine+alcohol self-administration increases cocaine intake and the motivation to seek drug and drug-associated cues in a dose-dependent manner, with a possible role for dopamine signaling in the PL.

Title: Effects of concurrent cannabis on cocaine use and relapse in Sprague Dawley rats

Authors: *K. M. GONZALEZ[1,2], T. N. THOMSON[3,2], M. L. HALCOMB[3,2], L. B. COTTLER[4,2], L. A. KNACKSTEDT[5,2], B. SETLOW[3,2];

Abstract: Polysubstance use (PSU), or the ingestion of multiple drugs of abuse within a defined period, is inarguably commonplace, with cannabis and cocaine being one of the most prevalent drug combinations. To better understand this phenomenon, we developed a rodent model of cocaine + cannabis use based on the most common patterns of human PSU determined as part of a collaborative NIDA-funded project with UF epidemiologists. Thirty-two male and female Sprague Dawley rats (10 wks.) were implanted with chronic indwelling jugular catheters and received 3 days of either cannabis smoke, placebo smoke, or clean air exposure before undergoing 3 days of training in intravenous (IV) cocaine self-administration (SA) for 3 hours/day at a dose of 0.5 mg/kg/infusion, with each infusion accompanied by an audiovisual cue. Following these 3 days of baseline cocaine intake, they resumed exposure to cannabis smoke, placebo smoke, or clean air for 5 hours/day, 5 days/week for 5 weeks. During this time, rats continued to undergo cocaine SA sessions 1 day/week, immediately following exposure to smoke or clean air. All rats then underwent a 30-day abstinence period in which they were left undisturbed in their home cages, followed by a cued cocaine relapse test. During the 3 days of IVSA training, rats previously exposed to cannabis smoke self-administered more cocaine than controls, a pattern that reversed when cannabis exposure immediately preceded IVSA sessions. During the cued relapse test session, the cannabis smoke group exhibited elevated cocaine-seeking compared to the two control groups. Overall, the results show that although cannabis co-use attenuates cocaine intake acutely, it produces heightened cocaine seeking when cannabis is not onboard, both during self-administration and cued relapse. These findings emphasize the importance of working with animal models that reflect real-world combinations and patterns of drug intake.

Title: The role of dopamine and glutamate mediating sex differences in oxytocin's effects on intravenous oxycodone demand

Authors: *H. L. BLOUNT[1,2], C. S. WILKINSON[1,2], A. SANCHEZ[1], T. D. THOMPSON[1], M. SCHWENDT[1,2], L. A. KNACKSTEDT[1,2];
[1]Psychology, Univ. of Florida, GAINESVILLE, FL; [2]Ctr. for Addiction Res. and Educ., Gainesville, FL

Abstract: Oxytocin is an emerging treatment for a variety of neuropsychiatric disorders, including substance use disorders. Previously, our lab has found that systemic and intra-accumbal oxytocin decreases cocaine cue-primed reinstatement, via a mGlu2/3 receptor-dependent mechanism. Further, we have found that systemic oxytocin produces dopamine and glutamate efflux in the nucleus accumbens core (NA core) of cocaine-experienced male rats but only increases glutamate, and not dopamine, efflux in cocaine-experienced females. Here we assess the effects of chronic, systemic oxytocin on economic demand for intravenous oxycodone in male and female rats. Male (n=25) and female (n=25) Sprague Dawley rats were implanted with jugular catheters. A subset received bilateral microdialysis cannulae aimed at the NA core. Rats were trained to self-administer intravenous oxycodone (0.4 mg/kg/infusion for males; 0.32 mg/kg/infusion for females) for 3 hr/day on FR-1 for 6 days then FR-3 for 6 days. Rats then began economic demand procedures in which the FR requirement to earn a reinforcer was increased in quarter log unit increments every second day until zero reinforcers were attained for a given FR. Rats were treated with oxytocin (1 mg/kg, IP) or vehicle (saline) prior to demand sessions. In a subset of rats, microdialysis was conducted after reaching FR-18. During microdialysis procedures, rats were unilaterally probed with a microdialysis cannulae and baseline samples were collected for two hours, followed by oxytocin (1 mg/kg IP). Thirty minutes later, intravenous oxycodone (1 mg/kg) was administered and samples collected for 3 more hours. HPLC was conducted to determine glutamate and dopamine content. We found that in males, but not females, chronic oxytocin increases demand elasticity (alpha) to self-administer oxycodone. Also in males, oxytocin reduces P_{max}, or the maximum price (FR) rats are willing to "pay" for intravenous oxycodone. Analysis of the effects of oxytocin on NA core dopamine and glutamate efflux may explain the sex-difference in oxytocin's effects on oxycodone demand. These data provide further evidence that oxytocin is effective at reducing drug-seeking, but indicate important sex differences in its ability to do so in the context of opioid-seeking.

Title: Local infusion of the D3 receptor agonist pramipexole into the prelimbic cortex reduces sucrose self-administration in male rats.

Authors: *D. GONZALEZ, F. J. CANO, H. UDAYASHANKAR, V. K. DANG, K. K. SZUMLINSKI;
UC Santa Barbara, Santa Barbara, CA

Abstract: High sugar consumption activates the mesocorticolimbic dopamine system resulting in an increase in extracellular dopamine at various terminal regions in the brain, including the prefrontal cortex (PFC). Despite this, relatively little is known regarding the functional relevance of specific dopamine receptor subtypes within the PFC in regulating the rewarding and reinforcing properties of sugars or other palatable foods. Herein, we employed classic neuropharmacological approaches to bi-directionally regulate the function of dopamine D1 and D3 receptors within the medio-dorsal aspects of the PFC and examine for effects on the self-administration of sucrose. For this, adult male Sprague-Dawley rats were trained to lever-press for delivery of 45 mg banana-flavored sucrose pellets for 2 h/day until responding stabilized. Using a within-subjects, semi-randomized design, rats were microinjected with vehicle (VEH) or the following dopaminergic compounds: the D1 receptor agonist A-6890, the D1 receptor antagonist SCH 23390, the D3 receptor agonist pramipexole and the D3 receptor antagonist NG 2904 (each at 10 µg/side). Two-three days were allowed between microinjections to examine for carry-over effects. Of all the compounds tested, only the infusion of the D3 receptor agonist pramiprexole reduced sucrose reinforcement and intake. This pramiprexole effect was apparent in rats in which the prelimbic subregion of the PFC was targeted, with no effects observed in rats with the more dorsal anterior cingulate subregion targeted. Our results do not support a major role for D1 receptor activation within either the prelimbic or anterior cingulate cortices in gating sucrose reinforcement. Further, our results indicate an active, inhibitory, role for D3 receptors selectively within the prelimbic cortex in sucrose reinforcement. This latter finding aligns with the purported inhibitory effects of D3 receptor agonists on the self-administration of drugs of abuse, arguing a key role for prelimbic D3 receptors in regulating the reinforcing properties of both drug and non-drug/food rewards of relevance to the potential therapeutic utility of D3 receptor-selective agonists and partial agonists for the treatment of over-eating and food-craving disorders and the potential off-target effects of such compounds during the treatment of substance use disorders.

Title: Sucrose intake and craving is dissociated from mTOR activity or expression within the PFC

Authors: *F. J. CANO[1], C. J. E. DENNING[2], V. K. DANG[2], H. UDAYASHANKAR[2], D. GONZALEZ[3], K. MOHAMMADI[2], K. K. SZUMLINSKI[2];
[1]Psychological and Brain Sci., Univ. of California Santa Barbara, Goleta, CA; [2]Psychological and Brain Sci., Univ. of California Santa Barbara, Santa Barbara, CA; [3]Psychological and Brain Sci., UC Santa Barbara, Santa Barbara, CA

Abstract: The similar temporal profile of incubated food- vs. drug-seeking posits that these behavioral phenomena may involve common, time-dependent, biochemical adaptations within neural circuits governing motivated behavior. Notably, Everolimus, an FDA-approved mTOR inhibitor, dose-dependently blocks incubated cocaine-seeking during late withdrawal and this anti-incubation effect is associated with a reversal of withdrawal-induced protein changes in the prelimbic (PL) subregion of the prefrontal cortex. Herein, we conducted a series of studies to examine the relationship between mTOR activity and measures of sucrose reinforcement in adult Sprague Dawley rats. For the first study, male and female Sprague Dawley rats were trained to self-administer 45 mg of banana-flavored sucrose pellets for 6 h/ day for 10 days and then were gavage infused with either vehicle (VEH) or the maximally effective Everolimus dose from our published cocaine study (1.0 mg/kg), prior to a test for cue-reinforced responding on withdrawal days (WD) 1 or 30. Immunoblotting was then conducted to examine for Everolimus' effects on mTOR activation within PL and infralimbic (IL) PFC subregions. As mTOR is upregulated by simple sugars, a distinct cohort of male Sprague-Dawley rats were trained to lever-press for the same sucrose pellets for 2 h/day until responding stabilized, at which point, bi-lateral microinjections of VEH or Everolimus (100 ng/side) into the dorsomedial aspect of the prefrontal cortex were performed to examine for effects of local mTOR inhibition on sucrose intake. Despite lowering phospho-mTOR levels within the IL, Everolimus gavage infusions did not alter the magnitude of incubated sucrose-seeking exhibited by either male or female rats, relative to early withdrawal controls. Microinjections of Everolimus into the PL or the more dorsal anterior cingulate also did not change sucrose intake, relative to an infusion of vehicle. These findings indicate that, unlike incubated cocaine-craving, incubated sucrose-craving is not correlated with elevated mTOR activity within prefrontal cortex subregions, nor does it require mTOR activation to manifest. Likewise, mTOR activity within the PL and anterior cingulate does not impact sucrose intake. These data indicate that the incubation of drug- and sucrose-seeking involve distinct molecular adaptations within the prefrontal cortex. Related to this, our data to date indicate negligible off-target effects of both systemic and intracranial Everolimus on the consumption of palatable food of relevance to its side-effect profile in the treatment of cocaine use disorder.

Title: A relatively brief history of oral methamphetamine self-administration is sufficient to induce some signs of negative affect: relation to mGlu1 receptor activity within vPFC

Authors: C. J. E. DENNING[1], R. A. CABRERA[1], L. E. MADORY[1], J. N. HERBERT[1], *K. SZUMLINSKI[2];
[1]Univ. of California, Santa Barbara, Santa Barbara, CA; [2]Univ. California-Santa Barbara, Santa Barbara, CA

Abstract: Anxiety is one of the most common comorbid neuropsychiatric conditions with methamphetamine (MA) use disorder and the abrupt discontinuance of MA following chronic exposure induces withdrawal symptoms in humans consisting of depression and anxiety. As negative emotional states can drive drug-seeking and relapse, we are working to develop procedurally facile mice model of high-dose oral MA self-administration to examine the effects of a relatively brief history of oral MA upon brain and behavior. For this, adult male and female C57BL/6J (B6) mice were trained to orally self-administer water or one of three MA concentrations (0.8, 1.6 and 3.2 g/L) under a fixed ratio 1 reinforcement schedule for 1 h/day for 7 consecutive days. Then, mice were subjected to a 1-day behavioral test battery for negative affect. Immunoblotting was then conducted on tissue from ventral and dorsal prefrontal cortex (vPFC and dPFC). Females consumed more MA than and males and mice of both sexes consumed equivalent amounts of MA from the 1.6 and 3.2 g/L solutions. A prior brief history of 3.2 g/L significantly elevated the number of marbles buried and reduced the number of exploratory dips in the elevated plus-maze exhibited by both male and female mice, but also increased the number of entries into the open arms. The 3.2 g/L MA concentration also increased the latency of females to first enter the light-side of the light-dark shuttle box. A less statistically robust effect of the 3.2 g/L MA concentration was detected for the number of novel object contacts. No MA effects were detected for acoustic startle, while a prior history of 1.6 g/L MA reduced the expression of active coping (i.e., swimming) in the forced swim test. Immunoblotting detected a significant increase in mGlu1 expression within the vPFC of mice with a history of 1.6 g/L MA, with a less robust increase observed also in mice with a history of 3.2 g/L MA. No changes in mGlu1 were detected in the dPFC. As mGlu1 antagonists can exert anxiolytic effects, we conducted a pilot study in MA-experienced mice (7 days of 3.2 g/L MA) in which mice were pretreated systemically with 5 mg/kg of the mGlu1 antagonist JNJ16259685 30 min prior to anxiety testing. The JNJ compound reduced the number of marbles buried by MA-experienced mice but did not alter behavior in the light-dark box or elevated plus-maze. Taken together, these data indicate that a relatively brief history of oral MA is sufficient to induce some signs of anxiety-like behavior during early withdrawal that may reflect, at least in part, a MA-induced increase in mGlu1 receptor activity within vPFC.

Title: Cocaine-craving elicited by extended-access self-administration procedures is dissociated from changes in PFC AMPA and NMDA receptor expression

Authors: *L. L. HUERTA SANCHEZ, H. H. T. DOAN, S. V. VO, M. G. TADROS, T. L. LI, P. B. JAMES, K. K. SZUMLINSKI;
UC Santa Barbara, Santa Barbara, CA

Abstract: The incubation of craving is a term coined to describe a behavioral phenomenon wherein cue-elicited craving intensifies during drug abstinence. Our laboratory has previously demonstrated an increase in extracellular glutamate within the medial prefrontal cortex (mPFC) in rats that exhibited an incubation of craving, which is theorized to activate AMPA and NMDA ionotropic glutamate receptors (iGluRs). However, the role for iGluRs within mPFC subregions in regulating incubated cocaine-craving is unexplored. As a first step towards this understanding, we examined for AMPA and NMDA receptor subunit expression in rats expressing incubated cocaine-seeking following two different short-access self-administration procedures and failed to detect any cocaine-related changes in iGluR subunit expression. To determine whether our prior negative results reflected the amount of cocaine experience of the rats, the present study examined for iGluR changes within the mPFC following a long-access cocaine self-administration procedure more typical of incubated cocaine-craving studies. For this, adult, male, Sprague-Dawley rats were trained to self-administer IV cocaine for 6-hr/day for 10 days where each cocaine delivery was paired with light-tone stimulus complex. Then, at 3 or 30 days withdrawal, rats underwent a 2-hr cue test for cue-reinforced responding and tissue from the prelimbic cortex (PL) and infralimbic cortex (IL) was collected for immunoblotting for AMPA and NMDA receptor subunits. While our long-access self-administration procedures did elicit incubation of craving, we detected no changes in AMPA or NMDA subunit expression either subregion of the mPFC using our conventional immunoblotting procedures. While these results indicate that the incubation of cocaine-craving is dissociated from changes in the total protein expression of iGluR, they do not preclude the possibility that incubated cocaine-craving is associated with an intracellular redistribution of AMPA and/or NMDA receptor subunits and/or post-translational modifications of specific receptor subunits that influence the functional status of iGluR receptors within PFC subregions to impact the magnitude of cue-elicited cocaine-craving.

Abstract: A relatively brief history of oral methamphetamine self-administration is sufficient to impair reversal learning in C57BL/6J mice and lower vPFC expression of NMDA receptor subunits.
R.A. Cabrera, C.J.E. Denning, J.N. Herbert, K.K. Szumlinski
Methamphetamine (MA) use disorder is characterized by cognitive impairments that impede treatment prognosis and recovery. In humans with MA use disorder, cognitive dysfunction is theorized to reflect glutamate-related neurotoxicity within frontal cortical regions. However, relatively little is known regarding the psychobiological consequences of subchronic MA exposure, more typical of recreational MA use. To that end, we worked to develop a mouse model of high-dose oral MA self-administration under operant-conditioning procedures to examine the effects of a relatively brief history of oral MA upon brain and behavior. For this, adult male and female C57BL/6J (B6) mice were trained to orally self-administer water or one of three MA concentrations (0.8, 1.6 and 3.2 g/L) under a fixed ratio 1 reinforcement schedule for 1 h/day for 7 consecutive days. Then, spatial learning and memory were determined in a Morris water maze, followed by testing for reference and working memory in a water version of the radial arm maze. Immunoblotting was then conducted on tissue from ventral and dorsal prefrontal cortex (vPFC and dPFC) for glutamate receptor expression. Females consumed more MA than and males and mice of both sexes consumed equivalent amounts of MA from the 1.6 and 3.2 g/L solutions. No effects of MA were detected for our measures of visually cued spatial navigation, spatial learning or memory in the Morris water maze. However, females with a history of 3.2 g/L MA exhibited deficits in reversal learning upon platform relocation. In the radial arm maze, mice with a history of 1.6 g/L MA exhibited more working memory incorrect errors and more “chaining” (a non-spatial navigation strategy). Immunoblotting revealed significantly lower expression the obligatory GluN1 subunit of the NMDA receptor in the vPFC.

These data indicate that a relatively brief history of oral MA is sufficient to induce some signs of cognitive dysfunction that may reflect impaired NMDA receptor function within vPFC. Funding provided by NIDA grant R01 DA053328.

Title: Sex differences in oxycodone self-administration after PKMζknockout

Authors: *A. KNIFFIN[1], M. KNOUSE[1], M. NENOV[1], L. BIRMINGHAM[2], L. A. BRIAND[3]; [2]Psychology & Neurosci., [3]Psychology and Neurosci., [1]Temple Univ., Philadelphia, PA

Abstract: Opioid addiction is increasingly prevalent and characterized by high rates of relapse and subsequent drug induced overdose. Although currently males exhibit higher rates of opioid use disorder and drug overdose, the gender gap is closing, with females exhibiting faster transition from use to abuse. As the patterns of use and abuse exhibit sex differences, understanding how opioid exposure impacts the underlying neurobiological systems in both males and females is critical. The constitutively active form of protein kinase C, PKMζ, is exclusively expressed in the brain and is increased after exposure to opioids. In the absence of PKMζ, mice consume more alcohol and engage in higher rates of cocaine seeking. However, it is not known whether PKMζ plays a role in opiate reward. Therefore, in the current experiments we examined the effect of constitutive PKMζ deletion on oxycodone self-administration in both sexes. At the 0.25mg/kg/inf dose of oxycodone, both male and female mice exhibit an increase in oxycodone taking on an FR1 schedule of reinforcement, while only male mice appear to exhibit an increase in motivation for oxycodone on a progressive ratio schedule. In contrast, at the 0.125mg/kg/inf dose, only female mice exhibit an increase in both oxycodone taking and seeking. Taken together, these data suggest that PKMζ deletion leads to dose- and sex-dependent alterations on oxycodone self-administration. Slice electrophysiology studies are underway to examine how PKMζ deletion impacts synaptic plasticity within the prefrontal cortex in both drug-naïve and oxycodone-experienced mice.

Title: Adolescent social isolation leads to sex-specific increases in microglia proliferation in the reward system of adult mice.

Authors: *B. RHOADS, M. PINIERO, B. ARMSTRONG, N. STOREY, A. MCGRATH, L. BRIAND;
Temple Univ., Philadelphia, PA

Abstract: Adolescence is a critical developmental period during which insults can have persistent effects on mental and physical health. The absence of social reward during adolescence can lead to widespread neuronal alterations, impacting behavior and brain function. Social isolation during adolescence increases the motivation for cocaine and leads to structural and synaptic plasticity within the reward system. As both stress and drugs of abuse have been shown to influence microglia and microglia play a critical role in plasticity, we hypothesized that adolescent social isolation would impact microglia in the reward system. The goal of this study was to analyze the impact of adolescent social isolation stress on microglia proliferation and morphology. Male and female C57/Bl6J mice were either socially isolated or group housed at weaning (PND21) and remained in these housing conditions until adulthood. At PND63-105, mice were euthanized, and brains were collected for immunohistochemical analysis of the microglial marker, Iba1, within reward-related brain regions. Results from whole cell count analysis revealed a sex-specific effect of social isolation on microglia proliferation across brain regions in the limbic system. Specifically, socially isolated male mice exhibited increased microglia cell counts across the prefrontal cortex, nucleus accumbens, hippocampus, and basolateral amygdala. No significant effect of social isolation was seen in female mice. Analysis of non-limbic regions is ongoing, but preliminary analysis of microglia cell counts in the barrel cortex suggests the increase in microglia proliferation may be brain wide. Additional studies are being conducted to determine the impact of adolescent social isolation on microglial morphology using confocal microscopy and IMARIS imaging software. Overall, it was seen that there are sex-specific alterations in microglia proliferation across all brain regions studied with socially isolated males demonstrating an increase in microglia cell counts as compared to all other conditions.

Title: Sex differences in nucleus accumbens synaptic plasticity: involvement of PKMζ

Authors: *M. NENOV, M. C. KNOUSE, L. A. BRIAND;
Psychology and Neurosci., Temple Univ., Philadelphia, PA

Abstract: The nucleus accumbens (NAc) is part of the corticolimbic reward system. Impairments in NAc circuits are associated with development of various psychiatric disorders including substance use disorder, depression, and anxiety. Epidemiological sex differences in these disorders are well characterized and understanding mechanistic sex differences within the NAc may shed light on these disorders. The current study examined sex differences in the main form of synaptic plasticity within the NAc, long term depression (LTD), using slice electrophysiology. We found that a 5-min low frequency stimulation protocol elicited LTD in the NAc of male mice but had no effect in female mice. However, when the duration of the stimulation protocol was increased to 10 min, LTD was evoked in both male and female mice to a similar extent. Next, we examined if sex differences in LTD induction could correspond to the pre- or postsynaptic changes in NAc medium spiny neurons. We found significantly higher AMPA/NMDA ratios and readily releasable pool size in female mice compared to male mice. This increase in readily releasable pool size was accompanied by a decrease in release probability in female mice. Finally, we tested whether these sex differences could be mediated, in part, by the atypical PKC, PKMζ. We found that constitutive deletion of PKMζ resulted in robust LTD induction in female mice at the shorter induction protocol, while disrupting LTD in male mice. Strikingly, there was no effect of PKMζ KO at the longer LTD induction protocol. As PKMζ plays a role in the insertion of AMPARs post-synaptically, studies are underway to determine whether PKMζ deletion alters the sex differences in AMPA/NMDA ratio seen in wildtype mice. Further, we will examine whether PKMζ deletion effects presynaptic transmission, including the size of the readily releasable pool and release probability. Overall, our results indicate that sex differences in NAc LTD are mediated by sex differences in synaptic strength that may be mediated by PKMζ.

Title: Impact of adolescent social isolation on microglial expression in male and female mice

Authors: *N. L. STOREY[1], B. J. ARMSTRONG[2], B. T. RHOADS[2], L. A. BRIAND[3]; [1]Temple Univ. Grad. Neurosci. Program, Philadelphia, PA; [3]Psychology and Neurosci., [2]Temple Univ., Philadelphia, PA

Abstract: Adolescence is a critical period for the development of multiple circuits within the brain, including the brain's reward circuitry. Social isolation during adolescence alters the development of this reward circuit, which can lead to long term detrimental changes in behavior, including increased drug seeking. Adolescence is a period of increased vulnerability to substance use disorder (SUD) and stressors like social isolation during this time can increase this vulnerability. Previous research in our lab demonstrates that adolescent social isolation increases motivation for cocaine as well as cocaine seeking in both male and female mice. However, the underlying mechanisms driving this stress-induced increase in vulnerability is not well understood. Both stress and drugs of abuse lead to an increase in microglial activation within the limbic system. As microglia play a critical role in synaptic plasticity, we hypothesized that adolescent social isolation would impact microglia with the reward circuit. Data from adult mice suggest that adolescent social isolation leads to sex-specific alterations in microglial proliferation, but it is not clear if these differences in adulthood are persistent changes that occur during adolescence. Therefore, the present research specifically examines microglial expression 2 weeks following post-weaning (PND21) social isolation. Analysis of cell counts within the prelimbic and infralimbic cortices indicate that microglial expression is higher in socially isolated mice compared to group housed controls. This increased expression appears to be driven by an effect in the male mice. In contrast, females are not exhibiting large effects of the social isolation on microglial expression in the prefrontal cortex. These sex-specific alterations in microglial proliferation are consistent with what we have seen in adult mice following adolescent social isolation, suggesting that these effects persist. Analysis of additional regions in the reward pathway including the nucleus accumbens, hippocampus, and basolateral amygdala are ongoing and will be presented at the meeting. The current findings suggest that adolescent social stress can lead to persistent, sex-specific alterations in microglial proliferation that could impact the response to future insults in adulthood including drugs of abuse. Future studies will examine how the effects of adolescent social isolation impact drug-induced changes in microglia.

Title: Suvorexant, an FDA-approved dual orexin receptor antagonist, effectively reduces oxycodone self-administration and conditioned reinstatement in male and female rats

Authors: *J. ILLENBERGER, F. J. FLORES-RAMIREZ, A. MATZEU, B. J. MASON, R. MARTIN-FARDON;
The Scripps Res. Inst., La Jolla, CA

Abstract: Amid the opioid crisis, effective strategies to prevent prescription opioid use disorder (OUD) are urgent. The orexin system is recruited by drugs of abuse and blockade of orexin receptors prevents drug-seeking behaviors. This study sought to determine whether repurposing suvorexant (SUV)-- a dual orexin receptor antagonist marketed as Belsomra® (Merck) for insomnia treatment-- can treat two features of prescription OUD: exaggerated consumption and relapse. Wistar rats (males and females; n=16/group) were trained to self-administer oxycodone (0.15 mg/kg, i.v., 8h/day) in the presence of a discriminative stimulus (S^D). The capacity to decrease self-administration with SUV (0-20 mg/kg, p.o.) was tested. Next, the rats underwent extinction training and the effect of SUV (0 and 20 mg/kg, p.o.) to prevent S^D-induced reinstatement of oxycodone-seeking behavior was tested. Repeated measures ANOVAs analyzed self-administration and reinstatement data. Withdrawal scores were analyzed with Friedman nonparametric tests. Males ($F(14,196)= 7.09$, $p< 0.001$) and females ($F(1,13)= 74.80$, $p< 0.001$) acquired oxycodone self-administration and exhibited physical signs of opioid withdrawal (males: $F_r= 36.23$, $p< 0.001$; females: $F_r= 37.24$, $p< 0.001$). Females consumed twice as much oxycodone (48.55 ± 5.01 mg/kg) vs. males (22.49 ± 4.83 mg/kg). At 20 mg/kg SUV decreased oxycodone self-administering during the first hour in males ($F(2,26)= 5.05$, $p< 0.05$) and females ($F(2,26) = 4.77$, $p < 0.05$). The oxycodone S^D reinstated oxycodone-seeking behavior with more efficacy in females ($t(9)= 4.10$, $p < 0.01$). Suvorexant reversed oxycodone seeking in males to extinction level (Bonferroni $p> 0.05$ vs. EXT; $F(3,35)= 6.72$, $p< 0.01$). In females while a reduction was measured, a substantial reinstatement persisted (Bonferroni $p < 0.01$ vs. 0 mg/kg; $F(3,13)=10.15$, $p< 0.001$). The findings support targeting orexin receptors for the treatment for prescription OUD and repurposing SUV as pharmacotherapy for prescription OUD.

Abstract: Exploring sex differences in naloxone conditioned place aversionHouda H. Chamseddine, Blake N Brady, Davis Van Dyk, Linda I. Perrotti
Substance use disorder is a chronic condition characterized by cycles of intoxication, withdrawal, and relapse. Negative affective and somatic symptoms commonly accompany cessation of substance use. These symptoms can be incredibly aversive, to the extent that they can be classically conditioned to be associated with cues or environments. Interestingly, women have been shown to demonstrate greater cue-reactivity to drug-associated stimuli. Women also progress from casual drug use to abuse at an accelerated rate compared to men. Human and animal literature also demonstrate elevated vulnerabilities in females associated with circulating ovarian hormones. Unfortunately, but surprisingly, studies investigating sex differences and hormonal influences during opioid withdrawal (OW) and its motivational influences are severely lacking, and the few that address sex as a variable report disparate findings. Much of what is currently known about OW has been derived from studies in exclusively men or male animals, and extrapolated to women, with most withdrawal scales having been developed using male subjects. Thus, the objective of the present study was to investigate sex differences and hormonal influences in the motivational consequences of opioid withdrawal using a conditioned place aversion paradigm. Specifically, we sought to determine (1) the degree to which gonadally intact, adult male and female rats displayed aversion to environments associated with an acute naloxone precipitated withdrawal after morphine pretreatment, (2) the degree to which ovariectomized female rats pretreated with estradiol benzoate or a peanut oil vehicle developed conditioned place aversion, and (3) the differences in aversion after administering varying morphine and naloxone doses in intact females. Overall, the results of this study demonstrated a robust naloxone-conditioned place aversion that seemed to be relatively unaffected by sex, ovariectomy, or estradiol treatment.

Title: Sex-specific role of CNIH3 in fentanyl IV self-administration

Authors: *T. LINTZ[1], H. E. FRYE[2], E. C. NELSON[3], J. D. DOUGHERTY[4], J. MORON-CONCEPCION[5];
[1]Washington Univ. in St. Louis Neurosci. PhD Program, St. Louis, MO; [2]Washington Univ. in St. Louis, Saint Louis, MO; [3]Dept. of Psychiatry, Washington Univ. Sch. of Med., Saint Louis, MO; [4]Washington Univ. Sch. of Med., St. Louis, MO; [5]Anesthesiol., Washington Univ., Saint Louis, MO

Abstract: Cornichon homolog-3 (CNIH3) is an AMPA receptor (AMPAR) auxiliary protein that traffics AMPARs to the postsynaptic membrane and potentiates AMPAR signaling. AMPARs are key components of hippocampal synaptic plasticity, which is important in opioid-seeking behavior. A previous genome-wide association study (GWAS) comparing humans that used opioids occasionally to those that used daily has shown that single nucleotide polymorphisms in CNIH3 provide significant protection against the development of opioid use disorder, particularly in women, however, the role of CNIH3 in opioid-seeking behavior has yet to be elucidated. To investigate sex differences in the role of CNIH3 in opioid use, we assessed fentanyl consumption using an operant intravenous self-administration (IVSA) approach in male and female wildtype and CNIH3 KO mice. Our results indicate that CNIH3 KO impairs the acquisition of fentanyl IVSA in female mice and prevents the increased consumption of fentanyl per session in males observed over time in control mice. Furthermore, CNIH3 KO dampens drug-seeking during cue-induced reinstatement in male CNIH3 KO mice. Additionally, we use viral approaches to determine the necessity of CNIH3 in the dorsal hippocampus for opioid-seeking behavior. This study, the first to identify sex-specific effects of the AMPAR auxiliary protein CNIH3 on opioid-seeking, begins to uncover the role of CNIH3 on sexually dimorphic AMPAR-dependent behavior and hippocampal synaptic plasticity.

Title: Oxytocin attenuates stress-induced responding for oxycodone under a progressive ratio schedule in male rats

Authors: *T. Q. YATES, E. C. MCNEELY, R. J. RAGER-AGUIAR, E. LORENZ, K.-C. LEONG;
Psychology, Trinity Univ., San Antonio, TX

Abstract: Instances of Opioid Use Disorder (OUD) are both prevalent in occurrence and significant in impairment caused. Stress is a major component in the expression of OUD,

increasing drug use, craving, and likelihood of relapse. Oxycodone is a commonly abused prescription opioid and use is highly susceptible to stress effects. Therefore, pharmacological interventions need to be explored to combat the negative effect of stress on oxycodone abuse. The neuropeptide oxytocin has been shown to be a potent anxiolytic compound and may be utilized to diminish the effect of stress on drug reward. The present study will investigate the ability for oxytocin to attenuate the effect of the pharmacological stressor yohimbine on oxycodone reward salience and motivation of oxycodone-seeking behavior. To better mirror the use of oral oxycodone in human abuse, male rats were trained to lever respond in operant conditioning chambers for oral self-administration of oxycodone. After stabilization of behavioral response for at least two sessions, the effect of stress on oxycodone-seeking was measured through systemic administration of the pharmacological stressor yohimbine (2 mg/kg; i.p.) 30 minutes prior to a progressive ratio (PR) test. Our results found that yohimbine increased lever responding and break point for oxycodone in male rats, thus demonstrating stress-induced motivation of oxycodone-seeking. Concurrent oxytocin, administered systemically (1 mg/kg; i.p.) attenuated the effect of yohimbine, reducing lever pressing and breakpoint. Subsequent experiments investigated the role of the central amygdala (CeA) in mediating this attenuating effect of oxytocin. Overall, our results demonstrate the potential therapeutic effect of oxytocin in diminishing the negative effect of stress on oxycodone addiction behavior.

Title: Sex-specific efficacy of a dual agonist of GLP-1Rs and Y2Rs in opioid-dependent male and female rats

Authors: *A. CAFFREY[1], E. LAVECCHIA[1], H. D. SCHMIDT[2];
[1]Univ. of Pennsylvania, Philadelphia, PA; [2]Univ. of Pennsylvania Sch. of Med., Univ. of Pennsylvania Sch. of Med., Philadelphia, PA

Abstract: Fatal opioid overdoses remain one of the leading causes of preventable death in the United States. The number of deaths caused by synthetic opioids continues to rise year-over-year. Current FDA-approved medications for opioid use disorder (OUD) are limited by high relapse rates. Therefore there is an urgent need to develop new pharmacotherapies to treat OUD. An emerging literature indicates that dual agonists of glucagon-like peptide-1 receptors (GLP-1Rs) and neuropeptide Y2 receptors (Y2Rs) have additive effects on opioid-mediated behaviors

compared to GLP-1R or Y2R monotherapies alone. Furthermore, GLP-1R/Y2R dual agonists are well-tolerated and do not produce emesis as seen with GLP-1R monotherapies. The goal of this study was to determine the efficacy of GEP12, a novel dual GLP-1R/Y2R agonist, to reduce fentanyl self-administration and reinstatement in both male and female rats. Rats were allowed to self-administer fentanyl (2.5 μg/kg, i.v.) for 21 days on a fixed-ratio 5 (FR5) schedule of reinforcement. Rats were then pretreated with vehicle or GEP12 (1.57 or 12.53 μg/kg) before the beginning of fentanyl self-administration test sessions. We found that systemic administration of GEP12 significantly reduced fentanyl self-administration in male rats at a dose that did not affect food intake or produce pica. These effects were sex-specific as GEP12 pretreatment did not alter fentanyl consumption in female rats. Opioid taking was then extinguished by replacing the fentanyl solution with saline. Opioid seeking during abstinence was elicited using an acute priming injection of fentanyl (45 μg/kg, i.p.). Prior to reinstatement test sessions, rats were pretreated with vehicle or GEP12 (1.57 or 12.53 μg/kg). Our preliminary findings indicate that GEP12 reduces fentanyl seeking during abstinence in both male and female rats. Taken together, these results indicate that GEP12 reduces voluntary opioid and taking. Future studies will explore the neural mechanisms underlying the sex-specific effects of GEP12 on opioid taking and work to expand the efficacy of dual agonists in opioid-mediated behaviors.

Title: Effects of Oxycodone Exposure and Withdrawal on NAc Opioid Receptor Expression in Male and Female Rats and Across the Estrous Cycle

Authors: *B. PATEL[1], A. KRISHNAN[2], J. LOWETH[3];
[1]Mol. Cell Biol. and Neurosci., Rowan Univ., Stratford, NJ; [2]Mol. Cell Biol. and Neurosci., Rowan Univ. Sch. of Osteo. Med., Stratford, NJ; [3]Mol. Cell Biol. and Neurosci., Rowan Univ. Sch. of Osteo. Med., stratford, NJ

Abstract: Effects of Oxycodone Exposure and Withdrawal on NAc Opioid Receptor Expression in Male and Female Rats and Across the Estrous Cycle
Bhumi P. Patel, Anuradha Krishnan, Jessica A. LowethGraduate School of Biomedical Sciences, Department of Cell Biology & Neuroscience, Rowan University School of Osteopathic Medicine
Prescription opioid misuse and abuse in the past two decades has significantly contributed to the current opioid epidemic. Although both men and women misuse prescription opioids, women are

more frequently prescribed opioids for pain, experience more intense opioid craving after chronic use, and transition more rapidly to substance use disorder compared to men. One likely factor contributing to these sex differences is fluctuations in ovarian hormone levels across the reproductive cycle. However, recent studies from our lab have found a significant and long-lasting dysregulation of the rat reproductive (estrous) cycle during extended-access oxycodone self-administration (6 h/day for 10 days, 0.1 mg/kg/infusion) and the first several weeks of withdrawal, preventing an accurate assessment of potential estrous cycle-dependent changes in oxycodone seeking behavior during earlier withdrawal time-points. Taking this estrous cycle dysregulation into account, we assessed the effects of estrous cycle fluctuations on cue-induced oxycodone seeking following prolonged withdrawal (~44 days), a time period when estrous cycle lengths and stages have returned to normal. Interestingly, we observed a significant reduction in cue-induced oxycodone seeking in females in the estrus stage of the estrous cycle (Estrus Females) compared to both females in diestrus and males following prolonged abstinence or withdrawal. One potential mechanism mediating these effects could be interactions between ovarian hormones and opioid receptor signaling within the mesolimbic reward circuitry, as ovarian hormones can influence opioid receptor expression and function which, in turn, can influence responding to opioid-associated cues. To begin to investigate this, we assessed surface and total protein expression levels of opioid receptors (mu, delta and kappa) in the nucleus accumbens core and shell in males and females and across the estrous cycle following prolonged withdrawal from saline or oxycodone self-administration. Together these findings will begin to identify potential neuroadaptations contributing to estrous cycle-dependent changes in oxycodone seeking and relapse vulnerability.

Title: The Effects of Transitioning from Morphine to Buprenorphine During Pregnancy on Offspring Development in a Translational Rodent Model

Authors: *A. M. MYERS[1], L. M. RICHARDSON[1], J. DURAN[1], S. A. PERRINE[2], S. E. BOWEN[1], S. BRUMMELTE[1];
[1]Psychology, [2]Psychiatry and Behavioral Neurosciences, Wayne State Univ., Detroit, MI

Abstract: Opioid use during pregnancy has increased drastically in the last two decades. Pregnant women who use opioids are often prescribed Medications for Opioid Use Disorder (MOUDs), including buprenorphine (BUP) to mitigate negative effects on the fetus. However,

BUP exposure during pregnancy is not without risk as preclinical studies have shown a negative impact on maternal care behavior and offspring neurodevelopment. Further, it is not known how the transition from an opioid of abuse (i.e., morphine) to a MOUD (i.e., BUP) during gestation affects offspring outcomes. In the current study, we used a translational rodent model to investigate acute offspring neurodevelopmental outcomes following either the transition from morphine to BUP or continued use of morphine or BUP from preconception (drug administration began 7 days prior to mating) to the early postpartum period. Dams were assigned to one of 5 experimental groups: BUP continued ("BC", 1mg/kg, s.c.), morphine continued ("MC", 3 - 10 mg/kg, s.c.), morphine to BUP ("MB"; 3 - 5mg/kg morphine until Gestational Day (GD) 5, then 1.0 mg/kg BUP; s.c.), morphine to vehicle ("MV"; 3 - 5mg/kg morphine until GD5, then 1.0 mL/kg saline; s.c.), or saline continued ("VEH", 1.0 mL/kg, s.c.). MB and MV groups switched to BUP or saline (respectively) on GD5, to roughly mimic the time in humans when a woman would discover she is pregnant (i.e. ~ 6-8 weeks of pregnancy). All dams and their litters were sacrificed on postnatal day (PN) 2. Our results reveal that continuous exposure to BUP or morphine and the transition from morphine to BUP results in higher pup mortality, lower pup body weight, smaller pup body length, and fewer milk bands as compared to the VEH or MV groups (p's < .05). Importantly, preliminary evidence suggests that the BC, MC, and MB dams had lower nesting quality and partook in less pup-directed maternal care behaviors than drug-naïve dams, potentially contributing to the high pup mortality rate. Pup brains collected on PN2 will be analyzed using High-Performance Liquid Chromatography to determine monoamine concentrations in the striatum, prefrontal cortex, and hypothalamus. These results suggest that (1) the transition from morphine to BUP in early pregnancy and continued use of BUP or morphine negatively impacts offspring outcomes and (2) opioid-induced maternal care deficits appear to contribute to offspring neurodevelopmental outcomes following opioid exposure *in utero*.

Title: Adolescent binge drinking alters prelimbic somatostatin circuitry in mice

Authors: *A. SICHER[1,2], K. GRIFFITH[2], D. STARNES[2], G. SMITH[3], M. SPRINGER[2], D. BROCKWAY[1,2], N. CROWLEY[1,2,3];

Abstract: Somatostatin (SST)-expressing neurons are a population of inhibitory neurons implicated in stress and neuropsychiatric illnesses. Our lab recently showed that binge drinking in adult mice can disrupt the function of SST neurons in the prelimbic (PL) region of the prefrontal cortex. However, the consequences of alcohol exposure during critical developmental windows, including adolescence, for SST neurons and associated circuitry have not been characterized. Here, we use electrophysiology and behavioral studies to investigate the effects of adolescent binge drinking on PL SST neurons. We used the Drinking-in-the-Dark (DID) paradigm to model binge drinking in male and female SST-Cre:Ai9 reporter mice and SST-Cre:Ai32 mice expressing channelrhodopsin from postnatal days (PND) 28 to 52. This age range spans the bulk of the rodent adolescent period. Patch-clamp electrophysiology was performed 24 hr after the end of adolescent DID. SST neurons were identified based on the presence of fluorescence, while pyramidal and non-pyramidal neurons were identified by morphology and membrane properties (i.e. cell capacitance and membrane resistance). We found that SST neurons become hyperexcitable following adolescent DID, while pyramidal neurons became hypoexcitable. However, there was no change in SST-mediated GABA transmission onto other PL neurons at this timepoint. Ongoing experiments seek to characterize the impact of adolescent DID on subsequent binge drinking in adulthood and typical development of PL SST neurons during adolescence.

Title: Extended amygdala neuronal excitability and alcohol drinking: differential effects of hypocretin/orexin receptor signaling in CRF neurons

Authors: *Y. MA, H. SARDAR, A. R. MORNINGSTAR, M. E. BENABOU, R. N. FAJARDO, I. F. KANDIL, A. C. Y. YU, J. A. KAUER, W. J. GIARDINO;
Psychiatry and Behavioral Sci., Stanford Univ., Stanford, CA

Abstract: Alcohol use disorder (AUD) patients experience negative emotions and hyperarousal during withdrawal, which perpetuate the progression of addiction. These negative emotional features involve neurocircuitry of the extended amygdala and stress-related neuropeptides such as corticotropin-releasing factor (Crf) and hypocretin (Hcrt). The bed nucleus of stria terminalis (BNST) in the extended amygdala is a sexually dimorphic brain region that regulates negative valence, stress, and alcohol consumption. We hypothesized that signaling through two Hcrt receptor subtypes, HcrtR1 and HcrtR2, in Crf neurons may differentially impact alcohol intake and anxiety-like behaviors, and that neuronal excitability changes in the BNST may mediate these effects. To test these hypotheses, we deleted either HcrtR1 or HcrtR2 from Crf neurons by crossing Crf-Cre mice with floxed HcrtR mouse lines. The Crf-HcrtR1 and Crf-HcrtR2 cohorts along with Cre negative wild-type littermates underwent 8 weeks of two-bottle choice intermittent access alcohol drinking. To determine the impact on anxiety-like behaviors, the elevated plus maze and open field test were performed before alcohol access, and in the last week of alcohol drinking during acute withdrawal. Intrinsic excitability of BNST neurons was measured in brain slices collected after behavioral testing, and in age-matched alcohol-naive controls. Electrophysiological recordings indicated that the BNST neurons in females were more excitable, but 8 weeks of alcohol exposure blunted sex differences in BNST neuronal excitability. Deletion of HcrtR1 in Crf neurons significantly reduced alcohol intake in both male and female mice; however, no differences in intrinsic excitability of BNST neurons were observed that might account for these differences. By contrast, deleting HcrtR2 from Crf neurons revealed a trend toward sex-dependent effects on alcohol intake, with male Crf-HcrtR2 knockout mice displaying greater alcohol intake compared to wild-type littermates. Crf-HcrtR2 deletion also reduced baseline anxiety-like behaviors in male mice prior to alcohol drinking. These findings suggest that HcrtR1 signaling in Crf neurons is critical for excessive alcohol drinking in both males and females, and that HcrtR2 signaling in Crf neurons may play a sex-dependent role in alcohol intake and anxiety-like behavior. The differential effects of HcrtR1 and HcrtR2 deletion in Crf neurons provide valuable insights for developing potential AUD treatments that target these neuropeptide systems using subtype-selective HcrtR modulators.

Title: Chronic exposure to alcohol disrupts inflammatory protein marker abundances in the striatum.

Authors: *B.-L. DUFFUS;
Indiana University-Purdue Univ. Indianapolis, Indianapolis, IN

Abstract: Alcohol misuse is the third leading preventable cause of death in the world. The World Health Organization currently estimates that 1 in 20 deaths are directly alcohol-related. One of the ways in which consuming excessive levels of alcohol can both directly and indirectly affect human mortality and morbidity, is that it can produce chronic inflammation. Chronic inflammation, and neuroinflammation specifically, is one of the strongest risk factors for later developing a neurodegenerative disease. Recently, studies have suggested a link between increased alcohol use and the incidence of neurodegenerative disease. However, the mechanism in which alcohol potentially accelerates neurodegenerative processes remains unknown. To further elucidate how alcohol-induced neuroadaptations may drive neuroinflammation, we assayed changes in the inflammatory proteome after mice were exposed to voluntary chronic alcohol use. Here we show that mice chronically exposed to alcohol display unique alterations in their inflammatory proteome in multiple striatal brain subregions commonly associated with heavy drinking and chronic alcohol use. Using mass spectrometry following voluntary alcohol self-administration in mice we show that inflammatory protein marker abundances and signaling pathways are disrupted from chronic exposure to alcohol compared to water drinking control mice across striatal regions. Further, in mice that were allowed to experience abstinence from alcohol compared to mice that were non-abstinent, the inflammatory proteome and signaling pathways showed additional differences, suggesting that the inflammatory response evoked by chronic alcohol exposure is dependent on alcohol use history. These alterations may drive increased neurodegenerative pathophysiology in mice susceptible to these diseases. These findings suggest that proinflammatory responses driven by chronic alcohol use may be accelerating neurodegenerative diseases. Further, specific proinflammatory proteins that we found with largely upregulated abundances may serve as targets for intervention to reverse the adverse effects of alcohol-induced inflammation, and thus decrease the probability of developing a neurodegenerative disease due to excessive alcohol consumption.

Title: Interactive influences of chromosomal sex and gonadal sex on alcohol consumption in Four Core Genotypes Mice

Authors: *R. A. ZEGARELLI[1], K. D. REAM[2], E. P. ECCLES[1], D. P. UNDERWOOD[1], A. K. RADKE[1];
[1]Psychology, [2]Miami Univ., Oxford, OH

Abstract: Alcohol Use Disorder (AUD) is a persistent worldwide issue, with increasing rates in recent years. Clinical evidence has shown sex differences in onset and duration of AUD. Preclinical research also reveals an influence of biological sex on alcohol consumption, with rates of voluntary consumption consistently higher in female vs. male rodents. However, the neural mechanisms underlying these differences have yet to be understood. The Four Core Genotypes (FCG) mouse model provides a unique opportunity to investigate the influences of both chromosomal sex (i.e., XX vs. XY chromosome complement) and gonadal sex (i.e., ovaries vs. testes) on drinking behaviors. In this model, four different genotypes are tested: XX/Sry-, XX/Sry+, XY/Sry-, and XY/Sry+. In previous studies, we have uncovered influences of chromosomal sex on alcohol consumption using a continuous access drinking task (XX > XY) and a limited access Drinking in the Dark (DiD) paradigm (XY > XX in Sry+ mice with testes). Here, we determined the influence of chromosomal sex on intermittent 24-h alcohol consumption and explored interactions between chromosomal and gonadal sex in female FCG mice using ovariectomy. For Experiment 1, intermittent access (IA), mice were presented with two bottles of 20% ethanol and water solution for 24 hours every-other day (MWF) for 4 weeks. Bottles were weighed to calculate consumption and two water bottles were available on intervening days. In Experiment 2, XX/Sry- and XY/Sry- mice underwent surgical ovariectomy (OVX vs. SHAM) 4 weeks before the commencement of DiD. Mice received two bottles (15% ethanol and water) for 4 hours during their active (dark) cycle for 15 sessions. Aversion resistance was assessed by adding increasing levels of quinine to the ethanol bottle. Results from Experiment 1 (IA) showed that XY mice consume more ethanol than XX mice, similar to what has previously been observed with limited access, but not continuous access, consumption. These effects of chromosomal sex were dependent on gonadal sex and exposure, such that XY/Sry+ mice consumed more ethanol than XX/Sry+ mice in the first two weeks of drinking while differences in XY/Sry- vs. XX/Sry- mice only emerged after 4 weeks. We also observed that mice with ovaries (Sry-) consumed more water than mice with testes (Sry+). Data collection for Experiment 2 is ongoing and will clarify the role of chromosomal sex and potential interactions with gonadal sex in aversion-resistant drinking. Together, these studies reveal that gonadal and chromosomal sex interact to produce sex differences in alcohol drinking behaviors and call for further study of how sex chromosome genes influence alcohol consumption.

Title: Astrocytes and their role in mediating the increase in intrinsic excitability of lateral orbitofrontal cortex pyramidal neurons following chronic alcohol consumption

Authors: *A. KASTNER, M. OKAS, J. WOODWARD;
Med. Univ. of South Carolina, Charleston, SC

Abstract: Alcohol use disorder (AUD) is characterized by the progression from recreational drinking to uncontrollable and excessive consumption resulting in a myriad of social and neurobiological complications. The mechanisms underlying the dependence-induced escalation in drinking are not completely understood, however a key brain region disrupted in individuals with AUD is the orbitofrontal cortex (OFC). Studies from the Woodward laboratory show that acute ethanol inhibits action potential firing of lateral orbitofrontal (lOFC) cortex pyramidal neurons in a glycine dependent manner via reversal of the astrocyte GlyT1 transporter. Following repeated cycles of chronic intermittent ethanol (CIE) exposure, lOFC neurons become hyperexcitable and are no longer inhibited by acute ethanol. These effects are blunted in mice expressing a calcium exporter (PMCA) selectively in lOFC astrocytes. However, whether dampening lOFC astrocytic calcium also prevents the CIE-induced escalation in drinking is unknown. Male (n=8-9/group) and female (n=4-5/group) C57/Bl6J mice (~9 weeks of age) were infused with either an astrocyte specific PMCA (AAV2/5-GfaABC1D-hPMCA2w/b-mCherry) or control (AAV2/5-GfaABCD1-LCK-GFP) virus in the lOFC. Following recovery, they underwent 4 weeks of baseline drinking where Mon-Fri, they had free access to 15% ethanol or water for 2 hours beginning 3 hours into the dark cycle. Mice were then counterbalanced into CIE or Air groups based on alcohol consumption during baseline and then exposed to cycles of CIE or Air exposure followed by a test week of homecage drinking. Each CIE or Air exposure consists of 4 days of vapor exposure (16 hrs on, 8 hrs off) and a 3-day withdrawal period. Results from preliminary studies show that PMCA had no effect on baseline drinking in male or female mice. Following CIE exposure, both GFP control and PMCA male mice increased their ethanol consumption. No differences in drinking were observed after CIE exposure in GFP control or PMCA female mice. Next, we investigated the impact of expressing PMCA in lOFC astrocytes on lOFC neuronal excitability. Female C57/Bl6J mice expressing PMCA or LCK-GFP underwent 2-4 weeks of CIE or Air exposure and electrophysiology recordings were conducted 72 hours following the last exposure. Results from these ongoing studies suggest that PMCA may prevent the increase in evoked action potentials following CIE exposure. Together, these findings indicate a potential dissociation in the role of astrocytes in the increase in lOFC excitability and the escalation in drinking that follows CIE exposure.

Title: Characterization of human synaptic $GABA_A$ receptors sensitivity in Alcohol Use Disorder

Authors: *J. M. GRANCHI[1], B. MILLER[1], T. MEYER[2], A. TEIXEIRA[2], L. STERTZ[2], C. WALSS-BASS[2], A. LIMON[1];
[1]Grad. Sch. of Biomed. Sci., Univ. of Texas Med. Br., Galveston, TX; [2]Faillace Dept. of Psychiatry and Behavioral Sci., The Univ. of Texas Hlth. Sci. Ctr., Houston, TX

Abstract: Previous research highlights epigenetic changes made to $GABA_A$ Receptors following chronic alcohol use which may be related to synaptic changes of GABAergic signaling in individuals with Alcohol Use Disorder (AUD). Because $GABA_A$Rs play an integral role in alcohol pharmacodynamics and GABAergic signaling, AUD may lead to changes in their sensitivity to the endogenous GABA agonist. However, $GABA_A$Rs has not been electrophysiologically characterized in native human tissue of individuals with AUD. In this study, we used two electrode voltage clamp electrophysiology and microtransplantation synaptic membranes (MSM) methods to determine potential changes of $GABA_A$Rs affinity to GABA in AUD. We used postmortem dorsolateral prefrontal cortex samples from 6 control subjects and 6 subjects diagnosed with AUD (mean age of 53 ± 7 years) that were collected by the University of Texas Health Science Center at Houston Brain Collection. Ion current responses values were integrated with label-free proteomics datasets from the same brain region. We built concentration-response curves for GABA to determine EC_{50} and pEC_{50} values for each control and AUD sample. Additionally, we compared protein expression to find proteins that significantly correlate with AUD diagnosis, EC_{50}, and pEC_{50} for further analysis in Gene Ontology Pathways. Our results directly measuring the activity of native human $GABA_A$Rs complexes found a trend of lower affinity for GABA in AUD compared to controls ($p = 0.072$, t-test) and lower ion currents responses at 100 mM GABA, but not other concentrations. Initial one-way ANOVA analysis of the proteome by diagnosis revealed 124 proteins differentially expressed in AUD, among those GABBR2, a $GABA_B$ receptor protein, and GRIA3, a subunit of AMPA receptors, were expressed more in AUD samples. Response screenings analysis using the statistical software JMP 16Pro., found 116 proteins that were significantly correlated with EC_{50}, and 165 proteins significantly correlated with pEC_{50}. Gene ontological analysis with a background list of all 4,612 proteins from the original proteomic data collection indicates that the GNAI1-GNB5-GNB2 complex and proteins involved in GDP metabolic processes are significantly correlated with pEC_{50} values while proteins involved in valine, leucine, and isoleucine degradation are expressed differently based on diagnosis. These results suggest that GABA receptors in a subset of AUD subjects require higher GABA concentration than those of controls for activation.

Title: The inhibitory effects of ginsenoside Rb1 and Rg1 on alcohol-induced addictive-like behaviors in rodents

Authors: *W.-A. KOOK, Y. LEE, D. KIM, H.-W. MIN, S.-Y. LEE, C.-G. JANG; Sungkwunkwan Univ., Suwon, Korea, Republic of

Abstract: Chronic alcohol consumption leads to alcohol dependence, which is accompanied by neuroadaptive modulations in the brain that ultimately lead to serious health complications. In previous studies, ginsenosides, major components of Korean Red Ginseng (KRG), alleviate alcohol-induced hyperactivity and cognitive impairment and inhibit morphine-induced hyperactivity and reinforcement in mice. However, there is no evidence that ginsenosides inhibit alcohol-induced psychological behaviors. Therefore, we evaluate the inhibitory effects of major protopanaxadiol (Rb1) and protopanaxatriol (Rg1) components of KRG on alcohol-induced addictive-like behaviors in mice. Male C57BL/6J 7 weeks old mice were used for all behavior experiments including oral self-administration (SA), conditioned place preference (CPP). Ginsenoside Rb1 and Rg1 (25, 50 and 100 mg/kg) were dissolved in saline and administered intraperitoneally at 10 ml/kg. Ethanol solutions (for SA, diluted to 10% v/v in distilled water and for CPP, diluted to 20% v/v in physiological saline) were used to form an alcohol addiction model. Statistical significance was determined using an ANOVA followed by a Fisher's LSD for all behavior tests. In SA studies, treatment with ginsenoside Rb1 and Rg1 significantly reduce alcohol induced self-administration on a fixed-ratio 4 and progressive ratio schedule of reinforcement. In CPP studies, treatment with ginsenoside Rb1 and Rg1 significantly inhibit alcohol-induced CPP. We identified the inhibitory effects of ginsenoside Rb1 and Rg1 on alcohol-induced reinforcement, motivational dependence, and reward. Our finding reflects that ginsenoside Rb1 and Rg1 are responsible for therapeutic effect of KRG, and they have therapeutic potential as a treatment for preventing alcohol-induced psychological dependence and reinforcement.

Title: Converging effects of chronic pain and binge alcohol consumption on anterior insular cortex neurons projecting to the dorsolateral striatum

Authors: *Y. YIN, D. L. HAGGERTY, S. ZHOU, B. K. ATWOOD, P. L. SHEETS;
Indiana Univ. Sch. of Med., Indianapolis, IN

Abstract: Chronic pain and alcohol use disorder (AUD) are highly comorbid. Patients with chronic pain are more likely to meet the criteria for AUD. Studies suggest that the disruptions in the underlying neural circuitry for chronic pain and AUD are similar, yet this connection remains understudied. The anterior insular cortex (AIC) is a brain region that is involved in both chronic pain and AUD. However, many of the previous studies focused on local lesion or excitation/inhibition, which lack circuit specificity. One major innervation target of AIC is the dorsolateral striatum (DLS). Binge-like alcohol drinking has been shown to alter synaptic transmission at AIC-DLS synapses. However, disruption of AIC-DLS circuits by chronic pain has never been studied. The goal of this work is to study the converging effects of chronic pain and binge alcohol consumption on AIC neurons that send projections to the DLS. We performed intracranial injections of retrograde beads into the right DLS of mice to label AIC-DLS neurons. We subsequently performed the spared nerve injury (SNI) surgery to induce chronic pain behavior. Both sham (control) and SNI mice then underwent 3 weeks of drinking-in-the-dark (DID) paradigm to model binge-like alcohol drinking. Following DID, whole-cell patch-clamp recordings in acute brain slices were performed to measure intrinsic and synaptic properties of AIC-DLS neurons. Our results show that SNI mice with no prior alcohol exposure to injury consumed less alcohol compared to sham mice. Electrophysiological analyses showed that AIC-DLS neurons from SNI-alcohol mice displayed increased neuronal excitability and increased frequency of miniature excitatory postsynaptic currents. However, exposing mice to 3 weeks of alcohol DID prior to injury eliminated differences in both alcohol intake and AIC-DLS neuronal activity observed in mice with no alcohol pre-exposure. Together, our data suggest that chronic pain and alcohol drinking interact to have a direct effect on both intrinsic excitability and synaptic transmission of AIC-DLS neurons in mice, which may be critical in altering motivated behaviors associated with pain and alcohol use.

Title: Neural activity in anterior insula at drinking onset and licking predicts compulsive alcohol drinking

Authors: *P. STARSKI[1], M. MORNINGSTAR[4], S. N. KATNER[2], R. M. FRASIER[5], T. DE OLIVEIRA SERGIO[6], S. WEAN[1], C. LAPISH[1], F. W. HOPF[3];

Abstract: Compulsion-like alcohol drinking, where intake persists despite adverse consequences, can contribute strongly to alcohol use disorder (AUD). Previous work has shown that anterior insula cortex (AIC) is important for promoting compulsion-like drinking, but AIC activity patterns promoting pathological intake remain unknown. In 15 adult male Wistar rat, we used 32-wire arrays to record in vivo single unit AIC activity during alcohol-only intake and during compulsive-like drinking with moderate or higher challenge (low vs high quinine adulteration), which would help uncover AIC patterns associated successfully maintaining compulsion-like intake. Compulsive-like drinking intake level was predicted by a specific lick-synchronized firing pattern in AIC, while another lick-associated pattern related to greater intake across conditions. Also, many AIC neurons had session-long plateau firing changes, but only cells with firing increases at drinking onset had greater activity under compulsive-like drinking conditions, in agreement with previous findings that rats quickly assess drinking context and adjust action strategy. AIC did not show firing elevations with saccharin intake, congruent with AIC inhibition not altering such consumption. We provide an integrated model where some aspects of AIC activity relate specifically to compulsive drinking, while others would promote alcohol drinking more generally. Further, similar changes under moderate and higher challenge suggest that one critical role of AIC is to maintain commitment to respond regardless of challenge level. Thus, we provide novel insights into AIC role in compulsive-like drinking and point to central neural mechanisms promoting this key facet of AUD.

Title: Corticolimbic hyperreactivity to alcohol cues among people at elevated risk for alcohol use disorder

Authors: *R. U. COFRESI[1], S. UPTON[1], A. A. BROWN[2], T. M. PIASECKI[5], B. D. BARTHOLOW[3], B. FROELIGER[4];
[1]Psychological Sci., Univ. of Missouri, Columbia, Columbia, MO; [2]Psychiatry, [3]Psychological Sci., [4]Psychiatry & Psychological Sci., Univ. of Missouri, Columbia, MO; [5]Ctr. for Tobacco Res. and Intervention, Univ. of Wisconsin, Madison, WI

Abstract: Low sensitivity (LS) to alcohol is a risk factor for developing alcohol use disorder (AUD). Compared to peers with high sensitivity (HS), LS individuals drink more, report more alcohol-related problems, and exhibit amplified alcohol cue reactivity (ACR) in the form of cue-directed attention and approach, cue-evoked craving, and a larger amplitude P3/LPP response, an event-related potential (ERP) index of incentive salience attribution, to alcohol-related cues. This amplified ACR suggests LS confers risk for AUD *via* over-attribution of incentive salience to alcohol and its cues. Given that incentive salience attribution is strongly tied to activity in the mesocorticolimbic system, we hypothesized that alcohol cues would elicit greater activation in the mesocorticolimbic system among LS compared to HS individuals. To test this hypothesis, we conducted an fMRI pilot study of ACR with LS and HS individuals who had previously completed an event-related EEG-ERP ACR task as part of a different study. Participants (N=32, M_{age}=20.3) recruited based on their Alcohol Sensitivity Questionnaire scores (HS: n=16; LS: n=16; 9 females/group) completed an event-related fMRI ACR task. General linear modeling of the fMRI BOLD response was conducted to identify regions showing significant ACR within a mesocorticolimbic mask (FWE, p<.05). ACR beta coefficients from 5-mm spheres around peak voxels were extracted. Recent alcohol use and craving were assessed. Archival P3/LPP ACR task amplitudes also were obtained for each participant. ACR in the fMRI-BOLD response was observed in left medial orbitofrontal cortex and left ventrolateral prefrontal cortex (vlPFC). vlPFC ACR was significantly greater for LS than HS, Welch's t(29.89)=2.46, p=.010. vlPFC ACR correlated with the frequency and intensity of past-week alcohol craving, r_{sp}≥.385, p≤.030, which was greater for LS than HS, U=41, p<.001. vlPFC ACR also correlated with ACR in the EEG-ERP P3/LPP response, r_{sp}=.355, p=.047, which was significantly greater for LS than HS, t(28)=1.71, p=.049. These findings are consistent with LS conferring risk for AUD *via* over-attribution of incentive salience to alcohol and its cues. Findings suggest that amplified ACR in LS people may stem from corticolimbic contributions to incentive salience attribution. These preliminary findings provide a compelling rationale for future fMRI studies in larger samples aimed at identifying the neurobiological loci and mechanisms underlying LS-based risk for AUD.

Title: Involvement of the basolateral and central amygdala in stress-induced increase of alcohol intake in female mice

Authors: *V. GARCIA-RIVAS, M. A. THOMAS, A. R. SOARES, Y. S. MINEUR, M. R. PICCIOTTO;
Psychiatry, Yale Univ., New Haven, CT

Abstract: Recent data show that, compared to men, women are more likely to drink alcohol to cope with stress. Previous studies show that the basolateral (BLA) and central amygdala (CeA) mediate stress responses, while chronic ethanol exposure changes circuit function in both structures. It remains unknown whether these changes in amygdalar function could prime for sex-specific maladaptive responses to stress, which may increase voluntary alcohol intake to cope with stress. To test this hypothesis, we first developed a behavioral model that captures sex differences in stress-induced alcohol drinking. Male (n=24) and female (n=24) C57BL/6J mice were first trained to drink alcohol in their home cage through the introduction of 2 sippers (10% ethanol and water) for 2 hours daily for at least 10 days. Mice were then split into control (n=12 per sex) and 'stress' (n=12 per sex) subgroups. On sessions 12-13 and 21-22, 'stress' mice underwent foot shock stress sessions (120 shocks over 1 hour) at least 4 hours prior to the drinking session for that day, while control animals stayed in their home cage. 'Stress' female mice drank more alcohol in the 2 days following the stress session (day 13), when compared to all other subgroups. We then tested whether this female-specific phenomenon involved changes in amygdalar circuits, with a focus on principal, GABA and cholinergic neurons. We used dual-color fiber photometry to simultaneously record the activity of GABA and principal neurons (PN) in the CeA of freely moving mice drinking alcohol before or after stress (n=15 per sex). We found that repeated stress does not drastically change the pattern of activity of GABA and PN in the CeA of female mice during alcohol drinking bouts. Since we previously showed that limiting cholinergic signaling in the BLA decreases stress-related phenotypes, we then tested if chemogenetic inhibition of cholinergic terminals in the BLA could blunt stress-induced alcohol drinking. 24 hours after a first stress exposure, we observed that female mice reduced their alcohol intake after the inhibition of their BLA cholinergic terminals with a Gi DREADD. After a second stress exposure, this effect was lost in females but males showed an unexpected *increase* in drinking when inhibiting BLA cholinergic terminals. Collectively, we show that stress can promote an increase in alcohol intake in females, but not in males. Neither stress nor alcohol appear to modify the circuitry of the CeA in ways that would explain this effect. In contrast, restricting the cholinergic inputs to the BLA decreased stress-induced drinking in

females, indicating that acetylcholine in the BLA may be a mediator of stress-related alcohol intake in females

Title: The effect of ethanol consumption and cigarette smoke exposure in adolescent mice on the neuroimmune system

Authors: D. STERN[1], *E. UNTERWALD[2], J. SHINKLE[1], B. KOSMIDER[3], Z. DAVIS-LUIZER[3], H. HAYEK[3], K. BAHMED[3];

Abstract: Ethanol exposure can produce harmful effects by activation of neuroinflammatory responses in the brain. When high concentrations of ethanol interact with the neuroimmune system it can activate signaling cascades that amplify the expression of proinflammatory cytokines. Many drugs of abuse create this excessive inflammatory response, although some studies indicate that nicotine has anti-inflammatory effects. The current study measured the expression of the cytokines, TNF-a and IL-1b, and the chemokine CCL2 in the brains of mice that were exposed to either ethanol, cigarette smoke, or both during the adolescent period. Male and female C57/BL6 mice were exposed to cigarette smoke or air 2 hr/d, 5 d/wk for 4 weeks starting on postnatal day 28. Concomitantly, mice underwent intermittent two-bottle choice ethanol drinking; ethanol and water or 2 water bottles were provided for 21 hr beginning after smoke exposure 3 d/wk. Brains were obtained 20 hours after the last exposure to cigarette smoke. qRT-PCR was performed to measure the expression of TNF-a, IL-1b, and CCL2 mRNA in the prefrontal cortex (PFC). Results demonstrate higher expression of IL-1b mRNA in the PFC of male mice exposed to both smoke and ethanol compared to smoke only, ethanol only, or controls. Female mice that drank ethanol exhibited higher expression of IL-1b compared to controls. Male and female mice that drank ethanol had higher levels of TNF-a mRNA compared to mice exposed to ethanol and smoke, or water and smoke which were not different from controls. CCL2 showed sex-dependent regulation. Ethanol exposed male mice (with or without cigarette smoke) displayed lower expression of CCL2 mRNA compared to mice without ethanol. However, female mice that consumed ethanol without smoke exposure had higher expression of

CCL2 mRNA compared to no ethanol females. The results for IL-1b and TNF-a were consistent with the hypothesized stimulation of neuroinflammation due to ethanol exposure; the downregulation of pro-inflammatory chemokine CCL2 in male mice was unexpected. Additionally, the TNF-a regulation suggests the potential of nicotine being a protective factor when interacting with alcohol, which needs further study to establish.

Title: 3d brain-wide profiling of neuronal ensembles reactive to relapse-promoting vs. relapse suppressing cues in rats.

Authors: H. NEDELESCU[1], ***S. SRINIVASAN**[2], N. CONNOR[4], B. EASTWOOD[5], G. WAGNER[2], A. C. THAN[2], H. C. ZHANG[2], Z. MIKKULSKI[6], F. WEISS[7], J. R. GLASER[5], N. SUTO[3];

Neurosci., The Scripps Res. Inst., La Jolla, CA

Abstract: Drug addiction is a chronically relapsing brain disease. In rats, while environmental stimuli that signal drug availability (S+) promote relapse, we found that those signaling drug omission (S-) can suppress relapse. This bidirectional modulation of relapse is regulated by two functionally distinct neuronal ensembles (engram cells) of infralimbic cortex (IL) neurons, with each ensemble selectively reactive to S+ or S- (Fos protein). The neuroanatomical source of afferents that activate these neurons, however, remains unknown. Furthermore, procedures for automated brain-wide profiling are available for mice, but not rats, which is the preferred animal model for studying more complex models of drug addiction. To address both issues, in rats trained to self-administer cocaine/alcohol, we conducted a brain-wide analysis to identify neuronal ensembles that send axonal projections (AAV2retro-GFP) to IL. We developed an automated brain-wide 3D profiling procedure for rats, where image data and cell counts were registered using NeuroInfo to the Waxholm rat atlas (ref: https://www.nitrc.org/projects/whs-sd-atlas). Briefly, (1) whole slide images of serial brain sections (60 µm) were captured by a ZEISS

Axioscan slide scanner microscope, (2) these 2D images were aligned and registered using NeuroInfo to the Waxholm rat atlas coordinate system, (3) Fos- and GFP-positive IL-projecting neurons were detected with single cell resolution in NeuroInfo using deep learning methods with anatomic specificity conferred by matching image data to the atlas coordinate space. This method provides superior cellular tagging (staining) and image resolution - especially for the larger rat brains - than similar methods using brain clearing and light-sheet microscopes. Our new NeuroInfo tool can be used to identify brain-wide neuronal networks reactive to relapse-promoting vs. relapse-suppressing stimuli. In short, this study provides a new tool for automated 3D brain-wide profiling of rats and expands our knowledge of brain circuitry mediating environmental modulation of drug relapse.

Title: Acute and chronic ethanol effects on dorsal striatal cholinergic signaling

Authors: C. C. LEVY[1], L. E. SLADE[1], Y. MATEO[2], D. M. LOVINGER[2], *A. G. SALINAS[1,2]; [1]Pharmacol., LSU Hlth. Sci. Ctr. at Shreveport, Shreveport, LA; [2]Natl. Inst. on Alcohol Abuse and Alcoholism, Rockville, MD

Abstract: Alcohol use disorder (AUD) has adverse health and socioeconomic impacts totaling over $240 billion annually. Despite this, FDA approved medications for AUD are limited. Thus, further understanding of neurobiological mechanisms in AUD is required for new treatments. Given its role in cognition and decision-making processes, both of which are adversely affected in AUD, acetylcholine (ACh) signaling is an attractive pharmacotherapeutic target. Therefore, this study aimed to determine how ethanol affects ACh signaling in the dorsal striatum (DS). We previously showed that chronic ethanol treatment in mice and macaques results in a deficit in the cholinergic contribution to dopamine (DA) release. Similarly, we show here that acute ethanol (50 mM) depresses optogenetically evoked ACh-driven DA release measured with fast-scan cyclic voltammetry (FSCV). To more directly assess the effects of ethanol on striatal ACh, we used cell-attached electrophysiological recordings of cholinergic interneurons (CINs) and found that acute ethanol (40 mM) depressed CIN firing rate, supporting our FSCV results. To further evaluate ethanol effects on striatal ACh release, we used the iAChSnFR, a biosensor that increases in fluorescence intensity upon binding ACh. We used AAVs to express iAChSnFR in

DS of C57BL6J mice. After at least 4 weeks, brain slices containing iAChSnFR expression were used for slice photometry experiments. Similar to our previous results, we found that acute ethanol (40 mM) depressed ACh release. To determine if these effects applied in vivo, we used fluorescence fiber photometry with iAChSnFR and found a similar acute ethanol (2 g/kg) induced depression of ACh in DS. To assess chronic ethanol effects on ACh release, mice were injected with iAChSnFR as before. Following recovery, they underwent chronic intermittent ethanol vapor exposure (CIE) which consisted of ethanol vapor for 16 hours per day for four consecutive days followed by 72 hours of withdrawal. This cycle was repeated for four weeks. Following 72-96 hours of withdrawal, slice photometry was performed. CIE treated mice displayed deficits in ACh release compared to controls. Given the withdrawal period following the final ethanol exposure, this deficit is not likely due to any potential lingering acute ethanol effects. To determine the cause of this ACh deficit, we examined whether CIE resulted in a loss of CINs. We performed stereological counting of CINs in control and CIE mice and found no difference between groups. Thus, further work is required to determine the cause of the ACh deficiency following CIE. Altogether, our results show acute and chronic ethanol depresses ACh signaling in DS.

Title: Inhibition of Phosphacan regulates ethanol-induced changes in perineuronal nets and PV+ neurons in a sex-dependent manner during adolescence: Implications for ethanol consumption

Authors: M. GALÁN-LLARIO, M. RODRÍGUEZ-ZAPATA, T. FONTÁN-BASELGA, E. GRAMAGE, M. VICENTE-RODRÍGUEZ, J. ZAPICO, B. DE PASCUAL-TERESA, ***G. HERRADON**;

Abstract: Perineuronal nets (PNNs) are extracellular matrix structures surrounding neurons that are mainly formed during adolescence, when the brain is highly plastic and more vulnerable to the effects of drugs of abuse. Ethanol, which is frequently consumed by young adults in a binge-

like manner, alters the intensity of PNNs in different brain areas. However, little is known about possible sex differences in the regulation of the intensity of PNNs induced by ethanol. In addition, there is evidence showing the modulation of the effects of drugs of abuse through manipulation of PNNs, suggesting that pharmacological regulation of components of PNNs may be a novel therapeutic strategy in addictive disorders. One key constituent protein in PNNs is Phosphacan (Receptor Protein Tyrosine Phosphatase (RPTP) β/ζ). In the present work, we have assessed the capacity of MY10, a compound inhibitor of Phosphacan, to regulate ethanol consumption and ethanol-induced changes in PNNs in an Intermittent Access to Ethanol (IAE) model in adolescent mice. The data demonstrate that MY10 significantly decreases ethanol consumption in male mice, not in females. In general, ethanol consumption during the 4-week IAE paradigm induced a decrease in the intensity of PNNs in different cortical and hippocampal areas of male and female mice. We found a significant correlation between ethanol consumption and ethanol-induced alterations in the intensity of PNNs in the Dentate Gyrus (DG). Very interestingly, treatment with MY10 prevented this correlation in the DG of males and even reverted it in CA1 from both sexes, suggesting a connection between the capacity of MY10 to modulate the intensity of PNNs in the hippocampus and its ability to reduce ethanol consumption. In the insular cortex, a brain area that contains highly condensed PNNs around parvalbumin (PV)-expressing neurons, we found that inhibition of Phosphacan with MY10 potentiated the ethanol-induced increase of PV+ cells in male mice, whereas in females did the opposite. In conclusion, we have demonstrated that pharmacological inhibition of Phosphacan decreases ethanol consumption during adolescence only in male mice, which may be related to a sex-dependent regulation of ethanol-induced changes in the intensity of PNNs and number of PV+ cells in the hippocampus and the insular cortex.

Title: The kappa-opioid receptor in the nucleus accumbens shell: Subregional, sex-related, and intake-dependent effects on ethanol drinking

Authors: *B. E. PIRINO[1], B. A. CARPENTER[1], A. HAWKS[2], P. G. CANDELAS[2], A. T. GARGIULO[2], G. R. CURTIS[2], A. N. KARKHANIS[3], J. R. BARSON[4];

Univ., Binghamton, NY; [4]Neurobio. and Anat., Drexel Univ. Col. of Med. Neurosci. Program, Philadelphia, PA

Abstract: The kappa-opioid receptor (KOR) and its endogenous ligand, dynorphin, have been implicated in alcohol use disorder and are densely expressed in the nucleus accumbens (NAc) shell. Within the NAc shell, KORs are located on terminals of neurons originating from the ventral tegmental area (VTA), and the activity of the VTA to NAc shell pathway has been shown to suppress high-level ethanol drinking . Surprisingly, studies thus far have not found KOR activation in the NAc shell to affect ethanol drinking. Thus, we allowed male and female Long-Evans rats to drink under the intermittent access model, to investigate the effects of KOR manipulation in the NAc shell. Using microinjections of the KOR agonist, U50,488, we found that, although KOR stimulation in the middle subregion of the NAc shell had no effect on 20% ethanol drinking, KOR activity in the caudal NAc shell promoted ethanol drinking in males and higher-drinking females, while KOR activity in the rostral NAc shell instead decreased intake in males and lower-drinking females and enhanced intake in higher-drinking females. Conversely, blockade of KORs in the rostral NAc shell with the antagonist, nor-binaltorphimine, stimulated ethanol drinking in lower-drinking rats. To determine if these effects on ethanol drinking were substance-specific, we injected U50,488 into the rostral or caudal NAc shell of 2.5% sucrose-drinking rats and found no effect on sucrose intake. To determine if the differential effects of KOR manipulations could be due to ethanol-induced changes in gene expression, we performed quantitative real-time PCR on NAc shell tissue from ethanol-experienced and ethanol-naïve female rats. While there was no effect of ethanol on dynorphin gene expression, a history of ethanol drinking led to upregulated levels of KOR mRNA in the rostral NAc shell. To investigate if the effects of KOR manipulation could be due to KOR-mediated inhibition of VTA input, we injected an excitatory designer receptor exclusively activated by designer drugs (DREADDs) virus into the VTA and then injected CNO and U50,488 into the rostral NAc shell. We found that activation of the VTA to rostral NAc shell pathway suppressed ethanol drinking in high drinkers, and that U50,488, which otherwise enhanced ethanol drinking, reversed this DREADD-induced suppression. These findings demonstrate that (1) the KOR can affect ethanol drinking; (2) the direction of this effect depends on the level of intake, sex of the drinker, and subregion of the NAc shell; and (3) the ability of KOR activity in the rostral NAc shell to promote ethanol drinking in higher drinkers, which have upregulated KOR levels, may be due to its ability to suppress VTA input activity.

Title: Sex differences in stress-related neuropeptide signaling components and interaction with alcohol in GABAergic neurons of the lateral central amygdala in rats

Authors: *E. MOSS, E. BATSAIKHAN, D. KIRSON;
The Univ. of Tennessee Hlth. Sci. Ctr., Memphis, TN

Abstract: Alcohol use disorder (AUD) is characterized by compulsive seeking and consumption of alcohol. AUD involves the recruitment of brain stress systems leading to the negative affective states in withdrawal; relief of which drives further drinking. The central amygdala (CeA) is an important brain region that serves as a neuropeptidergic hub of stress, anxiety, and addiction processing, and CeA GABA transmission is involved in the regulation of alcohol consumption. The CeA consists of the lateral (CeL) and medial (CeM) subdivisions. The majority of neurons in the CeA are GABAergic, including both GABAergic projection neurons and local interneurons. Overall, studies show that acute alcohol application increases GABAergic transmission in the CeM, decreases glutamatergic transmission in the CeM, and increases spontaneous glutamatergic transmission in the CeL. However, the acute effects of alcohol on GABAergic transmission in the CeL are currently unknown. Stress related neuropeptides, such as oxytocin and CRF, have been shown to alter CeA GABA signaling in rodents, and modulating these systems can affect alcohol intake and withdrawal symptoms. In addition, we have previously shown sex-specific effects of alcohol and stress related neuropeptides on CeM GABAergic signaling. However, oxytocin receptors and CRF are primarily expressed in CeL neurons. In this study, we used whole cell patch clamp electrophysiology to examine the synaptic effects of alcohol and oxytocin on CeL GABAergic signaling in *ex vivo* brain slices from male and female Wistar rats. Additionally, we used *in situ* hybridization via RNAscope technology to identify differences in mRNA expression of these neuropeptide systems in the CeL of naïve and alcohol dependent male and female rats. These experiments provide important insight into sex differences in CeA neuronal functions that may contribute to the development of alcohol dependence.

Title: High-dimensional neural activity in the anterior insular cortex during natural and drug reward consumption

Authors: *S. JUNG[1], A. LAWRENCE[2], S. KOUKUNTLA[1], A. R. GRAVES[1,3,2], T. D. HARRIS[1,3,5], P. H. JANAK[2,4,3];
[1]Biomed. Engin., Johns Hopkins Univ., BALTIMORE, MD; [2]Neurosci., [3]Kavli NDI, [4]Psychological and Brain Sci., Johns Hopkins Univ., Baltimore, MD; [5]HHMI Janelia Res. Campus, Ashburn, VA

Abstract: The anterior insular (AI) cortex plays a major role in interoception where it mediates consummatory behaviors based on the current physiological state (Livneh and Andermann, 2021). Previous studies have shown that the insular cortex encodes expectation and consumption of natural and drug-related rewards and its chemogenetic modulation impacts their intake (Livneh et al., 2020; Jaramillo et al., 2018). Nevertheless, it is unclear how different reward-related variables are encoded by the population activity of AI neurons. In the current study, we recorded >100 neurons per session from three alcohol pre-exposed adult Long Evans rats (1 male and 2 females) using high-density Neuropixels 2.0 probes unilaterally implanted in the AI. We simultaneously recorded licks from rats as they freely drank from a bottle for 30 minutes containing either sucrose, alcohol, or a mixture of both. Kilosort 2.5 and manual curation were used to isolate single units. The modulation of these high-quality single units from the AI was assessed pre, during, and post each lick bout (defined as a continuous train of licks, with an inter-lick interval of ~ 0.16 sec and separated by > 0.5 sec) per recording session. Principal component analysis (PCA) was performed to investigate whether the tastant type or licking activity explained the variability in the population neural activity. We first observed that population activity in the AI is high dimensional (>7 principal components (PC) to explain ~80% of variance). We also found that the first two PCs discriminate licking from non-licking behavior. Furthermore, we found that PCs 3-7 encoded tastant identity, i.e., alcohol or sucrose. More specifically, projecting neural activity at the beginning and end of each lick bout onto PCs 3-7 showed a clear separation of activity by tastant. The separation persisted when we analyzed only the anticipatory neural activity (2s pre-bout), suggesting that these PCs encode tastant identity rather than licking patterns or perceived taste. These findings reveal moment-by-moment encoding of both general consummatory behavior and alcohol- and natural reward-specific variables including tastant anticipation and identity by simultaneously-recorded neuronal populations in the AI.

Title: The effect of chronic alcohol exposure on neuronal excitability and synaptic transmission in the nucleus reuniens: potential implication for cognitive dysfunction

Authors: *K. L. LINDQUIST, J. A. RINKER, P. J. MULHOLLAND;
Med. Univ. of South Carolina (MU Neurosci. Inst. - Grad., Charleston, SC

Abstract: Chronic alcohol use can cause cognitive deficits, particularly working memory, which persists during alcohol withdrawal and abstinence, increasing the odds of relapse. The extent to which alcohol exposure disrupts the circuitry underlying cognition is not fully understood. The nucleus reuniens (RE) is a ventral midline thalamic nucleus that plays a key role in cognitive function, especially spatial working memory. The RE is bidirectionally connected to the medial prefrontal cortex and the hippocampus, which have been highly studied in alcohol use disorder and cognition. Despite this, the RE remains highly understudied within the alcohol field. These studies aim to determine how chronic alcohol exposure alters intrinsic excitability and synaptic transmission within the RE in an exposure model that causes cognitive deficits. Alcohol dependence was induced using chronic intermittent ethanol (CIE) vapor exposure (4 cycles) in adult male and female C57BL/6J mice. Following CIE, mice were either tested on a T-maze delayed alternation spatial working memory task or sacrificed for whole cell patch clamp electrophysiology to measure intrinsic excitability or synaptic transmission in the RE. Mice used in the T-maze task were trained prior to CIE and tested following 2 and 4 cycles, to track cognitive decline across the development of dependence. Both male and female mice exhibited significant deficits in performance following CIE. Despite this similar behavioral phenotype, CIE had divergent effects on intrinsic excitability based on sex. CIE significantly increased spike firing in the females and significantly decreased spike firing in the males. Interestingly, in the absence of alcohol exposure, RE intrinsic excitability appears to be sex-dependent, where males have significantly greater excitability than females. Spontaneous inhibitory and excitatory post-synaptic currents are currently under analysis to determine how chronic ethanol impacts synaptic transmission in the RE. These results indicate that the RE could be an exciting new target for the study of chronic alcohol-induced cognitive deficits. Future studies will interrogate this RE in vivo during performance on the spatial working memory task following CIE exposure.

Title: Heavy adolescent drinking potentiates neuronal alcohol response later in life: involvement of GIRK and activin receptor signaling

Authors: *F. ZHENG, S. STÜRZENBERGER, N. BÜLOW, C. ALZHEIMER;
Univ. of Erlangen-Nürnberg, Erlangen, Germany

Abstract: Excessive ethanol consumption during adolescence is regarded as a risk factor for the development of alcoholism later in life, but the pathophysiological mechanisms that render the adult brain susceptible to alcohol are largely unknown. G protein-gated inwardly rectifying potassium (GIRK) channels are among the prime targets of alcohol to regulate neural activity. Previous work from our lab has demonstrated that activin A, a member of the TGF-β family, affects GIRK currents in mouse hippocampus. We asked here, (i) if hippocampal cells from adolescent and adult mice respond differently to alcohol exposure, and how GIRK channels are involved, (ii) how adolescent drinking affects alcohol response upon re-exposure in adulthood, and (iii) if activin plays a role as an adaptive factor. In whole-cell voltage-clamp recordings from dentate gyrus granule cells (GCs) in dorsal hippocampal slices, ethanol dose-dependently induced outward currents, which were significantly stronger in slices from adolescent compared to adult mice. Ethanol-evoked currents reversed near -90 mV, were largely diminished by the GIRK-inhibitor tertiapin Q, and were fully suppressed by low Barium. Unexpectedly, the effects of recombinant activin A on ethanol responses were stage-dependent, being potentiated in adolescence, but inhibited in adulthood. The inverse was true when ethanol responses were examined in GCs from adolescent and adult transgenic mice expressing a dominant-negative activin receptor IB mutant, which disrupts activin receptor signaling. These data underscore the essential role of endogenous activin signaling in determining the neural impact of alcohol consumption at different stages of life. Compared to alcohol-naive mice, sustained heavy drinking in the dark (DID, 20% alcohol) between postnatal days 32 and 45 produced a long-lasting sensitization so that ethanol-induced currents in adulthood were consistently potentiated, including its tertiapin Q-sensitive component. Consequently, the adolescent drinking paradigm enhanced the silencing of GC firing during ethanol exposure. Our results show that heavy adolescent drinking exerts a lasting impact on how GIRK channels react upon alcohol re-exposure later in life and that this process might possibly involve activin receptor signaling.

Abstract: The nucleus accumbens core (NAcc) is an important regulator of binge-like drinking. Male and female mice exhibit distinct transcriptional responses in the NAcc following limited access binge-like drinking. Moreover, chemogenetic manipulations of the NAcc results in opposite effects on binge drinking in male and female mice (inhibition decreased intake in males, but increased intake in females; stimulation decreased intake in females, with no change in males). We used whole-brain fluorescent imaging for the immediate early gene, c-Fos, and a viral retrograde green fluorescent protein (GFP) tracer to determine whether whole-brain activity and NAcc brain circuitry were differentially engaged in males and females during binge-like ethanol drinking [using the Drinking in the Dark (DID) assay]. We hypothesize males have greater c-Fos levels in excitatory regions that project to the NAcc, and females have greater c-Fos levels in inhibitory or peptidergic regions that project to the NAcc. C57BL/6J mice (n=15-16/sex/fluid) underwent stereotaxic surgery to infuse 0.5uL AAVrg-hSyn-eGFP bilaterally into the NAcc, recovered, and then underwent a 4-day DID (2hr on days 1-3, 4hr on day 4) with water or 20% ethanol. Immediately following DID, blood was collected for determination of blood ethanol concentration (BEC). Brains were collected and processed for whole-brain clearing, immunolabeling for c-Fos, GFP, and NeuN, and light-sheet imaging. Image atlas registration and cell detection was conducted using SmartAnalytics software. There was no effect of sex on 4hr ethanol intake, BEC, or water intake. Principal component analysis of c-Fos cell density reveal that sex, fluid, and a sex by fluid subgroups are associated with significant amounts of the total variance ($p<0.05$, one-way ANOVA). The peptidergic Edinger-Westphal nucleus (known sensitivity to ethanol) and subfornical organ (hypothalamic nucleus involved in osmoregulation) were engaged in both sexes following ethanol intake [$p<0.05$, with > 0.5 log fold change (lfc); compared to water drinking mice]. Ethanol drinking females had a greater number of regions engaged following DID than males, including the excitatory/glutamatergic claustrum, infralimbic and somatosensory cortices, and GABAergic/peptidergic pallidum, globus pallidus, and hypothalamic nuclei. In total, 94 regions had $p<0.05$, >0.5 lfc in female ethanol, compared to male ethanol drinkers. Analysis of c-Fos and GFP co-labeled neurons is underway. These findings indicate that binge-like ethanol drinking significantly impact whole-brain activity in a sex-specific manner, as measured by c-Fos induction.

Title: Determining the role of insula-S1 neurons in mediating affective behaviors during alcohol abstinence

Authors: *A. SALAZAR[1], J. R. LITTLE[2], S. W. CENTANNI[2];
[1]Physiology/Pharmacology, Wake Forest Univ. Sch. of Med., Winston Salem, NC;
[2]Physiology/Pharmacology, Wake Forest Sch. of Med., Winston Salem, NC

Abstract: Alcohol Use Disorder (AUD) is a growing problem in our nation and worldwide. COVID-19 has led to a significant rise in alcohol use, with many people relapsing due to the negative affective states correlated with abstinence. An understanding of the functional connectivity network of abstinence-induced negative affect is needed. Previous work in our lab has elucidated parts of this network, identifying an insula-BNST (bed nucleus of the stria terminalis) pathway activated during stress and negative affect in abstinence. The current study focuses on elucidating the control network for insula-BNST pathway mediation of abstinence-induced negative affect. We mapped 2nd order inputs into this pathway and identified the somatosensory cortex (S1) as a dense population of neurons that project to the insula-BNST pathway. As the S1 is involved in processing tactile information arising from external stimuli, we hypothesize the S1 serves in this pathway as a gateway between the external environment and the internal state. To test this potential pathway in alcohol abstinence, we injected anterograde AAV1.Cre into both S1 and DIO.hM3Dq into both insulae in female mice to isolate specific insula cells that receive projections from S1. We then subjected the mice to a chronic alcohol drinking forced abstinence (CDFA) model. After 6 weeks of drinking and 2 weeks of abstinence, mice were subjected to multiple behavioral tests (Novelty Suppressed Feeding Test (NSFT), Acoustic Startle, Foot Shock Startle, and Air Puff Startle). Chemogenetic activation of these insula^{S1} neurons causes a decreased startle response at lower shocks in alcohol abstinent negative affective behavior in the Foot Shock Startle test. Incorporating multiple measures of negative affect and normalizing them across tests is important to create a more holistic view of an animal's affective state in alcohol abstinence. To this end, we began using "emotionality scores" to normalize and combine affective states across tests, statistically determining an emotionality score for each subject based on validated measures of negative affect for each test (e.g., latency to bite on NSFT). Preliminary data using this "emotionality" method demonstrates chronic ethanol drinking increases negative emotionality (i.e., negative affective state) in mice in protracted abstinence. Follow up studies are looking at the opposite side of this pathway, isolating specific S1 cells that project to the insula; along with incorporating emotionality data

after behavioral assays, to show that the S1 is a critical regulator of the insula to BNST pathway, and an overall contributor to alcohol abstinence-induced negative affect.

Title: Inhibiting CRF and NPY1R+ Projections From the Central Amygdala to Lateral Hypothalamus Blunts Binge-Like Ethanol Drinking in Male, but Not Female Mice

Authors: *S. C. BENDRATH[1], J. M. L. CABRERA[2], M. F. CARVAJAL[2], A. P. S. DORNELLAS[1], M. NAVARRO[1], T. E. THIELE[1];

Abstract: Corticotrophin releasing factor (CRF) and Neuropeptide Y (NPY) are a critical 'pro-stress' and 'anti-stress' neuropeptides modulating binge-like ethanol intake in the central amygdala (CeA) and the lateral hypothalamus (LH). Both brain regions express these peptides, and are known to be particularly impacted by ethanol consumption. The CeA is an important region in relation to alcohol use disorder as it integrates stress and reward aspects to form behavioral responses. The LH is a very heterogeneous brain area, with a variety of neuropeptide and neurotransmitter systems which have been implicated in sleep regulation, food intake, and recently drug reward. Previous data from our lab indicates that CRF and NPY co-modulate ethanol intake, so we wanted to specifically investigate the role of the CRF and NPY systems in the CeA to LH pathway. To assess the role of these anxiety and reward pathways, chemogenetic approaches were used in male and female CRH-cre and NPY1R-cre expressing mice. The "drinking in the dark" behavioral model was used for two consecutive cycles of 20% ethanol solution, and 3% sucrose solution. Preliminary results showed interesting sex-differences regarding the CeA-LH pathway. Placing the Gi DREADD into the CeA, and micro-injecting CNO into the LH, we found a sex-specific reduction in ethanol drinking in male, but not female mice for both CRF and NPY1R+ projections. Silencing this CRF or NPY1R+ pathway had no effect on sucrose drinking in either male or females, suggesting a specific effect for ethanol. The present findings are in line with our prior hypothesis about the NPY system working, in opposition to CRF, as a protective mechanism against ethanol consumption. Interesting sex trends emerged in CeA to LH pathway, such that both CRF and NPY1R+ neurons in this

pathway only appear to modulate ethanol consumption in male, and not female mice. Supported by NIH: AA022048 & AA013573.

Title: Non-ablative focal irradiation restores the functional connectivity between the nucleus accumbens and the dorsal anterior cingulate cortex in miniature pigs with long history of alcohol consumption

Abstract: Excessive alcohol drinking is a globally prevalent condition and is linked to many negative health and social consequences. One essential site where ethanol acts directly on neurons is the nucleus accumbens (NAc) - one of the critical structures related to alcohol craving. However, most contemporary treatment options do not achieve a long-term reduction in alcohol usage. In this study, we investigated how the functional connectivity between the NAc and the dorsal anterior cingulate cortex (dACC) was affected by long-term alcohol consumption, and how radiation-based neuromodulation might affect the NAc-dACC functional connectivity and animals' alcohol-drinking behavior. Eight Lee Sung miniature pigs were included in the study: five were trained with operant procedures to voluntarily consume ethyl alcohol solution over 2-3 years, and three served as non-drinking controls. An Achieva 3.0 T scanner (Philips) with an 8-channel body surface coil was used as the receiver for magnetic resonance imaging (MRI) of the brain to obtain images, including T1- and T2-weighted, fast gray matter acquisition T1 inversion recovery (FGATIR) for structural identification, and echo planar imaging (EPI) for resting-state *f*MRI time series. Seed-based functional connectivity analysis was implemented by calculating correlation voxel-wisely throughout the brain with the time series retrieved from the NAc. Preliminary results showed that the NAc-dACC functional connectivity of alcohol-

consuming animals was lower than that of non-drinking controls. We irradiated the NAc using a cross-firing stereotactic radiosurgery approach in three highly motivated alcohol-seeking animals (Dmax = 30 Gy with a 5mm collimator). The selected dose has been shown to elevate metabolic activity at the target without evidence of tissue destruction (Yeh et al., 2021). Thereafter, voluntary alcohol consumption was shown to be significantly reduced in the three irradiated animals. Preliminary analysis of functional connectivity showed an increase in the NAc-dACC connectivity six months after radiosurgery. Overall, we have demonstrated a viable larger animal model of Alcohol Use Disorder, with behavioral measures of motivation that reasonably approximate "craving." NAc-dACC functional connectivity reduction may be a characteristic of excessive alcohol consumption, and the restoration in connectivity strength may be a restorative result of focal neuromodulation using non-ablative radiation. These results suggest that non-ablative focal radiation has the potential to be an effective neuromodulation tool for the treatment of chronic alcohol-seeking behaviors.

Title: Drinking severity mediates the relationship between hypothalamic connectivity and rule-breaking/intrusive behavior in young adults

Authors: *Y. DONG[1], G. LI[2], C.-S. R. LI[3];
[1]Univ. of North Carolina Chapel Hill, Chapel Hill, NC; [2]Beijing Univ. of Technol., Beijing, China; [3]Yale Univ., Yale Univ., New Haven, CT

Abstract: Background
Hypothalamic circuits play a key role in supporting motivated behavior. Problem drinking may compromise hypothalamic circuit functions, as in altered hypothalamus-pituitary-adrenal axis response to stress. Here, we investigated how alcohol use severity may impact hypothalamic resting-state functional connectivities (rsFC) and how the latter inter-relate the severity of drinking and other problem behaviors.

Methods
We curated the data of the Human Connectome Project S1200 data and identified 870 subjects with both physiological data and rs fMRI data meeting "scrubbing" criteria. Alcohol use severity was quantified by the first principal component (PC1) of PCA of all drinking measures, as in our published work. All participants were assessed with the Achenbach Adult Self Report syndrome scales, including rule-breaking and intrusive subscales. Imaging data were processed with published routines and evaluated at a corrected threshold.
Results
Whole-brain linear regression of the hypothalamus rsFCs against PC1 revealed across all subjects a cluster in the paracentral lobule (PCL, x, y, z = -4, -32, 66; Z = 4.49, 2440 mm3) and, in women alone, a cluster in the left temporo-parietal junction (left TPJ, x, y, z = -58, -54, 4; Z= 5.33, 824 mm3) in positive correlation with PC1, at voxel $p<0.001$, uncorrected, and cluster $p<0.05$, FWE-corrected. The β's of hypothalamus-PCL rsFC were significantly correlated with rule-breaking score in all ($r = 0.088$, $p = 0.009$) and in men ($r = 0.152$, $p = 0.002$), but not in women in linear regressions with age as a covariate. The β's of hypothalamus-left TPJ rsFC were significantly correlated with intrusive score in women ($r = -0.127$, $p = 0.006$), but not in all or men. In mediation analyses PC1 mediated the correlation between hypothalamus-PCL rsFC and rule-breaking in men and between hypothalamus-left TPJ rsFC and intrusive problems in women, both bidirectionally.
Conclusions
Hypothalamus-parietal cortical connectivities associate problem drinking and rule-breaking and intrusive problems each in men and women.

Title: Interneuron properties in the ventral subiculum of male and female rats

Authors: *E. BACH, O. ORTELLI, S. PITCAIRN, J. WEINER;
Wake Forest Baptist Med. Ctr., Winston Salem, NC

Abstract: Inhibitory neurons play an essential role in maintaining normal physiological function throughout the brain, and a wide array of pathological conditions have been linked to aberrant inhibitory synaptic processes or associated excitatory-inhibitory imbalance. The ventral

subiculum (vSub) of the hippocampus has received increased attention for its role in acute anxiety, anxiety disorders as well as comorbid alcohol and substance use disorders. Our prior studies using models of alcohol dependence and vulnerability to alcohol use disorders revealed both sex-dependent and sex-independent adaptations of inhibitory input onto pyramidal neurons in the vSub. This finding prompted our interest in better understanding plasticity mechanisms in GABAergic neurons that ultimately dictate inhibitory tone within this brain region. One challenge in studying GABAergic neurons is their identification, particularly when studying functional adaptations using electrophysiological techniques. Relying on identification approaches such as action potential firing patterns or protein expression profiles can limit the types of interneurons being studied, the animal model being utilized and/or the types of electrophysiological studies that can be conducted. More recently the discovery of a specific GABAergic enhancer element (mDlx+) in a broad array of GABA neurons has allowed interneurons to be virally targeted for fluorescent identification or optical/chemogenetic manipulation. Here, we used this viral approach to fluorescently label and conduct electrophysiological recordings in mDlx+ vSub neurons of adult rats. We found that these mDlx+ neurons have shorter spontaneous EPSC (sEPSC) rise and decay times, but not amplitude differences, relative to vSub pyramidal neurons. Across sexes our results reveal that vSub mDlx+ neurons of female rats have a higher sEPSC frequency than males; a finding that could begin to explain the pathological sex-dependent adaptations seen in our animal models. Additional studies are underway to determine the GABAergic subtype(s) (protein expression identity) seen in mDLX+ neurons of the vSub.. Future studies aim to use our findings to integrate electrophysiological and molecular approaches and confirm the presence of distinguishing kinetic features of GABAergic neurons in young animals. This confirmation will allow us to circumvent limitations beset by viral expression windows and enable us to study the developmental progression in the broader vSub GABAergic neuronal population in our animal models of alcohol dependence and vulnerability to this disorder.

Title: Tip60 histone acetyltransferase regulates PDF neuropeptide expression and alcohol-tolerance acquisition in Drosophila melanogaster

Authors: *M. J. ÁLVAREZ-CORTÉS, C. D. DEL VALLE-COLÓN, N. L. FUENZALIDA-URIBE, A. GHEZZI;
Biol., Univ. de Puerto Rico, Rio Piedras, San Juan, PR

Abstract: Alcoholism is a condition characterized by behavioral and physiological changes, which can significantly impact an individual's health and interpersonal relationships. After prolonged alcohol consumption, the organism induces neuroadaptations that lead to tolerance, dependence, and a series of alterations in sleep patterns and circadian rhythms. Drosophila melanogaster has emerged as an effective model for studying alcohol neuroadaptations due to its behavioral responses to alcohol that closely resemble those observed in humans. Here, we explore the role of the histone acetyltransferase (Tip60) in the regulation of alcohol responses through its modulation of the ventrolateral neuronal system (LNv) of Drosophila. These neurons are known to regulate the sleep/wake cycle in Drosophila. We hypothesized that Tip60 would have a major role in the capacity of Drosophila melanogaster to acquire ethanol tolerance. Using the UAS-Gal4 system to knockdown Tip60 expression in LNv neurons (pdf-Gal4/UAS-Tip60-RNAi) we record the activity of flies during alcohol exposure and measure alcohol sensitivity and tolerance, against age-matched adult female flies. In parallel, we assessed the expression of the neuropeptide PDF to study the involvement of Tip60 in regulating PDF expression and LNv branching pattern. We found that Tip60 knockdown flies display increased alcohol sensitivity and reduced alcohol tolerance. Moreover, we found that Tip60 knockdown in LNv neurons leads to a significant reduction in the LNv branching pattern and that alcohol exposure exacerbates this reduction in pdf-Gal4/UAS-Tip60-RNAi flies, decreasing overall LNv neuronal branching. These results suggest that Tip60 is involved in the regulation of alcohol tolerance acquisition and brain branching patterns of LNv neurons. Understanding the molecular and cellular mechanisms underlying ethanol neuroadaptations can potentially lead to the identification of new therapeutic targets for alcohol-induced disorders.

Title: Involvement of connexin-36 gap junctions in the activity of ventral tegmental area neurons

Authors: *A. J. PAYNE[1], S. SANDOVAL-PISTORIUS[2], A. B. AMENDOLARA[1], J. OBRAY[3], S. B. WILLIAMS[4], S. STEFFENSEN[4];
[1]Noorda Col. of Osteo. Med., Provo, UT; [2]Univ. of California San Francisco, Oakland, CA; [3]Med. Univ. of South Carolina, Summerville, SC; [4]Brigham Young Univ., Provo, UT

Abstract: Gap junction proteins facilitate transmission of ions and other small molecules across electrical synapses. Vertebrate gap junctions are comprised of connexin subunits that join together to form a hemichannel known as a connexon. We have previously demonstrated that connexin-36 (Cx36) is expressed in the mature nervous system in a subpopulation of neurons in the ventral tegmental area (VTA). Cx36 has been evidenced previously to have a role in brain stimulation reward, and it has also been observed that Cx36 expression levels change in response to cocaine and methamphetamine self-administration. We hypothesize that these Cx36+ gap junctions play a role in alcohol reward and/or dependence. Here we customize a Gq-coupled Designer Receptor Exclusively Activated by Designer Drugs (DREADD) viral vector (AAV8.hCx36.hM3D(Gq)-mCherry.WPRE.rBG) with expression targeted to Cx36+ neurons. This vector or a control vector (AAV9.CB7.CI.mCherry.WPRE.rBG) was injected into the VTA of CD-1 GAD67 GFP transgenic mice and Wistar rats. *In vivo*, intraperitoneal administration of clozapine-N-oxide (CNO, 3 mg/kg), the ligand for the DREADDs, significantly increased VTA GABA neuron single-unit activity in anesthetized rats. *Ex vivo*, similar increases in VTA GABA neuron activity were observed but with a concomitant increase in VTA dopamine (DA) neuron activity. These *ex vivo* increases were dose-dependent and greater in amplitude in VTA GABA neurons than in VTA DA neurons. We furthermore utilized the calcium-sensitive fluorophore GCaMP6f to evaluate the impact of CNO and ethanol on calcium dynamics in the VTA. These two viruses were combined, aliquoted and flash frozen for storage. They were then co-injected into the VTA of C57BL/6J wild type mice. Following an incubation period, we sectioned the brains and measured the calcium-dependent fluorescence of many VTA neurons simultaneously in the presence of CNO, ethanol, NMDA, or combinations of these. High pass and low pass filters were applied to the mean fluorescence intensity of each region of interest to separate the fast calcium transients from the slow calcium swell instigated by the bath application of CNO. Neurons were categorized based on their response to CNO, including subpopulations whose calcium transient activity was increased, decreased, or unaffected by the presence of CNO. This work suggests that activation of Cx36+ neurons in the VTA may play a modulatory role of mesolimbic circuitry. Additional work is warranted to elucidate the connection between these effects and alcohol reward and/or dependence.

Title: Real-time Dopaminergic Encoding of Reward Consumption in the Prelimbic Cortex

Authors: *L. CASTELL[1], Y. CHENG[1], R. MAGNARD[1], A. DRISSI[1], Z. H. CAMHI[1], P. H. JANAK[2];
[1]Psychological and Brain Sci., [2]Psychological and Brain Sciences, Neurosciences and Kavli NDI, Johns Hopkins Univ., Baltimore, MD

Abstract: The prelimbic cortex (PrL) is implicated in both ethanol seeking and drinking (Khoo et al., 2019; Rinker et al, 2023; Siciliano et al., 2019; Timme et al, 2022). Ethanol stimulates the activity of midbrain dopaminergic neurons, however, the role of PrL dopamine in the control of alcohol drinking is unclear. The aim of this study was to decipher whether changes in dopamine release within the PrL cortex mediate cued reward consumption of an ethanol and/or natural reward within a task that allows separation of the seeking and consummatory phases of behavior. We used *in vivo* fiber photometry with DLight (AAV5-hSyn-dLight1.2) in the PrL cortex in freely-moving male (n=5) and female (n=8) rats to assess dopaminergic activity across task acquisition. Rats received pre-exposure in the home-cage of ethanol 15% (w/v) or water for 4 weeks, followed by daily behavioral training and dopamine signal recording. In each 40 min behavioral session, reward delivery (0.2ml/delivery of either 15% ethanol w/v or 3% sucrose w/v) was contingent upon port entry during an auditory cue presentation (interstimulus interval mean 78+/-45 sec), with a maximum of 21 rewards per session. Dopamine signals were obtained over at least two weeks of task acquisition; after stable acquisition with one reward (ethanol or sucrose), rats received test sessions with alternative rewards (sucrose or water). Bootstrapped confidence intervals (CI 95%, 1000 permutations) were used to determine statistically significant changes from baseline fluorescence as in Jean-Richard-Dit-Bressel et al. (2019). We found a consistent and sustained increase in dopamine during ethanol and sucrose consumption. This increase initiated before rats entered the drinking port and terminated at port exit, and the magnitude of this signal correlated with the relative value of the reinforcer with strongest signals for sucrose, intermediate for ethanol, and weakest for water. Our findings suggest PrL dopamine release scales with reward value. These data complement prior neural activity recordings (Amarante et al, 2014; Horst and Laubach, 2013) showing changes in PrL neuronal activity just prior and during reward intake and implicate dopamine in the modulation of this process.

Title: Neuronal ensemble in the medial orbitofrontal cortex as a brake to excessive bing alcohol drinking.

Authors: *P. GIMENEZ GOMEZ[1], T. LE[1], M. ZINTER[1], S. MOLAS[2], P. M'ANGALE[1], T. FREELS[1], J. POPOOLA[3], T. THOMSON[1], A. TAPPER[1], D. SCHAFER[1], G. MARTIN[1]; [1]Univ. of Massachusetts Chan Med. Sch., Worcester, MA; [2]Univ. of Colorado, Boulder, CO; [3]The Catholic Univ. of America, Washington, DC

Abstract: Alcohol abuse is the seventh leading risk factor for both death and the burden of disease. While several drugs have been approved to treat this disorder, their efficacy remains modest due in part to their lack of specificity. In this study we identified a group of neurons (neuronal ensemble) in the medial prefrontal orbital cortex (mOFC) that shows activity when the mice reach an elevated blood ethanol content (BEC). Also, we have characterized this neuronal ensemble and its implications for alcohol consumption. We are using “Targeted recombination in active populations” (TRAP2) mice (males and females), a mouse line that in presence of 4-hydroxitamoxifen allows permanent genetic access to neurons activated by a specific experience. In TRAP2 mice subjected to the drinking in the dark paradigm of alcohol consumption we performed fiber photometry, single cell RNA-seq, electrophysiology and light-sheet microscopy to understand the characteristics of the neuronal ensemble (cellular type, intrinsic and extrinsic properties, layer location, areas of projection or transcriptional pattern among others) and then optogenetics to manipulate the ensemble and measure the effect of both inhibition and activation in the amount of alcohol consumed. We found that about 5% of mOFC neurons are activated by alcohol as it reaches intoxication level (i.e., BEC higher than 80mg/dL). Moreover, those neurons don’t show activity if the mice don’t reach that level of intoxication Single cell RNAseq shows that the neuronal ensemble is GABAergic and shows a decrease in transcripts related to ion channels. Calcium recording with fiber photometry while the mice drink shows a strong peak of calcium only at the end of the episode of consumption with no response at the beginning of the episode of consumption. Moreover, we show that this response is dependent on alcohol concentration since when they reach an intoxication level at the beginning of consumption (using a pharmacological approach) the neurons show also early activity indicating that those neurons acts in response to intoxication. Finally, using optogenetics we modulated the neuronal ensemble showing that an activation using Channelrhodopsin produces a strong decrease in the consumption while their inhibition using Halorhodopsin renders the opposite effect. Our data demonstrate that binge alcohol drinking recruits a neuronal ensemble with a unique set of properties and whose role is to act as a brake reducing drinking when the mice reach intoxication level.

Title: Assessing behaviors associated with discontinuation of subchronic methamphetamine administration in C57Bl/6J mice using a novel, automated machine learning technology

Authors: *B. MENARCHEK[1,2,3], A. WHITE[1,2,3], C. MELVIN[1], V. SETOLA[1,4,2], D. REYNOLDS[5,6], Z. WRIGHT[6];
[1]Neurosci., [2]Rockefeller Neurosci. Inst., [3]Physiol. and Pharmacol., [4]Behavioral Med. and Psychiatry, [5]Lane Dept. of Computer Sci. and Electrical Engin., West Virginia Univ., Morgantown, WV; [6]SwiftSCIENCE, Pittsburgh, PA

Abstract: Methamphetamine (METH) use is on the rise, and the drug is quickly becoming one of the most commonly misused substances in the United States. The devastating effects of METH appear not only through the short- and long-term physical and psychological damage of the person engaging in misuse, but also from the subsequent addiction elicited from the drug-taking behavior. Given individual and societal harm caused by METH, there is a pressing need to identify features amenable to screening various treatments for the potential to alleviate the unpleasant, relapse-predisposing symptoms associated with discontinuation of chronic methamphetamine. Although the current literature describes neurochemical, neuroanatomical, electrophysiological, and locomotor effects associated with METH discontinuation, these types of measurables are labor-intensive to compare in studies surveying potential pharmacotherapeutics. In that regard, we sought to identify quantifiable behaviors associated with discontinuation of subchronic METH administration to C57BL/6J mice. We hypothesize that such behaviors might represent a useful index for our and others' studies of potential interventions to prevent/treat METH withdrawal symptoms in humans. To identify METH-discontinuation-associated behaviors, mice were treated with METH (2.5 mg/kg) for ten days, after which they were observed under no treatment for seven days. Video footage was collected during both the administration and discontinuation phases, and recordings were scored by blinded experimenters. We found that, during the first day of METH discontinuation, mice that were administered METH showed a significant three-fold increase in digging behavior compared to mice administered saline. Other behaviors identified in this study included a control behavior (or a behavior that was identical between both groups throughout both phases) and two behaviors associated with METH treatment but not affected during the discontinuation phase. In an effort to increase throughput for eventual treatment screening, experimenter-scored videos were used to train a machine learning algorithm to identify digging behavior. In a time-efficient manner, the

machine learning algorithm was able to replicate manual scores with greater than 90% accuracy. The discovery of a behavioral biomarker associated with methamphetamine discontinuation coupled with the ability to apply automated behavioral scoring to this paradigm could offer a new, moderate-to-high-throughput method for screening interventions for potential efficacy in human METH withdrawal.

Title: Sex differences in compulsive methamphetamine intake and relapse to drug seeking during abstinence

Authors: *A. DAIWILE, J. SUBRAMANIAM, B. LADENHEIM, M. T. MCCOY, M. JOB, J. L. CADET;
MNRB, NIH, NIDA IRP, Baltimore, MD

Abstract: Sex differences in compulsive methamphetamine intake and relapse to drug seeking during abstinence Atul P. Daiwile*, Subramaniam Jayanthi, Bruce Ladenheim, Michael T. McCoy, Martin Job, and Jean Lud CadetMolecular Neuropsychiatry Research Branch, NIDA-IRP, Baltimore, MD 21224
Methamphetamine (METH) is an extremely addictive drug that continues to wreak havoc in the lives of individuals who suffer from METH use disorder (MUD). There is evidence for sex differences in patterns of abuse, amounts of METH taken, as well as in relapse rates among METH users who meet DSM criteria for MUD. We are actively investigating the behavioral differences between compulsive and non-compulsive METH self-administration (SA) by rats in the presence of an electric shock barrier. In the present study, we have used female and male Long Evans rats that were trained to self-administer METH (0.1 mg/kg/infusion, IV) on an FR-1 schedule for 22 days using a pattern of three 3-h sessions/day. After 22 days of METH SA, rats continued to self-administer METH in the presence of contingent footshocks (0.18mA to 0.36mA) for more 8 days. After 8 days of contingent punishment, we assessed relapse behaviors on withdrawal day 1 (WD3) and 15 (WD15) from SA. Both female and male rats escalated their METH intake during the first 22 days of SA training. There were significant effects of sex and training days, but their interaction was not significant, indicating that both female and male rats increased their METH intake. Interestingly, male rats took more METH than female rats during the first 10 days and last 7 days of training. Analysis of METH intake for all 22 days revealed only a trend towards significance ($p=0.0601$), with for male rats exhibiting somewhat higher total METH intake then females. Contingent punishment significantly reduced METH taking in

some of the female and male rats (shock-sensitive, SS; non-compulsive) but not in others (shock-resistant, SR; non-compulsive). Moreover, SR rats displayed a significant effect of training day (statistics), but a trend towards significance for sex (p=0.0772) and its interaction (p=0.0806). Furthermore, 72% (13/18) of males while 53% (9/17) of females showed compulsive METH intake in the presence of adverse consequences. Non-compulsive female rats were more prone to relapse during forced abstinence in comparison to non-compulsive male rats. In contrast, both compulsive female and male rats showed similar METH craving behavior during abstinence. These observations indicate that non-compulsive females that take less METH than males might be more prone to relapse to METH taking behaviors. **Acknowledgement:** This work is supported by DHHS/ NIH/ NIDA-IRP.

Title: Modeling methamphetamine use disorder and relapse in animals: short- and long-term, transcriptional consequences in the brain

Authors: *M. MCCOY, K. ELHADI, A. P. DAIWILE, J. L. CADET;
DHHS/NIH/NIDA/IRP, Baltimore, MD

Abstract: Methamphetamine (METH) use disorder (MUD) is a chronic neuropsychiatric disorder characterized by binge drug taking episodes, intervals of abstinence, and relapses to the use of the drug even while in treatment. MUD has been modeled in rodents in order to identify the molecular bases for persistent drug taking behaviors. These experiments promise to shed some light on potential neurobiological substrates of METH addiction, with the hope of developing more target-driven pharmacological interventions. In present study, we trained male Sprague-Dawley rats to self-administered METH (0.1 mg/kg/injection, i.v.) while control rats received saline infusions on an FR-1 schedule for 8 days [15-hours (hrs) sessions/day]. After the last METH SA session, rats were euthanized at 2 hrs, 24 hrs, or 1 month after cessation of drug exposure. Dorsal striata were dissected and used in microarray analysis. Rats escalated their METH intake over time. The microarray data were analyzed using **D**atabase for **A**nnotation, **V**isualization and **I**ntegrated **D**iscovery (DAVID); Kyoto Encyclopedia of Genes and Genomes (KEGG) pathways; and Sankey analyses. At the 2-hr time point, calcium, cAMP, and Ras

signaling pathways were significantly enriched. At the 24-hr time point, there was significant enrichment of genes involved in infectious diseases and immune responses. Interestingly, most genes showed decreased mRNA expression at the 1-month withdrawal time point. At that time, differentially expressed genes belong to cell differentiation and development processes. Cluster analysis revealed that genes upregulated at early time points tended to be down-regulated later on and vice versa. These observations suggest potential compensatory mechanisms at the later time point. Elucidation of the molecular machinery that form the substrates of cue-induced relapses that tend to be more prominent at later time points will provide better molecular targets for both pharmaceutical interventions for individuals who suffer from MUD.**Acknowledgement:** This work is supported Department of Health and Human Services/ National Institutes of Health/ National Institute on Drug Abuse/ Intramural Research Program.

Title: The effects of bupropion on Arc mRNA expression in mice with methamphetamine-induced neurotoxicity

Authors: J. EARL[1,2], A. S. GIBSON[1,3], *K. KEEFE[1];
[1]Univ. of Utah, Salt Lake City, UT; [2]The Comparative Hlth. Outcomes, Policy, and Econ. (CHOICE) Inst., Univ. of Washington, Seattle, WA; [3]Neurosci., Westminster Col., Salt Lake City, UT

Abstract: Studies in humans and in animal models suggest that exposure to methamphetamine (METH) leads to decreased striatal dopamine. Such toxicity is associated with decreased amplitude of phasic dopamine signals and alterations in gene expression in striatal efferent neurons, such as Arc. These long-term effects of METH may negatively affect striatally based learning and memory, contributing to a low probability of behavioral recovery. Bupropion (Bup), a dopamine transporter inhibitor, is theorized to increase phasic dopamine signaling and, consequently, restore Arc expression in striatum. The purpose of this study was to provide a preliminary test this hypothesis by determining whether acute treatment with Bup restores Arc expression in striata of mice with METH-induced toxicity. Adult male C57BL/6J mice (n=4/group) were pretreated with *d,l*-METH•HCl (4x10 mg/kg free base) or saline (Sal). Approximately 3 weeks later mice were randomized to receive and were acutely treated with Sal

or Bup•HCl (50 mg/kg free base) and then placed in a novel environment for 30 min. Mice were then sacrificed, and brains harvested, sectioned, and processed for Arc and preproenkephalin (ppe) mRNAs using RNAScope™. Digitized images were captured and analyzed to determine the numbers of Arc+/ppe+ (*i.e.*, D2-MSNs) and Arc+/ppe-negative (*i.e.*, D1-MSNs) cells in a 0.5x0.5 mm field. The numbers of cells were compared across groups via ANOVA. Statistical significance was set at $p \leq 0.05$. All RNAscope assays, imaging, and data analyses were conducted with the experimenter blinded to the treatment group of the animals. Acute treatment with Bup increased the number of Arc+ D1-MSNs. There was a significant main effect of treatment group, as well as a significant group x cellular phenotype interaction. *Post-hoc* analysis revealed significantly more Arc+ D1-MSNs in both the Sal-pretreated and METH-pretreated mice treated with Bup. Although the number of Arc+ D1-MSNs was significantly less in the METH-pretreated mice treated with Bup vs. the Sal-pretreated mice given Bup, the number of Arc+ D1-MSNs was similar to those in the Sal-pretreated mice acutely treated with Sal. Post hoc analysis revealed no effects of treatment group on the number of Arc+ D2-MSNs. These preliminary data suggest that acute treatment with bupropion restores Arc mRNA expression in D1-MSNs of mice with METH-induced neurotoxicity. Given the critical role of Arc in brain plasticity, the findings suggest that bupropion may be an option for improving striatally-based learning and memory processes necessary for optimal response to behavioral treatments for METH-use disorders.

Title: Mechanistic insight into microbial regulation of psychostimulant abuse

Authors: S. J. MABRY[1], X. CAO[2], S. PATEL[1], T. ROMANAZZI[3], Y. ZHU[1], D. P. SALEEBY[1], C. ROWE[1], A. ELAM[1], H.-T. LEE[1], H. WU[2], A. GALLI[1], ***A. M. CARTER**[1]; [1]Univ. of Alabama, Birmingham, Birmingham, AL; [2]Oregon Hlth. and Sci. Univ., Portland, OR; [3]Univ. of Insubria, Varese, Italy

Abstract: Amphetamines (AMPHs) are highly effective psychostimulants commonly used for the treatment of neuropsychiatric disorders and are abused with devastating outcomes. The stimulant properties and abuse potential of AMPHs have been associated with their ability to increase extracellular dopamine (DA) levels. This increase is mediated, at least in part, by the

reversal of DA transporter (DAT) function, which causes non-vesicular DA release, here defined as DA efflux. Recent studies suggest that imbalances in the gut microbiome (dysbiosis) participate in the pathogenesis of substance use disorders. Microbial products such as short-chain fatty acids (SCFAs), are suspected to play a fundamental role in this process. Among SCFAs, butyrate is known to cross the blood-brain barrier and directly act on neurons and glial cells. *Fusobacterium nucleatum* (*F. nucleatum*) is a bacterial species that secretes butyrate and whose abundance is increased by AMPH abuse in both rodents and humans. It is important to note that butyrate is a potent inhibitor of histone deacetylases (HDACs) and that inhibition of HDACs robustly increases expression of both DAT mRNA and protein levels in cultured cells. Changes in DAT expression regulates both AMPH-induced DA efflux and psychomotor actions. Here, we report that colonization of the intestinal tract of gnotobiotic *Drosophila* with *F. nucleatum* significantly enhances AMPH-induced DA efflux and associated behaviors such as locomotion, courting, and preference. This potentiation of AMPH actions by *F. nucleatum* was paralleled by oral administration of butyrate. In contrast, acetate and propionate, other SCFAs secreted by *F. nucleatum*, failed to enhance both AMPH-induced DA efflux and locomotion. Further, inhibition of HDACs using Trichostatin A, as well as genetic knockdown of HDAC1 in DA neurons *via* RNAi, both increased AMPH-induced DA efflux and locomotion. Importantly, both *F. nucleatum* colonization, as well as direct butyrate administration, also lead to a significant increase in DAT expression. These data provide evidence that *F. nucleatum* modulates AMPH-induced behaviors through secretion of butyrate, inhibition of HDACs, elevation of DAT expression, and increased DA efflux. These findings suggest modulation of the gut microbiome as a therapeutic approach for the treatment of substance use disorders.

Title: Activation of Melanin Concentrating Hormone Neurons in the Lateral Hypothalamus alter the expression of methamphetamine intravenous self-administration

Authors: *M. SUAREZ, H. SCHNEIDER, I. R. K. KUEBLER, K. T. WAKABAYASHI; Psychology, Univ. of Nebraska-Lincoln, Lincoln, NE

Abstract: Sensitivity to the reinforcing effects of methamphetamine (METH) can influence the motivation to work for the drug, or its associated cues; this in turn can contribute to the

development of METH use disorder (MUD). Several brain areas play a role in regulating METH associated behaviors. The lateral hypothalamus (LH) is a region that interfaces with mesolimbic neural circuitry associated with reward and MUD. Within the LH, melanin-concentrating hormone (MCH) neurons, mainly studied in the context of sleep wakefulness and energy homeostasis, have been shown to impact METH psychomotor sensitization. These and other findings suggest that LH MCH neurons regulate METH seeking and taking behavior, but relatively little is known about how the activity of these neurons influence METH self-administration behavior. In this study, male and female Wistar rats were trained to intravenously self-administer METH (0.05 mg/kg/inf) via nose pokes for 10 days. After this, a dose-response curve was generated by allowing rats to self-administer one of five doses (0.0625, 0.0125, 0.025, 0.05, or 0.1 mg/kg/inf, presented in a Latin-Square design) every other day. Using a combinatorial viral approach, we targeted activating designer receptors exclusively activated by designer drugs (DREADDs) to MCH-positive LH neurons. On test days, 30 minutes before self-administration sessions, rats received a saline vehicle control or clozapine-n-oxide (CNO, 0.3 or 1 mg/kg) in order to activate MCH neurons. Male rats readily self-administered METH and a dose response curve was generated where the lowest dose resulted in the most nose pokes, and the highest dose resulted in the fewest. Stable responding to the training dose was seen in between dose response days. In male rats, CNO administration of 0.3 mg/kg selectively increased infusions of METH, with the greatest effects on the two lowest doses. Conversely, CNO administration of 1 mg/kg reduced METH infusions, flattening the dose response function. Results for female rats and associated sex differences will be discussed at the conference. These finding suggest a nuanced behavioral interaction between LH MCH neuron activity and the reinforcing effects of self-administered METH, which may have further implications for MUD in humans.

Title: Reduced polysubstance self-administration and stress-induced reinstatement following systemic or central amygdala hypocretin-receptor blockade in rats

Authors: *T. A. ZARIN, B. E. SCHMEICHEL;
Biomed. Sci., East Tennessee State Univ., Johnson City, TN

Abstract: The hypocretin/orexin (HCRT) system is associated with compulsive stimulant and opioid use, involving both HCRT-receptor 1 (-R1) and HCRT-receptor 2 (-R2). Few studies, however, have examined the role of combined HCRT-R1/2 on compulsive drug taking behavior, and fewer have examined the role of HCRT in drug-taking behavior involving a combined methamphetamine and fentanyl polysubstance. In this study, we examined the effects of systemic and intracranial HCRT-R1/2 antagonism on compulsive polysubstance intravenous self-administration and stress-induced reinstatement, as modeled by escalated intake in rats allowed extended access to polysubstance. Male and female adult Wistar rats (N=40) were allowed either short (1h; ShA; n=8 male) or long (6h; LgA; n=16 male, n=16 female) access to polysubstance intravenous self-administration (fixed ratio 1) for 12 sessions. Rats in the LgA group significantly escalated their drug-taking over the 12 sessions ($p<.01$), and were taking significantly higher amounts of polysubstance during the first hour compared to the ShA group ($p<.01$). After escalation, a subset of LgA males and females were systemically administered a HCRT-R1/2 antagonist (suvorexant; SUV, 0 and 30mg/kg) 30 min prior to polysubstance self-administration testing. Systemic SUV administration elicited significant attenuation of polysubstance-taking in both the first hour ($p<.01$) and full 6h ($p<.05$) session for male and female LgA rats. Brains from drug-naïve, ShA and LgA (n=8/group) male rats were collected 1 day after the last self-administration session, and assessed for HCRT-1, HCRT-R1 and -R2 optical density using immunohistochemical assays. LgA rats had a significantly higher density of HCRT-1 peptide in the central amygdala (CeA) when compared to naïve rats ($p<.05$), and higher HCRT-R1 compared to both ShA and naïve rats ($p<.01$). There was no change in HCRT-R2 optical density across groups. A final subset rats extinguished their drug-seeking behavior via substitution of saline for polysubstance during self-administration. Once lever pressing was extinguished, the rats were tested for yohimbine-induced (2mg/kg) reinstatement of drug-seeking behavior. Stress-induced reinstatement was significantly attenuated in both males and females with systemic SUV administration ($p<.01$), and in females following intracerebral injections of SUV into the CeA (9 µg/hem; $p<.01$). Combined, these results suggest HCRT neurotransmission at both HCRT-R1 and -R2, particularly within the CeA, likely contributes to polysubstance-taking and stress-induced polysubstance-seeking behavior.

Abstract: Amphetamine (AMPH) is a commonly abused psychostimulant. The stimulant properties of AMPH are associated with its ability to increase dopamine (DA) neurotransmission via nonvesicular DA release, which is mediated by reversal of DA transporter (DAT) function. Syntaxin 1 (Stx1) is a SNARE protein that is phosphorylated at Ser^{14} by casein kinase II. We show that Stx1 phosphorylation is critical for AMPH-induced nonvesicular DA release and regulates the expression of AMPH-induced preference and sexual motivation in *Drosophila melanogaster*. Our molecular dynamics simulations of the DAT/Stx1 complex demonstrate that phosphorylation of these proteins is pivotal for DAT to dwell in a DA releasing state. This state is characterized by the breakdown of two key salt bridges within the DAT intracellular gate, K66-D345 and E428-R445, causing the opening and hydration of the DAT intracellular vestibule, allowing DA to bind from the cytosol, a mechanism that we hypothesize underlies nonvesicular DA release.

Title: A locomotor activity sign of amphetamine acute withdrawal is attenuated by kappa opioid receptor antagonist in rats

Authors: *W. WHITE, I. WHITE;
Morehead State Univ., Morehead, KY

Abstract: When rats are given 2.0 mg/kg amphetamine near light onset of a 12-12 hour light-dark cycle, hyperactivity, indicative of an acute state, occurs during the first four hours following

treatment, and reduced activity, indicative of an acute withdrawal, occurs from around 13 to 24 hours post-treatment. Recently, kappa opioid antagonists, such as nor-BNI, have been shown to attenuate withdrawal-related signs of stress, anxiety, and depression produced by chronically administered drugs of abuse. nor-BNI is a long-acting selective kappa opioid receptor antagonist. It is often administered 24-hours prior to a target manipulation, and the effects of a single nor-BNI treatment can persist for weeks. This study examined the capacity of nor-BNI to block acute withdrawal from amphetamine. Adult male Wistar rats were given a series of six one-week tests. On Day 1 of a test, animals were given a control treatment, and on Day 4, they were given a drug treatment. Distance moved in an open field was monitored for 24 hours following each treatment. During Tests 1-3, Day 4 drug treatments were: 2.0 mg/kg amphetamine alone ; 2.0 mg/kg amphetamine followed 15 minutes later by the non-selective opioid receptor antagonist naloxone (0.1 mg/kg); and 2.0 mg/kg amphetamine preceded 24 hours earlier by nor-BNI (7.5 mg/kg). During Tests 4-6, Day 4 drug treatment was 2.0 mg/kg amphetamine, so that the effect of nor-BNI on acute withdrawal could be assessed 1 week (Test 4), 2 weeks (Test 5), and 3 weeks (Test 6) following nor-BNI administration. Amphetamine alone (Test 1) produced hyperactivity 1-4 hours following treatment and reduced activity 13-24 hours following treatment. Neither naloxone (Test 2) nor nor-BNI (Test 3) appeared to alter acute amphetamine hyperactivity, but they both prevented the reduction in activity from hours 13-24, that is, they prevented acute withdrawal as assessed with a locomotor activity measure. Acute withdrawal to amphetamine also did not occur 1 week after nor-BNI (Test 4), but it began to reemerge 2 weeks following nor-BNI (Test 5). Withdrawal from both intermittently and chronically used drug appears to involve kappa opioid receptor activation. Careful assessment of determinants of acute withdrawal may disclose factors that promote the transition from intermittent recreational drug use to chronic drug abuse.

Title: A comparison of the neurobehavioral responses of rats exposed to original and counterfeit Captagon

Authors: *Y. ALTHOBAITI, A. ALSHANBARI, D. ALSHOAIBI, E. KHAN, H. ALGHAMDI, S. ALJUAID, A. ALZILIFI, N. ALSULIMANI, O. ALRIZQI, W. ALSANIE, A. GABER;
Taif Univ., Taif, Saudi Arabia

Abstract: A common drug of abuse in the Middle East is captagon. Captagon contains the active ingredient fenethylline, which has two major active metabolites: amphetamine and theophylline. Due to the lake and difficulty of obtaining the original Captagon (FEN), counterfeit Captagon (CC) has emerged. In addition to theophylline and amphetamine, CC contains paracetamol, caffeine, diphenhydramine, and lidocaine. The neurobehavioral effects of FEN and CC have never been compared previously. Therefore, the aim of this study was to investigate the neurobehavioral reactions of rats that were exposed to different doses of FEN and CC. A total of 36 male Sprague Dawley rats were randomly assigned to receive the vehicle, FEN (50 or 100 mg/kg), or CC (50 or 100 mg/kg). Body temperature was monitored, and locomotor activity was assessed following the treatment. Prefrontal cortex samples were extracted to assess the gene expression of antioxidant enzymes. Interestingly, CC as compared to the FEN caused more increases in body temperature posing more risks of fatal hyperthermia. Moreover, this new Captagon induced a significant increase in locomotor activity as compared to the original one. These behavioral changes were linked to increases in oxidative stress in the CC group due to modified gene expression of the antioxidant enzymes in the prefrontal cortex. These findings are the first to demonstrate the potential health harm caused by the new Captagon as compared to the original one. More efforts should be made to educate our society about the danger of these new drugs and to control their use.

Title: Cell-type and pathway specific synaptic adaptations in the rat nucleus accumbens core after incubation of methamphetamine craving

Authors: E.-K. HWANG, M. M. BEUTLER, ***M. E. WOLF**;
Oregon Hlth. & Sci. Univ., Portland, OR

Abstract: Use of methamphetamine (meth) is highly prevalent and the high rate of relapse even after prolonged abstinence is a major problem in treating meth use disorder. In a rat model of drug craving and relapse, cue-induced drug seeking progressively intensifies after withdrawal from drug self-administration (SA) (incubation of craving), which is associated with long-term synaptic adaptations of glutamatergic transmission in nucleus accumbens core (NAcc) medium spiny neurons (MSN). Our lab previously demonstrated that incubation of meth craving is

associated with synaptic calcium-permeable AMPA receptor (CP-AMPAR) upregulation in the NAcc and that CP-AMPAR activation is required for expression of incubated meth craving (Scheyer et al., 2016). However, it is not known whether meth incubation is associated with cell-type specific upregulation of CP-AMPAR in MSN that express either the dopamine D1 or D2 receptor and which specific glutamatergic inputs are involved in CP-AMPAR-mediated synaptic alterations in NAcc. Here, we examined CP-AMPAR plasticity during meth incubation in a cell-type and pathway-specific manner in the NAcc. Male and female rats self-administered saline or meth under extended access conditions (6 h/day for 10 days; 0.1 mg/kg/infusion; infusions paired with light cue). We measured cue-induced meth seeking after 1 and 21 days of abstinence. On withdrawal day (WD) 25-50, whole-cell patch clamp recordings were performed to characterize AMPAR-mediated synaptic transmission by measuring the rectification index and NASPM (CP-AMPAR selective antagonist) sensitivity. To enable identification of MSN subtypes, we use D1-Cre or A2a-Cre rats (the A2aR colocalizes with the D2R) crossed with ZsGreen or TdTomato reporter rats. During seeking tests, significantly higher cue-induced seeking was observed on WD21 than on WD1. We found upregulation of CP-AMPAR in D1+ but not D1- or A2a+ MSN after withdrawal from meth SA compared to saline controls. Furthermore, combining electrophysiology and optogenetics, we examined input-specific plasticity in the NAcc synapses projecting from the medial prefrontal cortex (mPFC), basolateral amygdala (BLA) and paraventricular thalamus (PVT). We found potentiated glutamatergic synaptic transmission through upregulation of CP-AMPAR in mPFC and PVT to NAcc pathways, but not the BLA to NAcc pathway. Experiments combining pathway and cell-type specific approaches are in progress. Our results are the first to demonstrate plasticity of specific excitatory pathways to NAc MSN after incubation of meth craving.

Title: Role of histone deacetylase 5 in nucleus accumbens in incubation of methamphetamine craving

Authors: *M. BURKE[1], A. OLANIRAN[2], X. LI[1];
[2]Psychology, [1]Univ. of Maryland, College Park, MD

Abstract: Methamphetamine seeking progressively increases after abstinence in both rats and humans. We previously showed that overexpressing histone deacetylase 5 (HDAC5) in rat dorsal striatum potentiates this incubation of methamphetamine craving, while knocking down HDAC5 suppresses it. Together these results demonstrated a critical role of HDAC5 in rat dorsal striatum in incubation of methamphetamine craving. However, whether the role of HDAC5 in this

incubation generalizes to nucleus accumbens (NAc) is unknown. Anatomically, NAc is further divided into two subregions, core and shell. Based on previous literature showing that the NAc core and shell play distinct roles in drug relapse behaviors, here we aimed to examine the role of HDAC5 in incubation of methamphetamine craving in NAc core and shell, respectively. We first injected adeno-associated viruses (AAVs) expressing either a nuclear-localized HDAC5 (AAV-HDAC5) or GFP (control, AAV-GFP) bilaterally into NAc shell. One week later, we trained both groups of rats to self-administer methamphetamine for 10 days (0.1 mg/kg/infusion, 9 h/d). After the training, we tested all rats for methamphetamine seeking on both abstinence days 2 and 35. We found that overexpressing HDAC5 in NAc shell had no effect on methamphetamine seeking on either abstinence day 2 or 35, suggesting that HDAC5 in NAc shell does not play a role in incubation of methamphetamine craving. Our ongoing study is examining whether overexpressing HDAC5 in NAc core impacts incubation of methamphetamine craving. Together, these results may reveal a sub-region-specific role of HDAC5 in NAc in mediating methamphetamine relapse.

Title: Deep brain stimulation of nucleus accumbens shell does not alter methamphetamine seeking in male rats

Authors: *T. J. SACKO, S. E. SWINFORD-JACKSON, R. C. PIERCE;
Brain Hlth. Inst. and Dept. of Psychiatry, Rutgers Robert Wood Johnson Med. Sch., Piscataway, NJ

Abstract: Methamphetamine use disorder is a chronic, relapsing condition for which there are currently no available FDA-approved treatments. Deep brain stimulation (DBS) is a well-established surgical intervention approved for Parkinson's Disease and other neurological conditions which is also under exploration as a possible treatment for neuropsychiatric disorders including depression and substance use disorders. Relapse, a major obstacle to recovery, is often precipitated by craving which can be modeled as drug seeking in rodents. DBS of the nucleus accumbens shell reduces cocaine-seeking behavior in rats; however, its effectiveness for methamphetamine is not well understood. Here, we examined the effect of deep brain stimulation of the nucleus accumbens shell on methamphetamine priming-induced reinstatement of drug-seeking behavior in male Sprague Dawley rats. Rats were allowed to self-administer intravenous methamphetamine (0.1 mg/kg/infusion) for 2-hours daily over 21 days, followed by

an extinction phase where lever pressing was extinguished by replacing methamphetamine with saline. Methamphetamine seeking was reinstated by a priming injection of methamphetamine (1.0 mg/kg, i.p.) administered 15 minutes prior to the session. Immediately after the rat was placed in the operant chamber, DBS was administered bilaterally to the nucleus accumbens shell through bipolar electrodes. Biphasic symmetrical pulses were delivered at a frequency of 160 Hz and a current intensity of 150 µA throughout the entire 2-hour reinstatement session. Rats received sham (0 µA) and stimulation (150 µA) in a counterbalanced within-subjects design. DBS of the nucleus accumbens shell had no significant effect on methamphetamine seeking behavior in male rats, contrary to its effect on cocaine reinstatement. Future experiments could explore the effect of DBS delivered using different parameters or in other limbic regions, and should investigate the effect of DBS on methamphetamine seeking in female rats.

Title: Role of TRUSS in the development of methamphetamine-induced rewarding effect

Authors: *K. MIZUO, T. YAGMAGUCHI, S. HATTORI, S. WATANABE;
Sapporo Med. Univ., Sapporo, Japan

Abstract: Methamphetamine is one of the most abused drugs in Japan and produces a strong rewarding effect. However, little is known about the mechanisms underlying methamphetamine-induced rewarding effect. Our recent findings suggested that tumor necrosis factor receptor-associated ubiquitous scaffolding and signaling protein (TRUSS) may play role in the development of methamphetamine-induced rewarding effect. In the present study, we investigated the expression of TRUSS in methamphetamine-induced rewarding effect. The rewarding effect was evaluated by conditioned place preference. Methamphetamine (1mg/kg, s.c.) produce a significant rewarding effect. The mice were killed by decapitation and the limbic forebrain (containing nucleus accumbens) was dissected. The expression of TRUSS in limbic forebrain was significantly decreased in methamphetamine-induced rewarding effect. We next investigated the role of TRUSS in the development of methamphetamine-induced rewarding effect. Methamphetamine-induced rewarding effect was significantly enhanced by i.c.v. treatment of TRUSS antibody. In conclusion, our findings suggest that the TRUSS may be a negative regulator for methamphetamine-induced rewarding effect.

Title: Sex differences in the effect of exercise on the cognitive consequences of methamphetamine abuse

Authors: *I. DE LEON, *I. DE LEON, K. DE LEON, J. PELLETIER, N. CABRERA, S. GALEANO, A. FRICKS-GLEASON;
Psychology and Neurosci., Regis Univ., Denver, CO

Abstract: Methamphetamine (METH) is a widely used psychostimulant drug, and its use in the United States has reached a near-epidemic in the past 15 years, due to the ease with which METH can be manufactured, as well its highly addictive properties. METH use costs the government billions per year through crime, foster care, lost workplace productivity, and other social problems, in addition to causing destructive effects in the lives of users. In humans, METH abuse has been shown to result in long-lasting brain injury as well as significant cognitive impairments. METH interacts with the catecholamine nerve terminals in the brain, inducing non-exocytotic transmitter release, which results in the initial euphoria after taking the drug but then leads to long-lasting brain injury for the user. The neurotoxic effects of the drug are responsible for inducing the cognitive consequences associated with abuse, which include impairments in memory, attention, executive functioning, and decision making skills. The memory impairments caused by METH are seen as the most prominent and persistent cognitive problems, because they interfere with the user's ability to adhere to and benefit from addiction treatment. Therefore, it is of utmost importance to find ways to attenuate these cognitive deficits and thereby improve treatment outcomes for METH users. The impacts of exercise on the rodent brain, such as induction of synaptic plasticity, increased production of neurotrophins, and enhanced neurogenesis, have been extensively characterized, and the beneficial effects of exercise on cognition are well-documented. Here we investigated whether exercise can improve performance on cognitive tasks known to exhibit METH-induced deficits. The studies described herein focused on two well-validated tests of memory in an animal model: object recognition and odor recognition. Notably, work on this question has historically left out a critical portion of the population - females. Women are just as likely as men to develop substance use disorder, but women often use and respond to drugs differently. Research in both humans and animals suggests that women may be more vulnerable to the reinforcing effects of stimulants, potentially making them more susceptible to craving and relapse. Here we demonstrate critical sex differences in the ability for exercise to attenuate METH-induced cognitive deficits, as evidenced by variability in scores on object-in-place and odor recognition tasks.

Title: Sex differences in the ability of exercise to attenuate methamphetamine-induced monoaminergic neurotoxicity

Authors: *M. GOLDSCHMIDT[1], J. PELLETIER[2], I. DE LEON[3], K. A. DE LEON[3], L. J. HERRERA[3], A. A. FINEBERG[3], E. SAURINI[3], Y. K. VILLAGOMEZ[3], A. FRICKS-GLEASON[3];
[1]Regis Univ. Neurosci. Program, Denver, CO; [2]Neurosci., Regis Univ. Neurosci. Program, Westminster, CO; [3]Regis Univ., Denver, CO

Abstract: Methamphetamine (METH) use continues to be a major public health concern. Upwards of 14.7 million people in the U.S. report having tried METH. The use of METH is highly problematic, not only due to the acute effects of the drug which can include psychosis and aggressive behavior, but also due to the long-term consequences including neurotoxicity, cognitive deficits, and addiction. METH-induced monoaminergic neurotoxicity has been modeled in numerous species. One well-known rodent model of METH use utilizes binge administration, where repeated doses of METH are given in a single day. This dosing regimen has been shown to cause long-lasting damage to monoaminergic nerve terminals in the striatum and prefrontal cortex similar to that seen in human METH users. In fact, individuals who use METH are more likely to develop Parkinson's disease, suggesting enduring and possibly progressive dopamine loss as a consequence of METH use. Exercise is well known for its beneficial physiological effects and cognition-enhancing properties and has long been investigated in the context of neurodegenerative disease; only recently has exercise gained traction in the treatment of drug use and addiction. Here we demonstrate a critical sex difference in the ability of exercise to attenuate METH-induced neurotoxicity. Previously, we've shown that 3 weeks of voluntary running after a METH binge protects against METH-induced dopaminergic neurotoxicity. Critically, delaying the start of exercise for 7 or 30 days also results in attenuated neurotoxicity, suggesting that post-METH exercise isn't simply disrupting the mechanisms that lead to neurotoxicity, but is reversing the neurotoxic effects post-hoc. While METH-induced neurotoxicity has been modeled in many species, these studies have largely excluded female subjects. The goal of this project was to replicate our previous work in females. Female Sprague Dawley rats were dosed with a neurotoxic regimen of (+)-METH-HCl (4 x 3 mg/kg, s.c. at 2-hr intervals) or saline (4 x 1 ml/kg, s.c. at 2-hr intervals). Beginning 1, 7, or 30 days after injections, animals were then subdivided into one of two exercise conditions, voluntary exercise (rats were given continuous access to a running wheel for 3 weeks) or sedentary control (rats were housed with a locked wheel for the same duration). Our results demonstrate critical sex differences in the ability for exercise to attenuate METH-induced neurotoxicity, as evidenced by variability in degree of damage to dopaminergic nerve terminals.

These results highlight the necessity of including sex as a biological variable in methamphetamine neurotoxicity studies going forward.

Title: The role of neurotrophic factors in the ability of exercise to facilitate extinction of methamphetamine conditioned place preference and attenuation of drug-primed reinstatement.

Authors: *G. AIMALE, H. SIMPSON, E. SAURINI, S. GALEANO, A. FRICKS-GLEASON; Psychology and Neurosci., Regis Univ., Denver, CO

Abstract: Over 60 million people worldwide report using amphetamine-type stimulants, especially methamphetamine (METH), and use is endemic in the western United States. METH use is particularly problematic due to the well-documented long-term consequences on the structure and function of the brain. Exposure to multiple high doses of METH produces damage to central monamine systems. Long-lasting decreases in markers of dopamine (DA) innervation of the striatum have been reported in both human METH users and rodent models of binge METH use. Importantly, this METH-induced damage is accompanied by impairments in cognition in both humans and rodent models. These cognitive deficits include impairments in memory, decision making, and executive function and significantly impact the ability of METH users to engage in and ultimately benefit from treatment. Reported relapse rates for METH users are as high as 61% during the first year post-treatment and 25% during the 2-5 years post-treatment. Conditioned place preference (CPP) is a widely used paradigm used to study the impact of cue and stress triggers on relapse to drug seeking behavior. While exercise has been reported to attenuate the rewarding effects of drugs of abuse, no studies to date have directly investigated the effects of exercise on extinction and reinstatement of methamphetamine-cue memory. Here we show that voluntary exercise led to facilitated extinction of methamphetamine-cue memory and attenuated reinstatement to a priming injection of the drug. We also investigated the role that neurotrophic factors, such as BDNF, might play in the ability for exercise to impact methamphetamine-cue memory. Together these results demonstrate the potential for exercise to serve as a non-pharmacological treatment for METH addiction by protecting against risk of relapse.

Title: Modeling opioid maintenance treatment in Oprm1-Cre knock-in rats: effect of chronic buprenorphine on incubation of heroin seeking

Authors: *K. E. CALDWELL, I. FREDRIKSSON, A. BATISTA, Y. GERA, R. MADANGOPAL, Y. SHAHAM, J. M. BOSSERT;
Natl. Inst. of Drug Abuse, Baltimore, MD

Abstract: Background: We recently modeled opioid maintenance treatment in rats and found that chronic buprenorphine decreased several relapse-related behaviors, including incubation of heroin seeking during abstinence. We also recently introduced a novel CRISPR-based *Oprm1-Cre* knock-in rat that allow us to visualize and manipulate μ-opioid receptor (MOR)-expressing cells in the brain. Here, we used the *Oprm1-Cre* rats to identify brain MOR-expressing cells involved in the inhibitory effect of buprenorphine on incubation of heroin seeking. Methods: We trained male and female *Oprm1-Cre* rats and their wildtype littermates to self-administer heroin in Context A for 12 days (6-h/day). One day after the last training session, we tested the rats under extinction conditions in Context B. Two weeks later, we implanted osmotic minipumps containing buprenorphine (0 or 6 mg/kg/day). One week later, we tested the rats for incubation of heroin seeking in context B and then anesthetized, perfused, and extracted their brains for immunohistochemistry. Results: There were no genotype or sex differences in heroin self-administration and non-incubated heroin seeking on abstinence day 1 prior to buprenorphine treatment. In both genotypes and sexes, chronic buprenorphine decreased incubated heroin seeking on abstinence day 21. We currently perform double immunohistochemistry of Fos (a neuronal activity marker) and MOR protein to determine which brain areas are activated during incubation of heroin seeking and subsequently inhibited by chronic buprenorphine. Conclusions: Our study using the new *Oprm1-Cre* rats confirms previous results on incubation of heroin seeking after homecage abstinence. We will present the immunohistochemistry results at the meeting.

Title: Role of the posterior claustrum in incubation of opioid seeking after electric-barrier induced voluntary abstinence

Authors: *A. BATISTA, K. E. CALDWELL, S. CLAYPOOL, J. BOSSERT, Y. SHAHAM, I. FREDRIKSSON;
Natl. Inst. of Drug Abuse, Baltimore, MD

Abstract: Background: We recently found a critical role of ventral subiculum (vSub) in incubation of oxycodone seeking after electric barrier-induced abstinence, a procedure mimicking human voluntary abstinence due to adverse consequences of drug seeking. Here, we used this model to further study the role of vSub afferent projections in incubation of oxycodone seeking. **Methods:** We trained male and female Sprague-Dawley rats to self-administer oxycodone for 14 days. Next, we exposed the rats for 13 days to an electric barrier of increasing shock intensity near the drug-paired lever, which produced voluntary abstinence. We tested the rats for relapse to oxycodone seeking without shock and drug on abstinence day 1 and 15. First, we determined projection-specific activation of vSub afferents during incubated oxycodone seeking with Fos plus the retrograde tracer cholera toxin B. Oxycodone relapse was associated with modest (anterior claustrum) and strong (posterior claustrum) Fos induction in claustrum neurons projecting to vSub. We then determined the causal role of posterior claustrum in incubation of oxycodone seeking by inactivating this region with the GABAa and GABAb receptor agonists muscimol-baclofen. **Results:** Incubation of oxycodone seeking after electric barrier-induced abstinence was associated with increased Fos expression in anterior and posterior claustrum neurons projecting to vSub. Muscimol-baclofen inactivation of the posterior claustrum decreased incubated oxycodone seeking on day 15 after electric barrier stress-induced abstinence but not non-incubated oxycodone seeking on day 1. **Conclusion:** Results indicate that the posterior claustrum is critical to incubation of opioid seeking after voluntary abstinence induced by adverse consequences of drug seeking.

Title: Avoiding naloxone-induced precipitated withdrawal: A procedure for studying opioid negative reinforcement in rats

Authors: *J. CHOW[1], K. M. PITTS[1], J. M. CHABOT[1], R. ITO[2], Y. SHAHAM[1];
[1]NIDA IRP, Baltimore, MD; [2]Univ. of Toronto, Toronto, ON, Canada

Abstract: Background: Operant negative reinforcement (withdrawal avoidance) plays a key role in human opioid addiction. Preclinical rat model of this human condition do not exist. Here we describe a rat model of operant negative reinforcement inspired by the primate model of Downs & Woods (Pharmacol Rev. 1975). **Methods:** We trained rats (n=30,15 females) to lever-press to escape and then avoid mild-footshocks (0.15-0.31, mA) for 35 days (30 trials/d). Next, we catheterized them and implanted minipumps containing methadone (10 mg/kg/day) or saline. We then paired (4 times), in a single session, a light cue (20-s) with naloxone infusions (20 µg/kg, i.v) that precipitated opioid withdrawal symptoms. Next, we trained the rats on an operant procedure for naloxone escape for 10 days (30 trials/d). Each trial started with the onset of the opioid-withdrawal cue. After 20-s, a lever extended, and an infusion of a low naloxone dose (1 µg/kg) began; a lever-press during an 11-s window would terminate the withdrawal-paired cue and the infusion. **Results:** The rats learned to lever-press to escape or avoid mild-footshocks. Methadone-dependent rats, but not drug-naïve rats, lever-pressed to escape naloxone infusions. **Conclusion:** We introduce an operant negative reinforcement procedure in which opioid-dependent rats lever-press to escape infusions of naloxone that induce opioid withdrawal. Pending independent replications, the procedure can be used to study mechanisms of operant negative reinforcement in opioid-dependent rats.

Title: Effect of peer-sex on operant responding for social interaction: Role of estrous cycle and striatal dopamine

Authors: *K. M. PITTS, A. SCHOENBAUM, K. M. COSTA, G. SCHOENBAUM, Y. SHAHAM, J. CHOW;
Natl. Inst. of Drug Abuse, BALTIMORE, MD

Abstract: Background: Preclinical models that simulate human social interaction demonstrate that rats will choose a social peer over addictive drugs, even after extensive drug self-administration experience. Investigation into how operant social interaction functions as a reward indicates that it supports lever-pressing like other self-administered rewards. However, these studies were conducted with peers of the same sex. Here we examined if peer-sex influences operant social interaction and the role the estrous cycle and striatal dopamine on same- vs. opposite-sex social interaction.
Methods: We trained rats (n=13; 7 females) to lever-press for access (15 s) to a same- or opposite-sex peer for 16 d (8 d/sex) and tracked females' estrous cycle. Next, we transfected GRAB-DA2m and implanted optic fibers into nucleus accumbens core and dorsal medial striatum. We then retrained the rats for social interaction for 16 d (8 d/sex) and recorded striatal dopamine during operant responding for a peer for 8 d (4 d/sex). Finally, we recorded striatal dopamine during assessment of economic demand for a peer (10 d/sex).
Results: Male rats responded more when a female peer was present; there were no differences in responding in female rats. Estrous cycle had no effect on operant social interaction. Striatal dopamine signals during operant social interaction were dependent on the peer's sex.
Conclusions: Results indicate that, unexpectedly, estrous cycle fluctuations did not influence opposite-sex operant social interaction. Additionally, striatal dopamine activity was dependent on the peer's sex.

Title: An operant procedure to study choice between rewarding physical activity and heroin in male and female rats

Authors: *S. CLAYPOOL, H. BONBREST, K. CALDWELL, R. MADANGOPAL, J. J. CHOW, H. P. JEDEMA, Y. SHAHAM;
Natl. Inst. of Drug Abuse, Baltimore, MD

Abstract: Background and rationale: We and others have previously reported that in a discrete choice procedure, rats of both sexes strongly prefer palatable food or social interaction over

opioid drugs. Here, we adapted this procedure to test whether rats will prefer rewarding physical activity (wheel running) over the opioid drug heroin. Methods: We gave rats (n=6, 3 females) free access to a running wheel for 30-60 min/d for 6 d. Next, we paired in a single 30-min session a tone-light cue with unlocking the wheel, signaling running availability (15 1-min trials/d;1-min intertrial-interval). Next, we trained them to lever-press to unlock the running wheel for 30-s to 1-min for 1-h/d for 14 d; fixed-ratio-1 schedule. During this phase, we also trained the rats to lever-press for heroin (0.05-0.1 mg/kg infusion for 11 d; fixed-ratio-1 schedule). Next, we tested the rats for 8 d in a discrete choice procedure where they chose between lever-pressing for access to the wheel running for 30-s versus lever-pressing for heroin infusions (15 trials/d; 2-min intertrial interval, 4-min to make a choice, 2-min between trials, 6-min total). Results: Our preliminary results indicate that rats would reliably lever-press to gain access to a running wheel and that, under our current experimental conditions, some rats preferred running wheel while others preferred heroin, resulting in ~50% preference for wheel running at the group level. Conclusions: We introduce an operant procedure to study choice between rewarding physical activity versus an addictive drug that can be used to study mechanisms of choice between the two rewards.

Title: Fentanyl seeking is attenuated by iboga alkaloid congeners

Authors: *J. D. LAYNE[1,2], M. J. HOCHSTETLER[1,2], B. M. CURRY[1,2], M. MAULIK[3], A. F. CARMEN[3,4], C. SMITH[3], K. LOOSCHEN[3], H. R. ARIAS[1], S. MITRA[3], C. T. WERNER[1,2]; [1]Pharmacol. and Physiol., [2]Natl. Ctr. for Wellness and Recovery, Oklahoma State Univ. Ctr. for Hlth. Sci., Tulsa, OK; [3]Biomed. Sci., Joan C Edwards Sch. of Med., Huntington, WV; [4]Jacobs Sch. of Med., The State Univ. of New York at Buffalo, Buffalo, NY

Abstract: Background. The prevalence of opioid use disorder (OUD) has reached epidemic proportions with a record-breaking number of overdose deaths. Over 70% of the overdose deaths are caused by synthetic opioids, including fentanyl. Fentanyl is commonly administered intravenously or by inhalation (smoking/vaping), which results in rapid drug bioavailability in the brain. There is an urgent need to identify novel pharmacotherapies to treat OUD. There is increasing evidence to support the use of ibogaine analogs, also known as iboga alkaloids, to

treat OUD and other psychiatric illnesses. In preclinical models, iboga alkaloids, such as 18-methoxcoronaridine (18-MC), have been shown to decrease opioid self-administration and seeking and induce antidepressant and anxiolytic effects. To our knowledge, there is no published research examining the effects of catharanthine (Cath) on drug seeking behaviors. Here we used a preclinical fentanyl vapor self-administration model to study the anti-addictive effects of two iboga alkaloid congeners, 18-MC and Cath.
Methods. Male and female C57BL/6 mice were trained to self-administer vaporized fentanyl (5 mg/mL) or vehicle in air-tight operant chambers for 10 1-hour sessions. Mice learned to self-administer vapor reward with 3-second vapor deliveries for the first 3 sessions of training, which was then reduced to 1.5-second vapor deliveries for the remaining 7 sessions. After training, mice were returned to their home cages for a forced abstinence period. Cue-induced drug seeking tests were conducted on abstinence day (AD) 20 and AD25. Cue-induced drug seeking tests were conducted using a crossover design where half of subjects were injected (i.p.) with iboga treatment (18-MC or Cath), while the other half received vehicle (ddH2O), on AD20 1 hour before seeking tests. On AD25, subjects received the opposite treatment compared to AD20. To examine the molecular mechanisms of Cath, a separate cohort of male and female mice were euthanized 1 hour after Cath injection (i.p.), and brain tissue was extracted and processed for molecular analyses.
Results. We found that both 18-MC and Cath significantly reduced fentanyl seeking during prolonged abstinence in both males and females with no effect on mice that had previously self-administered vehicle vapor. Molecular analysis provides a potential mechanism for this behavioral effect.
Conclusion. In this study, we report that both 18-MC and Cath decrease fentanyl seeking during prolonged abstinence in both males and females. These results add evidence to the existing literature that iboga alkaloids may be a promising class of compounds for novel pharmacotherapeutic treatment of OUD.

Title: Examining how prelimbic cortical neuronal ensembles encode behaviors during fentanyl vapor self-administration

Authors: *M. J. HOCHSTETLER[1,3], J. D. LAYNE[1,3], B. M. CURRY[1,3], C. T. WERNER[3,2]; [1]Pharmacol. and physiology, Oklahoma State Univ., tulsa, OK; [2]Pharmacol. and physiology, Oklahoma State Univ., Tulsa, OK; [3]Natl. Ctr. for Wellness and Recovery, Tulsa, OK

Abstract: The prevalence of opioid use disorder (OUD) and overdose deaths have reached epidemic proportions that constitute a global crisis. Comparing January 2021 to January 2020 synthetic opioids, including fentanyl, were responsible for a 31% increase in non-fatal opioid overdoses across the United States. Fentanyl, which is often used clinically for anesthesia and analgesia, is commonly administered intravenously or by inhalation (smoking/vaping), which results in rapid drug bioavailability in the brain. Technical challenges have contributed greatly to our lack of understanding of the neurobiology of OUD, including limitations of behavioral models, difficulty tracking individual neurons longitudinally in freely behaving animals, and inadequate behavioral analysis tools. Intravenous drug self-administration is considered the "gold standard" model to investigate the neurobiology of OUD preclinically, but it remains difficult to perform *in vivo* electrophysiology or calcium imaging during drug self-administration due to the tangling of drug catheter and recording cable. This technical challenge was overcome with the development of a noninvasive mouse model of opioid self-administration using vaporized fentanyl that recapitulates key features of OUD. Imaging freely behaving animals is difficult, and conventional single-unit recordings can neither distinguish neuron subtypes nor track individual neurons longitudinally. In contrast, *in vivo* imaging using miniaturized fluorescence microscope (miniscope) systems allows for examining spatially and temporally coordinated activity in hundreds of individual neurons longitudinally in freely behaving animals. Complex behavioral analysis is infrequently incorporated in preclinical models, which likely contributes to limited translational impact. Recent computational advances in convolutional neural networks, pose estimation, and machine learning analysis has overcome these challenges to provide tools for computational neuroethology. Here, we implemented a multi-faceted approach combining custom operant vapor chambers and single-photon miniscope to examine how prelimbic cortical neuronal ensembles encode behaviors during fentanyl vapor self-administration . Following data collection, we utilized deep behavior learning to perform a fine-grain analysis of behavior, which we overlayed with calcium transient data. We are leveraging these cutting-edge imaging technologies and behavioral analysis tools to gain a deeper insight into how neuronal ensembles in the prefrontal cortex encode opioid-related behaviors during fentanyl vapor self-administration and relapse.

Title: Estradiol protects against pain-facilitated fentanyl use via suppression of opioid-evoked dopamine activity

Authors: *J. HIGGINBOTHAM[1], J. ABT[2], R. TEICH[2], T. LINTZ[2], J. DEARMAN[2], J. MORON-CONCEPCION[3];
[2]Anesthesiol., [1]Washington Univ. Sch. of Med., St. Louis, MO; [3]Washington Univ., Saint Louis, MO

Abstract: Opioid analgesics are commonly used for pain management despite their potential for abuse. Evidence suggests that the risk for opioid misuse under conditions of pain may vary based on gender/sex, but the biological basis of this relationship is unclear. Using a rat model of fentanyl self-administration (SA) with wireless *in vivo* fiber photometry, we showed that males with inflammatory pain exhibit increased rates of fentanyl intake that are associated with, and dependent on, maladaptations within mesolimbic reward circuitry. A cre-dependent calcium indicator (jGCaMP7c) was targeted to the ventral tegmental area (VTA) of male and female TH-Cre+ rats (2-3 mo.) and optic fibers were implanted in the VTA or nucleus accumbens (NAc) to monitor VTA dopamine neuron at the soma (VTA^{DA}) or terminal (VTA^{DA}->NAc), respectively. Rats were implanted with IV catheters, received hind-paw injections of Complete Freund's Adjuvant (CFA) to produce inflammatory pain, and were trained for fentanyl SA (2-5 µg/kg/infusion) during five 2-hr sessions/week for 3 weeks. Pain did not affect the acquisition of fentanyl SA during week 1, but males with pain had greater intake than any other group by week 3. This pain and sex-specific behavior was associated enhanced fentanyl-evoked VTA^{DA} and VTA^{DA}->NAc activity that developed in paralleling magnitude with fentanyl SA. Chemogenetic inhibition of VTA^{DA} cells during week 3 prevented males with pain from increases in fentanyl use. Ovariectomized (OVX) females developed a male-like phenotype with increased fentanyl SA and associated VTA^{DA} activity. Estradiol (E2) treatment failed to reverse the effects of OVX. Instead, we demonstrate the therapeutic potential of E2 treatment in males and its ability to reverse the effects of pain on VTA^{DA} function and fentanyl use via VTA estrogen receptors. These findings are the first to implicate a role for gonadal hormones in pain-facilitated opioid use and provide novel therapeutic targets within the mesolimbic DA reward circuitry that may contribute to pain-related motivational impairments and risk for opioid abuse.

Title: Effect of suvorexant on economic choice between remifentanil and food in squirrel monkeys.

Authors: *J. HECKER, N. BOOKWALA, H. JEDEMA, C. BRADBERRY;
NIH, NIDA IRP, Baltimore, MD

Abstract: Opioid use disorder (OUD) is clinically treated through opioid maintenance therapy using mu-opioid agonists and partial agonists such as methadone and buprenorphine. These compounds may cause unfavorable side effects such as respiratory depression, constipation, and a continuing state of dependence. Because of this, research into non-conventional therapeutics that don't involve the mu-opioid receptor is needed. One area of interest includes the orexin receptor sites, as they have been linked to arousal and motivation. Suvorexant is a dual orexin antagonist clinically used for the treatment of insomnia, although recent studies have shown potential for the attenuation of opioid reward. To evaluate the effects of suvorexant on opioid reward, we are utilizing a nonhuman primate (squirrel monkey) model, in which opioid reward is evaluated using an established economic choice paradigm that tracks subject choice allocation between differing quantities of remifentanil (an ultrashort-acting opioid) and a food reward. Additionally, actigraphy monitors (Axivity AX3) were placed on each subject as a non-invasive way to record activity data. Based on these raw activity scores, total sleep time (TST) and sleep onset latency (SOL) for each night were determined using an algorithm in Matlab. These sleep parameters provide supplementary information to determine if suvorexant is altering sleep, an expected behavioral effect. Suvorexant was administered orally at 0.3-3.0 mg/kg with no significant differences in choice valuation, TST, or SOL compared to contemporaneous individual baselines. At these doses, plasma level concentrations of suvorexant were much lower than expected, suggesting inadequate delivery to their bloodstream. Ongoing studies using slow, intravenous (IV) delivery of suvorexant will continue to evaluate the effects on opioid reward, sleep parameters, and achieved plasma levels.

Abstract: The ongoing opioid epidemic has underlined the need for treatment of opioid use disorder (OUD) with alternatives to opioid medications. Such interventions could impact central dopamine systems regulating opioid reward and the aversive aspects of opioid withdrawal, abstinence, and craving. We and others have shown that glial cell derived neurotrophic factor (GDNF) has protective and restorative effects on midbrain dopamine neurons and synaptically facilitates dopamine release. At the same time, chronic use of opioids induces deficits in mesolimbic dopamine release, which can drive relapse. Our current studies test whether intranasal administration of GDNF plasmid DNA nanoparticles (pGDNF NPs) can correct central dopamine deficits in a rat model of oxycodone (OXY) intravenous self-administration (IVSA); whether any observed effects are different in male and female animals; and whether changes in dopamine exocytosis in real time correlate with behavioral parameters of oxycodone IVSA that assess motivation to work for receiving oxycodone injections. We assessed *ex vivo* dopamine release kinetics in dorsal striatum (DS), nucleus accumbens (Nacc), and medial prefrontal cortex (PFC) of male and female rats trained identically in OXY IVSA (0.1 mg/kg/infusion; 6 h/day; 13 training days). Rats were then administered either intranasal saline vehicle or pGDNF NPs (90 μg DNA). This was followed by 28 days of abstinence from OXY prior to the *ex vivo* dopamine release studies. Amperometric electrodes with 5 μm carbon fibers (Amoco) and a positive 700 mV voltage (vs Ag-AgCl ground) were employed to measure dopamine. The electrodes were placed in acute DS, Nacc or PFC 300 μm coronal slices. A bipolar stimulating electrode was placed 100-200 μm away from the carbon fiber electrode and a current stimulus of +500 μA was applied 3 times per site every 5 min for 2 msec. The output was digitized at 50 kHz to record dopamine exocytosis in real time and low-pass filtered at 1 kHz. The number of dopamine molecules per stimulation was determined by Faraday's equation, and, so far, estimated to increase up to 2-fold in the Nacc of pGDNF NPs-treated rats. We are running further correlation analyses between behavioral (IVSA) and dopamine release parameters to detect any differences between subpopulations of pGDNF NP and vehicle-treated groups, such as males versus females and high- versus low-responders in the OXY progressive ratio session. These results will determine if correction of dopamine deficiencies in the brain's reward centers may serve as a mechanism for the efficacy of intranasal pGDNF NPs in reducing relapse behavior in our OXY IVSA studies.

Title: An intranasal GDNF gene therapy for opioid relapse reduction: Neural modifications associated with reduced opioid reinstatement following intranasal administration of GDNF plasmid DNA nanoparticles

Authors: K. E. BUDGE[1], J.-L. LOPES[1], K. R. GILDAWIE[1], F. M. VASSOLER[1], O. SESENOGLU-LAIRD[2], R. C. MOEN[2], M. J. COOPER[2], J. D. ELSWORTH[3], E. N. POTHOS[4], B. L. WASZCZAK[5], *E. BYRNES[1];

Sch. Med., Boston, MA; [5]Dept Pharmaceut Sci., Northeastern Univ., Boston, MA

Abstract: Treatments for opioid use disorder (OUD) include the opioids methadone and buprenorphine, which moderate withdrawal symptoms and reduce craving. However, both of these treatments have abuse potential. Thus, new non-opioid based treatments that can effectively reduce craving and decrease the risk of relapse are still needed. We are testing the hypothesis that an intranasal glial cell line-derived neurotrophic factor (GDNF) gene therapy may be able reduce craving and relapse due to effects on the brain dopamine system. Adult male and female Sprague Dawley rats were implanted with jugular catheters and trained to lever press for oxycodone (OXY) (0.1 mg/kg/infusion; 6 h/day) for 12 days. On Day 13 all animals were tested for OXY motivated responding using a progressive ratio (PR) schedule. The next day rats were administered either intranasal saline vehicle or GDNF plasmid DNA nanoparticles (pGDNF NPs) (90 μg DNA; Copernicus Therapeutics, Inc.), with groups counterbalanced based on total drug intake and PR breakpoint. All animals then underwent forced abstinence for 30 days and were then tested for cue-induced reinstatement (90 min). Consistent with our

hypothesis, intranasal administration of pGDNF NPs significantly decreased cued reinstatement in abstinent oxycodone self-administering males and females when examined 30 days after intranasal delivery. Having shown potential for reducing relapse behavior, our current studies are addressing several follow-up questions: 1) Do levels of GDNF mRNA and protein remain elevated several weeks after intranasal infusion in rats? 2) Are the effects of intranasal GDNF NPs on cued reinstatement in rats associated with changes in Fos activity in tyrosine hydroxylase (TH) expressing dopamine neurons? 3) Do intranasal infusions of pGDNF DNA NPs increase GDNF mRNA and protein in the brains of non-human primates (NHPs)? For the rat studies, all animals were immediately euthanized at the end of reinstatement; half were used to quantify Fos positive TH neurons using immunohistochemistry with florescence while half were used to measure GDNF mRNA using qPCR and GDNF protein using ELISAs. For the NHP study, African Green Monkeys were anesthetized and intranasally administered different doses of pGDNF NPs. Two weeks later levels of GDNF mRNA and protein were assessed across a number of brain regions (prefrontal cortex, striatum, VTA, and cerebellum). These studies will begin to identify the neural mechanisms underlying decreased reinstatement following intranasal pGDNF NPs in rats and determine the potential efficacy of intranasal delivery of pGDNF NPs to upregulate GDNF mRNA and protein in the primate brain.

Title: Gating of opioid withdrawal aversion by a unique class of neurons in the nucleus accumbens

Authors: *J. TUCCIARONE[1,2], M. POMRENZE[2], J. BAEK[2], Z. ZHANG[2], A. SHANK[2], P. A. NEUMANN[2], N. ESHEL[2], R. MALENKA[2];
[1]Stanford Univ., Stanford, CA; [2]Nancy Pritzker Laboratory, Dept. of Psychiatry and Behavioral Sci., Stanford, CA

Abstract: Lethal overdose from opioids have increased dramatically over the past decade, critically contributing to the "opioid crisis". The aversion of opioid withdrawal and its associated environmental cues act as potent drivers of relapse and increase the risk of future overdose. More detailed understandings of circuit mechanisms underlying opioid withdrawal aversion are needed to develop new therapeutic strategies to target opioid dependence and relapse. The nucleus accumbens (NAc) has been long known to be involved in drug reward and cued reinstatement. We identified neurons in the NAc that express mu opioid receptor (MOR) and found two major populations expressing D1 dopamine receptors, one marked by *Pdyn* and another with *Tshz1*, a cell-type recently found to mediate aversion learning in the dorsal striatum. Photometry recordings with GCaMP6f revealed distinct activity dynamics, such that acute morphine intoxication reduced activity in both cell-types yet naloxone precipitated withdrawal triggered a large rebound in activity selectively in *Tshz1* cells. Reducing activity of *Tshz1* neurons with hM4Di disrupted morphine withdrawal conditioned place aversion (CPA), while inhibition of *Pdyn* neurons had no effect on withdrawal CPA but reduced morphine conditioned place (CPP). Acute stimulation of *Tshz1* neurons with ChR2 led to avoidance of the stimulation-paired chamber in a real time place preference test, whereas stimulation of *Pdyn* neurons led to a preference. We hypothesized that these behavioral effects are mediated through cell-type specific modulation of dopamine (DA) release in the NAc. To test this idea, we stimulated *Tshz1* or *Pdyn* cells with ChRmine while performing photometry recordings with GRAB DA. Stimulation of *Tshz1* neurons led to a rapid suppression of DA release in the NAc, whereas stimulation of *Pdyn* neurons increased DA release. DA levels rose substantially after morphine administration but were significantly suppressed below baseline after naloxone injection, indicating a hypodopaminergic state during withdrawal. Ongoing studies are examining the discrete mechanism by which *Tshz1* neurons modulate DA release in the NAc, whether *Tshz1* neuron activity mediates withdrawal-induced decreases in DA, and the role of MOR in *Tshz1* neurons in these effects. Together, our data demonstrate a unique population of NAc neurons that mediate the aversive nature of acute opioid withdrawal through strong modulation of mesolimbic DA release.

Title: Opioid withdrawal increases excitability and synaptic output of ventral pallidal glutamatergic neurons

Authors: *J. TOOLEY[1], M. CREED[2];
[2]Anesthesiol., [1]Washington Univ. in St. Louis, St. Louis, MO

Abstract: Withdrawal from opioids is associated with a highly aversive affective state, and avoidance of this state is a main reason people with opioid use disorder continue to use or relapse to opioids. Activity in the ventral pallidum (VP) is necessary for opioid relapse after withdrawal. Recent studies from our group and others have shown that glutamatergic VP neurons (VP_{Glu}) constitute a unique subpopulation of VP neurons, and that VP_{Glu} activity constrains reward seeking, particularly in decision-making tasks where negative consequences are associated with choosing a reward. However, how self-administration and withdrawal from prescription opioids alters the function of VP_{Glu} neurons and their activity in conflicted decision-making tasks is completely unknown. With fluorescent in situ hybridization, we discovered that VP_{Glu} neurons are enriched in mu opioid receptors. Patch-clamp electrophysiology experiments revealed that application of mu opioid agonists decreased excitability of VP_{Glu}. Thus, we predicted that self-administration of oxycodone, the mu opioid receptor agonist, would potently modulate function of these neurons. Indeed, protracted abstinence from oxycodone increased the intrinsic excitability of VP_{Glu} neurons and their synaptic output. Using in vivo calcium imaging and Pavlovian behavior tasks, we investigated the response of VP_{Glu} neurons to positive and negative stimuli throughout oxycodone self-administration to determine whether the response of these neurons is altered throughout opioid exposure. Given our previous work showing that activation of VP_{Glu} neurons is highly aversive, we hypothesize that these opioid-induced adaptations contribute to the aversive state of drug withdrawal that drives opioid relapse through negative reinforcement.

Title: Mitragynine-associated drug intoxication increases with fentanyl use

Authors: *A. SURIAGA;
Epidemiology, Harvard Univ., West Palm Beach, FL

Abstract: The neurobiology of mind-altering substances, particularly Mitragynine, and how it disrupts the chemical processes that maintain homeostasis and essential functions such as breathing within the brain is complex. Mitragynine is a natural indole alkaloid of Mitragyna speciosa that grows in Thailand, Indonesia, and the Philippines; used primarily for pain relief and

to improve work endurance. People in Western countries use Mitragynine for its analgesic effect, self-treatment for opioid withdrawal, and to reduce cannabis and opioid use. Mitragynine users among U.S. adults 12 years and older account for > 2,00,000 in the past year. Consuming Mitragynine in higher doses stimulates the brain while producing a sedative/hypnotic effect in lower doses. Polysubstance use potentiates the dose-dependent adverse effects of Mitragynine. While Mitragynine depresses the respiratory center lesser than Morphine, its mechanism of action remains unclear. In this study, we report the risk of Mitragynine-Associated Drug Intoxication (MADI) when co-using an opioid. We used de-identified data from the Florida Department of Law Enforcement in 2021. We used descriptive statistics to describe decedents with MADI and logistic regressions to examine the odds of dying from MADI with opioids (n=10). We analyzed all data using Stata 17. Results: 305 people died from Mitragynine use in Florida in 2021, up 24% from 2020. The average age was 37.79 (SD=9.38). More males died than females (81.64% vs. 18.36%), 24-44 years old were mostly affected (>75%), and white at 94.43%. 85% (n=260) died from drug intoxication, suicide (n=16), natural cause (n=11), and the rest from homicide, suicide, and accidents. More than 90% of decedents had used multiple drugs other than Mitragynine (n=281). Fentanyl was the most frequent drug used among Mitragynine users (n=221); then fentanyl analogs (n=138), Morphine (n=33), Ethanol (n=79), Cannabinoids (n=57), Methamphetamine (n=43), and Amphetamine (n=40). No statistically significant relationship between gender, ethnicity, age, population density, and MADI (p>.05). The odds of dying from MADI increased by six-fold among Fentanyl users versus non-Fentanyl users (OR=6.48, 95% CI, 3.87, 11.02), *p*= .001. Adjusting for age, gender, ethnicity, and population density, the odds of dying from MADI went up by 6.53 times the odds versus those who did not use Fentanyl. Controlling for neurocognitive, cardiovascular, and respiratory conditions, the odds of dying from MADI remain stable (OR=6.50, 95% CI, 3.70, 11.43), *p*=.001. MADI is a severe public health problem. More research is needed to curb preventable deaths from this psychoactive substance.

Title: Identification of dot clusters in a Gaussian-distributed field: the range of human perception and a comparison with spectral graph clustering.

Authors: *A. D. CATE;
Psychology, Roanoke Col., Salem, VA

Abstract: This study characterized human biases in the perception of clusters from random dot fields. It also compared human-chosen clusters with those identified by a state-of-the-art

machine learning algorithm. This study introduced a novel cluster identification task that was ensured to reveal participants' individual differences. Unlike other visual cluster identification displays, which present several potential clusters with different features for participants to choose, this study presented random dot fields with Gaussian-distributed density. These were densest in the center of the display (the peak of the distribution) and became gradually less dense radially toward the periphery; there was no salient discontinuity in dot spacing. 24 18-27 year-old participants viewed 180 displays, and were instructed to select the dots that appeared to form the most noticeable cluster on each display using a mouse interface, with no time limit. Their clusters were analyzed for number of dots; convex hull area, perimeter, and compactness; dot density within the hull; and mean nearest neighbor distance. A spectral clustering algorithm using a density-aware kernel (Zhang, 2011) that assigns higher scores in denser regions of a graph and which is capable of identifying concentrically-arranged clusters (the Spectrum R package; John et al., 2020) was applied to the dot displays for comparison with the performance of human participants. The participants' clusters had a range of dot numbers, in a distribution that was not significantly different from normal (Shapiro-Wilk's test $p=0.85$). However, unlike in many perceptual magnitude estimation or production tasks, the standard deviations of the participants' means, did not scale in correlation with the mean values. The degree of overlap between the human and the spectral algorithm-defined clusters was modest, with a mean F1-score of 0.63 (SD 0.035). It was found that the clusters (all produced by Gaussian point processes) showed strong correlations among all of the features measured, provided that they were centered on the Gaussian distribution's center. It was determined that the spectral clustering algorithm may have matched the human participants less well because its matching cluster was frequently not centered. Although different individuals consistently preferred clusters of distinct sizes, cluster perception appears to function differently from magnitude perception processes.

Title: A functionally time-resolved reconstruction technique for high-resolution fMRI (fTR-MRI)

Authors: *A. MORGAN, I. GEPHART, D. A. HANDWERKER, J. GONZALEZ-CASTILLO, P. A. BANDETTINI;
NIMH, Bethesda, MD

Abstract: Functional MRI (fMRI) with sub-millimeter spatial resolution is a promising technique to probe the human brain's mesoscopic scale [1,2]. However, typical spatial resolutions remain too coarse to sample individual human columnar and laminar structures. Moreover, high-resolution fMRI measurements using echo-planar trajectories (EPI) and blood oxygen-dependent (BOLD) contrast suffer from spatial distortions and T2* blurring due to long readout trains. Recently, time-resolved reconstruction methods have alleviated some of these issues by keeping track of the timing of data acquisition in reference to signal properties [3] or physiological cycles [4]. We utilize this conceptual framework to time resolve data with respect to events in a neuroscience experiment. The current work, which we call functionally time-resolved MRI (fTR-MRI), has high spatial resolution (0.5 mm) and is not affected by phase-encoding distortions yet reconstructs brain responses with reasonable temporal resolution (400 ms).

We acquired data from 3 participants (2 male) on a Siemens MAGNETOM 7T+ with a Nova 32-channel head coil. We collected a multi-echo 2D-GRE sequence (TR=31 ms, TEs=[4.22, 8.38, 12.54, 16.7, 20.86, 25.02] ms, slice thickness=0.8 mm, matrix=360x270, no acceleration or Partial Fourier). Acquisition times were tracked for each k-space line by sending an external trigger to a stimulation computer. The experimental paradigm consisted of a 10 Hz flashing radial checkerboard presented for 2 s (15 s ISI). We reconstructed data via low-rank tensor completion [5] with modes for k-space, receivers, echoes, and experimental response time. The resulting reconstruction depicts brain responses from -2 to 32 seconds after stimulus presentation with 6 echoes.

Primary visual cortex displayed a prominent dip in T2* decay times in middle layers, allowing us to identify infra- and supra-granular layers. Functional responses peaked between 2.5 and 3 s after the short stimulus presentation and superficial layers showed larger peak response and post-stimulus undershoot amplitudes, as reported in rodent studies [6].

The fTR-MRI reconstruction method incorporates experimental designs into the image reconstruction process to capture high spatial and temporal resolution brain responses. These features expand the arsenal of tools available to non-invasively examine mesoscopic responses in the human brain.

Title: Neural correlates of the embodied sense of agency support two-level processing: A pre-registered EEG study

Authors: *A. REGEV KRUGWASSER[1], R. VAN DER GOOT[1], G. MARKUSFELD[1], Y. ZVILICHOVSKY[1], R. SALOMON[2];
[1]Bar-Ilan Univ., Ramat Gan, Israel; [2]Haifa Univ., Haifa, Israel

Abstract: The Sense of Agency (SoA) is the subjective experience that 'I am in control of my actions'. It has been suggested that SoA relies on an internal comparator mechanism, whereby predictions about the consequences of an action are compared to the perceived consequences of the performed action. A mismatch between one's predicted and perceived action's consequences leads to a reduced SoA. More recent accounts have distinguished two levels in the formation of SoA - early implicit sensorimotor processes (feeling of agency) and later explicit higher-level processes, incorporating one's thoughts and beliefs (judgment of agency). Even though SoA is fundamental to our interactions with the external world and the construct of the self, its underlying neural mechanism remains elusive. In the current pre-registered electroencephalography (EEG) study, we used time-frequency and Multivariate Pattern Analysis (MVPA) to investigate the electrophysiological characteristics associated with SoA. We used an established virtual reality, embodied SoA paradigm in which visual feedback of a finger movement is modulated to examine the effect of either a match or a mismatch between the predicted and perceived sensory feedback. Participants (N = 30) moved their finger and were presented with an anatomical or a spatial alteration (different finger or angular shift, respectively), then rated their SoA over the observed movement, while their neural activity was recorded using EEG. In accordance with our pre-registered hypothesis, we found that a reduction of SoA is associated with decreased attenuation in the alpha frequency band, in line with the well-established finding of Mu suppression during voluntary motor action. Increased power in the theta frequency band was also associated with SoA reduction. Importantly, we show that trials in which participants reported having SoA vs. not having SoA, can reliably be decoded with ~70% accuracy starting around 200ms after movement onset. Finally, Cross-decoding analyses revealed similar neural patterns between reduced SoA in the anatomical and spatial conditions, at a later processing stage starting around 500ms after movement onset. Together, our results identify and characterize reduced alpha attenuation, as well as increased theta power as cortical signatures of loss of SoA and provide the first neural evidence that supports the hypothesis of a two-level formation of SoA - an early component that could be decoded within condition only (domain-specific), possibly the equivalent of the implicit feeling of agency, and a late domain-general component, possibly the equivalent of the explicit judgment of agency.

Title: Intracranial neural prediction of imagined melodies from relative pitch height decoding

Authors: *J. KWON[1], J. KIM[2,3], C. CHUNG[4];
[1]Seoul Natl. Univ., Seoul, Korea, Republic of; [2]Seoul Nat Univ., Seoul, Korea, Republic of; [3]Clin. Res. Inst., Konkuk Univ. Med. Ctr., Seoul, Korea, Republic of; [4]Seoul Natl. Univ. Hosp., Seoul Natl. Univesity, Seoul, Korea, Republic of

Abstract: Music is our oldest and most fundamental expression. Melody, consisting of a pitch series, is considered an essential component of music, as playing an essential role in distinguishing music. In the perspective of decoding music in general, imagined music decoding remains rudimentary. In the present study of human electrocorticography, we aimed to reconstruct an imagined melody by decoding the relative pitch heights. Furthermore, we tried to elucidate the key areas in imagined pitch decoding. Ten medically intractable epilepsy patients without professional musical backgrounds participated in the present study. They were trained with 5 common children's songs. After training, they performed the task of listening, followed by imagery of certain melody parts. During the music imagery, we observed significantly increased high gamma activities in the temporal cortex, the inferior frontal cortex and the sensorimotor cortex. Neural features of electrodes in those areas activated during music imagery were used in decoding the relative pitch height (Do-Re-Mi-Fa-Sol-La) by a random forest algorithm. To reconstruct the imagined melody, decoding was performed in order within one melody chunk. Pearson's correlation coefficient was employed to evaluate the performance of reconstructing an imagined melody. We could reconstruct imagined melodies by decoding single-pitch heights, with a mean Pearson's correlation coefficient of 0.42 and cosine similarity of 0.86 with the original music. The performance of reconstructing imagined melodies was correlated with familiarity scores for 5 songs for subjects, with a correlation coefficient of 0.53. Notably, the left primary motor cortex (M1) and the right homotopic Broca's area significantly contributed to imagined pitch decoding. A previous EEG study suggested the involvement of the left sensorimotor cortex and the bilateral frontal opercular regions during music imagery. Previous fMRI studies revealed that the right pars triangularis is sensitive to tonal differences and reflects controlling pitch processing. Extending previous studies, we ascertained that left M1 and right homotopic Broca's area, significantly contributed to pitch decoding.

Title: Binocular Rivalry spatiotemporal neuronal dynamics connectivity through nonlinear EEG measures

Authors: *C. SARACINI, A. CANALES-JOHNSON, B. LUCERO;
The Neuropsychology and Cognitive Neurosci. Res. Ctr. (CINPSI Neurocog), Univ. Católica del Maule, Talca, Chile

Abstract: Perceptual multistability offers a privileged possibility to observe neuronal networks at different processing stages as they build up perceptual awareness. Binocular Rivalry (BR) is a special kind of multistable phenomena where each eye is simultaneously presented with an inconsistent image, causing that, at the phenomenological level, the individual starts to experience alternating percepts. The mechanisms through which the neuronal assemblies give rise to the conscious perceptual awareness of each stimulus at a time, temporarily shadowing the other through interocular suppression, are still unclear, with several and somehow opposite theoretical attempts to explain this peculiar phenomenon. Classical linear measures of brain connectivity currently used to explore perceptual multistability are only able to capture some aspects of the activity performed by neuronal assemblies during these processes, leaving others unexplored. Nonlinear analyses of brain connectivity have been shown to assess in a more direct way temporal dynamics of bistable alternations in different perceptual modalities, allowing to shed light on perceptual integration and differentiation at the basis of these phenomena. In this preliminary study, we used superposed red/green grids (with horizontal/vertical lines) to produce BR by means of ophthalmology filters. In an EEG experiment, we registered exogenously (control condition) and endogenously (BR) driven perceptual changes reported by participants, counterbalancing all the stimuli orientation and color and filter/eye association through the experimental blocks within subjects (preliminary sample: N=10 of 30 participants). We isolated response-locked epochs in order to calculate the proper time-window when the change of percept occurs. We conducted a BR analysis through a nonlinear EEG connectivity measure, that is Transfer Entropy (TE). This information-theoretic measure allows to explore how brain connectivity unfolds over time and brain areas (frontal ←→ posterior and right ←→ left hemispheres). Preliminar results reveal a specific directionality of the integrated information before subjects indicate to experience a perceptual switch. If this result is confirmed, it would support feedback accounts of BR. Moreover, specific dynamics in the interhemispheric stream of processing have been found, representing the peculiarity of the BR phenomenon with respect to other multistable phenomena. These results have relevant implications in the actual theoretical debate on the directionality of the neural networks temporal dynamics involved in the conscious perception.

Title: Mystery of illusory perception: an inspection of 3D impossible objects

Authors: Y.-C. HSIEH[1], K. SUGIHARA[2], H.-H. LIU[3], C.-L. TSAI[4], ***W.-S. LAI**[1];
[1]Natl. Taiwan Univ., Taipei, Taiwan; [2]Meiji Inst. for Advanced Study of Mathematical, Meiji Univ., Tokyo, Japan; [3]Dept. of Clin. Psychology, Fu Jen Catholic Univ., New Taipei City, Taiwan; [4]Natl. Palace Museum, Taipei, Taiwan

Abstract: This study aims to enhance our understanding of illusory perception and sensory processing in 3D illusions by introducing updated task designs and advanced analysis methods, building upon our previous research (Hsieh et al., 2022). While there has been extensive research on 2D optical illusions, empirical investigations into 3D illusions remain scarce. To fill this gap, we collaborated with the second author to transform well-known 2D illusions into 3D impossible objects, which exhibit incongruity between the front view and their reflection in a mirror. To investigate the matching process between prior predictions and observed sensory data, as well as the signaling of sensory prediction errors, we developed the peekaboo task 2.0. Additionally, we designed the perceptual inference task 2.0 to explore the process of perceptual inference on novel objects and identify potential neural correlates. These tasks were accompanied by video clips showcasing authentic 3D impossible objects, providing a more realistic experimental setting. To gain insights into the neural dynamics and visual attention related to illusory perception, we employed two crucial measurement techniques: electroencephalography (EEG) and eye tracking. Through the combined use of EEG and eye tracking, we aimed to unravel the complex interplay between neural activity, visual attention, and illusory perception. These techniques allowed us to examine the temporal dynamics of brain responses and the allocation of visual attention during the processing of 3D illusions. To enhance our analysis, we incorporated two advanced methods: time-frequency analysis and graph-based connectivity analysis. Time-frequency analysis enabled us to explore the spectral dynamics of brain activity, providing insights into the temporal characteristics of neural responses during the perception of 3D illusions. Furthermore, the utilization of graph-based connectivity analysis, enabled us to explore the patterns of connectivity among the brain regions engaged in illusory perception. Through this investigation, we have expanded our understanding of the intricate mechanisms that underlie perceptual illusions in a three-dimensional context. The exploratory results uncover the neural dynamics involved in these illusions and provide valuable insights into the sensory processing of these unique 3D impossible objects.

Title: Atypical belief updating and novelty detection in psychedelic users during saccadic planning task

Authors: *C. L. WEST[1], A. DURAN[1], S. NADEEM[1], N. VAN LEEUWEN[2], J. P. HAMM[1]; [1]Neurosci., Georgia State Univ. Neurosci. Inst., Atlanta, GA; [2]Philosophy, Georgia State Univ., Atlanta, GA

Abstract: To infer the dynamic structure of our world, the human brain must be able to process information within context. One explanation of this function comes from the predictive coding framework, which posits that the brain continually generates and updates internal models of the environment. These models produce predictions of sensory input which derive from top-down prior beliefs, that are then compared to bottom-up sensory information. When stimuli that do not align with internal predictions are present, a prediction error is generated (i.e., novelty detection), signaling that the model needs to update its beliefs. Current research suggests serotonergic psychedelics' therapeutic effects may result from changes to the flexibility of individuals' belief systems, stemming from altered predictive processing. However, this remains untested. In the present study, we hypothesized that psychedelic use alters the distinct neurophysiological processes of belief-updating and novelty detection.

Here, we tested this hypothesis by recording EEG during a saccadic planning task. Twenty control participants and twenty psychedelic participants (those who used serotonergic psychedelics within 30 days) observed different colored stars that appeared in expected locations 80% of the trials and unexpected locations 20% of the trials. The color cues indicated whether the next star would appear at a new location (i.e., surprise update trials) or at the same location as previously (i.e., surprise no-update trials), allowing to experimentally tease apart brain processes related to "novelty detection" and "belief updating." We analyzed typical visual event related potentials (P3A, P3B, vMMN) as well as fronto-visual coherence - an index of top-down modulation, theoretically involved in predictive processing. We found that psychedelic users generated significantly smaller prediction errors in response to novel stimuli in both surprise trial types, as measured through P3A and vMMN. P3B, a potential an index of belief-updating, was modulated by surprise trial type in both groups. These findings suggest that the psychedelic participants were less "surprised" by the novel stimuli, potentially resulting from weaker priors. This research provides a potential mechanism for the effect of psychedelics, suggesting that psychedelics de-weight pathologically over-weighted prior beliefs that underlie various expressions of mental illness. The process of basic, cortical sensory belief updating may share basic neural mechanisms with higher level changes in beliefs that result from psychedelic use, and may underlie these changes.

Title: Contextual feedback signals during amodal completion and visual imagery in the early visual cortex

Authors: *Y. HUANG[1], Y. LAZAROVA[1], A. PATON[1], L. S. PETRO[1], L. MUCKLI[2]; [1]Sch. of Psychology and Neurosci., [2]Inst. of Neurosci. and Psychology, Col. of Medical, Vet. and Lif, Univ. of Glasgow, Glasgow, United Kingdom

Abstract: Amodal completion is representation of the occluded parts of a perceived object for which we receive no sensory stimulation, while visual imagery refers to visual representations or mental images without sensory input. Both amodal completion and imagery can generate visual experiences, which is related to internally-generated top-down signals. To investigate how top-down signals support amodal completion and visual imagery, we conducted a human 7T fMRI experiment with natural scene images combined with a visual occlusion paradigm that allows us to isolate top-down contextual signals in a non-stimulated region of V1 cortex. We recruited 28 healthy human participants to attend the fMRI experiment. In the first half of the fMRI experiment, participants viewed trials of the scene images with a white occluder placed over the lower-right image quadrant, and on other trials they had to try to imagine the full version of the previously seen occluded image. In the second half of fMRI scanning, on separate trials, participants either viewed the full scene image, or imagined the full image. This design allowed us to separate imagery trials where participants imagined image content that they had seen, from imagery trials where they had to generate images of the missing scene information based on the available contextual information. We performed a multi-voxel pattern analysis (MVPA) with a linear support vector machine approach and representational similarity analysis (RSA) for the fMRI data. The MVPA decoding results from the amodal completion condition show that the category information can be decoded in the occluded early visual cortex, replicating our previous findings that non-stimulated early visual areas carry information about surrounding context. The MVPA cross-decoding results between amodal completion and imagery trials show that the classifier cannot cross-decode the category information in amodal completion and imagery, which indicates that the feedback information in these two mental processes is different. The RSA results between imagery based on amodal completion and imagery based on full perception show a dissimilarity. This finding suggests that imagery activity differs if it is based on image-

specific memory, as opposed to being contextually-driven. Our findings, in conclusion, show that the feedback information utilised in amodal completion heavily relies on surrounding contextual information, whereas the feedback information employed in visual imagery might instead draw upon prior knowledge stored in the brain that can be updated by the feedforward information.

Title: Information-theoretic basis of the physical nature of voluntary movement and perception

Authors: *D. S. GUPTA;
Sch. of Pharm., South Univ., Savannah, GA

Abstract: Gupta and Bahmer (2019) had previously proposed that sensoryinput and motor activities during an interaction of the brain with physicalsurroundings lead to an increase in Shannon entropy (a measure of information)measured in the resulting spiking activities of the cortex. This increase inentropy is reduced by increased mutual information, resulting from an increasedprobability of joint activation of pairs of neurons in different parts of thecortex. Rolf Landauer proposed in 1961 that an irreversible change ininformation dissipates a minimum amount of heat to its surroundings. Landauer'sPrinciple was first verified experimentally by Bérut A et al. (2012). Whenеverthere is a successful interaction, there will be an increase in the correlatedactivation of specific pairs of cortical neurons due to the constraints of theinteraction between the brain and physical surroundings. This increase inmutual information, from the correlated activation of neurons, in a successfulinteraction leads to an irreversible change in information. According toLandauer's Principle, this irreversible change in information after asuccessful interaction dissipates a tiny amount of energy to the environment, resultingin an increase in thermodynamic entropy in surroundings. The author argues thatan increase in thermodynamic entropy is consistent with the second law ofthermodynamics, which is responsible for the spontaneous physical nature ofawareness of surroundings and voluntary control of movements. Notethat action potential (AP) at the threshold carries one bit of informationsince there is an equal probability of an AP being triggered or not triggered.According to Landauer's Principle to use a single bit of information, theenergy needed is $3X10^{-21}$ J. Moreover, given an assumption that Na+ions behave as gas molecules during the passage through Na+ channels, with anaverage kinetic energy of $6.41X10^{-21}$ J, and there is an equalprobability that Na+ ions will be entering or exiting through the channels atthe threshold, the author argues Na+ entry or exit will be on average stoppedonce in two movements to prevent or trigger an AP. Thus, on average, the energyneeded to prevent/activate an AP will be $3.2X10^{-21}$

J, which agreeswith the energy needed to use a single bit of information. Thus, when an AP inthe cortex becomes biased by sensory or motor inputs, there is a decrease inthe average uncertainty, which is further decreased by temporal coupling, givena cognitive task, giving rise to perception and voluntary motor control.

Title: Larger than life: Cartoons drive infant visual cortex more than realistic movies

Authors: *T. S. YATES[1], A. LETROU[1], J. E. TRACH[1], D. CHOI[1], L. BEHM[1], C. T. ELLIS[3], N. B. TURK-BROWNE[1,2];
[2]Wu Tsai Inst., [1]Yale Univ., New Haven, CT; [3]Psychology, Stanford Univ., Stanford, CA

Abstract: The human visual system exhibits sophisticated structure and function even in infancy, including retinotopic organization in early visual areas and category-selective responses in late visual areas. Yet, there is also dramatic plasticity and perceptual learning early in development, and thus it is unclear how the tuning of infant visual cortex relates to adults. For instance, infant visual cortex may be optimized to process realistic input, given the types of visual input it experiences the most. Alternatively, developing sensory systems may respond more to exaggerated features that emphasize diagnostic information. Here, we evaluate this sensory exaggeration hypothesis directly, testing whether cartoonized content drives activity in the human infant visual cortex more strongly and consistently than naturalistic content. In an ongoing study, we collected fMRI data from infants (4-15 months) while they watched two versions of a 3-minute movie: 2-D animated cartoon and 3-D realistic computer-generated imagery. Critically, the two movies were almost perfectly matched in content on a frame-by-frame basis. This allowed us to examine how the infant brain responds to certain combinations of visual features (i.e., shape, contrast, color) while controlling for semantic content and storyline. Infants watched the two movies in a random order, and there was no significant difference across movies in the amount of fMRI data excluded for head motion or looking away. As a baseline, we also collected data from 12 adults who watched the same movies under similar conditions, but for whom we did not expect a preference for cartoons. We performed intersubject correlation analyses in both infants and adults to assess the robustness and reliability of brain activity evoked by the two movie conditions. As expected, visual cortex responded consistently to the movies across adult participants, and there were no significant differences between the cartoon

and realistic conditions. However, the cartoon movie drove more similar spatiotemporal patterns of activity in visual cortex across infant participants, compared to the realistic movie, across the visual hierarchy. To assess how these results relate to certain visual features (e.g., color) or processes (e.g., face detection) in the movie, we are conducting multivariate pattern classification and pattern similarity analyses. These preliminary results suggest that the visual system may be especially attuned to diagnostic visual features in early development. This informs our understanding of infant visual experience and supports the sensory exaggeration hypothesis of perceptual development.

Title: Developmental prosopagnosics have normal visual field coverage in face-selective regions

Authors: *D. A. STEHR[1], Y. ZHANG[1], A. KIDDER[1], K. KAY[2], B. DUCHAINE[1]; [1]Dartmouth Col., Hanover, NH; [2]Ctr. for Magnetic Resonance Research, Dept. of Radiology, Univ. of Minnesota, Minneapolis, MN

Abstract: Developmental prosopagnosia (DP) is a neurodevelopmental condition characterized by extreme difficulty with facial identity recognition despite normal low-level vision and no known brain damage. Preliminary evidence from population receptive field (pRF) modeling suggests that pRFs in face-selective and intermediate visual areas, which normally cover a wide field of view, are strikingly restricted in DPs (Witthoft, 2016, bioRxiv), an organization that could hinder the formation of complex, holistic representations of facial features and their inter-relationships. Although this finding came from a small sample of DPs (n=8), it comports well with reports from DPs that they often base their decisions on slow, effortful piecemeal analysis of featural details. To more thoroughly investigate receptive fields in DP, we measured pRF properties using the compressive spatial summation (CSS) model applied to early, intermediate, and category-selective visual areas in 20 controls and 13 DPs. Participants fixated centrally while colorful, high-contrast images of scenes, faces, limbs, and objects windowed by bar-, wedge-, and wheel-shaped apertures traversed the visual field. In both DPs and controls, we observed sharply defined polar angle and eccentricity maps in early visual areas, typical scaling between pRF eccentricity and size, and strong spatially-modulated responses in face-selective areas with pRF density concentrated just to the contralateral side of the fovea. Absent, however, were reductions in pRF size in early, intermediate, or face-selective regions in DPs. These findings,

using a larger sample of DPs and the latest methods for modeling pRFs, indicate that receptive field size is normal in DP and that their deficits with face recognition result from differences in other neurocomputational characteristics.

Title: Poiesis (psychedelic outcomes: interaction of environment, self-identity, and success) - importance of naturalistic elements and religion/spirituality in a psychedelic dosing space

Authors: *S. LEE[1,2], C. EPLAND[2], R. R. GAJIPARA[2], N. A. KAITZ[2], C. J. WENTHUR[3,2,1]; [1]Univ. of Wisconsin - Madison Neurosci. Training Program, Madison, WI; [2]Sch. of Pharm., UW-Madison, Madison, WI; [3]Psychoactive Pharmaceut. Investigation Program, Univ. of Wisconsin-Madison, Madison, WI

Abstract: Racial and ethnic minorities remain underrepresented in psychedelic-assisted psychotherapy, which has shown promising therapeutic effects for mental illness. Greater inclusion of racial and ethnic minorities may indirectly influence therapeutic outcomes, which are proposed to be mediated through the "set and setting" framework. Since differences in psychotherapy acceptance could possibly be based on self-identity with race and ethnicity, self-identity may also act as a therapeutic filter in the psychedelic dosing room. We hypothesize that the environment, such as artwork, in the psychedelic dosing room influences one's experiences based on racial self-identity connectivity. Online surveys (n = 141; 49% BIPOC) were filled out by members of psychedelic societies based in Wisconsin and Texas. The survey content included demographics (age, gender, race/ethnicity, religion/spirituality) and artwork object connectivity (visual analogue scale) to 15 different objects found in the psychedelic dosing space. Furthermore, 7 focus groups (FG) (n = 1-4; 63% BIPOC) were formed based on demographic information given in the survey. The FGs were split into Black, Latino, Native American, and Non-Hispanic White participants. They were virtually interviewed for perceived connections with dosing room items and the dosing room itself. Multiple regression analyses revealed that racial/ethnic, age, and gender identities has a small impact on perceived connection with the artwork. Religion/spirituality had the largest effect size and is significantly greater than other identity-perceived connections. The major theme that arose in the FGs was a preference for *natural*-like settings and objects, specifically *plants*, in both the dosing room and art.

Additionally, both *physical* and *mental comfort* were another major theme mentioned in both the art objects and the dosing room. While *intention* regarding both the dosing room and art objects was mentioned, it was more prevalent in the latter. Lastly, many individuals from the FGs *narratively engaged* with the art object through *autobiographical*, *religion/spiritual*, and/or *time/mortality* statements. In conclusion, we find that religion/spirituality had a much larger impact on perceived connectivity to art objects than race or ethnicity. One's own comfort and the presence of naturalistic objects were important aspects in the psychedelic dosing room. With increasing movement towards adopting psychedelic-assisted psychotherapy, we recommend crafting the psychedelic dosing space with the themes we identified here.

Title: Covert and spontaneous brain to brain communications during memorization of simultaneous images

Authors: *S. CALMELS[1], E. JEULAND[2], M. LENNE[2], F. JARRY[3], J. DEBRUILLE[2]; [1]McGill Univ., Integrated Program in Neurosci., Montreal, QC, Canada; [2]McGill Univ., Montreal, QC, Canada; [3]Univ. de Montréal, Montreal, QC, Canada

Abstract: Many times, science starts by reporting facts that cannot be explained. This is the aim of the present work. With methods that have been refined for 10 years our goal is to see whether one can definitely confirm a surprising hypothesis. In effect, two previous works report that the event-related brain potentials (ERPs) that are evoked by presenting a picture to a participant can be modulated by simultaneously and privately presenting a picture to a partner. A reprocessing of the data of these works showed that these modulations existed only, or mostly, in precise circumstances, which were then copyrighted. A new experiment was thus run only in those circumstances to obtain simple and robust effects. We recorded the ERPs evoked by presenting, at each trial, the photograph of a face. Simultaneously and again, privately, we presented the same face or a different one to the partner. (S)he was in an adjacent room and could not

communicate. The ERPs of these partner-participants were found to strongly depend on the sameness of the two photographs, unbeknownst to them. These joint processing effects (JPEs) confirm that a simple and robust method can be used to study the sensitivity of the human brain to the brain activity of another person. This should help future works answering the many questions raised by this sensitivity, starting with the nature of the physical phenomenon at stake.

Title: Exploring Facial Feature Influence in Masked Face Recognition: Insights from Brain Activity and Eye Fixation Duration on the Face Feature Area

Authors: *I. CHANPORNPAKDI[1], Y. WONGSAWAT[2], T. TANAKA[1];
[1]Tokyo Univ. of Agr. and Technol., Koganei-shi, Japan; [2]Mahidol Univ., Nakhon Pathom, Thailand

Abstract: Objective: During the SARS-CoV-2 pandemic, communication with face masks was common. Nevertheless, people retrain the ability to distinguish and recognize faces. Previous studies showed that the eye might be a crucial component in face cognition, but the face cognition mechanism of the masked face is still under discussion. This study aimed to identify the influence of each face feature using the relationship between brain response and eye-tracking in partial face cognition. We hypothesize that people focus on the eye area the most, and recognizing a full face and a masked face is highly correlated. Method: The experiment was performed on 18 healthy volunteers, nine females (mean age 28.21±2.34, min 23 and max 33). The electroencephalogram (EEG) and eye-tracking were recorded when the participant performed the partial face cognition task. The task consisted of the six face images shown in seven conditions; full and part face, including faces with eyes covered, nose covered, mouth covered, eyes and nose covered, eyes and mouth covered, and nose and mouth covered. Among six face images, one face image was set as the target face, and the participant was asked to identify that target face. To find the relationship between the brain and eye-tracking response, the canonical correlation between event-related potential (ERP) component, calculated by grand averaging the EEG among all participants, and the total fixation duration of the eye-tracking in eyes, nose, mouth, and fixation area was calculated. Results: We found that the ERP amplitude when the eye component was presented was more significant than that when the eyes were absent. Moreover, longer fixation duration was observed in the eye area when the eyes were

visible. We also observed a high correlation between the full face and the masked face-like partial face; the face with mouth covered and the face with nose and mouth covered. Discussion: The results confirmed that the eye component plays the most crucial role in face cognition, and there is a similarity between full face (holistic face) cognition and partial face (masked face) cognition. This could explain how people can recognize masked faces correctly.

Title: Dissociating the roles of category selective visual and medial parietal regions during perception and recall of familiar stimuli: an EEG-MRI fusion approach

Authors: *C. L. SCRIVENER, E. H. SILSON;
Univ. of Edinburgh, Edinburgh, United Kingdom

Abstract: The interaction between networks facilitating visual perception and recall is not fully understood. It has often been assumed that the same regions are activated in response to both perception and recall of the same stimuli (Dijakstra, 2019) and that reinstatement of the perceived stimuli during recall would result in similar MRI or EEG activity during both states (Xie, 2020). However, category selective regions of medial parietal cortex (MPC) (Silson, 2019) are active during recall, differing from the category selective regions in the visual cortex recruited during perception. We used an EEG-fMRI fusion approach to ask how the similar neural dynamics of category selectivity reported in EEG relates to activity within these visual and MPC regions.
Multivariate pattern analysis (MVPA) was first used to decode the category of personally familiar stimuli (people or places) across all EEG electrodes. During both perception and recall, category information was decoded above chance level throughout the trial, emerging around 140ms after stimuli onset for perception and 200ms for recall. Further, the patterns identified at the emergence of category selectivity in both states successfully time generalized throughout the rest of the trial, indicating a stable representation through time. Using a cross-decoding approach, we also found that category representations identified during perception (around 100ms and 200-300ms) were able to classify stimuli type during the recall trials (between 200ms-1000ms). This indicates a reinstatement of the perceptual classification of category during recall, and adds to the evidence for a link between these two processes (Xie, 2020, Steel, 2023).
How does this reinstatement relate to visual and parietal activation? We used EEG-MRI fusion to correlate representational similarity matrices for all stimuli constructed at each time point in the

EEG with similar matrices constructed across all MRI voxels in the parahippocampal place area, fusiform face area, and people/place memory areas in the MPC. Two peaks of high correspondence were identified in both conditions, occurring between 150-200ms and 350-600ms after stimuli onset for perception, and between 200-300ms and 1000ms-2000ms for recall. Although we expected perception representations to correlate more strongly with visual ROIs, and recall with MPC ROIs, we found similar time courses across all regions. These results suggest the involvement of both visual and parietal regions during perception and recall, with representations emerging at different points throughout the trial. Further work is therefore needed to delineate the exact nature of their contributions

Title: Phenotypic clusters of cancer-related cognitive impairment based on subjective reports and objective computerized cognitive function scores.

Authors: *T. GOTO[1], L. SALIGAN[1], P. JUNEAU[2], S. GONSALVES[1], C. RIO[1], L. Y. GRAVES[3], D. VON AH[4];
[1]NIH/NINR, Bethesda, MD; [2]Natl. Inst. of Hlth. Library, Natl. Inst. of Hlth., Bethesda, MD; [3]Univ. of Texas Med. Branch, Sch. of Nursing, Galveston, TX; [4]The Ohio State University, Col. of Nursing, Columbus, OH

Abstract: Cancer survivors experience cancer-related cognitive impairment (CRCI) affecting productivity and quality of life. CRCI is often clustered with conditions (e.g., symptoms, behaviors) and influenced by intrinsic factors (e.g., sociodemographic characteristics). The management of CRCI and its clusters remains challenging because there is no agreed standardized assessment of CRCI. This study identified CRCI clusters based on subjective reports and cognitive function test scores. VARCLUS™ (SAS/STAT; SAS 9.4; Cary, NC) and k-means clustering technique were used based on CRCI reports assessed by the PROMIS® short-form subscales of Cognitive Abilities and Cognitive Concerns and computerized CANTAB Cambridge Cognition® scores (i.e., visuospatial working memory capacity, visual episodic memory, new learning, working memory, executive function, and sustained attention). This clustering technique identified five CRCI cluster groups. Phenotypic characteristics of each

cluster identified associated demographic profiles, physical/ psychosocial factors (i.e., physical function, affect, optimism, social support), and symptoms (i.e., anxiety, depression, fatigue, neuropathic pain, sleep disturbance). Of the 414 participants, 99% were female and 93% self-identified as White. Cluster groups 4 and 5 had the highest cognitive abilities and the lowest cognitive concerns. In terms of demographic factors, participants in cluster group 5 were mostly employed full time and have higher education and income than the other cluster groups. Further, participants in cluster group 5 had the highest physical function, positive affect, optimism, and social support among the cluster groups. Moreover, participants in cluster 5 were less likely to experience severe cancer-related symptoms such as anxiety, depression, fatigue, neuropathic pain, and sleep disturbance than other cluster groups. On the other hand, participants in cluster group 1 showed the worst cognitive function, had worst physical function, low affect and optimism, and less social support with more severe symptoms than the rest of the cluster groups. The clustering approach that we employed in this study using both subjective and objective cognitive function information may provide promising phenotypes that can potentially be clinically relevant to categorize patient CRCI presentations. Validation of the study findings is warranted particularly enrolling a more diverse cohort of participants across demographic populations from a broad spectrum of psychosocial experiences and investigating the influence of social determinants of health on CRCI.

Title: Behavioral and neural correlates of impaired scene perception following saccadic eye movements

Authors: *Y. CHOI[1], T.-Y. CHIU[3], J. D. GOLOMB[2];
[1]Psychology, [2]Dept of Psychology, Ohio State Univ., Columbus, OH; [3]The Ohio State Univ., Columbus, OH

Abstract: People make ballistic eye movements, known as saccades, several times per second to efficiently explore visual environments. Visual input projected onto the retina drastically changes across saccadic eye movements, and it is known that our sensitivity to simple visual stimuli (e.g., Gabor patches) decreases when they are presented around the time of the saccade. However, it is less clear how visual information processing for more realistic and complicated visual stimuli is affected by saccades. Through behavioral and fMRI experiments, we presented scene images

filtered at different spatial frequencies and presented at different times relative to a saccade, to explore how saccadic eye movements influence the processing of visual scenes. In a behavioral experiment, a scene image was flashed for a short duration (50 ms) either immediately (5 ms) after saccadic eye movement or after a delay (500 ms). Subjects were asked to categorize scene images into six categories (e.g. beach, mountain, forest, city, office, and highway). Scene images were filtered through either low- or high-pass spatial frequency filters to further investigate whether post-saccadic scene categorization performance depends on spatial frequency information. For both spatial frequency conditions, we found decreased scene categorization performance for images flashed immediately after the saccade compared to later after the saccade, indicating non-specific impaired visual information processing for realistic scene images. Subsequently, the fMRI study investigated neural correlates of impaired post-saccadic scene perception in the absence of an explicit categorization task, to explore how neural representations of scene category and spatial frequency are influenced by saccades. In the scanner, subjects performed a 1-back task on scene images flashed after a short or long post-saccadic delay. Scenes were drawn from four scene categories (two urban, two nature) and four spatial frequencies (two high SF, two low SF). Consistent with the behavioral findings, preliminary results revealed reliably decreased activity in the scene-selective cortex (PPA) for trials when the scene image flashed within 100 ms after a saccade, compared to when it flashed at least 200 ms after the saccade. Furthermore, multivariate Representational Similarity Analyses were conducted to compare the representation of scene contents and spatial frequency across the post-saccadic delays.

Title: Altered perceptual decision-making in aphantasia versus visualisers - a comparative electroencephalograhy analysis

Authors: *F. M. O'SULLIVAN, K. KALOU, R. G. O'CONNELL;
Trinity Col. Dublin, Dublin, Ireland

Abstract: Aphantasia, an inability to voluntarily form visual images, is estimated to affect 300 million people worldwide. Its study has enormous potential to inform several areas of cognitive neuroscience, but due to its recent identification and parsing out from confounding phenomena, aphantasia remains heavily under-researched. Here, we fill a critical neuroimaging gap by

reporting the first electroencephalography (EEG) study explicitly comparing people with aphantasia (n=13) and people who can visualise (n=25), as a control. We utilised a modified contrast discrimination paradigm to assess differences in perceptual decision-making between groups. Both groups received cues to imagine a grating either congruent or incongruent to the direction of a subsequently presented grating. As an exploratory study, we conducted several analyses at each stage of the sensorimotor hierarchy. Differences in sensory signal strength were measured through the amplitude of steady steady visual evoked potentials (SSVEPs), evidence accumulation to a bound through the centro-parietal positivity (CPP) build-up, and motor preparation through lateralized mu/beta band desynchronisation. Aphantasics performed faster, which may fit with the 'alternative strategies' accounts of aphantasia. Our study has implications for both mental imagery and perceptual decision-making research. We integrate our electrophysiological findings with existing fMRI, psychophysics and binocular rivalry studies of aphantasia and mental imagery. We also discuss how our findings inform debate on the differential mechanisms of modulation of perception due to prior expectations, imagery and attention.

Title: Cortical activations for spatial configuration processing in skilled and poor readers

Authors: *S.-C. HUNG[1], H.-L. WANG[2], C.-C. CHEN[1];
[1]Natl. Taiwan Univ., Taipei, Taiwan; [2]Natl. Taiwan Normal Univ., Taipei, Taiwan

Abstract: Analysis of spatial configuration is important in identifying visual word forms. We investigated the effect of symmetry on character composition, which would require the visual system to analyze the spatial relationships among strokes during visual word form processing in developmental dyslexic (DD) children and chronological aged (CA)-matched typical children. We measured BOLD activations for real-, non-, and scrambled characters with symmetric or asymmetric compositions in a block-design functional magnetic resonance image (fMRI) experiment. Participants were asked to match the presented character with that of the previous trial. Compared to scrambled characters, real-characters elicited activations in the fusiform gyrus for the CA group but in the lingual gyrus for the DD group. Compared to real-characters, non-characters elicited activations in the lingual and fusiform areas for the CA group, whereas this pattern was absent for the DD group. The left fusiform activation in the CA group was consistent with the visual word form areas in the literature. Comparing the symmetric with the asymmetric

conditions, the CA group showed activations in the bilateral fusiform gyri, lingual and inferior occipital areas, whereas the DD group did not. Our findings reveal differential neural evidence between dyslexic and typical children, suggesting that the fusiform gyri and occipitotemporal areas may play a role in analyzing symmetric configurations in orthographic characters. Typical children showed neural responses in the fusiform gyri and occipitotemporal areas during processing symmetric versus asymmetric configurations, but these activations were absent in dyslexic children. Thus, the poor reading performance of dyslexic children may result from impaired spatial configuration processing in identifying visual word forms.

Title: Synchronous and asynchronous spiking states in the human cortex during image viewing

Authors: *V. WANG, K. A. ZAGHLOUL;
Natl. Inst. of Neurolog. Disorders and Stroke, Bethesda, MD

Abstract: Intracranial electroencephalography (iEEG) recordings in the human brain show a spectrum of neural ensemble activity states, but the cognitive drivers behind these empirically observed states are not yet well understood. Such population activity states range from synchronous regimes exhibiting discrete bursts of communal spiking activity to asynchronous regimes lacking clear patterns of neural coordination. To explore the causes differentiating these states, we design an experiment informed by computational neural network simulations suggesting that distinct activity states (synchronous regular, synchronous irregular, asynchronous regular, asynchronous irregular) arise from variations in the strength of external drive to a neural ensemble. Four experimental behavioral conditions—viewing an image, thinking about an image, resting with eyes open, and resting with eyes closed—are used to modulate this external drive to the brain in human subjects, with the hypothesis that increased external input induces more chaotic, asynchronous states, while decreased external input leads to more patterned, synchronous states. During iEEG data collection, implanted microelectrode arrays record activity from individual neurons in the anterior temporal lobe (ATL) of epilepsy patients undergoing a task session that spans the experimental conditions. From the recorded voltage traces, spikes associated with individual units are detected and their timestamps are extracted. To quantify the degree of ensemble spiking synchrony for condition comparison, we calculate a neural synchrony measure based on variances in individual unit and ensemble firing rates. A preliminary analysis in three subjects demonstrates slight decreases in neural synchrony when

moving from the eyes-closed state to the eyes-open state, aligning with our hypothesis. Furthermore, by implementing a probabilistic hidden Markov model with Poisson emissions, we detect “On” (vigorous spiking activity) and “Off” (relative quiescence) episodes within all experimental trials in a systematic manner. This analysis permits the characterization of ensemble spiking behavior in greater detail. Initial pairwise comparisons across experimental conditions reveal statistically significant differences in the mean durations of “On” episodes between viewing-image vs. thinking-about-image, thinking-about-image vs. eyes-open, and thinking-about-image vs. eyes-closed conditions. By applying these mathematical models, we can assess whether empirically observed brain states are experimentally replicated and subsequently elucidate the cognitive modes that underlie them.

Title: Establishing task-general representations and the cues which drive them in spatial perception

Authors: *P. MAHABLESHWARKAR[1], J. PHILBECK[2], D. J. KRAVITZ[3];
[1]The George Washington Univ., District of Columbia, DC; [2]The George Washington Univ., Washington, DC; [3]NIH, BETHESDA, MD

Abstract: Visual representations are remarkable in their ability to integrate multiple cues towards unified percepts and to adapt to various tasks, both of which make them powerful but difficult to study. Here, we leverage natural scene image databases paired with a novel series of pre-registered crowd-sourced behavior studies to discern a task-general representation of egocentric depth and the pictorial cues which drive it. We presented 156 novel scenes with embedded targets and found a remarkable level of scene specific systematicity and generalization across independent groups of participants performing different tasks (metric depth estimation MDE, depth discrimination DD) with distinct stimulus durations (125, 250, 1000ms). In MDE, participants showed not only a strong overall sensitivity to target depth in these 2D scenes, but also highly reliable differences across individual scenes distinct from the general effect of depth (e.g., r^2=.801, $p<10^{-76}$). Moreover, these scene-specific deviations strongly predicted DD performance in an independent group of participants for particular scene pairs (e.g., r^2=.312, $p<10^{-20}$). Overall significant relationships were found that generalized across participants, tasks, durations, and outcome measures, indicating systematic biases for individual scenes independent of those factors. For instance, DD RT predicts MDE RT at every combination of duration (all r >

0.27, all $p<10^{-3}$). Thus, cues within the 2D images must consistently drive 3D spatial perception, enabling in-depth examinations of individual cue contributions (e.g., familiar size, ground plane). Using an unbiased computer vision approach to quantify pictorial information, we uncover a novel relationship between the real-world size of the ground plane and egocentric depth perception even with stimulus presentations as short as 125ms ($F(1,146.62)=34.26$, $p<10^{-7}$). These findings suggest a finely tuned and rapid mechanism for integrating relative depth information, spatial cues, and object information towards depth perception. Further, the success of this method suggests a scalable approach (for all 6 tasks: N=2,178, collection time = 2 weeks, total cost ~$5,500) to quantifying task-general representations which can guide stimulus selection and task design for neurophysiological investigations.

Title: What aspects of the electrophysiological signal contain stimulus information?

Authors: *D. GENG[1], A. ALREJA[3], J. A. COLAN[4], R. M. RICHARDSON[6], T. ABEL[5], A. S. GHUMAN[2];
[2]Neurolog. Surgery, [1]Univ. of Pittsburgh Sch. of Medicine, Carnegie Mellon Univ., Pittsburgh, PA; [3]Carnegie Mellon Univ., Pittsburgh, PA; [5]Neurolog. Surgery, [4]Univ. of Pittsburgh Sch. of Med., Pittsburgh, PA; [6]Neurosurg., Massachusetts Gen. Hosp., Boston, MA

Abstract: Introduction.
Electrophysiological signals can be decomposed in many ways, with different aspects of the signal thought to arise from particular neurophysiological processes. Studies often focus selectively on specific components of a neural signal (e.g., high-frequency broadband [BB], event related potentials [ERP], or spectral decomposition), potentially overlooking critical information. Little is known regarding what aspects of the signal carry the most information about task or stimulus conditions. To address this question, we examined which components of human intracranial electroencephalography (iEEG) signals carry the most informative data about categories of visual stimuli.
Methods.
We analyzed iEEG recordings from 40 participants using 5700+ total electrodes during a six-

category one-back test. We pre-processed raw iEEG signals to extract two neural signal components: ERP and BB components. Furthermore, we explored information distribution among the oscillatory (periodic) and non-oscillatory (aperiodic) components using the FOOOF toolbox. We used multivariate classification performance to measure the amount of information contained within the ERP and BB signal components (or the periodic and aperiodic components). We first identified if the activity in the electrode contained significant information about the stimulus categories in the ERP, BB, or both (or the periodic, aperiodic, or both) components, then compared the relative amount of information contained in these different components.
Results.
Across all categories and patients, we discovered that 3.8% of electrodes contained significant information in the ERP, 6.5% in the BB, and 1.2% in both components. Among these, some electrodes preferentially held information in the ERP (9.0%) and in the BB (13.0%). Notably, there was consistency within participants as to which component held information, with the heterogeneity arising primarily between participants. The aperiodic component of the signal was notably more informative (5.8%) than the periodic component (0.9%), emphasizing the value of non-oscillatory background components of neural signals. We are also analyzing iEEG data from an auditory task to assess the generalizability of these results across sensory domains.
Discussion.
Our findings highlight the need to examine all signal components collectively for comprehensive understanding of neural activity. They also underscore the need for deeper understanding of the neurophysiological basis of the heterogeneity regarding which aspects of electrophysiological signals give rise to information processing.

Title: Spatiotemporal dynamics of self-generated imagery reveal a reverse cortical hierarchy from cue-induced imagery

Authors: *Y. HU[1,2], Q. YU[1];
[1]Inst. of Neuroscience, Ctr. for Excellence in Brain Sci. and Intelligence Technology, Chinese Acad. of Sci., Shanghai, China; [2]Univ. of Chinese Acad. of Sci., Beijing, China

Abstract: Visual imagery, the ability to generate visual experience in the absence of direct external stimulation, allows for the construction of rich internal experience in our mental world. Most imagery studies to date have focused on cue-induced imagery, namely the to-be-imagined contents were triggered by external cues. It has remained unclear how internal experience derives volitionally in the absence of any external cues, and whether this kind of self-generated imagery relies on an analogous cortical network as cue-induced imagery. Here, leveraging a novel self-generated imagery paradigm, we systematically examined the spatiotemporal dynamics of self-generated imagery, by having participants volitionally imagining one of the orientations from a learned pool; and of cue-induced imagery, by having participants imagining line orientations based on associative cues acquired previously. Our results revealed that: at the behavioral level, self-generated imagery was experienced as less vivid compared to cue-induced imagery; at the neural level, using electroencephalography (EEG) and functional magnetic resonance imaging (fMRI), in combination with multivariate encoding and decoding approaches, cue-induced and self-generated imagery demonstrated largely overlapping neural signatures in both EEG and fMRI; yet, these neural signatures displayed substantially differential sensitivities to the two types of imagery: self-generated imagery was supported by an enhanced involvement of anterior cortex in generating and maintaining imagined contents, as evidenced by enhanced neural representations of orientations in sustained potentials in central channels in EEG, and in posterior frontal cortex in fMRI. By contrast, cue-induced imagery was supported by enhanced neural representations of orientations in alpha-band activity in posterior channels in EEG, and in early visual cortex in fMRI. These results jointly support a reverse cortical hierarchy in generating and maintaining imagery contents in self-generated versus externally-cued imagery.

Title: Morphological and transcriptomic diversity of thalamocortical projections

Authors: *M. T. SUMMERS[1], B. LONG[2], T. CHARTRAND[1], A. KAMALOVA[3], D. TOGLIA[1], H. MYERS[1], J. ROHDE[1], M. TURNER[2], N. OUELLETTE[1], K. CAO[1], A. CARTER[3], A. WILLIFORD[2], B. TASIC[2], A. GLASER[1], H. ZENG[2], K. SVOBODA[1], J.

Abstract: The thalamus is a central hub of the forebrain, and aside from recurrent intratelencephalic connections, is the primary excitatory driver of cortical activity. The thalamus contains several nuclei with structurally and molecularly diverse thalamocortical projection neurons, yet the correspondence between gene expression patterns, cortical projection targets, and subcortical inputs is poorly understood. We are using a combination of approaches to investigate how non-sensory thalamus routes subcortical information to frontal cortex. We use spatial transcriptomics to understand gene expression motifs and transcriptomic cell types within and across thalamic nuclei. Multiplexed error-robust fluorescent *in situ* hybridization (MERFISH) delineates the spatial arrangement of transcriptomic types and gene expression gradients, while projection types are identified using expansion-assisted selective plane illumination microscopy (ExaSPIM) to create single neuron reconstructions on specific genetic backgrounds. We combine this with traditional viral tracing techniques to generate a comprehensive view of circuit inputs and outputs for molecularly defined cell types in the thalamus. Our cell-type resolved anatomical analysis of the thalamus is a foundation for understanding computation in multi-regional circuits with thalamus in the middle.

Title: Differential Roles of the Medial Prefrontal and Sensory Cortices in Integration of Prior Knowledge and Sensory Inputs in Perceptual Decision-Making in Mice

Authors: *K. ISHIZU, A. FUNAMIZU;
Inst. of Quantitative Biosci., Tokyo Univ., Tokyo, Japan

Abstract: In perceptual decision-making, the integration of sensory inputs and prior knowledge of action outcomes plays a crucial role in optimizing choices. Our previous study (Funamizu, iScience, 2021) examined this integration through an auditory discrimination task in mice. This study investigates the necessity of the auditory cortex (AC) and medial prefrontal cortex (mPFC)

in auditory-perceptual decision-making processes through optogenetic manipulation. Wild-type CBA/J mice were used for the experiments. We injected AAV-CKIIa-stGtACR2-FusionRed and implanted optical fibers bilaterally into either the AC or mPFC of the mice. The delivery of 473 nm photo-illumination through the fibers allowed to activate the stGtACR2 protein and suppress neural activity in the target region (AC or mPFC). The mice performed a tone-frequency discrimination task, associating high- or low-frequency tones with left- or right-spout water rewards. We differenced the reward amounts for the left and right spouts, and interchanged the reward difference for each block of 90 to 100 trials, with each trial presenting either a long- or short-tone. Light stimulation was applied during sound representation in every second trial. The choices were influenced by both the reward amounts and tone durations. Inhibiting mPFC activity led to biased choices, while inhibiting AC activity resulted in variable behavioral changes across sessions. We are going to inhibit the activity during non-sound timings to understand the roles of AC and mPFC in decision making.

Title: Coding by medial prefrontal neurons is not random, but respects the logic of a contextual visual discrimination task

Authors: *A. AMIR, D. B. HEADLEY, L. F. GOMEZ-ALATORRE, A. KARKI, A. DADSON, M. M. HERZALLAH, D. PARE;
Ctr. for Mol. and Behavioral Neurosci., Rutgers Univ., Newark, NJ

Abstract: It was reported that the combination of features encoded by individual prefrontal (PFC) neurons is random, but that task features and performance can be detected at the population level. However, assessing whether PFC coding is random requires much larger cell samples than used previously. Thus, we examined the relation between the cluster of features encoded by PFC cells in a contextual visual discrimination task. Rats implanted with Neuropixel probes in the medial PFC were presented with visual stimuli via 2 monitors placed on either side of their heads. 2 epochs of visual stimulation occurred on each trial: (1) when rats step on a platform, triggering the presentation of one of two stimuli signaling context, identical on both sides; (2) when rats nose-poke, during which different stimuli to be discriminated are presented on the left and right. The latter varied along two dimensions (speed & contrast; 5 levels each). Rats had to determine on what side the target dimension is highest, ignoring the left-right difference in distractor levels. Rats reported their decision by pressing a lever on the side where the target dimension is higher. Quantifying explained variance revealed that outcome and response/choice information were encoded by ~50% PFC cells compared to ~25% for context

information and ~12% for stimulus information. To test if the cluster of variables encoded by PFC cells is random, we identified cells showing significant rises (+) or drops (-) in firing rates (within 0.15 s of nose-poking) as a function of speed (S) or contrast (C) on the left (L) or right (R), after balancing the number of trials requiring left or right lever responses. This analysis yielded the following features (SL+,SL-,SLnil; SR+,SR-,SRnil; CL+,CL-,CLnil; CR+,CR-,CRnil), in 81 possible combinations. The number of cells with opposite responsiveness to contrast on left vs. right (CL+ & CR-; CL- & CR+) was 13 times > chance (p=0.001). Opposite responsiveness to speed on left vs. right (SL+ & SR-; SL- & SR+) was 5 times > chance (p=0.003). Moreover, the number of cells with opposite eye dominance for speed vs. contrast was 3.63 times > chance (p=0.007). Finally, we noted that cells with opposite eye dominance for speed vs. contrast rarely exhibited a lever preference compared to cells with eye dominance for only one dimension (1.2% vs. 19.5%). Thus we asked whether cells with eye dominance for only one dimension also exhibited a firing preference for lever on the same vs. opposite side. The number of cells with lever and eye dominance on the same side was 5.6 times > chance (p=0.039). Overall, our results indicate that the clusters of variables encoded by individual PFC neurons reflect the logic the task.

Title: Frontal cortex impacts on exploratory attentional resource allocation in mongolian gerbils: insights from a probabilistic foraging paradigm

Authors: *P. SARAVANAKUMAR[1], V. KANNAN[1], M. VOLLMER[1,2], F. OHL[1,3,4], M. HAPPEL[1,4,5];
[1]Systems Physiol. of Learning, Leibniz Inst. for Neurobio., Magdeburg, Germany; [2]Exptl. Audiology, Univ. Hosp. Magdeburg, [3]Inst. of Biol., Otto-von-Guericke Univ., Magdeburg, Germany; [4]Ctr. for Behavioral Brain Sci. (CBBS), Magdeburg, Germany; [5]Fac. of Med., MSB Med. Sch. Berlin, Berlin, Germany

Abstract: In our constantly changing world, it is necessary to continuously adapt choice options to current needs and, if necessary, to change our current behavioural strategy and to explore the environment in order to adaptively reallocate resources. For example, imagine a Mongolian gerbil that forages a desert habitat for distributed food patches. When these patches become exhausted, the gerbil is in an exploitation/exploration dilemma: Should it exploit the current

patch further or should it explore an alternative patch, suffering travel costs but achieving potentially higher food density? Such a foraging example shows a fundamental resource allocation problem. The patch-leaving decision needs to be made based on probabilistic information (how much food is usually available in the alternative patch?) in a potentially changing environment. Previous studies have suggested that the anterior prefrontal cortex (aPFC) plays a decisive role for the neuronal realization of exploratory resource allocation in human and non-human primates (*Daw et al., 2006*). In the present study, we investigated the performance of Mongolian gerbils in a probabilistic foraging paradigm (*adapted from Lottem et al., 2018, Nat Comm.*) while simultaneously recording laminar current source density (CSD) profiles in Frontal field A (FrA) using 32 channel chronic electrodes (Neuronexus probes). We were able to show that activity in the frontal cortex depends on both the received reward as well as the expected probability of the reward. As the latter decreases due to the exponential decrease in reward delivery, activity patterns in frontal cortex reflected an accumulating evidence that accompanied switching from exploitative to explorative search strategies. Using the laminar signal resolution, the goal is to obtain insights into different neuronal circuit elements in frontal cortex that contribute to the optimal selection of exploitative versus explorative search strategies, thereby gaining a better understanding of the neural regulation of attentional resource allocation.

Title: History of sensorimotor event representations in mouse medial prefrontal cortex serves reward foraging functions

Authors: J. LOPEZ-YEPEZ, A. BARTA, J. MARTIN, M. MOLTESSEN, T.-F. WOO, ***D. KVITSIANI**;
Aarhus Univ., Aarhus C, Denmark

Abstract: Prefrontal cortical regions are believed to play a crucial role in integrating information from various sensory, motor, and internal variables to guide decision-making in animals. It has been proposed that neurons in these areas, either individually or as a population, compute a decision variable (DV) that influences an animal's choices. However, representations within the prefrontal regions are complex, encompassing not only DVs but also current and past sensory, motor and internal variables. This complexity is especially apparent when analyzing population-level representations, as they can simultaneously encode different behavioral variables in a high-dimensional space. As a result, a key unanswered question is which representations are utilized by animals out of this diverse and mixed array. To address this question, we conducted experiments involving the recording of neurons in the medial prefrontal cortex (mPFC) of mice engaged in probabilistic reward-based foraging. During the task, animals were required to track both their reward history and choice history, which we refer to as history of sensorimotor events. To quantify the decision variable based on the animals' behavior, we employed a reinforcement learning framework. In our previous studies we have demonstrated that a reinforcement learning model incorporating both reward and choice history performs better than other models of the same class. By analyzing both single neurons and populations of neurons, we found that while neurons represent both the decision variable and the history of sensorimotor events, the representations of sensorimotor events were more pronounced than those of the decision variable. Furthermore, when we manipulated the temporal delay in choices while maintaining the task structure, we observed that representations of sensorimotor history remained robust, whereas the representation of the decision variable degraded. This suggests that the representations in the mPFC primarily serve to encode the history of sensorimotor events rather than directly compute the decision variable. To further test this hypothesis, we inactivated the mPFC and observed behavioral effects only when the relevant sensorimotor events were delayed. Our study provides evidence that neural representations in the mPFC function to maintain a working memory of past events, with little support for the notion that it directly computes the decision variable that guides an animal's choices.

Title: Top-down modulation of autonomic arousal by the anterior cingulate cortex

Authors: *N. CHINTALACHERUVU, A. KALELKAR, C. OH, C. TUMBOKON, R. HUDA; Rutgers University–New Brunswick, New Brunswick, NJ

Abstract: Hyperactivity of arousal-mediating circuits are implicated in a variety of neuropsychiatric disorders. Therefore, insight into the arousal system of the brain could lead to a better understanding of the neurological basis of these disorders. Subcortical structures such as the locus coeruleus, hypothalamus, and periaqueductal gray (PAG) are known to be involved in the regulation of autonomic arousal but much less is known about the role of higher level cortical circuits. We investigated the role of a major subdivision of the prefrontal cortex, the anterior cingulate cortex (ACC), in modulating autonomic arousal. Pupil size, heart rate, and movement were used as non-invasive measures of arousal. To test how ACC activity contributes to arousal levels, we simultaneously measured arousal and recorded fiber photometry signals from mice virally expressing GCaMP8m. Aligning these signals to the onsets of pupil dilations revealed that pupil dilations were preceded by increases in ACC calcium activity. Further, ACC activity was associated with heart rate increases. To better understand how the ACC can directly modulate arousal, we optogenetically manipulated ACC pyramidal neuron activity. We found that photostimulation of pyramidal neurons in mice expressing CaMKII-ChR2 caused pupil dilations that were time-locked to activation. ACC activation also led to increased heart rate and movement. ACC inactivation via photostimulation of GABAergic neurons caused pupil constrictions. Additionally, closed-loop optogenetic inactivation of the ACC using DeepLabCut Live suppressed ongoing pupil dilations. Vasoactive intestinal peptide-expressing (VIP) interneurons exert disinhibitory control over pyramidal neuron activity by inhibiting other inhibitory cells. We tested whether and how VIP neurons are involved in ACC modulation of arousal. Optogenetic VIP neuron stimulation caused pupil dilations. Next, we investigated a possible ACC to periaqueductal gray (PAG) projection pathway that may be involved in arousal modulation. We used fiber photometry to record calcium activity from ACC axons in the PAG. Aligning calcium activity to onsets of pupil dilations revealed pupil dilations were preceded by increases in ACC-PAG axon activity, similar to what we found in ACC neurons. We also found that optogenetic stimulation of ACC axons in the PAG caused pupil dilations. Together these findings indicate that the ACC modulates autonomic arousal, possibly via projections to the PAG. We are currently evaluating how ACC VIP neurons regulate outflow of information to the PAG for top-down modulation of arousal.

Title: Role of VIP-expressing neurons in the prefrontal cortex in probabilistic reversal learning

Authors: *J. YI[1,2], Y. YOON[3,2], S. CHOE[1], M. JUNG[1,3];
[1]Inst. for Basic Sci., Deajeon, Korea, Republic of; [2]These authors contributed equally, Deajeon, Korea, Republic of; [3]Korea Advanced Inst. of Sci. and Technol., Deajeon, Korea, Republic of

Abstract: The prefrontal cortex (PFC) plays a crucial role in flexible control of behavior. Of various types of neurons in the PFC, vasoactive intestinal polypeptide (VIP)-expressing neurons are thought to exert powerful influences on PFC circuit operations by disinhibitory control of other inhibitory interneurons. To obtain insights on the role of VIP neurons in flexible control of behavior, we investigated modulation effects and activity dynamics of VIP neurons in the medial PFC (mPFC) in mice performing reversal learning under a probabilistic classical conditioning paradigm. We found that chemogenetic or optogenetic modulation of VIP neuronal activity impairs reversal learning as assessed by the animal's cue-dependent anticipatory licking responses. We also found that VIP neurons undergo diverse types of activity change across trials following cue-outcome contingency reversal. During the progress of behavioral reversal (~100 trials since cue-outcome contingency reversal), but not before or after it, VIP neurons conveyed strong signals related to reward history and reward prediction error (RPE). Moreover, there was a significant correlation between the persistence of RPE signals across trials and the number of trials required for each animal to reach the reversal criterion. These findings suggest VIP neurons play a crucial role in behavioral flexibility by modulating mPFC neural circuit activity in response to reward history and reward prediction error. They also suggest the potential significance of VIP neurons in developing interventions for conditions associated with impaired behavioral flexibility.

Title: Synergistic dynamics of norepinephrine, dopamine, and serotonin in mouse frontal cortex during naturalistic decision making.

Authors: *J.-H. YANG[1], A. BASU[2], R.-J. LIU[1], S. STASZKO[1], A. YU[1], J. RONDEAU[1], S. GLAESER-KHAN[1], Y. LI[3], A. CHE[4], A. P. KAYE[1];
[1]Dept. of Psychiatry, Yale Univ., New Haven, CT; [2]Yale Univ. Interdepartmental Neurosci. Program, New Haven, CT; [3]Peking Univ., Beijing, China; [4]Yale Sch. of Med., New Haven, CT

Abstract: In nature, animals must forage for food under environmental danger to survive. Neuromodulators including norepinephrine (NE), dopamine (DA), and serotonin (5HT) play a fundamental role in this process, enabling flexible switching between motivational drives. The question of how neuromodulators synergistically encode motivational state is thus fundamental to systems neuroscience, yet the interplay between these neuromodulators during naturalistic decision making are not fully understood. Here, we developed a naturalistic approach/avoidance task in mice involving a tradeoff between seeking reward versus safety in the presence of looming predation risk. We utilized whole-brain cFos mapping, multi-fiber photometry, computational behavior tracking, and slice electrophysiology in this task. Mice that experienced looming stimuli showed increased c-fos expression in regions including frontal cortex, locus coeruleus, and ventral tegmental area, but decreased expression in dorsal raphe nucleus. Moreover, by using multi-fiber photometry combined with GPCR-based sensors, we found that cortical NE plays a more prominent role in encoding looming threats while DA represents reward. In contrast, 5HT dynamic negatively correlates to both valences. Furthermore, bath application of 5HT-related treatments increase spontaneous spikes in locus coeruleus NE neurons in an ex vivo slice physiology experiment, suggesting the importance of cross-talk between different neuromodulatory circuits. In conclusion, monoamines such as NE, DA, 5HT can converge in their encoding of naturalistic motivated behaviors as well as dissociate from one another. By utilizing this approach, interactions between innate fear and incentive for food may be delineated in terms of basis in neurochemical signaling events during natural behavior, and may contribute to the understanding of neural mechanisms underlying emotional disorders including anxiety and post-traumatic stress disorder.

Title: Role of prefrontal dopamine in effort-based decision making

Authors: *M. FERNANDEZ GOMEZ, A. KASHAY, T. A. GUPTA, F. N. VEENKER, S. A. WILKE;
Psychiatry, UCLA, Los Angeles, CA

Abstract: Effort-based decision-making (EBD) requires establishing action selection policies that maximize effort-reward tradeoffs and is disrupted in several neuropsychiatric disorders. The anterior cingulate cortex (ACC), a prefrontal subregion, is critical for encoding effort-related value, model-based action selection, resolving uncertainty and other functions relevant to EBD. Our lab has found that the activity of ACC excitatory neurons is necessary for effortful action selection, while a subpopulation of striatal projecting neurons is transiently required to switch from a low to a high effort choice strategy. Dopaminergic inputs strongly modulate function in target regions and striatal dopamine (DA) is heavily implicated in EBD. However, the role of DA in shaping ACC neural activity during EBD remains poorly understood. Here, we deploy temporally precise optical tools to measure and manipulate ACC DA in an effort-based T-maze task. In this assay, mice must choose whether to surmount an effortful obstacle for a large reward vs. taking an unimpeded path to a small reward. Using fiber photometry and GRAB-based fluorescent DA sensors, we observed ramping of ACC DA as mice approach the maze choice point. Distinct DA dynamics emerged during specific epochs of choice trials and were differentially modulated during high vs. low effort choices. Moreover, these DA dynamics correlated with ACC activity patterns as detected by measuring GCaMP signals during the same behavior. In ongoing work, we are now using optogenetic approaches to manipulate DA terminals in ACC to further investigate these relationships.

Abstract: In the process of decision-making, subjects recognize the external situation, refer to their memory and knowledge to assess the value and cost of an action and alternatives, and decide on a course of action. The prefrontal cortex may play a part in this process in the form of a complex interplay of bottom-up information, driven by the sensory perception of the external environment, and top-down information, driven by retrieval and inference of memories and knowledge encoded in the brain. In rodents, the medial prefrontal cortex (mPFC) is reportedly involved in decision-making; this warrants a detailed analysis at the cellular level. To examine the neural activity during decision-making, we first developed a behavioral task using a touch-screen device. In this task, mice had to make decisions based on visual information, memory and/or knowledge and were given rewards for correct responses. To date, more than 30 mice have been trained and have exhibited a high rate (>80% on average) of correct responses despite a chance level of 50%. To analyze neural activity, GCaMP6f, a genetically encoded calcium indicator, was expressed in the mPFC (n = 3) and primary somatosensory cortex (SSp, n = 2) of the mice. After these mice were trained, calcium signals were measured via *in vivo* Ca^{2+} imaging using a microendoscope during the behavioral task. Task-related cells were assessed using one-way repeated measures ANOVA ($p < 0.0001$) and defined as those whose $\Delta F/F$ before and after visual cue stimulus changed at a consistent time across repeated trials. The results indicated that the mPFC (190/293 cells; 64.85%) had a greater proportion of task-related cells than the SSp (50/199 cells; 25.13%) ($\chi^2(1) = 73.25$, $p < 0.0001$). As temporal variations in the activity of task-related cells in the mPFC were observed, hierarchical cluster analysis was used to classify the cells according to their activity patterns. Interestingly, in addition to activating cells after visual cue stimulus, many deactivating cells were present in the mPFC. Furthermore, choice-specific activity may have occurred in some cell populations of the mPFC along with the initiation of choice. These results suggest that mPFC neurons are involved in decision-making with distinct activity and temporal properties and that some cell populations are part of a network that regulates choice.

Title: Frontal dynamics underlying flexible decision making in mice

Authors: *F. ABELA[1], J. J. BOS[1], F. P. BATTAGLIA[1], P. TIESINGA[1], L. MA[2];
[1]Radboud Univ., Nijmegen, Netherlands; [2]departmet of psychology, York university, Toronto, ON, Canada

Abstract: Humans and other animals require flexibility to make decisions appropriate for an ever-changing environment. The way mammalian brains achieve flexible decision making is not fully understood. The probabilistic reversal learning (PRL) task is a powerful tool used to assess behavioral flexibility and how positive and negative feedbacks influence decision making. It has been administered to healthy partecipants and patients with a wide range of neurological conditions, including Autistic Spectrum Disorder and Schizophrenia, as well as to animal models. We trained C57BL/6 mice on PRL and conducted high-density single unit recordings using Neuropixels probes from the medial frontal cortex in well-performing animals. The animals had binary choices (e.g., left vs right) associated with different reward probabilities (e.g., 80% vs 20%), which they discovered via trial and error. Once a consistent choice was established, the contingencies were reversed, so the previously highly rewarded side became unfavorable and vice versa. After one month of training, mice were able to flexibly switch contingencies multiple times in one training session. So, as contingency undergoes multiple changes, animals were able to maximize the accumulated reward, via the integration of positive and negative feedback . We have identified the neural correlates for the choice value (i.e., the probability of reward) and the reward prediction error (RPE, i.e., when the obtained reward differs from the value). We will then examine how the choice value and RPE propagate in the mammalian brain by recording from multiple regions simultaneously.

Abstract

Effort-based decision making (EBD) requires weighing predicted gains against the physical effort costs required to obtain them, and is disrupted in several neuropsychiatric disorders. The anterior cingulate cortex (ACC) is postulated to compute effort-related value and exert control over action selection policies during EBD. Our lab has found that the activity of ACC excitatory neurons is necessary for effortful action selection, while a subpopulation of striatal projecting neurons is transiently required to switch from a low to a high effort choice strategy. These causal manipulations suggest that ACC neuronal subpopulations may mediate specific functions during EBD. However, little is known about how the computations underlying such effort-related decisions are represented by ACC neural dynamics. Here, we have deployed UCLA Miniscopes to image calcium signals arising from large numbers of ACC neurons simultaneously during EBD. ACC neural activity was recorded in a barrier T-maze task in which mice choose between surmounting an effortful obstacle (climbing a barrier) for a high reward or taking an unobstructed path to a low reward. Calcium signals were extracted using the *Minian* pipeline and aligned to behavior using DeepLabCut and BehaviorDEPOT open-source software. We then used receiver operating characteristic analyses to establish the tuning of ACC neurons to specific behavioral events. We have found that the tuning of ACC neurons during decision making is enhanced when an effort cost is operative. A subset of these neurons exhibited increased or decreased activity that was significantly tuned to approach of the maze choice point. Interestingly, largely non-overlapping subpopulations were tuned to high vs. low effort choices, suggesting that effort-reward tradeoffs drive segregated representations of potential actions in ACC. In ongoing work, we are now using dimensionality reduction and decoding algorithms to further evaluate these relationships.

Abstract: Value-based decision-making generally entails evaluating and comparing options before choice. Often, it requires integrating multiple pieces of information to determine the optimal choice in which the prefrontal cortex (PFC) plays a major role. However, how PFC neuronal populations accumulate evidence during evaluation and comparison of options are relatively less explored. Based on decoding analysis, this study aimed to examine the neural correlates of evidence accumulation in the PFC of two non-human primates during information gathering for decision-making. We decoded the outputs of various cognitive processes, such as valuation and comparison, from neuronal populations at multiple PFC regions including dorsal lateral PFC (DLPFC), orbitofrontal cortex (OFC) and anterior cingulate cortex (ACC). The analysis on decoding outcomes across trials revealed that each subject exhibited a distinct level of neural representation of evidence accumulation for each process. A subject with less clear neural representation of accumulated evidence tended to gather more information compared to another with clearer neural representation of accumulated evidence. Furthermore, we calculated an association index to estimate the likelihood of decoding outcomes from preceding processes being associated with current processes through information gathering in a trial. The result showed a significant association between the decoding outcomes of the current and preceding processes. We also observed that a subject with neural representation of more evidence exhibited a stronger association index between temporally adjacent cognitive processes, while the opposite was true for the other with less evidence. These findings highlight the relationship between neural representations of evidence accumulation in PFC and decision-making behavior via information gathering.

Title: Network physiology metrics reveal a dynamic balance between excitatory and inhibitory functional connections in rodent prefrontal cortex during decision making

Authors: *G. W. DIEHL, A. D. REDISH;
Neurosci., Univ. of Minnesota, Minneapolis, MN

Abstract: The balance between excitatory and inhibitory inputs is critical for proper network function, but this balance is thought to change as behavior changes. Measuring Excitatory:Inhibitory (E:I) balance in vivo has thus far remained difficult, limiting the ability to

probe E:I dynamics during behavior. Recent work has argued that examining spectral power of local field potentials (LFP) and specifically the exponential decay rate of the underlying aperiodic component (**χ**;; of 1/f^**χ**;;) can provide a window into E:I balance in vivo (Gao et al., 2017; Donoghue et al., 2020). In concert, spike timing cross-correlation histograms (CCHs) have long been identified as a means of measuring direct monosynaptic connectivity and the functional strength of local connections (Csicsvari et al., 1998). In addition, concurrent spiking between cells (within 1ms) provides a lens into functional network activity and has been found to depend on NMDA receptor functionality (Zick et al., 2021).

Using these methods, we evaluated recordings from the medial prefrontal cortex (mPFC) of rats as they performed the economic decision task Restaurant Row. In this task, rats must make a series of decisions whether or not to wait out temporal delays to receive food rewards based on presented information. Critically, this task involves multiple distinct behavioral phases, with distinct cognitive demands and decision processes. Evaluating the aperiodic component of the LFP spectrum we found that aperiodic decay rates varied dynamically throughout the task, implying changes to E:I balance. Notably, there was increased excitatory drive as rats entered the Offer Zone where they were presented with information to make their decisions, and decreased excitation during the Wait Zone when rats must hold their decisions in working memory and wait to receive a reward. In examining CCHs and monosynaptic connections between mPFC cells, we found a complementary picture. Local connections were weaker in the Offer Zone and stronger in the Wait Zone. These findings suggest parallel brain states during the Offer and Wait phases of the RRow task. In the Offer Zone, excitatory information arrives into the mPFC from other brain areas while local communication is muted. In the Wait Zone, there is less external input and instead mPFC is engaged in local processing. Finally, we combined these two methods to evaluate if E:I balance, as measured from LFP, influenced the coupling strength of co-spiking pairs. Interestingly, we found that when the spectrum was flatter (implying more excitation) there was stronger coupling between co-spiking pairs of cells.

Title: Rotational dynamics help stabilize cortex

Authors: *T. BATABYAL, S. L. BRINCAT, E. K. MILLER;
MIT, Cambridge, MA

Abstract: The cortex requires stability to recover after disruption. Events such as distractions, eye movements, sensory inputs, and more can trigger strong neural responses that have the potential to disrupt cortical processing. It is crucial for the cortex to "regain its focus" and return to the task at hand, reverting to its previous state prior to the disruption.
We found that this may be explained by rotational dynamics. We examined spiking in the prefrontal cortex during working memory tasks in which there was a disruption during the memory delay (a saccade or a distractor stimulus). The disruption led to the emergence of organized rotational structures in subspace dynamics. This effectively restored the system to its pre-disruption state.
The rotations were correlated with behavioral performance. When trials were performed correctly, the rotational structure was more likely to complete a 360 deg rotation. On incorrect trials, trajectories failed to complete a full rotation.The rotations changed with expectation. Rotational velocity was inversely correlated with the expected delay duration. The velocity was faster on shorter delays as if the cortex was "rushing" to complete the rotation before the delay ended.
We found some evidence that the rotation through subspace may, in fact, be rotations in cortex itself. Spiking organized into traveling waves that showed rotational dynamics in rotational Principal Component Analysis (jPCA) space. We also observed rotating traveling waves in local field potentials.
Neural stability is crucial for cognition and consciousness. Our results suggest that it may be attributed to brain rhythms rotating the brain back to its previous state.

Title: Encoding of structured knowledge in the medial prefrontal cortex

Authors: *M. PROSKURIN[1], **M. MANAKOV**[1], H. WANG[1], E. KULESHOVA[1], A. LUSTIG[1], R. BEHNAM[1], S. DRUCKMANN[2], D. G. TERVO[1], A. Y. KARPOVA[1];

Abstract: One of the most interesting, and mysterious, aspects of biological brains is that they form representations of environments that are richer than an interlinked series of associations, and more "conceptual" than partitions in a multidimensional representation of the sensory input. Our best intuition about how this happens is that brains have evolved to pick up on, and exploit, the ubiquity of structure in the natural world and in the types of tasks that animals might have to

solve over their life span, efficiently forming structured relational models of the animal's world that can be used for planning and action. But even with that intuition, we know little about how structured knowledge is acquired or updated, especially when the extraction of the relevant structure must happen incidentally, without explicit instruction or feedback. Here, by examining neural ensemble activity in rats that sample different sequences of binary choices in a self-guided search for latent task structure, we reveal a relationship between the incidentally acquired structured knowledge and the neural activity in the medial prefrontal cortex is strong enough that we can begin to decode it with confidence on single trials. Going forward, this puts us in a position to probe how structured knowledge about the world is acquired by the brain, and how it is updated with experience.

Title: The ventrolateral prefrontal cortex underlies decision making based on structured sequences

Authors: *Y. BAI[1,2], T. YANG[1];
[1]Ctr. for Excellence in Brain Sci. and Intelligence Technol. (Institute of Neuroscience), Chinese Acad. of Sci., Shanghai, China; [2]Univ. of Chinese Acad. of Sci., Shanghai, China

Abstract: Humans are capable of understanding a sequence of events based on the structure of the sequence. The sequence structure indicates how components of the sequence relate to one another and how they should be integrated for decision making. The neural mechanism underlying sequence processing is, however, not well understood. Therefore, we trained two male macaque monkeys to perform a sequence decision-making task. They viewed eight centrally-presented visual stimuli sequentially, which represented a math expression consisting of four signed numbers and four operators that indicated whether each number needed to be added or subtracted. The monkeys were required to report whether the resulting value was positive or negative by making a saccade towards either a red (positive) or a green (negative) peripheral target. Following the monkeys' successful learning of the task, we conducted recordings of single-unit activities from the ventrolateral prefrontal cortex (vlPFC). Neurons in the vlPFC encoded both the operators (addition or subtraction) and the signed numbers in the stimulus sequence. In addition, vlPFC neuronal activities reflected the intermediate result indicated by the stimuli during the stimulus presentation period. Finally, after the sequence was presented and when the fixation point vanished, which served as a cue for the monkeys to initiate

a saccade towards the target, the population responses in the vlPFC was transformed into a binary encoding of the eye movement direction. Together, these results suggest that the vlPFC plays an important role in processing sequence information for decision making.

Title: Prefrontal and Striatal activity during a Strategy Board Game

Authors: *M.-Y. PARK[1], M. OEMISCH[1], B. VAN OPHEUSDEN[2], K. OSBORNE[1], H. LIANG[1], M. FERGUSON[1], W. MA[3], D. LEE[1];

Abstract: Planning for sequential movements in a social context is challenging, because the agents must anticipate the actions of others. Although many previous studies have investigated computational algorithms applicable in such iterative social interactions, how the values of self and opponent's actions are computed and represented in the brain remains poorly understood. In this study, we trained rhesus monkeys to play a competitive strategy board game called a four-in-a-row. During this game, the monkeys placed their stones one at a time using a joystick on a 4-by-9 board while taking turns with a computer opponent. Each player could win by placing 4 pieces in a row horizontally, vertically, or diagonally, and the game outcome could be a win, loss, or tie for the animal, which was rewarded only for wins. We recorded the activity of individual neurons from the dorsomedial prefrontal cortex (dmPFC), the dorsolateral prefrontal cortex (dlPFC) and the caudate nucleus of one monkey using two 64-channel silicone probes simultaneously in two of these areas in a given session. During the recording experiment, the computer opponent always initiated the game, and probabilistically alternated between defensive and offensive strategies while making its move randomly with a small probability so that the probability of winning for the animal did not become too low. We used a linear regression model to evaluate the neural signals related to the value of the board position chosen by each player, the ordinal position of the move in a game, and whether the given move connected 4 stones and therefore led to winning. The value of the chosen position was approximated by the maximum number of stones continuously connected by the current move of each player. Neurons in these brain areas modulated their activity more frequently according to the board positions chosen by the animal than in response to the positions chosen by the computer opponent. In addition, whereas many of the neurons changed their activity according to the ordinal position of the move

throughout the game, the signals related to the number of stones connected by the animal and the computer opponent were both present in these brain areas. This suggests that the prefrontal cortex and the striatum might play an important role in computing the action values of the choices made by the self and others during iterative social interactions. Furthermore, many neurons modulated their activity when either player won the games, indicating that these brain areas play multiple roles in learning and decision making during rule-based social interactions.

Title: The role of the macaque anterior cingulate cortex in reward expectancy and/or goal attainment

Authors: *P. KUSMIEREK[1], J. PARK[2], B. M. BASILE[3], E. A. MURRAY[2];
[1]Lab. of Neuropsychology, NIMH, Bethesda, MD; [2]Lab. of Neuropsychology, NIMH, NIH, Bethesda, MD; [3]Dept. of Psychology, Dickinson Col., Carlisle, PA

Abstract: The anterior cingulate cortex (ACC) has been proposed to be involved in cognitive control of action selection, including that based on expected reward value (e.g., Chudasama et al, *Cereb Cortex*, 2013; Shenhav et al, *Nat Neurosci*, 2016). Neural activity consistent with representations linking reward outcomes to motor actions have been found in the region (e.g., Shima & Tanji, *Science*, 1998; Matsumoto at al, *Science*, 2003), and activity indicative of reward expectancy has been described as well (Shidara & Richmond, *Science*, 2002). Here we assessed the ACC's causal contribution to the expression of reward expectancy via an autonomic measure. Three rhesus macaques received bilateral neurotoxic lesions of ACC. Together with four unoperated controls (CON), they were presented with a Pavlovian procedure whereby visual stimuli predicted reward delivery, independent of the animal's actions. Mildly thirsty monkeys sat in a primate chair facing a monitor screen. In each trial, two blue circles (1° diam) were presented 8° away from the screen center opposite each other in one of four cardinal/intercardinal orientations. The circles slowly moved towards each other for 15 seconds until they touched, disappeared, and fluid reward was delivered. A 15-s intertrial interval ensued, during which the screen was blank. Pulse signal was acquired with a plethysmography sensor placed on the ear, and heart rate was extracted off-line. We found a group difference in heart rate in anticipation of reward. Whereas CON monkeys exhibited a gradual heart rate increase while the circles moved closer together, monkeys with ACC lesions did not. This implies that the autonomic reflection of reward expectancy was lost as a result of the ACC lesion. In contrast, we observed a significant heart rate change after reward delivery in all monkeys, controls and

monkeys with ACC lesions alike, suggesting that the autonomic response to receipt of reward was intact after ACC lesions. Taken together, the results support a role for the ACC in reward expectancy, but not in the reaction to reward receipt.

Title: Neurophysiological investigation of effort monitoring and decision-making dynamics in the anterior cingulate cortex in macaque

Authors: *A. LESPART[1], S. BOURET[2];
[1]Inst. du Cerveau, 75013, Paris, Paris, France; [2]Inst. du cerveau, Inst. du Cerveau et de la Moelle Epiniere, Paris, France

Abstract: Understanding cerebral processes leading our behavior toward efficient choices and performance in effortful situations is a central topic in neurobiology of decision making. The anterior cingulate cortex (ACC) is involved in at least 2 aspects of effort: effort as a decision variable and effort as an amount of energy invested to overcome a difficulty. The dynamic neurophysiological processes underlying these functions, however, remains unclear. To address this issue, we used a neurophysiological approach in rhesus monkeys. We recorded 160 single units from the ACC in 1 macaque performing a choice task, which manipulates both effort and reward, and where monkeys must produce the chosen effort by pressing a grip at each trial in order to obtain the chosen reward. The monkey's choices were clearly influenced by both reward and effort levels, and the animal applied the required force on the grip, showing appropriate option valuation (effort discounting of reward value) and appropriate mobilization of resources for action. In addition, the latency between cue onset and first saccades toward the chosen option was highly dependent upon the choice difficulty (absolute difference in value between the 2 options), whereas latency from this saccade to action onset was not. This suggests a sequential relationship between decision and action processes, but further analysis is necessary to further understand the dynamics of effort processing in this task. Preliminary analysis indicates that ACC units show a stronger sensitivity to the side chosen, the reaction time and errors compared to benefits and costs (reward and force proposed). This result suggest that ACC is more involved in the implementation of effort in an effector specific way than in the processing of effort as a decision variable. In addition, a dynamic analysis of the firing patterns in the task suggests that ACC single units are not only related to the dynamics between decision and action, but also show change of states outside choice epoch that are strongly related to behavioral variables. Together these preliminary results provide a new insight into the dynamic implication of ACC neurons in effort, and they are in line with the proposed role of the ACC in monitoring

action/outcome as a function of expected costs and benefits, to facilitate the adaptation of goal-directed behavior.

Title: Dynamics of population activity in macaque prefrontal cortex predict impact of prior expectation during perceptual decision-making

Authors: T. LANGLOIS[1], J. CHARLTON[2], *R. GORIS[3];
[1]Univ. of Texas at Austin, Austin, TX; [2]Princeton Univ., Princeton, NJ; [3]Univ. of Texas At Austin, Austin, TX

Abstract: Perceptual decisions are informed by the present sensory input and by expectations, or "priors", that reflect previously experienced statistical regularities in the environment. The neural mechanisms that integrate sensory signals with priors that are specific to a given context likely engage a network of association areas. However, it is not known how neural circuits perform this integration. To shed light on this matter, we developed an analysis that relates the dynamics of population activity in the prefrontal cortex to perceptual decisions on a trial-by-trial basis. We used multi-electrode arrays to record neural population activity in the prearcuate gyrus of two macaque monkeys as they performed a perceptual orientation discrimination task. The animals judged the orientation of drifting grating stimuli under two contexts, each associated with a different distribution of stimulus orientation, as described in Charlton & Goris (2022 - bioRxiv). The choices of both monkeys were biased in a context-specific manner, reflecting the impact of their priors on their perceptual interpretations. To study the neural correlate of this behavior, we decoded a time-varying decision variable (DV) from jointly recorded neural responses. We previously reported that this decoded DV reflects the formation of a perceptual choice, and differs across the two task-contexts (Charlton & Goris, 2022). To determine the functional significance of these differences, we measured the DV's initial value and dynamic range on a trial-by-trial basis. We found that the initial value on average differed across the task contexts, but by itself, did not predict choice outcome. In contrast, the dynamic range on average did not differ across the two task contexts, yet it accounted for systematic differences in the choice behavior. On trials in which the DV exhibited a small dynamic range, the animals tended to be more biased by the context-specific expectation compared to trials in which the DV exhibited a

large dynamic range. These findings reveal how prefrontal circuits integrate prior stimulus expectations and incoming sensory signals at the behaviorally relevant timescale of the single trial.

Title: Flexible representations of prior expectations and sensory evidence in the macaque dorsolateral prefrontal cortex

Authors: *L. W. THOMPSON[1,2], V. SUBRITZKY-KATZ[1,2], K. SCHAPIRO[3], A. DALLSTREAM[1,2], J. ZWEIGLE[1,2], J. I. GOLD[1,2];
[1]Neurosci., [2]Computat. Neurosci. Initiative, Univ. of Pennsylvania, Philadelphia, PA; [3]Brandeis Univ., Waltham, MA

Abstract: Successful decision-making relies on our ability to accumulate sensory evidence in a context-dependent manner. For example, our previous choices and learned expectations can modulate the amount of sensory evidence needed to guide future decisions. Here we used an adaptive oculomotor-delayed response (AODR) task to study the role of working-memory representations in the macaque dorsolateral prefrontal cortex (dlPFC) to flexible, sensory- and expectation-dependent decision-making. The task required the monkeys to choose which of two visual saccade targets would provide a reward on each trial based on two factors: (1) sensory evidence, indicated by the proximity of a flashed cue to each target; and (2) prior expectations, or the probability that the rewarded target is switched from the previous trial (i.e., hazard rate). Thus, the AODR task provides a common spatial framework to assess how representations of expectations, evidence, and choices interact within populations of dlPFC neurons to help guide behavior.
Monkeys performed the AODR task in two separate blocks: (1) a low hazard-rate condition (H = 0.05), where the rewarded target is usually the same as on the previous trial and thus the sensory evidence can be largely ignored; and (2) an intermediate hazard-rate condition (H = 0.5), where the rewarded target is independent from trial to trial and thus the sensory evidence is maximally informative. We estimated the contributions of both sensory evidence and expectations to the monkeys' decisions by fitting logistic psychometric functions to choice data with respect to the strength of the sensory evidence (position of the flashed cue) that the reward target switched from the previous trial for each hazard-rate condition. The monkeys behavior was roughly consistent with an ideal observer model, where the relative contributions of expectations and

sensory evidence were hazard-rate dependent. We found that this flexible decision-making strategy was reflected in neuronal activity in the dlPFC, which included sensory, memory, and/or saccade-related activity that for many neurons was also modulated by the hazard-rate condition to enhance or suppress the representation of sensory information and its persistence into working-memory. These preliminary results suggest that the macaque dlPFC likely contains spatial working-memory representations that interact with sensory and motor signals to support flexible decision-making behavior.

Title: Cortical State Dynamics in the Frontal Eye Field (FEF) during Spontaneous Activity

Authors: *G. CHAN[1], Y. SHI[2], X. CHEN[3], T. MOORE[4], T. ENGEL[2];
[1]Med. Scientist Training Program, Stony Brook Univ. Renaissance Sch. of Med., Stony Brook, NY; [2]Princeton Neurosci. Inst., Princeton, NJ; [3]Univ. of California, Davis, DAVIS, CA; [4]Howard Hughes Med. Inst. - Stanford Univ., Stanford, CA

Abstract: Neocortical activity is permeated with endogenous fluctuations. The pattern of spontaneous activity reflects variations in global cortical states, which form a continuum of spectra from sleep to wakefulness [1,2]. These spontaneous cortical-state fluctuations are also modulated locally by cognitive factors such as spatial attention [1,2], however these local cortical state dynamics during perception have only been studied previously in the occipital cortex. In this study, we investigated cortical state dynamics within the primate prefrontal cortex, specifically within the frontal eye field (FEF), a cortical area causally involved in deployment of visual attention. We recorded spiking activity across layers of multiple cortical columns in the FEF of monkeys during a fixation task. Using Hidden Markov Models (HMMs), we found that population neural activity in FEF spontaneously fluctuated between phases of vigorous (On) and faint (Off) spiking synchronously, similar to On-Off dynamics in the visual cortex. Next, we used gap statistics analysis to identify cortical columns within and across recordings based on correlations of receptive fields. On-Off dynamics were shown to be confined within local cortical columns, with synchrony gradually decreasing with the increase of lateral spatial distance.

Finally, we compared On-Off dynamics and fluctuations in local field potentials (LFPs) to identify the sequence of propagation of local On-Off activity along the cortical surface. By using wave signal detection methods, we find the time lag of On-Off phases is correlated with spatial distance, which suggests that the propagation of On-Off dynamical patterns across cortical columns takes the form of a traveling wave, specifically at the times when the phase transition occurs within one of the cortical columns. Combined, our results reveal columnar On-Off fluctuations in prefrontal cortex and their spatio-temporal propagation patterns across columns. The columnar synchrony and spatial coordination of cortical dynamics extend our understanding of the operating regime in cortical networks.

[1]Neurosci., Univ. of Rochester Sch. of Med. and Dent., Rochester, NY; [2]Neuroscience, Psychiatry, Univ. of Rochester Med. Ctr., Rochester, NY

Abstract: In humans and monkeys, prefrontal (PFC)-amygdala connections have a specialized role in decisional responses during social interactions. In the medial PFC, the perigenual (pgACC) and subgenual (sgACC) anterior cingulate cortex are adjacent sites that provide strong 'top-down' modulation. The pgACC and sgACC mediate conflict monitoring (including to social cues) and sustained arousal to salient stimuli, respectively. We previously showed that pgACC inputs to the amygdala always co-project with sgACC inputs, but only in select 'hotspots'. Here, we asked whether general PFC networks influencing the pgACC and sgACC are segregated or overlapping. We used neuronal tracing of each circuit in the same animal (n=2). pgACC injections resulted in fewer labeled cells in a more restricted number of PFC regions compared to sgACC injections. Surprisingly, PFC inputs to pgACC and sgACC nodes in the same animal were highly segregated. Following pgACC injections, labeled cell bodies were mainly in areas 9, 46, 8, 45, 12l, 12o, and 24b,c. In contrast, the sgACC injections resulted in labeled cells in broadly distributed regions including areas 10, 11m, 12o, 13a/b, 32, 24a/b, 14r/c. Area 12o was

unique in projecting to both pgACC and sgACC. Analysis of intrinsic connections indicated a one-way (top-down) flow of information from pgACC to sgACC. Taken together, we conclude that pgACC and sgACC act largely as separate hubs, conveying 'on-line' conflict monitoring and emotional valuation of sensory information, respectively. In specific amygdala 'hotspots', inputs from these distinct nodes are highly convergent, co-modulating common pyramidal neuron ensembles.

Title: Von Economo neurons are present throughout the medial surface of the human prefrontal cortex

Authors: *D. ORTIZ-MUÑOZ[1], C. A. GONZALEZ-ACOSTA[1], O. A. PLAZA-PATIÑO[2], E. BURITICA-RAMIREZ[1], **L. V. BECERRA-HERNANDEZ**[1];
[1]Dept. de morfología, Univ. del Valle, cali, Colombia; [2]Regional Suroccidente, Inst. Nacional de Medicina Legal y Ciencias Forenses, cali, Colombia

Abstract: Von Economo neurons (VENs) are large spindle-shaped soma cells located in the Vb sublamina of the cerebral cortex of large mammals such as elephants, whales, and higher primates including humans. In the latter, VENs have been found in the anterior cingulate, the frontoinsular, the dorsomedial prefrontal, and the medial frontopolar cortices. Due to their morphology, laminar and cortical locations, they have been linked functionally to social cognition, and their alteration has been linked to diverse neuropsychiatric pathologies. **Objective:** To explore the presence of VENs in other areas of the human medial prefrontal cortex and to confirm its presence in the precuneus. **Materials and Methods**: nissl staining and anti-NeuN immunohistochemistry were performed in the areas of Brodmann 11m, 14r, 10m, 10r, 25, 32s, 32p and precuneus on the medial surface of both hemispheres from postmortem subjects (4M:1F) without a history of neurological, or psychiatric diseases or brain damage from the National Institute of Forensic Medicine and Forensic Sciences in Cali, Colombia. 288 tissue sections (50 μm) per subject to histological observation with a light microscope ZEISS Scope.A1. After checking the cytoarchitectural of areas and searching the VENs throughout the Vb layer, according to the two observers' expertise. In the microphotographs 10x, we determined the VEN/pyramidal ratio and the differences between the crest and walls of the same gyre, while in the microphotographs 40x, determined and compared the size of the cell body of the pyramidal neurons and VENs. These counts and measurements were made with the assistance of

the Fiji program. **Results:** We found VENs in all areas studied, although were present in all subjects, they were not present in all processed tissue sections nor were they evenly distributed on the crest and walls of each section, because they are very scarce. A higher proportion of VENs was found in the crests than in the walls. We confirmed the interhemispheric asymmetries by finding more VENs in the studied cortical areas of the right hemisphere. Additionally, the inter-area differences in the size of the VENs, are larger in areas with fewer of them and also found a greater number of VENs in the areas closest to the anterior cingulate cortex. 354 VEN/57.186 Pyramidal **Conclusions:** These findings give further support to the hypothesis that VENs could establish a bridge between cognition and its emotional expression, given that all these cortical areas and their connections have been related to the control of attentional and motivational processes. as well as with the symptomatology in pathologies that compromise them.

Title: Causal evidence of directed interactions supporting cognitive control via transcranial magnetic stimulation of the lateral prefrontal cortex

Authors: *A. MEYER, D. E. NEE;
Psychology, Florida State Univ., Tallahassee, FL

Abstract: The frontoparietal control network (FPCN) supports the flexible integration of demands of the external environment with internal goals. Recent research has shown the FPCN can be delineated into distinct control sub-subsystems organized along a present to future axis across sensorimotor-proximal to sensorimotor-distal areas (Nee, 2021). Moreover, effective connectivity modeling has suggested asymmetries in influences among areas suggesting 1) a future-oriented sensorimotor-distal sub-system of the FPCN excites itself, but suppresses other FPCN sub-systems (Nee, 2021), and 2) a mid-dorsolateral prefrontal cortex (mid-DLPFC) area within the future-oriented sub-system is particularly influential (Nee & D'Esposito, 2016; Badre & Nee, 2018). However, these models require causal validation. Here, we contrasted the effects of continuous theta burst stimulation (cTBS) to two areas within the future-oriented control sub-system: the lateral frontal pole (FPl) and the mid-DLPFC, as well as a control site (S1) in 34 healthy human adults while they performed a task designed to manipulate present- and future-oriented cognitive control (Nee & D'Esposito, 2016). Activation changes attributable to cTBS

were examined with post-cTBS fMRI during the task in a within-subjects, cross-over design. cTBS was predicted to downregulate efferent influences providing a causal test of models of effective connectivity (Bergmann & Hartwigsen, 2021). First, we observed cTBS to the future-oriented sub-system produced numerically reduced activation locally, but increased activation in other sub-systems of the FPCN. This suggests cTBS dampens within-system excitation and between-system suppression (i.e. disinhibition). Second, cTBS to the mid-DLPFC uniquely elevated activation in conditions requiring future-oriented control with increases most pronounced in the present-oriented control sub-system. Interestingly, these activation changes were paralleled by improved performance selectively in conditions requiring future-oriented, but not present-oriented control. These results suggest the increases in activation help to boost performance in a compensatory manner. Moreover, these activation changes and behavioral improvements were unique to mid-DLPFC-cTBS suggests the mid-DLPFC is a particularly influential area within the FPCN. Collectively, these data indicate downregulatory cTBS paradoxically increases activation in a manner consistent with models of effective connectivity. Improvements in behavior indicate these changes need not be disruptive, but can facilitate performance in some situations, which may have future clinical utility.

Title: Causal role of lateral frontopolar cortex in decomposing complex choice information

Authors: ***C.-K. LAW**, N. H. L. WONG, J. J. WONG, B. K. H. CHAU;
The Hong Kong Polytechnic Univ., Hong Kong, Hong Kong

Abstract: Digesting complex choice information is often essential for making important decisions in daily life. Our recent neuroimaging study revealed that lateral frontopolar cortex (FPl), a region that is uniquely well-developed in the human brain, has a specific role in decision making when complex information is involved (Law et al., 2023). Particularly, it is suggested that FPl decomposes complex information and passes this information to posterior cingulate cortex (PCC) for guiding decision making. Nonetheless, based on correlational neuroimaging data, the frontopolar cortex is implicated in a wide range of cognitive functions, surprisingly, few of these links receive support from data that establish casual relationships. Hence, in this study, we tested the causal role of FPl in digesting complex choice information using transcranial magnetic stimulation (TMS). Healthy human participants (n=27, 12 females, aged 18-37) had their FPl disrupted by continuous theta burst stimulation and then performed a two-stage

decision making task. In Stage 1 they chose between two options that involved complex information and in Stage 2 between two simple options. Our results revealed disruption of FPl, but not the control vertex region, led to poorer choices only with complex options in Stage 1, but not with simple options in Stage 2. Previous studies have demonstrated that TMS does not only influence a local region, but also extends its effect on functionally connected regions that are distant (Fox et al., 2012). Hence, we focused on the FPl-PCC functional connectivity, which is involved in decision making with complex information. We found that participants with stronger resting-state FPl-PCC functional connectivity also showed poorer decision making with complex information after FPl-TMS. Next, we scrutinized the specific aspects in decision making that were modulated by FPl-TMS. This was achieved by fitting nine computational models with variable computational complexities. We found that after FPl disruption participants tended to employ simpler heuristics for integrating complex information. Our findings support the causal role of FPl in integrating complex information during decision making.

Title: Formation of an abstract task representation for generalization

Authors: *A. R. VAIDYA[1], N. MOUSSA[2], D. BADRE[3], T. KAHNT[4];
[1]NIH, Natl. Inst. on Drug Abuse (NIDA), Baltimore, MD; [2]NIH, Natl. Inst. on Drug Abuse, Baltimore, MD; [3]Brown Univ., Providence, RI; [4]NIDA Intramural Res. Program, NIH, NIDA IRP, Baltimore, MD

Abstract: Prospectively considering the consequences of actions is key to goal-directed behavior. This capacity is believed to depend on an internal model of the world that can be used for planning and making inferences about the outcomes of choices. Failure to utilize or build such an internal model is thought to contribute to failures of goal-directed behavior in substance use disorders and other neuropsychiatric conditions. We are investigated the processes involved in the formation of such an internal model, as well as its use for making novel inferences. Over multiple days, healthy young participants completed a task where they learned that the stimulus-reward associations of multiple contexts were equivalent while undergoing fMRI scanning. After acquiring new stimulus-reward associations in a subset of these contexts, participants were tested on these new stimulus-reward associations in the held-out contexts without feedback. Importantly, this manipulation requires that participants infer the current value of these stimuli based on an abstract representation of the task. We will examine how neural representations of

task conditions change over multiple sessions as this abstract task structure is discovered, and whether different networks are involved in uncovering this structure and implementing abstract rules for controlling behavior.

Title: Frontal mechanisms underlying primate calls recognition by humans

Authors: *L. CERAVOLO[1], C. DEBRACQUE[2], E. POOL[3], T. GRUBER[4], D. GRANDJEAN[5]; [1]Swiss Ctr. For Affective Sci., Geneve, Switzerland; [2]Univ. of Geneva - CISA - NEAD, Geneve, Switzerland; [3]Univ. de Geneve, Geneve, Switzerland; [4]Univ. of Geneva, Geneva, Switzerland; [5]Neurosci. of Emotion and Affective Dynamics Lab., Geneva, Switzerland

Abstract: The ability to process verbal language seems unique to humans and relies not only on semantics but on other forms of communication such as affective vocalisations, that we share with other primate species—particularly great apes (*Hominidae*). To better understand these processes at the behavioural and brain level, we asked human participants to categorize vocalizations of four primate species including human, great apes (chimpanzee and bonobo), and monkey (rhesus macaque) during MRI acquisition. Classification was above chance level for all species but bonobo vocalizations. Imaging analyses were computed using a participant-specific, trial-by-trial fitted probability categorization value in a model-based style of data analysis. Model-based analyses revealed the implication of the bilateral orbitofrontal cortex and inferior frontal gyrus *pars triangularis* (IFG_{tri}) respectively correlating and anti-correlating with the fitted probability of accurate species classification. Further conjunction analyses revealed enhanced activity in a sub-area of the left IFG_{tri} specifically for the accurate classification of chimpanzee calls compared to human voices. Our data—that are controlled for acoustic variability between species—therefore reveal distinct frontal mechanisms that shed light on how the human brain evolved to process non-verbal language.

Title: Insula target cells within the prelimbic cortex are necessary for social affective behaviors

Authors: *A. DJERDJAJ[1], Z. BHATHENA[1], A. CALLEN[1], T. MATULIS[1], J. P. CHRISTIANSON[2];
[2]Psychology & Neurosci., [1]Boston Col., Chestnut Hill, MA

Abstract: The ability to detect, appraise, and respond to another's emotional state is an essential component of social affective behavior. This is mediated by a network of brain regions that include subcortical and cortical structures and is responsible for integrating external cues with internal states to yield appropriate behavioral responses. Dysfunction in the connectivity of this network contributes to abnormal social behavior that occurs in several neuropsychiatric disorders, including autism and schizophrenia. The insula, a site for sensory integration, and prelimbic (PL) cortex, a site involved in decision-making, are reciprocally connected nodes within this network. Here, we investigated the functional role of insula-innervated neurons in the PL in a social affective preference (SAP) test in which experimental rats presented with two age-matched conspecifics, one naïve to treatment and one stressed via 2 footshocks, exhibit approach to stressed juveniles but avoidance of stressed adults. In separate experiments, a transsynaptic viral genetic transfer technique was used to specifically inhibit target neurons within the PL that receive input from either the anterior or posterior insula. Male test rats received bilateral infusions of AAV1-hSyn-Cre into either the anterior or posterior insula and AAV5-DIO-hM4Di into the PL. Prior to SAP testing with either juvenile or adult conspecifics, test rats received an injection of saline or clozapine-N-oxide (CNO, 3 mg/kg) to inhibit insula target cells within the PL. Inhibition of both anterior and posterior insula target cells of the PL abolished preference for stressed juveniles and naïve adults. To determine whether these cells are specific to more complex social interactions, a SAP test was performed with adult male and female conspecifics. Inhibition of target cells had no effect on male test rats' preference for interactions with the opposite sex, indicating that these cell populations may contribute specifically to emotionally-motivated interactions. Future studies aim to identify the cell-type of these PL populations and define their neural activity in response to different social interactions. Findings presented here identify a tract by which social emotional information can be shared between cortical regions and shape behavioral responses to others.

Title: Flexible adaptation of mPFC neuronal dynamics before, during and after auditory fear conditioning

Authors: *H. KONDO, R. KIM, R. SHIMODA, R. YAMASHITA, J. KIM, L. S. BREBNER, H. SONG, K. INOKUCHI, Y. KONDO, M. OKAMURA, K. OTA, H. FUJII, H. BITO;
Dept. of Neurochemistry, Grad. Sch. of Med., The Univ. of Tokyo, Bunkyo-ku, Japan

Abstract: The medial prefrontal cortex (mPFC) is one of the neural substrates that underlie cognitive and emotional functions in mammals. In particular, the mPFC has been suggested to guide animals to adaptive behavior by processing a novel external stimulus that triggers attention and/or a sensory stimulus that elicits emotion. While a topographic map for stable responses to sensory stimuli is maintained as a whole in the sensory cortices, whether the information representation of the sensory attributes also remains stable in prefrontal cortex or are dynamically influenced by external stimuli has not been investigated at single cell resolution. Using repetitive two-photon calcium imaging on head-fixed awake mice, we longitudinally monitored the single-cell dynamics of mPFC neuronal populations responding to trials of auditory cue exposures, over several days. In the first and second series of trials (Day 1 and Day 2), an auditory stimulus of a single frequency (CS) was repeatedly presented. Then, in a third series of trials (Day 3), the same CS was presented but an aversive foot-shock was paired five times at the end of the CS presentation epoch. Control experiments demonstrated that under these conditions, the CS-US pairings caused an auditory fear conditioning in a context distinct from the microscopic stage (freezing change 15.2%, N= 3 mice, p= 0.030). Finally, during a fourth series of trials (Day 4) an identical auditory stimulus (CS) was presented again, as a cue for fear memory recall. We found that the CS-triggered neural activity of the excitatory neurons in the mPFC gradually and significantly decreased in a stepwise manner during repeated presentation of the auditory CS in a neutral context (-55%, CS 2^{nd} response vs 1^{st} CS response, $p< 0.05$; -117%, 5^{th} CS response vs 2^{nd} CS response, $p< 0.01$, N= 9 mice; n= 347 neurons). This decrease persisted on Day 2. When the mice were subjected to auditory fear conditioning on Day 3, however, the proportion of up-regulated responsive neurons significantly increased as the animal underwent paired CS-US exposure, and augmented responsiveness persisted on Day 4 when CS only was presented as a cue for fear memory recall. Finally, using a linear discriminant analysis, we found that encoding accuracy of CS was significantly increased after the CS-US pairings. These results suggest that the mPFC neurons can dynamically adapt their responsiveness to auditory cues in a bidirectional manner depending on the immediate affect. Elucidating the origin of this flexible activity changes at the neural circuit level will shed light on fundamental cognitive processing in the mPFC.

Title: Identifying the relationship between prefrontal executive function, eating habits, eating behavior, and academic achievement in university students

Authors: *M. CHAVEZ HERNANDEZ;
Univ. Panamericana, Mexico, Mexico

Abstract: In recent decades, diet has changed increasing availability of ultraprocessed foods, which contributes to high levels of overweight and obesity. Studies have shown that there is a bidirectional relationship between prefrontal executive function (PEF) and overweight/obesity, and that there is a cognitive effect derived from poor diet quality, skipping breakfast, and consumption of ultraprocessed foods. University life represents a change in an individual's development, and studies indicate that only 17.4% of university students maintain a healthy diet; additionally, academic load and poor time management in college students have been linked to diet quality and weight gain. The aim of the present study was to evaluate the relationship between PEF, eating habits, eating behavior, and academic achievement in college students, considered a vulnerable population. A cross-sectional correlational study was carried out in a group of undergraduate students from public and private universities within Mexico City. Eating habits were measured by a frequency questionnaire including healthy food intake, ultraprocessed food intake and meal skipping; the Executive Functions in University Students Questionnaire was used to evaluate PEF; eating behavior was measured with the Eating Behavior and Physical Activity Scale; and academic achievement was measured with the self-reported GPA in a 0-to-10-point scale. A sample of 1903 undergraduate students was included in the study (1070 women, 911 men); the mean age was 20.91 years (SD ±2.10). Spearman's rho correlation analysis revealed that there are significant correlations between all variables of interest (rs range -0.20 to 0.36). Specifically, there is a positive relation between academic achievement and PEF, healthy food intake and PEF, and emotional undereating and PEF; also, a significant negative correlation was found between PEF and emotional overeating, with ultraprocessed food intake, and with meal skipping. These results provide a broad vision and are consistent with previous reports that indicate that there is a significant correlation between PEF, eating habits, eating behavior, and academic achievement.

Title: Neural circuits underlying learning and adjustment to dynamic changes in the expected value of cognitive control

Authors: *I. GRAHEK, Y. DONG, A. OGBAA, J. KIM, A. SHENHAV;
Brown Univ., Providence, RI

Abstract: People calibrate the amount of effort they invest in a task based on the amount of reward they expect to accrue, and the extent to which they think their effort matters for achieving that reward (versus, e.g., being determined at random). Recent work has explored the neural and computational mechanisms by which people combine information about these two components of motivation, reward and efficacy, to determine the overall expected value of investing mental effort (cognitive control), but how they learn this information in the first place remains unknown. To uncover the mechanisms by which people learn and dynamically adjust to the expected value of control in their current environment, we had 38 human subjects perform a control-demanding Stroop task while measuring BOLD fMRI. Over the course of the experiment, we varied the probability of obtaining a large vs. small monetary reward and the probability of those rewards being based on performance vs. random chance (high vs. low efficacy). Thus, participants had to continually update reward and efficacy estimates based on feedback, and were sporadically asked to report their current estimates of each. We show that these subjective estimates are best captured by a reinforcement learning model that assumes independent updating of reward and efficacy estimates based on respective feedback. Model-based analyses showed that participants integrated reward and efficacy estimates to determine the expected value of control, and adjusted control allocation accordingly. This resulted in them investing the most effort and achieving the best performance (fastest and most accurate) when they believed that rewards were likely to be (a) large and (b) determined by their performance. When participants received feedback for a given trial, we found signatures of signed reward prediction error within the ventral striatum. Notably, we found evidence that distinct frontoparietal regions tracked unsigned estimates of reward and efficacy prediction errors, providing neural evidence for separate learning of reward and efficacy, prior to the integration of this information into the expected value of control. While participants were performing the task, we found widespread encoding of model-based estimates of the value of control, including across regions of frontal and parietal cortex, consistent with behavioral findings suggesting concomitant increases in effort allocation. Our findings chart the

neural and computational mechanisms through which components of motivation are learned, integrated, and used to guide the allocation of cognitive effort.

Title: Evoked frontal rhythms in Parkinson's Disease during interval timing task performance

Authors: *F. TABASI[1], R. C. COLE[2], A. ROHL[3], K. JOHARI[4], N. S. NARAYANAN[5], J. D. GREENLEE[6];
[1]Dept. of Neurosurg., [2]Dept. of Neurol., [3]Univ. of Iowa, Iowa City, IA; [4]Dept. of Communication Sci. and Disorders, Louisiana State Univ., Baton Rouge, LA; [5]Neurol., Univ. of Iowa Roy J and Lucille A Carver Col. of Med., Iowa City, IA; [6]Dept Neurosurg, Univ. Iowa, Iowa City, IA

Abstract: Parkinson’s disease is commonly associated with deficits in cognitive functions, including cognitive control, an ability that exerts top-down regulation on executive functions enabling adaptive behavior. Cognitive control dysfunction can appear in the early or late stages of the disease. However, the underlying pathophysiologic mechanism of impaired cognitive control in PD patients is unclear. Prefrontal low-frequency activities are shown to be engaged in cognitive control. Previous studies showed that cue-evoked mid-frontal 4-Hz rhythm is attenuated in PD patients with cognitive impairments, predicting increased timing variability indicative of cognitive decline (Singh *et al.* npj Parkinson Disease 2021; Singh A, *et al*. J Neurol Neurosurg Psychiatry 2023). Here, we used electrocorticography recordings from the prefrontal cortex in eight PD patients and nine essential tremors (ET) patients (all without cognitive problems) during awake deep brain stimulation implantation while performing a simple interval timing task, in which patients needed to estimate short (1 s) and long (3 s) temporal intervals. Timing abilities depend on higher-order cognitive functions, including cognitive control. We compared cue-evoked and response-induced frontal activities in PD and ET. The timing variability was higher in PD compared to ET. Also, we observed differences in cue- and response-related prefrontal activities between the two groups. These observations will enhance our understanding of changes in prefrontal activities related to cognitive control in patients with the PD.

Title: Medial prefrontal cortical amplification of Reuniens output

Authors: *G. VANTOMME, G. DEVIENNE, J. M. HULL, J. R. HUGUENARD;
Stanford Univ., Palo Alto, CA

Abstract: The neuronal circuit interconnecting medial prefrontal cortex (mPFC), thalamic Reuniens nucleus and hippocampus is central for memory and executive functions. A critical gap exists between known structural and behavioral aspects of this network compared to the paucity of knowledge regarding functional connectivity, especially in mouse models. We applied a combination of electrophysiological recordings and optogenetic manipulation both *in vitro* and *in vivo* to reveal the consequences of Reuniens activity. Beyond direct excitatory monosynaptic connections and feedforward inhibition targeting both pyramidal cells in mPFC and CA1, Reuniens output shows a strong recruitment of feedforward excitation specifically in mPFC. This feedforward excitation was strongly enhanced upon pharmacological blockade of GABA receptors, could induce burst discharge of action potentials in mPFC neurons (8/12 cells), which may constitute a mechanism underlying the capacity of Reuniens inputs to synchronize activity in mPFC. Optogenetic activation of Reuniens *in vivo* evoked heterogeneous responses in mPFC neurons, as detected by unit responses recorded with NeuroPixel probes. Responses included increases in firing (12/22 units), decreased firing (2/22 units) and delayed firing responses (14/22 units) consistent with the observations made *in vitro* of delayed firing, and confirming that mPFC can amplify Reuniens output through delayed burst firing. Feedforward activation of cortical circuits was more prominent than what has been reported with activation in sensory thalamic regions, suggesting that intracortical amplification of Reuniens output is a specialized feature of this subsystem underlying memory/cognition. Our results also show that imbalance in inhibition/excitation can lead to excessive delayed activity, which might be a mechanism underlying hyper synchrony during seizures. Initial observations in the *SCN8A* mouse model of absence seizure revealed that Reuniens activation of mPFC neurons resulted in an increase in excitation/inhibition ratio as measured with composite evoked synaptic response recorded intracellularly and compared to wild-type littermates, and a slight increase in the amplitude of the sink in deep layers when recorded with LFP. Altogether, these data demonstrate the fundamental synaptic properties underlying the function of the mPFC-Reuniens-hippocampal circuit. They also suggest that mPFC network uniquely amplifies Reuniens output, which may be one of the mechanisms underlying normal hippocampal prefrontal cortical circuit function and abnormal synchronization in the *SCN8A* mouse model of absence seizure.

Title: The neural basis of the error-related negativity: A biophysical modeling study

Authors: *B. HERRERA[1], A. SAJAD[3], S. P. ERRINGTON[4], J. D. SCHALL[5], J. J. RIERA[2]; [2]Biomed. Engin., [1]Florida Intl. Univ., Miami, FL; [3]Psychology, Vanderbilt Univ., Nashville, TN; [4]Dept. of Neurosci., Washington Univ. Sch. of Med., St. Louis, MO; [5]Biol., York Univ., North York, ON, Canada

Abstract: The error-related negativity (ERN) is a biomarker of psychiatric disorders such as ADHD, OCD, and schizophrenia. However, the utility of ERN as a biomarker depends on our understanding of how it is generated at the cellular and circuit levels. Although ERN is known to originate from medial frontal areas such as the supplementary eye field (SEF), little is known about the underlying neuronal mechanisms. Here, we investigate the cortical origin of the ERN employing a multiscale approach that links cellular-level dynamics, local field potentials (LFPs), and scalp potentials. Recently, we demonstrated that *in-vivo* laminar current source density (CSD) maps can be used to accurately predict EEG reflections. In this study, we utilized our methodology to predict the contribution of SEF to the ERN from the *in-vivo* laminar field potentials. We recorded neuronal spiking and LFPs across all layers of SEF in two macaque monkeys performing a saccade countermanding stop-signal task. The observed laminar CSD comprised multipolar components, with dipoles explaining ERN features and quadrupoles reproducing those for the post-error positivity or Pe. Forward modeling of the estimated SEF current multiple moments explained the ERN generation but not the Pe, confirming the involvement of other areas, such as the anterior cingulate cortex. Additionally, we employed optimized biophysical models of error layer 3 (L3) and layer 5 (L5) pyramidal cells to evaluate their contribution to SEF CSDs, which was negligible. The CSD derived from L3 error pyramidal cells could not explain the observed association between their error-related spiking modulation and the ERN. This last finding suggests that error pyramidal cells are not the main

neuronal generators of the ERN but instead drive the activity of the performance monitoring circuit in SEF. These results provide the most advanced explanation of the cellular mechanisms generating the ERN.

Title: Practice-dependent effects of dorsolateral prefrontal cortex representational geometry on context-dependent behavior

Authors: ***D. BUYUKYAZGAN**[1], H. KEGLOVITS[1,2], A. BHANDARI[1], D. BADRE[1,2];
[1]Dept. of Cognitive, Linguistic & Psychological Sci., [2]Robert J and Nancy D Carney Inst. of Brain Sci., Brown Univ., Providence, RI

Abstract: Control representations in human dorsolateral PFC (dlPFC) have been implicated in flexible mapping of inputs to outputs in context-dependent tasks. Recent work has shown that

dlPFC representational geometry is organized into orthogonal subspaces for each context, and each subspace preferentially encodes context-relevant stimulus dimensions. The importance of dlPFC geometry for behavior remains poorly understood. Here, we examine how dlPFC representational geometry relates to behavior, and how this relationship changes with practice. We hypothesized that practice would shift the representational geometry to one that was more separable, thus contributing to making behavior more efficient, but also more sensitive to task-irrelevant information. We investigated representational geometry in dlPFC using fMRI and pattern analysis as participants (n=20) performed a context-dependent categorization task over 5 sessions. Participants were presented with stimuli with 3 features. The auditory feature (context) determined which of the two visual features was relevant for categorization on the trial. In a region of dlPFC encoding task decisions, we trained linear classifiers to identify the context-specific coding axes for each stimulus feature and estimated the location of multi-voxel patterns on each trial along these axes. Neural coding strength for a particular stimulus was defined as the absolute distance of the trial pattern from the relevant, context-specific classification hyperplane. Using mixed-effects models, we regressed trial-by-trial measures of task performance on estimates of neural coding strength for each task feature. Trial-by-trial variance in response time was explained by the strength of neural coding for task context, as well as the context-relevant and context-irrelevant stimulus features. Stronger coding of context, and the context-relevant stimulus feature, predicted faster responses, while stronger coding for the context-irrelevant feature predicted slower responses, providing evidence for a role of dlPFC representational geometry in behavior. Practice transformed the influence of the context-irrelevant feature on behavior such that in later scanning sessions, stronger coding of the context-irrelevant feature predicted faster responses. Our results suggest that dlPFC geometry contributes to context-dependent behavior, and this contribution is transformed with practice.

Title: Distinct population architecture for cognitive flexibility in frontal and parietal cortex

Authors: *Y. OSAKO[1], Y. SAITO[2], Y.-N. LEOW[3], G. R. HELLER[3], S. K. ÄHRLUND-RICHTER[3], Z. WANG[3], G. T. DRUMMOND[3], T. OSAKI[3], M. SUR[3];

Abstract: Cognitive flexibility, a vital ability for mammals to adapt to diverse situations and environments, is hindered by the curse of dimensionality in neuronal activity. To address this challenge, leveraging shared information among cognitive operations within the system to reduce information dimensionality is advantageous. However, the underlying mechanisms of such cognitive operations remain elusive. In this study, we trained mice on a behavioral task involving distinct cognitive operations and recorded neuronal activity simultaneously in the anterior cingulate cortex (ACC) and posterior parietal cortex (PPC), regions thought to be associated with cognitive flexibility. Mice were trained on a delayed match-to-sample (DMS) task, requiring them to discern whether two consecutive stimuli were matched. During the delay period between stimuli, the stimulus information was maintained as working memory (WM). Subsequently, a second delay period served as an action planning (AP) period, allowing mice to make decisions and prepare for the behavior. This task enabled investigation of different cognitive processes (WM and AP) driven by identical stimuli. Our findings revealed that both the ACC and PPC represented WM and AP using linearly separable neural decoders. Moreover, the neuronal subspaces corresponding to these representations were independent (orthogonal) in PPC, while partially overlapping in ACC. Notably, this population architecture correlated with animal behavior, collapsing during error trials. Additionally, recurrent neural networks trained on the same task exhibited latent representations akin to those observed in the ACC, implying an efficient geometric structure for achieving cognitive flexibility. These results suggest that the ACC represents WM and AP in a more abstract manner within a higher-dimensional space to facilitate cognitive flexibility, while the PPC achieves flexibility by utilizing distinct neural subspaces. Future experiments will explore potential interactions between these geometric structures in efficiently representing cognitive flexibility.

Title: Physical and cognitive training interventions to improve everyday-like dual-task driving behavior in older adults

Authors: *R. STOJAN[1], M. MACK[2], O. L. BOCK[3], C. VOELCKER-REHAGE[1]; [1]Univ. of Muenster, Muenster, Germany; [2]Univ. of Geneva, Geneva, Switzerland; [3]German Sport Univ. Cologne, Cologne, Germany

Abstract: Driving is an important everyday behavior in older adults that heavily relies on various cognitive and motor functions. Engaging in additional tasks while driving (i.e., dual-tasking), such as interacting with in-vehicle devices, places extra demands on neurocognitive resources and may lead to compromised driving performance. Enhancing neurocognitive capacity through structured cognitive and/or physical training may provide support in performing such complex everyday tasks. This study therefore aimed to investigate the effects of physical, cognitive, and combined physical-cognitive training on dual-task driving performance in healthy older adults. A total of 106 older adults (age: M = 69.15 years ± 2.71, 59 female) participated in a simulated car driving scenario. Participants followed a lead car at a constant speed (70 km/h) on a slightly winding rural road. While driving, they engaged in two additional tasks. Additional tasks, i.e. typing 3-digit numbers and stating arguments for/against public issues, were presented visually or auditorily at intervals of about 15-25 s. Dual-task driving performance was assessed by measuring average velocity (speed control) and variability in lateral position on the road (lane keeping) during a 0-10 s interval after each additional task onset. Brain activity was recorded using functional near-infrared spectroscopy (fNIRS) in frontal and parietal brain regions. After pre-test, participants were randomly assigned to one of three training groups: physical, cognitive, or combined physical-cognitive training. Training sessions lasted for 45 min and were conducted twice a week for twelve weeks (24 sessions or 1080 min in total). The effect of the different training programs on dual-task driving performance was analyzed by use of linear mixed models (Time x Training Group x Task Type). We observed no significant main or interaction effects for speed control, although all training groups exhibited slightly improved speed control at post-test (p = .097, ηp^2 = .15). For lane keeping, the triple interaction was significant (p = .044, ηp^2 < .01), indicating that only during the typing task, lane keeping benefited from training, mainly in the physical-cognitive training group. In summary, effects of training effects on dual-task driving performance appear to be small and specific to the outcome parameter and type of additional task. Combined physical-cognitive training showed the greatest effectiveness, possibly due to the additive advantages of physical and cognitive training. Whether this effect is moderated through an improvement of multitasking skills or motor/cognitive performance needs to be further investigated.

Title: Microcircuitry of performance and outcome monitoring in the supplementary eye field and mid-cingulate cortex

Authors: *A. SAJAD[1], S. P. ERRINGTON[2], P. THIRUNAVUKKARASU[3], J. D. SCHALL[3]; [1]Vanderbilt Univ., Nashville, TN; [2]Dept. of Neurosci., Washington Univ. Sch. of Med., St. Louis, MO; [3]Biol. Dept., York Univ., North York, ON, Canada

Abstract: Successful interaction with the environment requires the monitoring of performance and outcomes and exerting adjustments on behavior. The medial frontal cortex (MFC) is critical to these functions; however, the precise neural mechanisms remain unclear. To address this, we recorded laminar neural data using linear vector arrays (164 penetrations) from the Supplementary Eye Field (SEF) and the dorsal (dMCC) and ventral (vMCC) banks of the Mid-Cingulate Cortex, in two monkeys. Here, we report the laminar organization of different error signals in SEF and dMCC in a stop-signal task. Fluid reward was earned for generating a saccade to a target and for inhibiting it when a stop-signal appeared. The target location cued whether the upcoming reward value was high or low; this target-reward mapping changed across blocks unpredictably. Following the response, two distinct auditory feedback tones indicated whether or not reward would be provided. On ~10% of correct trials, an unexpected negative feedback tone was presented. This design enabled the identification of signals related to internally generated errors (saccades made after stop-signal appearance), feedback, feedback prediction error (FPE), and reward prediction error (RPE). These signals were largely observed in non-overlapping neuron populations. Overall, error neurons (SEF: n = 142; dMCC: n = 54) in SEF had an earlier modulation onset than those in the dACC. In the SEF, the error signal initially emerged in the middle layers (L3 and L5) and subsequently the upper (L2/3) and lower (L5/6) layers. In contrast, in the dMCC, error neurons were present across all layers, with the earliest modulation in L2/3. Negative feedback in both SEF and dMCC resulted in facilitation of neurons (SEF: n=40, dMCC: n = 56) largely confined to L2/3 and suppression (SEF: n=25, dMCC: n = 20) of neurons mainly in L5/6. FPE was first encoded by neurons (SEF: n=36, dMCC: n = 64) in L5/6 in SEF, in contrast to the dMCC where it first appeared in L2/3. Finally, positive (SEF: n=24, dMCC: n = 28), negative (SEF: n=35, dMCC: n = 28), and unsigned (SEF: n=33, dMCC: n = 39) RPE signals were found across all layers in both areas, with a larger proportion of negative RPE neurons in L2/3. These results illustrate similarities and differences in laminar organization of complementary error monitoring signals in SEF and dMCC, and contribute to future models of cortical microcircuitry and MFC function.

Title: Brain Oscillations Related to Prolonged Reaction Times in Go/No-go Tasks with Different Meanings of Stimulus Color

Authors: *T. HORINOUCHI[1,2], T. WATANABE[3], H. KIRIMOTO[1];
[1]Hiroshima Univ., Hiroshima, Japan; [2]Res. Fellow of Japan Society for the Promotion of Sci., Tokyo, Japan; [3]Fac. of Hlth. Sci., Aomori Univ. of Hlth. and Welfare, Aomori, Japan

Abstract: *Background*: Color has meaning in particular contexts, and the meaning of color can impact behavioral performance. For example, the meaning of color about traffic rules (blue/green and red mean “go” and “stop” respectively) influences reaction times (RTs) to signals. Specifically, in a Go/No-go task, RTs have been reported to be longer when responding to a red signal and withholding the response to a blue signal (Red Go/Blue No-go task) than when responding to a blue signal and withholding the response to a red signal (Blue Go/Red No-go task). However, the neurophysiological background of this phenomenon has not been fully understood. The purpose of this study was to investigate the brain oscillatory activity associated with the effect of meaning of color on RTs in the Go/No-go task.
Methods: Twenty participants performed a Blue simple reaction task, a Red simple reaction task, a Blue Go/Red No-go task, and a Red Go/Blue No-go task. We recorded responses to signals and electroencephalogram (EEG) during the tasks and evaluated RTs and changes in spectral power over time, referred to as event-related synchronization (ERS) and event-related desynchronization (ERD).
Results: The behavioral results were similar to previous studies. The EEG results showed that frontal beta ERD and theta ERS were greater when signals were presented in blue than red color in both simple reaction and Go/No-go tasks. In addition, the onset of theta ERS was delayed in the Red Go than Blue Go trial in the Go/No-go task.
Discussion and Conclusion: The enhanced beta ERD may indicate that blue signals facilitate motor response, and the delayed onset of theta ERS may indicate the delayed onset of cognitive process when responding to red signals as compared to blue signals in the Go/No-go task. Thus, this delay in cognitive process can be involved in the slow response in the Red Go/Blue No-go task.

Title: Juxtaposed regions in dorsolateral prefrontal cortex differentially support domain-specific scene construction and domain-flexible cognitive control

Authors: *L. DINICOLA, W. SUN, R. L. BUCKNER;
Harvard Univ., Cambridge, MA

Abstract: Primate prefrontal cortex (PFC) is heterogenous, and the roles that PFC regions play in higher-order functions remain debated. One debate surrounds the degree to which PFC regions support domain-flexible cognitive control functions or are specialized for domain-specific information processing. Here, we tested the hypothesis that side-by-side regions of PFC, linked to distinct parallel association networks, differentially support domain-flexible control or domain-specialized processes. Using networks estimated from functional connectivity MRI, we identified three separate PFC regions of distinct parallel networks within each of 9 repeatedly-scanned individuals. These regions included a dorsolateral PFC (DLPFC) region of default network A (DN-A), a broader PFC region of a frontoparietal network (FPN-A), and an inferior PFC region of a language network (LANG). Using independent task data, we explored the response properties of these three side-by-side regions. Results revealed a significant triple dissociation. Within DLPFC, DN-A regions were preferentially recruited by an Episodic Projection task contrast. Juxtaposed FPN-A regions were preferentially recruited by working memory (N-Back) task contrasts and in a domain-flexible way (i.e., across multiple categories). The inferior PFC region of the LANG network was preferentially recruited for sentence processing. Post-hoc trial-level analyses further supported that the DLPFC region linked to DN-A specifically responded to task demands involving scene construction and not cognitive effort. Our findings demonstrate that DLPFC possesses multiple differentially specialized regions that are spatially near to one another but support diverse aspects of cognitive function. These results also raise the possibility that PFC regions gain processing properties through segregated anatomical projections, including a specialized region in DLPFC that is connected to the hippocampal formation and distinct from more commonly studied domain-flexible regions supporting cognitive control.

Title: Error monitoring is modulated by activation of conjunctive representations of uncommitted correct actions

Authors: A. KIKUMOTO[1], D. BUYUKYAZGAN[1], S. POELLNITZ[1], A. PEETZ ALIO[1], M. CRUZ[1], T. NISHIO[2], N. KAWAMURA[2], M. KAMINOKADO[2], Y. KANEKO[2], K. SHIBATA[2], ***D. BADRE**[1];
[1]Brown Univ., Providence, RI; [2]RIKEN Ctr. for Brain Sci., Wako, Japan

Abstract: Monitoring and detecting action errors allows cognitive control systems to adjust behavior promptly and learn from mistakes. Thus, understanding the neurophysiological mechanisms of the subjective perception of errors is important for cognitive control theory. However, the link between standard event-related potentials (ERPs) of error processing in humans (e.g., error-related negativity and positivity) and error monitoring and awareness has been surprisingly inconsistent. One possibility is that the geometric and dynamic properties of encoded task representations, which are typically missed in conventional ERP approaches, directly inform error monitoring decisions, as well as influencing ERP markers of error processing. In this study, we applied time-resolved multivariate analyses to EEG data to track representations of uncommitted correct actions and committed erroneous actions and related them to error monitoring. Participants performed a rule-based response selection task with a response deadline that provided variable time to prepare before compelling a response. Deadlines were calibrated to set expected error rates at approximately chance levels. Following a response of the main task, participants pressed a key to report when they detected an error before the next trial. During action selection of error trails, conjunctive representations of uncommitted correct actions did not differ between detected and undetected errors. However, the difference emerged immediately following error commissions, coinciding in time with error-related negativity. Surprisingly, stronger activation of conjunctions of uncommitted correct actions resulted in more failures of error detection. These results suggest that error awareness is directly modulated by the retrieval of conjunctive task representations.

Title: Role of central medial thalamus to orbitofrontal cortex pathway in reversal learning

Authors: *K. TUITE[1], M. GIROTTI[1], D. A. MORILAK[1,2];
[1]UT Hlth. San Antonio, San Antonio, TX; [2]South Texas Veteran's Hlth. Care Syst., San Antonio, TX

Abstract: Stress-related psychiatric disorders, such as major depressive disorder and anxiety disorders, have cognitive flexibility deficits that persist even after other symptoms of these disorders go into remission. Reversal learning, a form of cognitive flexibility necessary to adapt to a changing environment, is disrupted in stress-related psychiatric disorders. The orbitofrontal cortex (OFC) mediates reversal learning, and hyperactivity in the OFC is associated with depression and obsessive-compulsive disorder in humans. Using a reward-based discrimination digging task to assess reversal learning in rodents, we have previously reported that chronic stress impairs reversal learning and potentiates responses to excitatory input in the OFC, and that inducing long-term depression in the mediodorsal thalamus to OFC pathway reverses these deficits, indicating that increased activity in projections to the OFC is detrimental to reversal learning. However, the circuit-level mechanisms underlying stress-induced reversal learning deficits are not well established. Preliminary data using Fos immunohistochemistry, showed a significant decrease in Fos in the lateral OFC following reversal learning, and a significant increase in Fos induction in the central medial (CM) thalamus. Other preliminary data suggest that the CM projects to the OFC and converging evidence suggests the CM activates inhibitory interneurons in the OFC which are crucial for reversal learning. Therefore, we next tested the hypothesis that excitatory input from the CM to the OFC is essential to reversal learning. We used an adeno-associated virus to deliver an inhibitory (Gi) DREADD, an excitatory (Gq) DREADD, or GFP control into the CM under the control of the CaMKII promoter, and implanted guide cannulae into the lateral OFC for pathway specific in/activation. Animals received microinjections of the DREADD agonist clozapine-N-oxide (300 μM, i.c. 0.75 μL) directly preceding the reversal learning task. Inactivating the CM-OFC pathway in non-stressed animals significantly impaired reversal learning. Based on these results we hypothesize that activating the CM-OFC pathway in chronically stressed animals will reverse stress-induced deficits in reversal learning, these experiments are ongoing. These results suggest that activation in the CM-OFC pathway is important for reversal learning and that it is a potential target for reversing stress-induced deficits. This implicates a circuit not yet investigated in the role of chronic stress in disruptions of cognitive flexibility.

Title: Eeg decoding of task switching effects on hierarchical task representations

Authors: *H. MORROW[1], K. HWANG[2];
[1]Psychological and Brain Sci., [2]Univ. of Iowa, Univ. of Iowa, Iowa City, IA

Abstract: Adapting responses flexibly based on contextual circumstances is a fundamental cognitive ability that is thought to be mediated by hierarchical task representations (Badre & Nee 2018). Prior research has shown that task-switching cost is likely associated with reconfiguration of task representation, as indicated by a decrease in decoding accuracy from fMRI and EEG data. However, most studies switched between simple stimulus-response mappings, without considering the multi-faceted, hierarchical structure of task representations. In the present study, we developed a hierarchical control task that necessitated subjects switching between tasks by taking into account multiple task contexts and features. Importantly, the task encompasses three critical components of task representations: context, feature, and response rule. Thus, during task switching, not only was the response rule altered, but the context and features of the task also underwent changes. Our goal is to determine which constituent representation of such hierarchical task representation is affected by task switching. We used encephalography (EEG) based linear discriminatory analysis to decode task representations. The rational being that when trained a classifier to decode task representations, decoding accuracy will decrease when the to-be-decoded representation is affected by task switching. We collected EEG data from 36 healthy participants. From the time-frequency decoding analysis, we found that participants had higher decoding accuracy when trials kept the same context-dependent rules as the previous trial, and lower decoding accuracy when the context of the current trial was switched from the previous trial. This difference in decoding accuracy is most prominent in the alpha-to-beta high frequency range, indicating a potential neural signal reconfiguring contextual representation. Notably, decoding accuracy of other task features and response rules did not show significant difference when switched between tasks. Our results indicate reconfiguration of context representations in a hierarchical task representation likely has the strongest contribution to task-switching cost.

Title: Neurons in prefrontal cortex respond to abstract pattern violations

Authors: *K. E. CONEN, T. M. DESROCHERS;
Neurosci., Brown Univ., Providence, RI

Abstract: The ability to identify patterns in events around us shapes our expectations and helps us adapt to changing environments. One example of pattern recognition is the detection of abstract sequences - higher-order relationships that remain consistent across stimuli (e.g., AAAB, &&&*). Both humans and nonhuman primates can detect abstract sequences and respond when these patterns are violated. Recent work in our lab identified specific subregions of macaque LPFC with robust BOLD responses to pattern deviants during awake sequence viewing. However, it is not clear how these signals translate to neuronal responses, or whether specific features of LPFC responses distinguish it from other regions. We performed fMRI-targeted neuronal recordings in LPFC and orbitofrontal cortex (OFC) while monkeys performed a no-report sequence viewing task. Monkeys fixated on a central point as fractals appeared in four-item sequences. Each recording session included multiple five-block runs (4-20 runs/session). Within a run, sequences were defined by a standard pattern (e.g. AAAB). Images were drawn pseudorandomly from a set of fractals generated daily. Each run consisted of a habituation block (30 trials, standard sequence), followed by four blocks with deviant sequences on 20% of trials. Deviants were either new images in the standard pattern (NI) or pattern deviants (PD), and were drawn from a separate pool of fractals. Juice was delivered on a graduated schedule contingent on fixation and independent from sequence presentation. We recorded ~500 neurons from the LPFC and ~400 from the OFC of one monkey and analyzed a subset of these neurons. Using two-way ANOVAs, we examined how activity in each neuron varied with ordinal position, reward, sequence type (standard, NI, or PD). While the two regions contained a comparable fraction of reward-sensitive neurons (LPFC: 15%; OFC: 17%; chi-square test $p = 0.59$), effects of sequence-type were more prevalent in LPFC (LPFC: 23%, OFC: 13%; chi-square test $p = 0.008$). Notably, most sequence-type responses in LPFC showed the highest activity during pattern deviants (PD: 53%; NI: 33%, standard: 14%). In contrast, OFC neurons were most likely to respond to NI sequences (PD: 33%, NI: 42%, standard 24%), suggesting that they are more sensitive to rarity of the images rather than the abstract sequence pattern. These results provide preliminary evidence that LPFC networks preferentially respond to abstract sequence patterns. Future analyses will test how these responses change with task demands and examine whether they contribute to a generalizable representation of abstract sequences.

Title: Investigating the effect of transcranial alternating current stimulation paired with cognitive exercises on cerebral blood flow with functional near-infrared spectroscopy

Authors: *S. AZARBARZIN;
Biomed. Engin., Univ. of Manitoba, Winnipeg, MB, Canada

Abstract: ***Introduction:*** Transcranial alternating current stimulation (tACS) is a promising approach to modify brain oscillations, as it enables precise entrainment of cortical oscillations at specific frequencies. ***Method:*** The present double-blind cross-over study aims to evaluate the effect of tACS treatment at 40 Hz paired with cognitive exercises on Alzheimer's Disease (AD). Study participants received either real or sham tACS daily (excluding weekends) for 4 weeks, followed by the opposite treatment after a 2-month wash-out period. Participants were randomly assigned to two groups based on age and cognitive level. An eight-channel fNIRS (functional near-infrared spectroscopy) device was used to measure participants' blood oxygenation levels in their prefrontal cortex to investigate treatment efficacy. These measurements were taken before and after each treatment cycle in combination with a verbal fluency task. Previous studies have indicated that individuals in the early stages of AD exhibit increased oxygen consumption in their prefrontal cortex while performing specific cognitive tasks as a compensatory mechanism. In contrast, healthy individuals do not show such patterns. Therefore, it was hypothesized that a lower oxygenated blood flow would present in patients' post-intervention as compared to baseline as a result of real tACS treatment. ***Results:*** A total of 15 older adults (50-95 years old) completed the study as of January 2021. The data of all who received real tACS versus those who received sham tACS was averaged regardless of treatment order. The difference of blood oxygenation changes between real and sham treatment was statistically significant using a non-parametric test ($p = 0.05$). Results further indicated a statistically significant decrease in blood oxygenation level (by a mean difference of 0.09μM) after real tACS when compared to its corresponding baseline ($p = 0.04$). There were no significant changes in the blood oxygenation level between pre and post sham tACS treatment. These results confirm our hypothesis although the power of the test is low due to small sample size.***Conclusion:*** Active tACS treatment can potentially enhance cognitive abilities in patients with AD, as evidenced by reduced oxygenated blood flow measured with fNIRS.

Title: Combined mindfulness-based intervention with non-invasive brain stimulation for metacognitive processing

Authors: *E. MIYAUCHI[1], M. KAWASAKI[2];
[1]Inst. of Systems and Information Engin., Univ. of Tsukuba, Tsukuba, Japan; [2]Inst. of Systems and Information Engin., Univ. of Tsukuba, Ibaraki, Japan

Abstract: Our previous study which combined repetitive transcranial magnetic stimulation (rTMS) with electroencephalogram (EEG) demonstrated the effectiveness of using specific task-relevant stimulation frequency and target location for the modulation of cognitive and behavioral performance. In the previous study, we initially investigated the correlations between the EEG oscillations and cognitive giving-up processes during problem-solving tasks and found that the frontal theta rhythm is associated with the giving-up processes. We then conducted online rTMS to examine the frequency-dependent stimulation effects of rTMS on the performance of problem-solving tasks and ongoing oscillations by applying rTMS to induce theta and alpha amplitudes in the frontal area. The results showed that theta-frequency rTMS application induced an increase in theta amplitudes and shortened the giving-up response, while a control alpha-frequency rTMS application induced an increase in alpha amplitudes, but not the giving-up responses. Giving-up behaviors, such as intentionally quitting problem solving or disengaging from goals that are too difficult to attain, are considered adaptive and important for mental health. For instance, it has been suggested that rumination, a risk factor for the onset and maintenance of depressive states, plays a role in hindering adaptive giving-up behaviors, due to impairments in metacognition, the higher-order cognitive skills that help individuals to monitor and control their information processing. In this preliminary study, to find an effective approach to reduce rumination, we examined the effect of online rTMS with a mindfulness-based cognitive intervention on metacognitive processing. Performance of sustained attention to response task and EEG data were obtained the pre- and -post intervention. We found that the task performance was associated with the frontal theta amplitude and our results suggest the

neuromodulatory effectiveness of combining non-invasive stimulation with psychological approach on cognitive function.

Title: Mental representations of latent states in the human brain

Authors: *F. BOUCHACOURT[1], L. YU[2], A. R. VAIDYA[4], A. AKHMETZHANOVA[2], S. BRUINSMA[3], M. NASSAR[2];
[1]Carney Inst. for Brain Sci., [3]Neurosci., [2]Brown Univ., Providence, RI; [4]Cognitive, Linguistic and Psychological Sci., NIH, Natl. Inst. on Drug Abuse (NIDA), Baltimore, MD

Abstract: We don’t always need to relearn behavioral policies from scratch when the environment changes. When appropriate, we build mental representations of the hidden outcome contingencies (“latent states”) and we flexibly use these representations to retrieve a previous behavior more rapidly. The prefrontal cortex, orbitofrontal cortex and dorsolateral prefrontal cortex in particular, have been argued to be the locus of the neural representations of latent states, however with a limited characterization of their implementation. To examine the formation and reuse of latent states in the brain, we designed a human task that dissociates latent states from action-outcome contingencies, so that we can quantify behaviorally when a latent state is being reused. At each trial, participants were asked to move the position of a colored cue in a circular arena. Five color cues were used, and participants were required to learn and switch between two distinct patterns. A pattern was defined by the association between the five cues to different locations on the screen, and participants received supervised feedback about the expected location at each trial. Two sessions were run and counterbalanced between participants. In one session, the switch between patterns was signaled on the screen ; in the other session, it was not. Looking at behavior after the initial learning phase, we found evidence for single trial reuse of the patterns after switches. In the unsignaled session, this is seen by looking at the retrieval of the four remaining cue-location associations from knowing the location of the color cue that was first presented after a switch. This means that participants in both conditions learned the two patterns and retrieved them when needed as two separate latent states. However, the degree to which they do so varied across participants. Using computational modeling and model-driven analysis of fMRI data allowed us to study the mechanism of the formation of latent states in this task and to explain individual differences in behavior.

Title: The role of trait mindfulness in self-regulatory processing during an affective Stroop task

Authors: *G. BATCHALLI MARUTHY[1], L. HIMES[2], B. P. RYPMA[3];
[1]The Univ. of Texas at Dallas, Richardson, TX; [2]Abbott Neuromodulation, Austin, TX;
[3]Behavioral & Brain Sci., Univ. of Texas At Dallas, Dallas, TX

Abstract: Trait mindfulness (TM) is the dispositional ability of an individual to be attentive in the present moment, with a nonjudgmental, curious, and accepting attitude. Mindfulness practice aims at enhancing one's TM. The mechanisms underlying the salutary benefits of mindfulness are thought to involve modification of cognitive and emotion regulation processes. If so, individual differences in TM should be related to the neural processes that occur during cognitive and affective processing. To assess the brain bases of TM and emotion regulation, we examined associations between TM and Blood Oxygen Level Dependent (BOLD) signal while participants performed an emotional Stroop task. During scanning, participants responded to the font color of emotional words shown on a screen via button press. Words were chosen from the Affective Norm for English Words (ANEW; Bradley and Lang et al., 1999) and were either positive or negative in valence ratings. Words were equivalent in length, arousal, and frequency ratings. Functional echo planar images were acquired on a 3T Prisma SIEMENS scanner. Anatomical MPRAGE T1-weighted images were also obtained. Responses to words did not differ on accuracy or Reaction time (RT) to font color. fMRI data were preprocessed with slice-timing correction, realignment, co-registration, normalization to Talairach space, and smoothing. Functional connectivity analysis revealed that, for the negative words, higher TM was related to higher connectivity between a Posterior Cingulate Cortex (PCC) seed and regions attributed to self-regulatory processes including the right medial frontal gyrus, left insula, right anterior cingulate and right inferior frontal gyrus. These results provide support for the idea that the mechanisms underlying mindfulness, in fact, might be related to neural processes of both cognitive and emotion regulation. They suggest that a core network of regions interact to bring about the present-moment non-judgmental awareness that characterizes TM.

Title: Multitasking: does task-switching add to the effect of dual-tasking in everyday activities?

Authors: P. A. G. ASUAKO[1], R. STOJAN[1], M. MACK[2], O. L. BOCK[3], *C. VOELCKER-REHAGE[1];

Abstract: The investigation of potential negative effects of performing multiple tasks simultaneously or switching between multiple tasks has gained significant attention in various research fields. Most studies focus on task interference as the reason for the observed performance decrement when performing multiple tasks. Task interference is usually examined by asking subjects to perform two tasks either concurrently, known as dual-tasking (DT), or sequentially, known as task-switching (TS). However, little is known about the interplay effect of TS and DT as observed in everyday activities, such as car driving. Car driving is a complex activity that often requires switching between two or more concurrent activities, such as driving while conversing with a passenger and switching to manipulating in-vehicle stereo. In this scenario, we expect that the cost of dual-tasking will be further compounded by task-switching, leading to a stronger deterioration in driving performance due to the increase in cognitive load required to handle multiple task-sets. We conducted an experiment with 43 young adults (age: 23.62 ± 2.51, 26 females) in a driving simulator. Participants were instructed to follow a lead car driving at a constant speed (70km/h) through a rural landscape while concurrently performing two additional tasks (stating arguments, typing) modelled after realistic driver activities. The additional tasks were presented through visual and auditory modalities. We presented the additional tasks either in separate blocks to simulate conventional dual-task conditions (condition A) or intermixed them to replicate task-switching conditions (condition B). We quantified the average velocity and standard deviation of the lateral lane position within 0 to 10 seconds after the additional task onset. We performed 2x2x2 repeated measures ANOVA with Condition (within: separate, mixed) Tasks (within: argument, typing) and Modality (within: auditory, visual) as factors. None of these variables showed significant differences between conditions (all $p > 0.05$), although our statistical power was sufficient to detect a moderate difference between conditions ($f = 0.25$, a = 0.05, 1-ß = 0.95, 4 repetitions -> required n = 34). The results do not support the hypothesis that in realistic multitasking, the costs of dual-tasking are compounded by the costs of task switching. That is, our findings suggest that the cognitive load of handling multiple sets of additional tasks rather than just one additional task does not significantly degrade driving performance of young adults.

Title: Set-shifting function predicts dynamic balance in people with Parkinson's disease

Authors: *G. R. HARKER, C. SILVA-BATISTA, A. RAGOTHAMAN, J. ELLISON, A. PREWITT, P. CARLSON-KUHTA, F. B. HORAK, M. MANCINI;
Neurol., Oregon Hlth. & Sci. Univ., Portland, OR

Abstract: Background: Parkinson's disease (PD) is associated with cognitive, as well as motor, impairments. Cognitive function is essential for balance performance. Balance is composed of at least 4 different domains, as measured by the Mini Balance Evaluation System Test (Mini-BESTest). Recent laboratory studies have shown that cognitive assessments (e.g., Montreal Cognitive Assessment [MoCA]) are related to standing balance in people with PD, but it is unknown whether specific executive functions are related to different balance domains. Here, we aimed to investigate if executive function, assessed with a Tablet-based Cognitive Assessment Tool [TabCAT], can predict variations in Mini-BESTest total score and its subscores among people with PD. We hypothesize that Set-Shifting executive function will predict dynamic balance control during gait, which may require cognitive flexibility to create appropriate balance and postural responses. **Methods:** A total of 39 individuals, diagnosed with idiopathic PD (age=69.4 years, disease duration=9.5 years, MDS-UPDRS-III=36.4 score, MoCA=26.4 score) took part in the study. The Mini-BESTest and TabCAT were assessed in the laboratory. The TabCAT included assessments of visuospatial function (the Line Orientation task modeled on the Benton Judgement of Line Orientation task) and executive function (the Set-Shifting and Flankers tasks). **Results:** The multiple linear regressions showed that Set-Shifting was a predictor for the Mini-BESTest total score (R^2=0.35, $p<0.001$), as well as the Reactive Postural Control (R^2=0.17, p=0.009), Dynamic Gait (R^2=0.24, p=0.001), and Anticipatory Postural Adjustments subscores (R^2=0.20, p=0.004), but not the Sensory Orientation subscore. The Flanker and Line Orientation TabCAT tasks did not predict Mini-BESTest total score or its subscores. **Conclusions:** Our novel results show that better performance in instrumented set-shifting, assessing cognitive flexibility, is related to better dynamic balance during gait but not to static balance during standing in people with mild-to-moderate PD. These results suggest that people with PD lose ability to selectively switch attention to generate appropriate reactive, anticipatory and gait postural control, which seem not to be required for static balance control.

Title: Neural representation modulated by impression of trustworthiness generated from social interaction in memory for other persons

Authors: *A. KAMO, M. MIHARA, T. TSUKIURA;
Kyoto Univ., Kyoto, Japan

Abstract: Memory for other persons is modulated by impression of trustworthiness, which is mainly categorized into stimulus-dependent trustworthiness from faces and context-dependent trustworthiness formed in social interaction with others. Functional neuroimaging studies have demonstrated that the insula and amygdala are involved in the effect of stimulus-dependent trustworthiness on memory for other persons. However, little is known about the neural mechanisms underlying the effect of context-dependent trustworthiness on memory for other persons. To investigate this issue, using fMRI, we scanned healthy young adults during the encoding of objects associated with trustworthy, intermediate or untrustworthy persons, whose impression of trustworthiness was formed in the Trust Game before fMRI scanning. In the multivariate pattern analysis (MVPA), we investigated activity patterns represented in a region-of-interest (ROI) reflecting the social brain network including the medial prefrontal cortex (mPFC), precuneus/posterior cingulate cortex (PCC), anterior temporal lobe (ATL), and temporoparietal junction (TPJ). In addition, MVPA was applied to analyze activity patterns in the amygdala and insula ROIs related to the processing of stimulus-dependent trustworthiness. MVPA used three support vector machine (SVM) binary classifiers of other person's trustworthiness: Trustworthy vs. Intermediate, Intermediate vs. Untrustworthy, and Untrustworthy vs. Trustworthy, which were trained and tested using a leave-one-run-out cross-validation. Classification accuracies in MVPA for the social brain network ROI were significant in all classifiers, whereas activity patterns in the amygdala ROI significantly discriminated between Untrustworthy and Trustworthy. In the insula, activity patterns significantly differentiated Untrustworthy from the other conditions. These findings suggest that activity patterns in the social brain network represent the social knowledge related to impression of trustworthiness generated from social interaction with others. In addition, amygdala activity

could represent the socioemotional information associated with trustworthy and untrustworthy persons, whereas insular activity could represent the socioemotional information to specify untrustworthy persons.

Title: Neural mechanisms underlying the effect of prediction errors in facial attractiveness between masked and unmasked faces on face memories in young and older adults

Authors: *M. MIHARA, R. IZUMIKA, T. TSUKIURA;
Kyoto Univ., Kyoto, Japan

Abstract: The COVID-19 pandemic has forced people to predict facial attractiveness from partially covered faces. Given that facial attractiveness is processed as a social reward, differences between the predicted and observed facial attractiveness are defined as reward prediction error (RPE) in a social context. The age-related decline of RPE-dependent learning in monetary rewards has been explained by the impaired mechanisms including the RPE-related ventral striatum (VS) and memory-related hippocampus in older adults (OAs). However, little is known about the age-related difference in activation during the encoding of faces with social RPE derived from facial attractiveness. To elucidate this, using fMRI, we scanned healthy male young adults (YAs) and healthy male OAs during the encoding of female faces. In each encoding trial, participants rated the predicted attractiveness of a face covered except for around the eyes (prediction phase) and then rated the observed attractiveness of the face without any cover (outcome phase). The difference in ratings between these phases was defined as RPE in facial attractiveness, and RPE was categorized into positive RPE (increased RPE from the prediction to outcome phases), negative RPE (decreased RPE from the prediction to outcome phases), and non-RPE (no difference in RPE between the prediction and outcome phases). During retrieval, participants were individually presented with faces seen and unseen in the encoding trials, and judged whether or not each face had been seen in the encoding trials. In behavioral data, OAs showed significantly higher hit rates vs. false alarm (FA) rates in positive RPE than in negative RPE, whereas there was no significant difference in hit rates vs. FA rates among the RPE categories in YAs. Univariate fMRI activity in the VS and precuneus reflected a linear increase with increased RPE in facial attractiveness in YAs but not in OAs. Significant activation

reflecting linear decrease with increased RPE or increase with both positive and negative RPE was not identified in either YAs or OAs. These findings suggest that encoding-related activation underlying the processing of social RPE changes with age and that the age-dependent change is modulated by the RPE categories in face-based social rewards.

Title: Memory decisions modulate ongoing performance and brain state engagement

Authors: *J. WHEELOCK, N. M. LONG;
Univ. of Virginia, Charlottesville, VA

Abstract: We frequently encounter demands to switch between learning new information (encoding) and access-ing stored information (retrieval), yet how moment-to-moment fluctuations in these processes manifest in the brain is not well understood. Memory encoding and memory retrieval constitute neurally dissociable brain states which rely on distinct configurations of subcortical and cortical activity and connectivity patterns. Memory brain states tradeoff such that both encoding and retrieval cannot be engaged simultaneously and impact downstream processing and behavior. Although prior behavioral work has shown that memory judgments can have a lingering impact on subsequent judgments, these effects have not been directly linked to memory brain states. Our hypothesis is that memory brain states are modulated by memory judgments, and that these brain states persist for several hundred milliseconds, impacting subsequent memory judgments. To test this hypothesis, we conducted a recognition memory experiment in participants undergoing scalp electroencephalography (EEG) recording. Our critical manipulation was the inter-stimulus interval (ISI) between each recognition trial and we expected greater impact of memory states on subsequent judgments on trials with faster ISIs. We measured memory state engagement using a multivariate pattern classifier trained on an independent dataset in which participants were biased towards either encoding or retrieval. Replicating past work, we find that memory judgments influence subsequent judgments whereby successful recognition of targets (items that were studied; hits) improves memory accuracy for subsequently presented targets and decreases memory accuracy for subsequently presented lures (items that were not studied). Likewise, we find that correct rejection of lures improves memory accuracy for subsequently presented lures and decreases memory accuracy for subsequently presented targets. We expected to find greater retrieval state engagement on hits compared to

correct rejections and that memory states would persist for several hundred milliseconds after a memory judgment was made. However, we find that the memory retrieval state is more strongly engaged during correct rejections than hits and quickly decreases after a response is made. Our interpretation is that explicit, top-down demands inherent in the recognition task as well as preparation for the rapidly presented trials strongly influence the recruitment of memory brain states. This work enhances our understanding of how memory processes unfold on a moment-to-moment basis.

Title: Age effects on the encoding and retrieval of overlapping events

Authors: *I. L. MOORE, D. E. SMITH, N. M. LONG;
Univ. of Virginia, Charlottesville, VA

Abstract: Healthy older adults typically show impaired episodic memory, memory for when and where an event occurred, but intact semantic memory, knowledge for general information and facts. We hypothesize that these effects can be explained by an increased tendency to enter into and remain in a ‘retrieval state,’ a brain state in which attention is focused internally in an attempt to access prior knowledge. Engaging in a retrieval state can lead to impairments in subsequent memory, potentially because the retrieval state trades off with an ‘encoding state,’ a brain state in which attention is focused externally. To test our hypothesis, we conducted multivariate pattern analyses of scalp electroencephalographic (EEG) data while participants were explicitly directed to encode or retrieve object images. We find that both young and older adults can flexibly engage in memory brain states as directed. However, whereas young adults' memory state engagement gradually increases throughout the stimulus interval, older adults’ memory state engagement plateaus early in the stimulus interval. These findings suggest that the temporal dynamics of encoding and retrieval states differ across the lifespan, with possible implications for the ability to maintain versus flexibly shift between memory states.

Title: Response-locked theta power tracks successful retrieval independent of memory goals

Authors: *D. E. SMITH, N. M. LONG;
Univ. of Virginia, Charlottesville, VA

Abstract: Test-phase theta power (4-8Hz) is greater for identification of previously studied items (hits) compared to rejection of novel lures (correct rejections, CRs). In our preliminary work, we find that this theta power dissociation between hits and CRs 'flips' following a response. As theta power is greater following negative relative to positive outcomes across cognitive control tasks, the post-response theta 'flip' that we have identified in our preliminary work may represent a positive feedback signal in response to successful retrieval. This hypothesis is consistent with neuro-imaging work showing that reward-related regions (e.g. striatum) are more active during hits compared to CRs in the absence of explicit reward. However, reward signals during hits may instead reflect goal attainment; in a typical recognition experiment, the subjects' goal to identify old items is confounded with successful retrieval. To adjudicate between these hypotheses, we conducted two recognition memory experiments (E1, E2) in participants undergoing scalp electroencephalographic recording. The critical manipulation was the test-phase instructions. Subjects' goal was either to successfully retrieve study items (E1) or to detect new items (E2). If feedback signals reflect successful retrieval, the same post-response signals should dissociate hits vs. CRs regardless of memory goals. We find decreased theta power following hits vs. CRs in both E1 and E2. These preliminary findings are consistent with the hypothesis that successful retrieval is intrinsically rewarding.

Title: The neurocognitive mechanism of knowledge construction during on-line teaching

Authors: *X. XU, X. HE, X. FENG, S. ZHOU, C. LU;
Beijing Normal Univ., Beijing, China

Abstract: It has been long-debated that knowledge will be constructed into a hierarchical architecture in the human brain to facilitate encoding and later recall. However, there are few studies investigating this issue when learning knowledge with complex hierarchy, particularly during a naturalistic teaching process. To address this issue, 80 healthy adults were scanned using functional magnetic resonance imaging (fMRI) while they learnt a complex physical knowledge through video teaching. The knowledge taught by the video were either with an intrinsic hierarchy (intact condition) or not, i.e., the conceptual events of the video were temporally scrambled (structure-scrambled condition) or the words of the video were temporally scrambled (word-scrambled condition). First, a representational similarity analysis was conducted to determine the neural underpinnings of the content and hierarchy representation in the learner's brain. The results of the intact condition showed that the precuneus was significantly associated with the representation of knowledge hierarchy. Interestingly, the precuneus also had a significant role in representing knowledge hierarchy even no explicit structure existed in the video teaching process (i.e., the structure-scrambled condition). However, the precuneus did not appear in the word-scrambled condition. Most importantly, it seemed that learners reconstructed the structure-scrambled knowledge into a well-organized hierarchy that was consistent with the intrinsic hierarchy of the knowledge. Finally, the representation of hierarchy in the precuneus significantly predicted subsequent behavioral performance of knowledge recall. Together, these findings provide novel and important support for the knowledge construction theory, and suggest that the default mode network is involved in both content and hierarchy representation of high-level naturalistic stimuli during on-line teaching.

Title: Effects of spontaneous lapses of attention on goal representation and episodic memory retrieval

Authors: *D. MILLER[1], S. T. SCHWARTZ[2,3], T. T. TRAN[2,4], J. E. RATHMANN-BLOCH[2], J. PARK[2,4], A. ROMERO[2,4], J. SHENG[2,4], H. YANG[2], E. C. MORMINO[4,3], A. D. WAGNER[2,3]; [1]Stanford Univ., Palo Alto, CA; [2]Psychology, [3]Wu Tsai Neurosciences Inst., [4]Dept. of Neurol. & Neurolog. Sci., Stanford Univ., Stanford, CA

Abstract: Episodic memory is a complex process, involving the interaction of multiple systems, including the medial temporal lobe as well as frontoparietal networks of attention and cognitive control, and midbrain structures subserving fluctuations in arousal and sustained attention. While extant data indicate that attention at the time of retrieval can affect memory performance, less is known about how fluctuations in sustained attention in the moments just prior to a retrieval attempt impact neural mechanisms of memory and performance. Here, we investigated trial-to-trial fluctuations in preparatory sustained attention and the brain networks supporting goal-state processes and episodic retrieval in younger adults (18-30 yrs) as they completed a goal-directed associative memory task. At encoding (not scanned), participants made conceptual (living/non-living) and perceptual (bigger/smaller) judgments on images of everyday objects and animals. At retrieval and concurrent with functional MRI, participants performed one of two source memory tasks (i.e., one of two retrieval goal states), indicating whether they remembered test probes as having been encountered in the perceptual or conceptual encoding task. Associative memory was assayed at the trial-level (i.e., associative hits vs. misses) and at the individual-level using associative memory d'. During fMRI, participants also underwent concurrent pupillometry to assay moment-to-moment tonic fluctuations in preparatory sustained attention. Initial analyses revealed classifier evidence of retrieval goal-state representation correlated to performance on the associative memory task. Furthermore, associative memory performance varied with pupil size (an assay of arousal/sustained attention) in the pre-goal-cue and pre-stimulus periods just prior to attempts to remember. Additionally, participants completed a gradual-onset continuous performance task (i.e., the gradCPT) across two sessions (separated by up to one month) to assay sustained attention. Predicted analyses suggest trait-level sustained attention varies with associative memory *d'*. Together, these results highlight the impact of "readiness-to-remember" preparatory mechanisms on retrieval, further advancing understanding of the mechanisms of memory expression.

Abstract: The ability to attend to relevant event features, and sustain that attention from moment-to-moment, contributes to episodic memory encoding and retrieval. Sustained attention is posited to decline in older adulthood, with individual differences in sustained attention potentially accounting for variability in episodic memory performance. Given that aging is marked by changes in structural connectivity in the brain (e.g., white matter degradation) and some cognitively unimpaired older adults demonstrate an increased presence of amyloid plaques (biomarkers of Alzheimer's disease (AD) pathology), we sought to understand how white matter integrity and amyloid-β burden relate to the ability to sustain attention. Trait-level sustained attention was behaviorally assessed using a gradual-onset continuous performance task (i.e., the gradCPT, FC Fortenbaugh et al 2015) in a large cohort of cognitively unimpaired (CU) older adults (60-90 yrs.) enrolled in the Attention Memory and Aging Study at Stanford (AMASS) and the Stanford Aging and Memory Study (SAMS). We collected structural MRI, diffusion-weighted MRI, and amyloid PET scans. Initial results from a sample of 27 CU older adults suggest that global white matter integrity measured by mean diffusivity (MD) and fractional anisotropy (FA) mediated the relationship between age and trait-level sustained attention (as measured by gradCPT d'). Subsequent analyses focused on structural integrity of the superior longitudinal fasciculus (SLF), a tract posited to support attention, with the integrity of corticospinal tract (CST), serving as a control. Both FA and MD values of the SLF, but not of the CST, significantly mediated the relationship between age and trait-level sustained attention. For further analysis, we plan to include data from the larger cohort, and investigate how amyloid and tau pathology interact with structural connectivity measures and jointly contribute to the observed variability in sustained attention capabilities. Collectively, these data add to the growing understanding of how structural connectivity changes and early-stage AD pathology partially explain trait-level attentional differences in CU older adults.

Abstract: Episodic memory performance varies across cognitively unimpaired (CU) older adults, with multiple potential underlying causes. Possible sources of variance in memory function include changes in structural connectivity in the brain (e.g., white matter degradation) as well as the detrimental effects of early-stage Alzheimer's disease (AD) pathology (e.g., amyloid plaques and neurofibrillary tau tangles). Extant data further suggest that AD pathology correlates with deterioration in white matter integrity, particularly within the medial temporal lobe (Kantarci et al., 2017). Here, we examined the relationships between episodic memory performance, white matter integrity, and early-stage AD pathology (specifically, amyloid-β burden) in CU older adults (60-90 yrs.) enrolled in the Attention Memory and Aging Study at Stanford (AMASS), Stanford Aging and Memory Study (SAMS), and the Stanford Alzheimer's Disease Research Center (ADRC). An episodic memory composite score was computed from delayed recall performance on the (1) logical memory subtest of the Wechsler Memory Scale, (2) Hopkins Verbal Learning Test-Revised, and (3) Brief Visuospatial Memory Test-Revised. Participants underwent 3T amyloid-PET/MR imaging, which included diffusion-weighted imaging to evaluate white matter integrity. Early-stage AD pathology was assessed using amyloid and tau PET scans and cerebrospinal fluid assays. Based on prior literature, we identified the cingulum cingulate gyrus (CGC) and the fornix as tracts that might play a role in

episodic memory performance and the corticospinal tract (CST) as a control (Alm et al., 2022). Initial analyses on a sample of 27 CU older adults revealed that there was a trend-level association between mean diffusivity (MD) in the right CGC and episodic memory performance. Moreover, global DTI white matter integrity metrics (e.g. MD) and amyloid status jointly mediated the relationship between age and episodic memory performance. Collectively, these data suggest that the integrity of structural connectivity, in tandem with AD biomarker pathology, explain variability in episodic memory performance in CU older adults.

Title: Effects of attention, goal representation, and amyloid burden on episodic retrieval in cognitively unimpaired older adults

Authors: *S. T. SCHWARTZ[1,2], D. S. MILLER[1], T. T. TRAN[1,3], J. E. RATHMANN-BLOCH[1], J. PARK[1,3], A. ROMERO[1,3], H. VOSSLER[3], J. SHENG[1,3], H. YANG[1], J. R. WINER[3], E. C. MORMINO[2,3], A. D. WAGNER[1,2];
[1]Psychology, [2]Wu Tsai Neurosciences Inst., [3]Neurol. and Neurolog. Sci., Stanford Univ., Stanford, CA

Abstract: Episodic memory decline is prevalent in aging, yet the severity of age-related memory change is markedly variable across older adults. Differential structural and functional integrity in the medial temporal lobe, frontoparietal networks of attention and cognitive control, and midbrain structures subserving fluctuations in arousal and sustained attention likely partially explain individual differences in episodic memory and executive function in cognitively unimpaired (CU) older adults. The extent to which these changes co-occur with the early (asymptomatic) stage of the Alzheimer's disease (AD) pathophysiological cascade remains unknown. As such, there remains limited understanding of how moment-to-moment and

individual differences in sustained attention and goal-state representation explain variability in memory in CU older adults, and their relations with AD pathology. Here, we investigated age-related functional changes in the neural networks supporting episodic memory, goal-state processes, and trial-to-trial fluctuations in preparatory sustained attention as well as their relationship to amyloid beta (Aβ) biomarker status (assayed through Aβ-PET). CU older adults (65-80 yrs; half Aβ+/Aβ-) and younger adults (18-30 yrs) completed a goal-directed associative memory task. At encoding (not scanned), they made conceptual (living/non-living) and perceptual (bigger/smaller) judgments on images of everyday objects and animals. At retrieval and concurrent with functional MRI, participants performed one of two source memory tasks (i.e., one of two retrieval goal states), indicating whether they remembered test probes as having been encountered in the perceptual or conceptual encoding task. Associative memory was assayed at the trial-level (associative hits vs. misses), and at the individual-level using associative memory *d'*. During fMRI, participants also underwent concurrent pupillometry to assay moment-to-moment tonic fluctuations in preparatory sustained attention. As predicted, associative *d'* was lower and retrieval decision reaction times were slower in older compared to younger adults. Initial analyses revealed age-related differences in frontoparietal cognitive control network activation and classifier evidence of retrieval goal-state representation. Furthermore, associative memory performance varied with pupil size (an assay of arousal/sustained attention) in the pre-goal-cue and pre-stimulus periods just prior to remembering. These initial findings set the stage for understanding age-related changes in an ensemble of neural mechanisms that collectively orchestrate whether and how we remember.

Title: Category-level neural dedifferentiation is associated with memory and CSF biomarkers of Alzheimer's disease in cognitively unimpaired older adults

Authors: *J. SHENG, A. TRELLE, A. ROMERO, J. PARK, E. MORMINO, A. WAGNER; Stanford Univ., Stanford, CA

Abstract: Extensive human neuroimaging evidence indicates that neural responses evoked by stimuli from different visual categories (e.g., faces vs. scenes) are less distinctive in older relative to younger adults, a phenomenon termed *neural dedifferentiation*. While neural dedifferentiation has been consistently reported to relate to poor task performance in older adults, especially in episodic memory, the role of Alzheimer's disease (AD) pathology in neural dedifferentiation and its impacts on memory are poorly understood. In cognitively unimpaired (CU) older adults, two cerebrospinal fluid (CSF) assays -- a decrease in β-amyloid ($A\beta_{42}$; i.e., higher amyloid burden) and increase in phosphorylated tau_{181} ($p\text{-}tau_{181}$) -- are some of the earliest detectable biomarkers of the AD pathophysiological cascade. Here, we examined the relationships between neural selectivity during face vs. scene encoding and $A\beta_{42}/A\beta_{40}$, $p\text{-}tau_{181}$, and memory performance in a large sample of CU older adults (n = 166; 60-88 yrs) enrolled in the Stanford Aging and Memory Study (SAMS), with age, sex, and years of education as covariates. fMRI data were acquired as participants first encoded word-face and word-scene associations and then engaged in an associative retrieval task. Data were preprocessed with fMRIPrep (version 23.0.0) and then submitted to surfaced-based analysis. Category-level neural selectivity was measured by contrasting the amplitude of the blood-oxygen-level-dependent (BOLD) response to encoding trials that included faces vs. scenes, thus revealing a vertex's/region's preferred and non-preferred stimulus categories. Initial analyses examining how selectivity varied with factors of interest revealed that place-selective neural activity in the bilateral superior parietal lobule (SPL) decreased with age. Subsequently, initial examination of the relationships between neural selectivity and CSF (n = 121) $A\beta_{42}/A\beta_{40}$ and $p\text{-}tau_{181}$ revealed that place-selective neural activity in left occipital and left superior parietal cortex showed a significant positive association with CSF $A\beta_{42}/A\beta_{40}$. Finally, place-selective neural activity in the left SPL positively correlated with associative memory performance (i.e., associative *d'*). Taken together, these findings suggest that preclinical $A\beta_{42}$ burden is associated with neural dedifferentiation in CU older adults, pointing to one route through which early AD processes may impact memory performance.

Title: Eye movements are associated with neural differentiation in scene-selective and object-selective cortical regions

Authors: *S. SROKOVA, N. S. SHAHANAWAZ, M. D. RUGG;
The Univ. of Texas at Dallas, Richardson, TX

Abstract: Neural differentiation in cortical regions which are selectively responsive to distinct visual stimulus categories has been shown to have a critical role in episodic memory function. Specifically, neural differentiation during encoding is predictive of subsequent memory performance, and differentiation has also been shown to decline in older age (a phenomenon known as 'age-related neural dedifferentiation'). The neurobiological and behavioral mechanisms underlying the relationship between neural differentiation and episodic memory performance are, however, currently unknown. A wealth of behavioral research highlights the functional significance of eye movements in memory function, but it is yet to be examined whether eye movements and neural differentiation are related. In the present experiment, 24 healthy young adults (males and females, 18 - 30 years old) underwent fMRI with simultaneous eye-tracking as they viewed images of scenes and objects. The relationship between neural differentiation and eye-movements was examined with complementary within- and across-subject approaches, focusing on the scene-selective parahippocampal place area (PPA) and the object-selective lateral occipital complex (LOC). Trial-wise estimates of scene- and object-selectivity were obtained from multivoxel pattern similarity analyses, and linear mixed effects models were employed to determine whether trial-wise variability in neural differentiation covaried with the number and duration of gaze fixations during each trial. In the PPA, more gaze fixations and shorter fixation durations during scene viewing were predictive of greater scene selectivity. A similar, albeit trending only, pattern emerged in the LOC, where object selectivity also covaried positively with gaze fixations and negatively with gaze durations during object viewing. For each participant, we then computed their average number and duration of fixations across all scene and object trials, along with a univariate metric of differentiation. These metrics were then entered into a set of zero-order, across-participant correlations. Analogously to the within-participant analyses, object selectivity in the LOC correlated positively with the number of gaze fixations, and negatively with gaze durations. No across-participant relationships were evident in the PPA. These findings indicate that neural differentiation for scene and object stimuli are systematically associated with eye movements. Thus, the relationship between neural differentiation and memory performance is likely a reflection of the efficiency with which study items are visually sampled at the time of encoding.

(NIMH), Bethesda, MD; [6]Lab. Brain and Cognition, [5]NIH, Bethesda, MD; [7]Johns Hopkins Univ., Johns Hopkins Univ., Baltimore, MD

Abstract: When imagining your living room, your brain's activity patterns are similar to when you last saw it (known as cortical reinstatement), and your eyes tend to move as if you were looking at it (known as gaze reinstatement). Here, we hypothesized that cortical- and gaze reinstatement are deeply interrelated phenomena that jointly reflect the retrieval of memorized events. If so, gaze patterns and brain activity should be event-specific, and gaze-dependent brain activity should overlap between viewing and recall. To test these predictions, we combined eye tracking, spoken-recall recordings, and fMRI data acquired while participants watched and recalled an episode of the BBC show Sherlock. First, language modeling of participants' spoken recall showed that the movie was recalled accurately, and it allowed segmenting the movie into 48 narrative events. Second, gaze patterns and brain activity during movie viewing were indeed event-specific and consistent across participants. Third, by relating the eyeball multi-voxel pattern to brain activity we found substantial overlap in gaze-dependent activity between viewing and recall. Finally, we used a hidden-Markov model to capture the dynamics of gaze patterns during viewing, and found preliminary evidence that these patterns were sequentially reinstated during recall. Taken together, our findings suggest that gaze behavior is intrinsically linked with the process of remembering past events, and that cortical- and gaze reinstatement jointly support the recall of episodic memories.

Title: Direct suppression and thought substitution engage dissociated oscillatory neural mechanisms to achieve active forgetting

Authors: *S. CHEN[1,2,3], Y. WU[1,3], J. LI[1,2,3], H. LUO[1,2,3];
[1]Sch. of psychological and cognitive sciences, [2]IDG/McGovern Inst. for Brain Sci., [3]Beijing Key Lab. of Behavior and Mental Hlth., Peking Univ., Beijing, China

Abstract: Active forgetting is crucial for emotion regulation and psychological well-being. This could be achieved via two strategies: direct suppression (DS) and thought substitution (TS) yet their underlying neural mechanisms remain elusive. Here we recorded electroencephalography (EEG) activities on 49 human subjects while they were instructed to use DS or TS strategies in different trials to inhibit previously memorized word associations. Behavioral results show that both DS and TS strategies efficiently disrupt memories, displaying gradual reductions in intrusive memories and decreased recall performance for both the trained and independent probe word cues. Most importantly, we demonstrate dissociated oscillatory neural mechanisms for DS and TS strategies. First, DS elicits stronger sustained alpha-band (8-11 Hz) activities in the parietal region while TS shows stronger theta-band (3-6 Hz) activities in the frontal region, indicating their respective inhibitory and excitatory characteristics. Second, the decrease of alpha-band power across blocks is accompanied by a similar decline in intrusive memories in the DS condition, suggesting alpha-band inhibition may be required to facilitate forgetting. Third, the theta-band power during TS condition is correlated to individual executive control function measured in independent ANT tasks and could also predict subsequent forgetting. Taken together, we present new evidence for the dissociative neural mechanisms underlying different active forgetting strategies. While the DS strategy employs alpha-band inhibitory modulation to suppress intrusive memories, TS strategy relies heavily on theta-band frontal executive control activities to enable the formation and replacement of new and old memories, respectively.

Title: The neural dynamics of mental time travel in the stream of spontaneous thoughts

Authors: *H. LEE, S. BORN, X. LI, C. J. HONEY, J. CHEN;
Johns Hopkins Univ., Baltimore, MD

Abstract: When our minds wander, we often engage in remembering the past or imagining the future. What cognitive and neural mechanisms initiate and shape such spontaneous mental time travel? To explore this question, we conducted an fMRI experiment in which subjects verbally described any thoughts that entered their stream of consciousness for 10 minutes. Each subject's

speech was manually segmented into individual thought units (mean duration = 11 s) and categorized as episodic recall, future thinking, semantic knowledge, or current experiences. Episodic recall and future thinking on average accounted for 44% of thoughts and exhibited higher activation in the default mode network (DMN), known for its association with mental simulation, compared to current experiences. Mental time travel was not preferentially preceded by any specific thought category, including episodic recall or future thinking itself, more than expected by chance. Instead, mental time travel (e.g. imagining adopting a dog) was preceded by semantically associated thought content (e.g. other thoughts about dogs), irrespective of category. In general, thoughts that were nearby in time were more semantically similar than temporally distant thoughts. Independent observers detected boundaries when consecutive thoughts were semantically dissimilar. These semantic boundaries evoked transient responses across multiple cortical areas in fMRI subjects, generating an established DMN activation pattern associated with major transitions in mental context (Lee & Chen, 2022, eLife). The semantic boundary pattern was not observed during thought category changes or non-boundary periods within individual thoughts. Additionally, we found that individuals with greater functional connectivity between the hippocampus and the medial temporal cortical area in the DMN generated less tightly connected thought networks, indicative of more divergent and varied thinking. Greater functional connectivity between the hippocampus and DMN cortical areas was also associated with personality traits related to exploration and curiosity. Overall, these findings demonstrate that the DMN tracks the dynamics of mental time travel in the stream of spontaneous thoughts, and semantic connections may serve as a major trigger and organizing principle of spontaneous thought in general.

Title: Structured encoding in the orbitofrontal cortex facilitates long-term associative memory

Authors: *C. GONG, X. WAN;
Beijing Normal Univ., Beijing, China

Abstract: Individuals are required to encode substantial amounts of information and events on a daily basis. One effective approach to achieve such demanding tasks is organising large amounts of items into concise structures according to task demands, which can save cognitive resources and facilitate the integration of new information with prior knowledge or schema. The extent to which such structure impacts individuals' long-term memory has not yet been quantitatively measured, and the underlying neural representations remain unclear. In this study, we modified

the delayed colour estimation task to quantitatively measure participants' long-term associative memory performance towards a set of purposely structured stimuli inside the fMRI scanner (N=44). The results showed that both individuals' short-term (tested immediately after encoding) and long-term (tested 24 hours after encoding) memory errors displayed a pattern consistent with the designed stimuli structure. Items that were more likely to be encoded according to structures were also less prone to memory decay compared with items that were less likely to be encoded following structures. Such superiority of memory performance was absent after removing stimuli structure (control group, N=22). The activity in the OFC during encoding can predict the decay of memory performance over 24 hours, with stronger OFC activation linked with less memory decay. Importantly, activities in the OFC during encoding also displayed structural distinctions toward stimuli. More specifically, OFC showed greater differentiation between items within the same category than items from different categories. The observed differentiation in OFC activity during encoding might be a mechanism to facilitate the encoding of highly similar items by providing a foundation for forming distinct memory traces and ultimately helping mitigate systematic categorical interference. The results of the current study confirm the advantages of structural encoding for retaining long-term memory and reveal the role played by the OFC in forming abstract knowledge structures to assist better memory.

Title: The role of prefrontal spatial coding in supporting a contextual association task

Authors: *A. CUMPELIK, J. L. CSICSVARI;
IST Austria, Klosterneuburg, Austria

Abstract: The medial prefrontal cortex (mPFC) has a broad role in decision making, cognitive flexibility, and executive function, as well as consolidation of long-term memories. These distinct functions are reconciled by the mPFC’s role in context-dependent decision making, which requires the evaluation and selection of representations that are relevant for a particular task or goal.
The hippocampus and mPFC interact via direct and indirect pathways. Coordinated activity between these regions occurs both during hippocampal theta and sharp-wave ripples (SWRs) and is correlated with performance during tasks that rely on spatial information for correct decisions. The mPFC has been shown to encode spatial information and mPFC assemblies reactivate during sleep coincidentally with hippocampal SWRs. Moreover, the mPFC has recently been shown to replay temporally organized spatial sequences in well-trained animals during awake immobility while performing a spatial rule-switching task. Our work aims to identify the emergence of

spatial coding and trajectory replay in the mPFC and correlate this with performance in naive animals.
We use 32-tetrode microdrives to record from the hippocampus and mPFC while rats learn to associate a particular food cue with a specific reward location in an 8-arm maze. Two paired cue-reward associations are learned in parallel. To find the reward, the rats must flexibly adapt their behavior based on which cue is presented, i.e. which "context" they find themselves in. During the acquisition of the behavioral data, we observed a sudden jump in performance after 6-7 days of training. This shift may coincide with the emergence or refinement of spatial representations and trajectory replay in the mPFC.
Determining the time course of mPFC spatial representations and trajectory replay during the learning process will provide insight into how behavioral demands may drive the refinement of task-relevant information in the mPFC.

Title: Hippocampal-prefrontal dynamics during a spatial rule-switching task

Authors: *M. DING[1], S. P. JADHAV[2];
[1]Neurosci., Brandeis Univ. Grad. Neurosci. Program, Waltham, MA; [2]Psychology, Brandeis Univ., Waltham, MA

Abstract: The hippocampus (HPC) and medial prefrontal cortex (mPFC) play distinct roles in memory processing, and cooperatively support cognitive functions. Prior research indicates that mPFC neuronal activity corresponds with behavioral strategy switches in rats (Rich and Shapiro, 2009), and such transitions lead to dynamic changes in the hippocampus (Hasz and Redish, 2020). Nevertheless, the initiation of representational changes and the influence of HPC-mPFC interactions on action evaluation and planning, particularly after reward outcomes, remain elusive. Our research aims to explore the evolution of HPC and mPFC representations as animals transition between variations of a spatial working memory task, with a particular emphasis on offline replay activity. We trained animals on a rule-switching W-maze task where the task structure was kept constant, but the identities of trajectories were changed. Simultaneous high-density tetrode recordings were conducted in the rat hippocampal CA1 and mPFC during task execution. We observed a gradual drift in the joint CA1-mPFC population representations over rule switches during active running, mirroring improvements in behavioral performance. Our

ongoing work further investigates the shifts in content of hippocampal replay and coordinated CA1-mPFC replay as animals adjust to changing rules, which could elucidate the complex interplay between these brain regions during spatial memory tasks.

Title: Subiculum and CA1 coordination in rats during learning of a novel complex navigation task

Authors: *J. M. OLSON, C. W. REES, S. P. JADHAV;
Brandeis Univ., Waltham, MA

Abstract: Complex cognitive abilities such as decision-making and spatial navigation are built upon basic cognitive building blocks of memory formation and recall. A working hippocampus is necessary for successful memory encoding and retrieval, and coordination with extrahippocampal regions through rhythmic network patterns such as sharp-wave ripples and theta oscillations play important roles in spatial learning and decision-making. During sharp-wave ripples, hippocampus “replays” memory sequences, reactivating neural activity patterns originally experienced in behavioral timescales into a timescale amenable to Hebbian plasticity.Subiculum (SUB) and CA1 are the two main outputs of the hippocampus. SUB, the less studied of the two, receives strong inputs from CA1 and entorhinal cortex, and its outputs largely mirror CA1. SUB also has outputs to key decision-making brain regions such as prefrontal cortex and nucleus accumbens. Despite the extensive anatomical connectivity, little is known regarding CA1/SUB coordination during memory-guided navigation. We hypothesize that during rhythmic network activity, neurons in SUB and CA1 with overlapping spatial firing fields will be active, jointly “replaying” previous experience and linking categorical SUB representations with CA1 ensembles encoding specific experiences. Here, we recorded dorsal CA1 and SUB single cell activity using *in vivo* electrophysiology while adult male Long-Evans

rats navigated a novel complex environment. Through the use of dynamic barrier locations, we adapted the available paths to rewards over learning. SUB and CA1 ensembles do indeed show coordination during sharp-wave ripples during learning. Differences in field quantities and distribution between SUB and CA1 neurons were observed. Overall, this work adds to a growing body of evidence that SUB and CA1 must be considered together when understanding hippocampal output during navigation.

Title: Hippocampal-prefrontal neural correlates of schema formation during a transitive inference learning

Authors: *B. S. PORTER[1], C. SHI[2], E. KOZLOVA[2], S. P. JADHAV[2];
[1]Biol., [2]Psychology, Brandeis Univ., Waltham, MA

Abstract: Inferential reasoning is the process of animals making novel associations between parts of previously learned information. Memory schema, or relational networks of knowledge, may enable inferential reasoning. While previous studies have indicated that the hippocampus and prefrontal cortex are necessary for both inference and schema formation, the neural mechanisms supporting schema formation for inference are poorly understood. During learning, episodic information may be generalized over experiences and linked by common elements to create schema. We hypothesize that hippocampal sharp-wave ripples (SWRs) may replay past experiences that have common elements with the current experience. Such a mechanism can link distinct experiences together by their shared content and thus create memory schemata. Indeed, SWRs have been shown to be critical for memory consolidation between the hippocampus and cortex. To test our hypothesis, we recorded hippocampal and medial prefrontal neuronal ensembles in adult rats (Long-Evans, male and female, 3-12 months old, N = 5) while they learned a spatial transitive inference task (A>B>C>D>E). We found distinct populations in the hippocampus that represented each item in the transitive inference set. In contrast, prefrontal ensembles were more generalized and reflected the item that should be chosen first regardless of item identity. Furthermore, we identified SWR events that reactivated hippocampal neurons selective to different items together. Overall, these results indicate that SWR-mediated reactivation during learning may aid in forming schema through the retrieval of memories related to the current experience.

Abstract: Functional connectivity between rodent ventral hippocampus (vHPC) and medial prefrontal cortex (mPFC) supports many cognitive functions and is disrupted in the Df(16)$A^{+/-}$ mouse model of the schizophrenia-predisposing 22q11.2 deletion syndrome. Inhibition of vHPC inputs to mPFC or select mPFC interneuron (IN) populations in wildtype mice induces vHPC-mPFC dysconnectivity and cognitive deficits that mimic phenotypes observed in Df(16)$A^{+/-}$ mice. This phenotypic convergence raises three questions: (1) How do vHPC inputs to mPFC interact with mPFC INs *in vivo*? (2) Are these interactions disrupted in Df(16)$A^{+/-}$ mice? and (3) Are these interactions plastic, offering a means to correct circuit dysconnectivity? We characterized *in vivo* activity dynamics and plasticity of discrete mPFC IN population responses to vHPC input stimulation in adult wildtype and Df(16)$A^{+/-}$ mice. We expressed ChrimsonR in vHPC neurons and GCaMP6f in mPFC somatostatin (SST), vasoactive intestinal polypeptide (VIP), or parvalbumin (PV)-expressing INs (n=8-13). We delivered red light pulses to mPFC to excite vHPC inputs and monitored postsynaptic GCaMP6f Ca^{2+} responses using fiber photometry. SST-IN responses to vHPC input stimulation were initially weak in wildtype and Df(16)$A^{+/-}$ mice, but progressively increased with minimal, periodic stimulation over 50 days ($p<0.001$). This potentiation was blunted in Df(16)$A^{+/-}$ mice ($p<0.001$), but partially recovered with additional high-frequency vHPC input stimulation. Conversely, VIP- and PV-IN responses to vHPC input stimulation were initially robust but were rapidly and persistently depressed by repeated high-frequency stimulation in all mice ($p<0.001$). vHPC input stimulation also enhanced and diminished non-evoked, endogenous Ca^{2+} dynamics in SST- and VIP-INs, respectively ($p<0.05$). Ongoing work is characterizing synaptic, neuronal ensemble, and cognitive behavioral impacts of this plasticity. These studies reveal divergent and malleable *in vivo* responses across mPFC IN classes to vHPC input stimulation. Beyond their implications for optogenetic study design and interpretation, these findings demonstrate cell-type-specific

connectivity and plasticity within intact vHPC-mPFC networks that may be used to influence cognition-relevant circuit function and dysfunction.

Title: Keep me(dial PFC) in the loop: Closed-loop optogenetic stimulation on mouse hippocampal-prefrontal communication and spatial working memory performance

Authors: A. NTAMATUNGIRO[1], M. V. MYROSHNYCHENKO[1], A. A. DUIN[1], *D. KUPFERSCHMIDT[1], J. A. GORDON[1,2];
[1]Integrative Neurosci. Section, Natl. Inst. of Neurolog. Disorders and Stroke, Bethesda, MD; [2]Office of the Director, Natl. Inst. of Mental Hlth., Bethesda, MD

Abstract: Spatial working memory (SWM) is the ability to temporarily store and manipulate spatial information about one's environment to guide behavior. In mice, direct projections from ventral hippocampus (vHPC) to medial prefrontal cortex (mPFC) support SWM and vHPC-mPFC oscillatory synchrony. However, the causal contributions of oscillatory synchrony to SWM performance remain unclear. To explore these contributions, we developed a closed-loop optogenetic stimulation paradigm aimed at manipulating endogenous vHPC-mPFC oscillatory synchrony. We injected adult mice with viruses encoding ChR2 (n=8) or GFP (n=5) in bilateral vHPC and implanted them with local field potential (LFP) wires in unilateral mPFC and vHPC, stereotrodes in unilateral mPFC, and optical fibers in bilateral mPFC. We delivered blue light to vHPC terminals in mPFC in a manner governed by the real-time theta frequency-filtered (7±3 Hz), half-wave rectified vHPC LFP at various phase delays relative to ongoing vHPC theta oscillations. Closed-loop illumination delivered near-synchronously ("in-phase") with vHPC theta oscillations enhanced vHPC-mPFC theta coherence in ChR2- but not GFP-expressing mice; synchrony enhancement diminished with increasing phase delays (up to 1.5 theta cycles). In separate mice (n=17 ChR2, n=13 GFP), we tested the effects of our closed-loop paradigm on SWM, hypothesizing that in-phase stimulation will enhance SWM performance and phase-shifted stimulation will impair it. In mice trained on a delayed non-match-to-sample T-maze task with trials of 10- and 60-sec delay lengths, we delivered closed-loop illumination every other trial, either in-phase with vHPC theta oscillations or phase-shifted by 1.5 theta cycles. Closed-loop stimulation (in-phase or phase-shifted) did not impact SWM performance. Unexpectedly,

blue light illumination produced broadband reductions in mPFC power in ChR2 and GFP mice. However, ChR2 mice showed light-induced increases in mPFC theta power relative to GFP mice, particularly when light was delivered in-phase. Furthermore, light-induced changes in vHPC-mPFC theta coherence were phase shift- and delay length-dependent and more pronounced in ChR2 relative to GFP mice. Ongoing work is assessing effects of stimulation on mPFC unit phase-locking to vHPC theta oscillations. Together, our results reveal behavioral state-dependent effects of closed-loop optogenetic stimulation on long-range oscillatory synchrony.

Abstract: Dynamic interactions between the rodent ventral hippocampus (vHPC) and the medial prefrontal cortex (mPFC) support cognitive functions such as spatial working memory and innate spatial avoidance. *Df(16)A*$^{+/-}$ mice that model the schizophrenia-predisposing 22q11.2 microdeletion syndrome show functional dysconnectivity between these structures, disrupted spatial working memory, and reduced avoidance. Furthermore, inactivating vHPC inputs to mPFC and select mPFC interneuron (IN) classes in wildtype mice recapitulates these phenotypes. We have shown that repeated optogenetic stimulation of vHPC inputs to mPFC can persistently reshape *in vivo* functional connectivity between vHPC inputs and mPFC INs in wildtype and *Df(16)A*$^{+/-}$ mice, strengthening and weakening connections with somatostatin (SST) and vasoactive intestinal peptide (VIP)-expressing INs, respectively. How this plasticity influences spatial working memory, spatial avoidance, and task-relevant engagement of mPFC interneurons is unclear. Here we expressed the excitatory opsin ChrimsonR in bilateral vHPC neurons and Ca^{2+} indicator GCaMP6f in SST- or VIP-INs in bilateral mPFC of wildtype and *Df(16)A*$^{+/-}$ mice. Through fibers implanted in bilateral mPFC, we delivered repeated bouts of 40-Hz red light pulses to mPFC to excite vHPC inputs for 12 days over an 18-day period and

monitored postsynaptic Ca^{2+} responses on select days using fiber photometry. We then measured task-relevant Ca^{2+} activity in SST- and VIP-IN populations while mice explored an elevated plus maze (EPM) test of spatial avoidance, and during acquisition and performance of a delayed non-match-to-sample T-maze test of spatial working memory. We found that SST-IN activity increased during the sample and choice phases of the T-maze task, and diminished across the delay phase ($n=7$, $p<0.05$). In contrast, preliminary results suggest that VIP-IN activity diminished during the sample and choice phases, and progressively increased across the delay phase. Ongoing work is assessing the impact of vHPC input optogenetic stimulation and *Df(16)A*$^{+/-}$ deletion on performance and IN population-specific activity in the EPM and T-maze. These data reveal cell type-specific activity patterns during tasks of spatial cognition, and will inform how reshaping vHPC-mPFC microcircuit connectivity influences typical cognitive function and disease-relevant cognitive dysfunction.

Title: Value-dependent reactivation of prefrontal cortical neurons during hippocampal sharp-wave ripples

Authors: *G. YOUN, M. W. JUNG;
KAIST/IBS, 291 Daehak-ro, Yuseong-gu, Daejeon, Korea, Republic of

Abstract: Hippocampal-neocortical interactions during inactive states have been implicated in memory consolidation. To investigate how the hippocampus and prefrontal cortex exchange information during inactive states and how this process is modulated by value, we trained head-fixed mice to navigate in three different virtual environments associated with three different reward probabilities. The mice showed varying running speeds and/or lick rates across the three environments, indicating that they formed spatial context-reward probability associations. Using Neuropixels probes, we simultaneously recorded neural activity from the intermediate CA1 (iCA1) and its monosynaptic target, medial prefrontal cortex (mPFC). Preliminary analysis of neural activity revealed that mPFC neurons preferentially active in the high-value context were more likely to reactivate with hippocampal sharp wave ripples during the subsequent rest period. These results suggest that the hippocampus-mPFC neural system may preferentially process valuable experiences during rest states in order to facilitate the consolidation of valuable events.

Title: Interaction between the intermediate hippocampus and medial prefrontal cortex for optimal goal-finding behavior in a virtual reality environment

Authors: S.-W. JIN, S. PARK, *S.-M. LEE, I. LEE;
Seoul Natl. Univ., Seoul, Korea, Republic of

Abstract: The neural mechanisms of how the hippocampus (HPC) and medial prefrontal cortex (mPFC) work synchronously to achieve flexible decision-making are largely unknown, especially in a goal-directed navigation task. We recorded single units between the intermediate HPC (iHPC) and mPFC while rats (n=6) performed a spatial navigation task in an immersive virtual reality (VR) environment. In our task, the body-restrained rat ran on a spherical treadmill to navigate a circular arena in the VR environment to reach a goal zone where he found a liquid reward (120 trials/day). In a given trial, the rat started from the center of the arena, facing either north or south. There were two potential goal zones: the east reward zone (ERZ) and the west reward zone (WRZ). Rats initially learned to visit only WRZ to receive rewards to criterion (> 75% correct for 2 consecutive days). Then, rats underwent reversal learning as the reward was provided only in ERZ but not WRZ. Once they completed reversal learning, a 24-tetrode hyperdrive was implanted to record from the mPFC and iHPC. After 1 week of recovery, tetrodes were lowered to the target areas while rats were re-trained in the VR environment for 9 days in preparation for the main task. Once they were ready, the main recording sessions began with the same training sequence as in pre-surgical training. Rats naturally developed a stereotyped behavior for efficient navigation in our VR environment by turning clockwise as they searched for the goal location. Therefore, the critical indicator for learning was whether the rat inhibited the temptation of entering the nearest non-reward zone and continued to travel to the farther yet more rewarding zone. Among the single units (n=1002 in iHPC and n=681 in mPFC), some cells both in the iHPC (12%, n=123/1002) and in the mPFC (11%, n=74/681) significantly changed their firing rates in those trials where rats exhibited inhibitory behavior upon facing the nearest non-reward zone compared to those trials where they failed to do so. We also measured the degree of synchronous spiking activities between the cells from the iHPC and mPFC when

rats faced the nearest non-reward zone. The proportion of the neuronal pairs exhibiting significant co-firing was greater in trials where they showed inhibitory behavior in front of the nearest non-reward zone (3.6%, n=113/3168) than in those trials where rats failed to do so (1.7%, n=21/1250) ($p<0.001$; $\chi 2$ test). Our preliminary findings suggest that the synchronous spiking between the iHPC and mPFC at the right moment of behavioral control may serve as the physiological marker to predict the efficiency of goal-directed navigation in space using allocentric visual landmarks.

Abstract: In natural scenarios, different rules apply under different contexts, and a given context might be associated with a specific memory sequence. A change in context often involves adapting a memory sequence. How neural systems store and retrieve the correct elements of each memory sequence depending on context remains poorly understood. Contextual information may be hippocampal dependent if context acts as a memory cue or is integrated into a context-guided memory sequence. The prefrontal cortex may be involved if the memory is stored as a schema or when sequencing rules and contexts change. The present study is adapted from a context-guided sequence learning task originally undertaken in rats (Navawongse & Eichenbaum, 2013) to work with nonhuman primates (Rhesus macaques). The task involved two spatial contexts implemented over touch screen monitors attached to the macaques' home units. The background colours on the screen established the context with which a sequence of visual objects needed to be sequenced in order (Context 1: 'A to B'; Context 2: 'C to D'). Two macaques were tested (1M, 1F) and both performed well on the task (typically > 75% correct overall). Focused transcranial ultrasound stimulation (fTUS) was applied to the hippocampus (HC) or medial

prefrontal cortex (mPFC) during the task, using a protocol known to induce post fTUS ('offline') effects that can last for over an hour. Behavioural testing sessions and fTUS were counter-balanced with sham (no fTUS) conditions, and after fTUS, each animal was returned to their home cage to work on the task for 1-2 hours. In the early stages of learning, for both macaques, stimulation of the anterior HC increased performance (91-94%) compared to sham (86-89%, $p < .001$). In the final phase of testing, context was switched in the middle of the trial and the monkey needed to correctly sequence based on the updated context. During this phase of testing, fTUS specifically to the mPFC resulted in improved performance for both monkeys (sham: 73-75%, increased with mPFC fTUS to 82-85%, $p < .001$). fTUS to the HC, however, was either ineffective (anterior HC) or inconsistent in effect across the two monkeys (posterior HC). In summary, we obtained evidence that both hippocampal and prefrontal perturbation modulates cognitive performance during specific aspects of context-guided sequence learning, remarkably with site-specific and consistent improvement in performance using fTUS.

Title: A modulatory role of the nucleus reuniens in hippocampal-prefrontal communication

Authors: ***S. SHAO**[1], J. FERRERO[1], T. KAWANO[3], D. KHODAGHOLY[2], J. N. GELINAS[1]; [1]Neurol., [2]Electrical Engin., Columbia Univ., New York, NY; [3]Toyohashi Univ. of Technol., Toyohashi, Japan

Abstract: Memory consolidation requires functional synchrony between the hippocampus (HC) and the medial prefrontal cortex (mPFC). The nucleus reuniens (RE) has recently been reported as a structural and functional hub between HC and mPFC. The role of the RE in hippocampal-prefrontal communication during memory consolidation remains unclear. Here, we used *in vivo* electrophysiology to monitor the hippocampal-thalamic-prefrontal network in rats during non-rapid eye movement (NREM) sleep. We identified ripple-like activity in the RE in the 100-180 Hz frequency range with an average duration of 40 ms, and was associated with robust recruitment of thalamic neural spiking. RE ripple activity was phase-locked to both hippocampal sharp wave-ripples (SWR) and mPFC ripples. Hippocampal ripples are known to couple with cortical ripples for facilitating memory consolidation. Although ripples were independently detected in all three structures, we found that coupling between HC and mPFC ripples necessarily involved co-occurring RE ripples. These results suggest a modulatory role for the RE

in oscillatory synchronization between the HC and the mPFC, with potential implications for network mechanisms of memory consolidation.

Title: Enhancing Object-in-Place Memory Performance Through Optogenetic Priming of the Hippocampal-Prefrontal Cortex Network

Authors: *J. BUESCHER, M.-P. CONTRERAS SANTANDER, E. ATUCHA TREVINO, M. SAUVAGE, M. PRIGGE;
Neuromodulatory Networks, Leibniz Inst. for Neurobio., 39118 Magdeburg, Germany

Abstract: The ability to recall the spatial location of objects is crucial for our everyday life. Such memory capability relies on the intricated communication between the hippocampus (HIP) and the medial prefrontal cortex (mPFC) and can be impaired during ageing. Despite impressive progress in understanding the role of HIP-PFC communication in object memory, approaches to enhance and improve its functionality are very limited. Therefore, we set out to explore how optogenetic activation (priming) can facilitate object-location memory. To achieve this aim, mice of the Experimental group (n=11) received a stereotactic injection of a virus with an optogenetic opsin into CA1, while implantation of an optical fiber was placed in the mPFC to stimulate the projecting terminals. *Control* animals underwent the same surgical procedure. First, we sample efficiency of our optogenetic priming protocol by numbers of cFOS and pCreb+ neurons in the PFC. For this purpose, mice received unilateral light stimulation and were perfused one-hour post-stimulation, and compared to the contralateral hemisphere.Secondly, animals were subjected to four object-in-place (OiP) sessions that were repeated every other week. Each OiP session consisted of a study and a test phase separated by an 18-min delay. In the study phase the animals encounter 4 different objects where two of them are switched locations in the test phase. In every session, 4 new objects were introduced. To prime the HIP-to-PFC pathway, the *Experimental* group received stimulation 15-min before starting the study phase in the first OiP. *Control* animals were handled the same way but did not receive any light stimulation. In the fourth OiP task, only *Control* animals received light stimulation. Results showed that priming of one hemisphere induced significantly more pCREB+ neurons relative to the DAPI count in anterior cingulate, prelimbic and infralimbic cortex (independent ttest $p<0.05$). Indicating that priming induced higher excitability in the mPFC. Behaviorally, the *Experimental* group

exhibited a significantly better memory performance in the first OiP compared to the *Controls* (one sided independent t-test $p<0.05$). Interestingly, the higher performance of the *Experimental* group compared to the controls remained until the second OiP task ($p<0.05$), when none of the groups received any stimulation. These results suggest that object location recognition memory relies on the strength of the HIP-mPFC network which can be boosted artificially. Special training or pharmacological interventions boosting this network could have implications to counteract the cognitive decline in ageing.

Title: A maze paradigm to study hippocampal-frontal interactions underlying goal-oriented behavior in humans

Authors: *M. GEVA-SAGIV[1], K. KIM[2], C. LUO[2], J. J. LIN[3,4], R. O'REILLY[2], I. SAEZ[5], C. RANGANATH[2];

Abstract: The hippocampus and its functional interactions with cortical areas are thought to support flexible behaviors, guided by previous experience. Mazes have been used as a classic approach to studying learning and memory in animal models and humans for years, since Tolman's (1948) pioneering studies of maze navigation in rats. They provide a controlled environment to study memory-based behaviors. Many models predict that hippocampal memory-related activities (for example - activities underlying high-frequency ripple oscillations) would be most informative during route planning and navigational decisions. However, the difficulty of recording electrophysiological activity directly from the human brain has limited detailed characterization of hippocampal activities underlying goal-directed behavior in humans to date. Here, we present a novel maze paradigm, implemented as an animated video game, to test brain activity during memory-guided behavior. It was tailored for use in a clinical setting, with patients, implanted with depth iEEG electrodes. To ensure goal-seeking is based on memory, rather than achieved by random exploration, we first assessed behavior with a healthy cohort (n=34 students, 18-51y). Participants used button presses to find goal locations in 24 mazes. Each maze had a unique structural layout and a colorful content theme. Each maze was repeated 3 times, enabling us to examine learning across repetitions. Learning effects were evident, based on improved recall of goal locations across repetitions (comparing accuracy between 1st and 3rd repetition $t(30)=19.66$, $p < 10^{-20}$). Finally, participants successfully recalled the goal position based on the bare maze-structure alone, suggesting they could learn the maze topology separately from content cues. Upon informed consent, patients with pharmacoresistant epilepsy, implanted with intracranial electrodes for clinical monitoring in preparation for a possible surgical cure, participated in recordings while performing the task (8 sessions, 7 patients). Patients' performance was comparable to that of the healthy cohort. Depth electrodes recorded detailed spiking activity, local field potentials, and intracranial EEG (average of 9 electrodes per patient) across multiple brain regions (including medial and frontal cortex regions). Intracranial recordings during this task will be used to characterize hippocampal and prefrontal activity during navigational decisions.

Title: Representational drift in anterior cingulate neuronal ensembles during memory consolidation

Authors: *A. YANG[1], S. WANG[1], F. SU[2], W. LU[1];
[1]Inst. for translational brain research, Fudan Univ., Shanghai, China; [2]Peking Univ., Beijing, China

Abstract: Technological advancements have led to a general observation that cortical neuronal network activities are not stable, but susceptible to transient influence from sensory or behavioral feedback. This phenomenon, termed representational drift, plays a central role in the neocortex's continuous learning and memory-retaining function (Pikiw et al., 2022; Qin et al., 2023). There has been no examination of representational drift in the anterior cingulate cortex (ACC), a region key to long-term memory consolidation and retrieval. This study employs longitudinal in-vivo two-photon imaging after Pavlovian associative memory training to assess the degree of representational drift in the mice ACC. Network activities are evaluated by pairwise neuronal synchronization based on calcium spike time series. Calcium spikes are derived from raw calcium fluorescence traces using a deconvolution algorithm (Juczewski et al., 2020). Results demonstrate ACC representational drift (viewed by coactivity complex network structure) across 4 animals within one day up to 4 weeks post-training. The study corroborates the dynamic features of cortical neuronal ensembles during early memory consolidation and provides sampling frequency guidelines for longitudinal two-photon imaging analyses.

Title: Acquisition of trace fear conditioning in rats without functional nucleus reuniens did not require dorsal hippocampus NMDA receptor activation

Authors: *R.-H. LIU, C.-H. CHANG;
Natl. Tsing Hua Univ., Hsinchu, Taiwan

Abstract: The nucleus reunions (RE) plays an essential role in the cortico-thalamo-cortical circuit that connects the medial prefrontal cortex (mPFC) and the hippocampus (HPC), completing the HPC-dependent circuit that regulates the trace fear conditioning. In this procedure, a neutral conditioned stimulus (CS; tone) and an aversive unconditioned stimulus (US; foot shock) are paired but separated by a “trace” interval. Earlier, we demonstrated that RE inactivation during conditioning impaired the acquisition of trace fear, while RE inactivation during both conditioning and test led to heightened fear to tones throughout the entire test session. These findings prompted us to further investigate whether animals without functional RE acquired trace fear using the HPC-independent circuit. To first confirm the involvement of the dorsal hippocampus (DH) in trace fear acquisition, we pharmacologically blocked glutamate transmission in the DH during the conditioning phase using DL-2-Amino-5-phosphonovaleric acid (APV), an N-methyl-D-aspartic acid (NMDA) antagonist. We hypothesized that for rats without functional RE during both conditioning and test, they used the HPC-independent circuit for acquiring fear, and therefore would be insensitive to the DH manipulation. Our results showed that for the RE intact animals and compared to DH saline controls, DH NMDA blockade led to a slower increase in freezing levels during conditioning, suggesting that the within-session fear expression was impaired. Moreover, these RE intact animals displayed a significantly attenuated freezing response to the tone during the early retrieval test compared to DH saline controls, suggesting that the acquisition of trace fear in normal rats relied on DH NMDA receptor activation. On the other hand, for the rats without functional RE during both the conditioning and test, these animals showed equivalent fear expression in comparison to RE intact/DH saline controls, but were insensitive to the DH blockade of NMDA activities. Together, our results revealed that animals without functional RE acquired trace fear through the HPC-independent circuit.

Title: Top-down control of memory integration in the hippocampus

Authors: *A. F. DE SOUSA[1], A. LUCHETTI[4], S. SIMANIAN[2], D. ALMEIDA-FILHO[3], A. SILVA[2];
[1]Neurobio., UCLA, Los Angeles, CA; [2]UCLA, Los angeles, CA; [3]UCLA, Los Angeles, CA; [4]Neurobio., The Hosp. For Sick Children, Toronto, ON, Canada

Abstract: New learning can be affected by previous memories, shaping the way novel information is encoded and organized. Related memories are thought to be integrated during encoding and/or post-learning sleep via increases in the number of overlapping ensembles representing each experience. Interactions between the prefrontal cortex (PFC) and the hippocampus (HPC) are important for memory integration where the prefrontal cortex is thought to bias or inhibit memory reactivation in the HPC. However, it is currently not known how such top-down modulation is able to affect specific memories being integrated. Here we use a memory integration/linking paradigm in mice to investigate how the medial PFC is able to control the integration of similar memories encoded several days apart. We first observed that PFC activity increases during encoding of a second memory. Preventing this increase, using chemogenetics, led to memory integration and an increase in the number of overlapping memory ensembles in the dorsal CA1 but not in CA3 or DG. Whole brain analysis of cfos expression indicated that this process might be mediated via the medial entorhinal cortex (MEC). Accordingly, inhibition of PFC-MEC, but not PFC-HPC projections, was sufficient to promote memory integration. These results suggest the existence of a top-down, interregional mechanism that controls memory integration and allocation in the dCA1 via modulation of MEC activity during learning.

Title: Long Range Projections from Lateral Entorhinal Cortex into Hippocampal area CA1 in Episodic Memory Modulation

Authors: *M. HERNANDEZ FRAUSTO[1,2], J. BASU[3];
[1]Neurosci. and Physiol., New York Univ., New York, NY; [2]Neurosci. and Physiol., NYU Langone Med. Center, NYU Grossman Sch. of Med., New York City, NY; [3]Dept. of Neurosci. and Physiol., NYU Langone Med. Center, NYU Grossman Sch. of Med., New York, NY

Abstract: Interaction between entorhinal cortex (EC) and hippocampus CA1 area (HC-CA1) promotes sequential organization that lead to the formation of episodic memories of people, places, objects, and events. Within the EC, the medial part (MEC) acts as a spatial information detector that conveys position in space, and the lateral subdivision (LEC) functions as a contextual non-spatial sensor that conveys contextual features of the environment, related to objects, novelty, and odor. The LEC sends excitatory and inhibitory projections directly to HC-CA1 that bears in a microcircuit connectivity capable to induce dendritic spiking, however we know little about the functional role of this projections in episodic memory modulation. To address the functionality of the connectivity between LEC to HC-CA1. First, with chemogenetic strategies and fiber photometry recordings in freely moving mice, I assessed the functionality of the excitatory and inhibitory projections from LEC into HC-CA1 in episodic learning freely moving behaviors. Our results suggests that the network connectivity between LEC and HC-CA1 have a differential role during encode and recall phases of episodic learning that depends of the excitatory and inhibitory network connectivity.

Title: The Role of Excitatory and Inhibitory Inputs From Lateral Entorhinal Cortex to CA3 in Learning and Memory

Authors: *C. D. JOHNSON[1], V. ROBERT[2], J. BASU[3];
[1]NYU Grossman Sch. of Med., New York, NY; [2]New York Univ. Langone Med. Ctr., New York Univ. Langone Med. Ctr., New York, NY; [3]Neurosci. Institute, New York Univ. Sch., Neurosci. Institute, New York Univ. Sch., New York, NY

Abstract: The interactions between the entorhinal cortex (EC) and hippocampus are crucial for learning and memory. Within the hippocampus, area CA3 plays an important role in episodic memory formation and recall via its ability to form and reactivate ensembles of neurons. The

circuit and cellular mechanisms that functionally drive these dynamic neural representations within CA3 and govern its role in memory encoding and recall remains unknown. Distal dendrites of CA3 pyramidal neurons (PNs) directly receive local non-spatial or contextual information from the lateral entorhinal cortex (LEC). LEC has been shown to regulate activity in hippocampal area CA1 via long-range excitatory and inhibitory projections (Melzer et al., 2012; Basu et al., 2016). However, there is a gap in functionally defining the role these cortical inputs play in hippocampal area CA3. To address this, we examined the role of LEC glutamatergic and GABAergic projections to area CA3 in episodic memory formation and recall using chemogenetic manipulations of CA3-projecting LEC neurons during freely moving behavior. We used viral tracing techniques to isolate the excitatory and inhibitory projections found in CA3 originating from LEC. To evaluate the role of LEC glutamatergic (excitatory) and GABAergic (inhibitory) projections in learning and memory, we subjected wild-type mice to contextual (novel object recognition, NOR) and spatial (Barnes Maze) tasks perturbing the activity of LEC during learning. We found that silencing either excitatory or excitatory & inhibitory projections from LEC to CA3 impaired NOR memory, consistent with previous reports (Van Cauter et al., 2013). In contrast, performance in the Barnes maze was unaffected by LEC inputs silencing. We further explored their underlying spatial navigation by rotating external cues to introduce mismatch between the proximal and distal reference frames. We observed that control mice relied more on an egocentric strategy for navigation than those that had LEC inputs silenced. This is in line with LEC neurons coding for egocentric relation to salient landmarks of the environment (Wang et al., 2018). Our results show that both excitatory and inhibitory projections from LEC to CA3 contribute to hippocampal-dependent learning and memory.

Abstract: To extract behaviorally relevant information from our surroundings, our brains constantly integrate and compare incoming sensory information with those stored as memories. Cortico-hippocampal interactions could mediate such interplay between sensory processing and memory recall but this remains to be demonstrated. Recent work parsing entorhinal cortex-to-hippocampus circuitry show its role in episodic memory formation and spatial navigation. However, the organization and function of the hippocampus-to-cortex back-projection circuit remains uncharted. We combined circuit mapping, physiology and behavior with optogenetic manipulations, and computational modeling to reveal how hippocampal feedback modulates cortical sensory activity and behavioral output. Here we show a new direct hippocampal projection to entorhinal cortex layer 2/3, the very layer that projects multisensory input to the hippocampus. Our finding challenges the canonical cortico-hippocampal circuit model where hippocampal feedback only reaches entorhinal cortex layer 2/3 indirectly via layer 5. This direct hippocampal input integrates with cortical sensory inputs in layer 2/3 neurons to drive their plasticity and spike output, and provides an important novelty signal during behavior for coding objects and their locations. Through the sensory-memory feedback loop, hippocampus can update real-time cortical sensory processing, efficiently and iteratively, thereby imparting the salient context for adaptive learned behaviors with new experiences.

Title: Long-range GABAergic projections allow fine control of hippocampal area CA3 function by lateral entorhinal cortex

Authors: *V. ROBERT[1], K. O'NEIL[1], C. JOHNSON[1], R. DE LA TORRE[2], S. RASHID[1], J. BASU[1];

[1]New York Univ. Langone Med. Ctr., New York, NY; [2]Waisman Center, Univ. of Wisconsin-Madison, Madison, WI

Abstract: Functional interactions between the entorhinal cortex and the hippocampus are crucial for learning and memory. By integrating context-laden direct inputs from the lateral entorhinal cortex (LEC) with local feedforward dentate gyrus (DG) and feedback CA3 recurrent collateral (RC) inputs, area CA3 is poised to gate hippocampal information flow and mnemonic function. Interestingly, LEC inputs to the hippocampus comprise not only glutamatergic but also the long-range GABAergic projections which regulate dendritic excitability, synaptic plasticity and oscillatory activity in area CA1 (Melzer et al., 2012; Basu et al., 2016). However, the role of LEC glutamatergic and GABAergic inputs to area CA3 and the underlying circuit elements remain unexplored. Therefore, we manipulated LEC glutamatergic and GABAergic inputs with chemogenetics and optogenetics to examine their contributions to area CA3 function using freely moving behavior, head-fixed in vivo 2-photon imaging, and ex vivo patch-clamp electrophysiology. Silencing LEC glutamatergic inputs alone or together with LEC GABAergic inputs similarly impaired novel object recognition memory, suggesting complementary rather than opposing roles of these inputs. Silencing LEC glutamatergic inputs alone, but not together with LEC GABAergic inputs, increased the fraction of active CA3 pyramidal neuron somas and dendrites but decreased activity within each active cell, suggesting recruitment of direct excitation and feedforward inhibition. Indeed, LEC glutamatergic inputs evoked monosynaptic excitation in CA3 pyramidal neurons, as well as disynaptic inhibition which prevented somatic output. Expectably, LEC glutamatergic inputs drove spiking in CA3 SLM interneurons including putative soma-targeting subtypes, whereas LEC GABAergic inputs shunted their excitability. Further, LEC GABAergic inputs selectively boosted CA3 pyramidal neuron somatic output to combined stimulation of LEC glutamatergic and CA3 RC inputs. Accordingly, silencing LEC glutamatergic inputs alone, but not together with LEC GABAergic inputs, decreased novelty-induced remapping of CA3 place cell somas and dendrites. Altogether, our results uncover novel elements of the LEC to CA3 circuit supporting contextually-driven CA3 activity and mnemonic function through compartment- and pathway-specific disinhibition.

Title: Remapping properties of apical and basal dendrites in CA3 of navigating mice

Authors: *J. J. MOORE[1,2], D. CHKLOVSKII[2], J. BASU[1];
[1]NYU Sch. of Med., New York, NY; [2]Flatiron Inst., Simons Fndn., New York, NY

Abstract: Neurons maintain large dendritic arbors supporting non-linear input integration which can greatly boost their computational power. Input to hippocampal neurons arrives in a stratified manner onto different dendritic compartments, resulting in the remarkable property of spatial coding within an environment. Equally remarkable is neurons' ability to "re-map" or change their firing rate or location in a new environment. This happens rapidly, often within the first exposure to a new environment. Recent work suggests new place fields are formed after dendritic plateau potentials, but the dynamics of novel place field formation within dendrites and soma simultaneously has not been well characterized.
To address this issue, we used two-photon microscopy to measure calcium activity in the apical dendrites, soma, and basal dendrites of pyramidal neurons in area CA3 of mouse hippocampus during head-fixed navigation on a treadmill belt. Local textures on the belt served as spatial cues to define position. After repeated exposure to a familiar environment, the cues were switched to a novel environment to induce remapping. Regions of interest were identified and calcium signals were extracted using semi-automated methods developed by our lab. By tracking the tuning properties of soma and dendrites over several days in familiar and novel environments, we demonstrate that dendrites support flexible and stable representations of space. Specifically, apical dendrites showed higher day-to-day stability than soma or basal dendrites, and consequently provided more information to decode animal position. These are the first demonstrations of tuning, stability, and remapping in distal apical dendrites in CA3 during navigation.

Title: Stability and flexibility of hippocampal CA1 in an odor-cued navigational task

Authors: *M. HOPKINS[1], R. ZEMLA[2], J. BASU[3];
[1]New York Univ., New York City, NY; [2]Neurosci. Inst., New York Univ. Sch. of Med., New York, NY; [3]Dept. of Neurosci. and Physiol., Neurosci. Institute, New York Univ. Sch., New York, NY

Abstract: Place cells, hippocampal pyramidal neurons which show location-specific activity during animal navigation, form a spatial map of the environment and are hypothesized to be the neural substrate of episodic memory. However, place cells in low demand tasks, such as random foraging, tend to drift in their spatial tuning over days. Through chronic 2-photon calcium imaging of hippocampal area CA1, we find that the introduction of an odor-context based navigational task stabilizes place cell representations over long time scales, but that these ensembles remain flexible when task contingencies change. This supports the belief that CA1 can encode representations both stably and dynamically. We also explore mouse models that have impaired performance on this task and their underlying neural dysfunction. This work is currently ongoing.

Title: Anatomical and functional heterogeneity of the basolateral amygdala to ventral hippocampus circuit

Authors: *M. LI[1], Y. JIANG[1], M. C. LU[1], J. KINNEY[2], Q. SUN[1];
[1]Case Western Reserve Univ., Cleveland, OH; [2]Case Western Reserve Univ. Dept. of Neurosciences, Cleveland, OH

Abstract: The ventral hippocampus, including ventral CA1 (vCA1) and ventral CA3 (vCA3), plays an important role in social and anxiety-like behaviors. However, how the upstream brain regions innervate different sub-regions of the ventral hippocampus to participate in such behaviors properly is still incompletely understood. Although plenty of literature as well as our retrograde tracing data provided evidence that the basolateral amygdala (BLA), a region that is essential for emotion processing, projects to both vCA1 and vCA3, the detailed anatomical and functional connectivity pattern remains largely unknown. Here we performed Channelrhodopsin2 (ChR2)-based anterograde tracing and found that BLA fibers predominantly innervated basal dendrites of CA1a/b and CA3a/b in mid-ventral hippocampus, and were nearly devoid of CA1c and CA3c. Remarkably, our ChR2-assisted ex vivo patch clamp recording

revealed that BLA-CA3 synapses displayed robust temporal summation of postsynaptic potentials (PSPs) in responses to 20Hz light simulation (PSP10/PSP1 = 4.87 ± 0.67), whereas BLA-CA1 synapses did not display the facilitation (PSP10/PSP1 = 0.82 ± 0.15). To further explore whether different groups of BLA neurons innervate vCA1 and vCA3 and are responsible for the synaptic differences, we did retrograde AAV tracing in CA1 and CA3 and demonstrated that CA3-projecting BLA neurons were primarily clustered in BLA adjacent to the midline, while CA1-projecting BLA neurons were uniformly distributed in the whole BLA. By selectively targeting CA3-projecting or CA1-projecting BLA neurons using ChR2, we found that only a subset of CA1-projecting BLA neurons projected to CA3 (dual-projecting BLA neurons). Finally, our preliminary behavioral results showed that ChR2-mediated activation of BLA-CA3 projection impaired social behaviors, but had no effect on anxiety-like behaviors. Given that the previous studies showed that BLA-ventral hippocampus projection participates in both social and anxiety-like behaviors, our experiments are underway to examine the role of the subset of BLA neurons that project to CA1 only. Overall, our results provide the anatomical and functional evidence supporting the heterogeneity of BLA-ventral hippocampal connectivity, and raise the possibility that two populations of BLA neurons projecting to hippocampus differently may participate in different behaviors.

Title: Hippocampal CA3 synaptic mechanism for dorsoventral divergence in memory

Authors: M. LI, Y.-Q. JIANG, M. C. LU, ***Q. SUN**;
Case Western Reserve Univ., Cleveland, OH

Abstract: Area CA3 in the hippocampus is vital for memory formation. CA3 pyramidal neurons (PNs) receive two prominent excitatory inputs - recurrent collateral (RC) from CA3 and mossy fiber (MF) from dentate gyrus (DG) - that play opposing roles in pattern completion (memory generalization) and separation (memory discrimination), respectively. Although the dorsoventral divergence of hippocampal function has been well studied, the dorsoventral difference of CA3 synaptic connectivity remains largely unknown. Here, we report that the ratio of RC-to-MF excitatory drive onto CA3 PNs increases dramatically from dorsal CA3 (dCA3) to ventral CA3 (vCA3) by nearly 8-folds, with vCA3 PNs receiving significantly weaker MF, but stronger RC,

excitation than dCA3 PNs. In addition, we found that the weaker MF excitation in vCA3 results from a combination of the weaker unitary MF input and a smaller number MF synaptic number, compared to dCA3. The dorsal-ventral difference in RC excitation can be largely explained by the greater lengths of basal and apical dendrites in vCA3 than dCA3. Finally, using a contextual fear memory discrimination paradigm, we demonstrated that, compared to dCA3, vCA3 plays a more prominent role in recall and generalization of remote memory. Thus, our results reveal a novel CA3-based synaptic mechanism that may offer the computational advantage for ventral hippocampus to be more strongly involved in behaviors that require less precision but more generalization, such as remote memory.

Title: Top-down control of subcortical regions by hippocampal long-range inhibition

Authors: *J. KINNEY, M. ZHOU, D. LEE, H. WANG, M. LI, Y. JIANG, Q. SUN;
Case Western Reserve Univ. Dept. of Neurosciences, Cleveland, OH

Abstract: Inhibitory neurons are classically divided based on differences in neurochemical, morphological, and electrophysiological features and are considered *short-range* projecting neurons that suppress the activity of surrounding local neurons. Recent evidence, however, indicates that a variety of inhibitory neurons, including somatostatin-expressing (SOM+) and parvalbumin-expressing (PV+) inhibitory neurons, can send *long-range* projections to distant brain regions to coordinate brain-wide activity and contribute to behavioral tasks. We focus on area CA3 in the hippocampus, which is essential for *intra-hippocampal* information processing: linking dentate gyrus to CA1 via classic trisynaptic excitatory pathway (entorhinal cortex-->dentate gyrus-->CA3-->CA1). In comparison, little is known about the direct inhibitory connections between CA3 and *extra-hippocampal* regions. Intriguingly, here, we used cell-type and pathway-specific viral tracing to demonstrate that CA3 SOM+, but not PV+, inhibitory neurons send long-range projections to three subcortical regions: medial septum (MS), lateral hypothalamus (LH), and supramammillary nucleus (SuM). Our retrograde AAV (AAVretro)-based intersectional viral tracing indicates that the same CA3 SOM+ inhibitory neurons likely send axon collaterals to all three regions. Furthermore, our ex vivo patch-clamp recordings assisted by channelrhodopsin-2 (ChR2) demonstrated that the long-range inhibition preferentially suppresses fast-spiking (presumptive GABAergic) neurons in SuM and LH, and

preferentially suppress fast-spiking (presumptive GABAergic) and cluster firing (presumptive glutamatergic) neurons in MS. Thus, a key role of this long-range inhibitory output is to disinhibit these three subcortical regions. Moreover, we found optical stimulation of ChR2-expressing SOM+ terminals at theta frequencies are capable of entraining theta firing of the postsynaptic neurons in target subcortical regions. We propose that this long-range inhibitory projection is ideally positioned to coordinate and synchronize activity between the hippocampus and multiple subcortical regions simultaneously. We are currently using in vivo optogenetic manipulations in conjunction with behavioral assays to investigate the role of these novel long-range inhibitory neurons in behaviors.

Abstract: In recent years, research on computational brain models has rapidly increased, leading to large-scale implementations of brain circuits at single-cell resolution that have been proven to be instrumental for a better understanding of brain functions. The use of these models can become a disruptive technology, to significantly advance not only our understanding of the mechanisms underlying cognitive functions but also to investigate pathological conditions and discover new pharmacological treatments. Here, we describe a full-scale model of a human right hippocampus CA1 region at cellular resolution [Gandolfi et al., 2023]. Starting from high resolution microscopy images, 3D soma positioning was obtained through an image analysis

algorithm and a connectivity matrix was generated using a morpho-anatomical connection strategy [Gandolfi et al., 2022] based on axonal and dendritic probability density functions accounting for morphological properties of hippocampal neurons. The workflow, in a ready-to-use format suited to implement simulations at different scales and details, and the software to create additional network instantiations, or to generalize the process for other brain regions, are available as open access tools on the EBRAINS Knowledge Graph Platform (https://kg.ebrains.eu/). Preliminary results obtained with this model gave insight into the processes and mechanisms that can modulate and orchestrate the propagation of activity within a CA1 network. We show how the anisotropic connectivity emerging from the data-driven model building process, can generate a network global activity that can be significantly different from what expected by the widely assumed spatially uniform connectivity rule in most large-scale models.

Title: Dynamic Reconfiguration of Hippocampal CA1 Pyramidal Cell-Interneuron Circuits during Spatial Learning

Authors: *D. SUN[1,2,3], R. UNNITHAN[3], C. FRENCH[2];
[2]Neural Dynamics Laboratory, Dept. of Med., [3]Dept. of Electrical and Electronic Engin., [1]The Univ. of Melbourne, Melbourne, Australia

Abstract: The formation of memory-encoding neuronal ensembles in the hippocampus is thought to be facilitated by changes in functional connections between pyramidal cells and interneurons. However, how hippocampal neural circuits reconfigure during the learning process not clear. Here, we employed in vivo calcium imaging techniques to study the activity of large hippocampal neuronal populations to elucidate this issue.To label neurons, a combination of adeno-associated viruses carrying GCaMP6 (driven by the synapsin promoter) and ChR2 (driven by the mDlx promoter) was injected into the hippocampal CA1 region in C57BL/6 mice. The synapsin promoter enables broad expression in various neuronal populations, including

pyramidal cells and interneurons. In contrast, the mDlx promoter selectively expresses in GABAergic interneurons. This dual-virus approach allows for the labelling of calcium activity in all neurons using GCaMP6, while utilizing a different fluorophore to specifically highlight the spatial footprints of interneurons. The mice (n=5) were trained to traverse a linear track, while the hippocampal calcium activity was simultaneously recorded using a miniaturized fluorescence microscope.We observed an increase in spatial sensitivity in both pyramidal cells and interneurons when the experiment proceeded, with pyramidal cells demonstrating a more robust representation. Pyramidal cells showed lower firing rates (p=0.003) and plasticity (p=0.024), but higher information content (p=0.012) on average compared to interneurons. Neuronal populations were partitioned into distinct clusters using modularity analysis. We found that pyramidal cells exhibited broader interconnectivity within their respective clusters, which underwent reconfiguration over time. In contrast, interneurons displayed stable connectivity patterns within their assigned clusters. In summary, this study advances our understanding of the neural dynamics of hippocampal pyramidal cells and interneurons during the learning process. Our findings reveal that the reconfiguration of topological connections among neuronal populations plays an important role in the formation of new memories.

Title: Influence of environment size on CA1 spatial representations

Authors: *I. R. JAKHALEKAR[1], S. S. DESHMUKH[3,2];
[1]IISc Mathematics Initiative, [2]Ctr. for Neurosci., Indian Inst. of Sci., Bengaluru, India; [3]Dept. of Life Sci., Shiv Nadar Inst. of Eminence, Gautam Buddh Nagar, India

Abstract: Traditionally, rodent neural correlates of space have been studied in arenas of 1-2 sq.m. area. However, in the wild, rats have networks of burrows that run up to a few tens of meters. Apart from two recent studies, the spatial representations in spaces similar in size to rats' natural environments have not been studied. We recorded single-unit activity from dorsal CA1 in rats foraging in arenas of varying sizes and shapes ranging from 1 sq. m. to 16.5 sq. m. We observed that the number of place fields per cell increases as we go from the smallest to the largest arena while the fraction of the arena that a cell had place fields in decreases. This implies that as the area of the arena increases cells encode a smaller fraction of the arena and thus have higher spatial selectivity, but the firing is in the form of multiple distinct place fields. Our results suggest that CA1 employs an ensemble coding strategy to represent large environments.

Title: Non-theta and non-spatially modulated inputs shape phase precession dynamics in place cells

Authors: *A. BISHNOI[1], S. S. DESHMUKH[2,1];
[1]Ctr. for Neurosci., Indian Inst. of Sci., Bangalore, Karnataka, India; [2]Dept. of Life Sci., Shiv Nadar Inst. of Eminence, Gautam Buddh Nagar, Uttar Pradesh, India

Abstract: Spiking activity of place cells is modulated by the spatial location of the animal and ongoing theta oscillations. Phase precessing place cells maintain a temporal code of space by firing at earlier and earlier phases of theta as the animal traverses through the neuron's place field. CA1 place cells exhibit accelerating phase precession that is banana-shaped on an average. However, individual place cells can also exhibit linear precession dynamics with a constant rate of change of phase with position. Models based on the interaction of spatial excitation and theta inhibition can successfully generate phase precession (Castro & Aguiar, 2012; Seenivasan & Narayanan, 2020; Jaramillo et al., 2014), but the simulated dynamics are typically decelerating i.e., the rate of change of phase slows down towards the end of the place field. Such decelerating phase precession has not been reported in the rat CA1, to the best of our knowledge. In this study, we asked if non-theta non-spatially (NTNS) modulated inputs can contribute to theta-modulated spiking dynamics and generate more biologically realistic phase precession. We tested this possibility by adding presynaptic Poisson noise to the inputs in a previously published model of theta phase precession (Chadwick et al., 2016). Strength of the three input sources to the model - spatially modulated input, theta oscillations, and NTNS excitation - were varied systematically, along with the asymmetry of spatial input. A total of 13328 combinations of input parameters were tested, out of which 3712 combinations generated phase locking. Phase precession was observed for 969 combinations which included both decelerating phase precession (n = 254) as seen in existing models and more biologically realistic linear (n = 556) or accelerating phase precession (n = 159). Increasing the strength of NTNS inputs reduced the tendency of the model to generate decelerating precession and generated linear or accelerating precession. Increasing the asymmetry of spatial input along with the strength of NTNS inputs increased the propensity of the simulated phase precessing neurons to accelerate. We estimated the influence of different inputs and their interactions on the shape of precession and found that

NTNS inputs contributed to biologically realistic phase precession in conjunction with spatial input amplitude. Finally, a subset of combinations (n = 259) also showed theta skipping behavior observed in CA1, CA3 and MEC, in the presence of NTNS inputs. Thus, our simple computational model can simulate a range of biologically observed theta modulation dynamics and demonstrates the relevance of NTNS inputs to these phenomena.

Title: Hippocampal replay events are less temporally compressed during correct trials in rats performing a spatial delayed match-to-sample task

Authors: *M. DONAHUE, L. L. COLGIN;
Univ. of Texas at Austin, Austin, TX

Abstract: The hippocampus is thought to support spatial memory via the activity of place cells, neurons with spatial receptive fields. During periods of waking rest, populations of place cells reactivate sequences of firing that occurred during earlier active behaviors, a phenomenon known as “replay”. Here, we examined replay events during rest periods from a previously published dataset (Zheng et al., Nature Communications 2021) in which rats learned a reward location on a circle track across trials of a delayed match-to-sample task. We used a Bayesian decoding algorithm to estimate angular positions on the track represented by CA1 place cell sequences during replay events. Previous research has shown that the properties of replay events are dynamic and can vary depending on environmental novelty and memory engagement (Fernandez-Ruiz et al., Science 2019; Berners-Lee et al., Neuron 2022). Further, increasing replay event durations improves memory task performance (Fernandez-Ruiz et al., Science 2019). Here, we show that replay events are longer in duration during correct trials compared to incorrect trials of a delayed match-to-sample task. We additionally show that the temporal compression of replayed paths was lower on correct trials than error trials. The rate of replay events did not differ between correct and incorrect trials. These results provide further evidence that replay properties are related to learning and suggest that changes in the temporal compression of replay may facilitate memory-guided task performance.

Title: Ca2 place cells that respond to social odors are preferentially reactivated during sharp-wave ripples in subsequent rest

Authors: *E. ROBSON, M. M. DONAHUE, P. G. DEMETROVICH, L. L. COLGIN;
Univ. of Texas at Austin, Austin, TX

Abstract: The CA2 region of the hippocampus has been implicated in social memory. A recent study showed that CA2 place cell firing patterns change ("remap") during social interactions, a response that is not apparent in CA1 place cells (Alexander et al., Nature Communications 2016). Our preliminary results show that CA2 place cells remapped after a rat interacted with a familiar rat's empty home-cage containing the familiar rat's odors. On the contrary, CA2 place cells did not remap in response to interactions with an identical cage containing the rat but with clean bedding (i.e., minimal social odors). These results suggest that CA2 place cells respond to the olfactory component of social experiences. Much prior work has shown that place cell firing patterns from active exploration are reactivated in sharp-wave ripples (SWRs) during subsequent rest periods. This reactivation of place cells during SWRs is thought to contribute to memory consolidation. We recorded SWRs in CA2 during rest periods following exploration of a cage containing social odors or a cage containing a rat but minimal social odors. We found that CA2 place cells that responded to social odors preferentially increased their firing rates during subsequent SWRs more than CA2 place cells that were less responsive to social odors. In contrast, similar results were not obtained for CA2 place cells that were active during sessions with minimal social odors. These results suggest that SWR-related reactivation of CA2 place cells that code social odors may play a role in consolidation of salient aspects of social memories.

Title: Learning a Goal-Oriented Task Shapes the Evolution of Spatial Representation in Rat Hippocampal CA1

Authors: *E. FAILLACE[1,2], R. MITCHELL-HEGGS[1,3,2], F. GOBBO[3], J. GALLEGO[1,2], R. MORRIS[3], S. R. SCHULTZ[1,2];
[1]Bioengineering, [2]Ctr. for Neurotechnology, Imperial Col. London, London, United Kingdom; [3]Lab. for Cognitive Neuroscience, Edinburgh Neurosci., The Univ. of Edinburgh, Edinburgh, United Kingdom

Abstract: Studying spatial representation in the hippocampus is crucial for understanding spatial navigation and memory formation. Recent works have indicated that animal behaviour can have a functional effect on spatial representation. For instance, reward locations can be over-represented compared to other locations. Here, we aim to determine how learning a goal-orientated task affects the evolution of spatial representation of the task environment. In this work, we trained 5 rats in the "everyday memory task" over 21 days. Each session is composed of an exploration, sampling, and recall phase. After the initial exploration phase, we hid a food pellet in one of three sandwells, which location was learnt during the sampling phase. The rewarded well remained consistent throughout the session and was randomly repositioned for the subsequent day. GCaMP6f was expressed in CA1 pyramidal neurons. Miniscope calcium imaging recordings were performed at three learning stages representing different levels of task experience: naive (S1-2), intermediate (S8-9), and advanced (S18-21) and registered across sessions. We found that throughout the sessions, the animals significantly improved their performance, indicating an increased ability to recall the reward location. We investigated the impact of this learning on the spatial representation within the overall structural properties of the network and the dimensionality of neural dynamics. Furthermore, we characterised the spatial representation of the arena by examining changes in place cell features (e.g., field size, location, and variance) as task familiarity increased. We tracked these changes in rewarded locations versus other constant salient cues, such as the start-box and two objects at the side of the arena. This study develops our understanding of the mechanisms underlying spatial representation, specifically how individual place cells contribute to network dynamics during learning of goal-directed behaviours.

Title: Comparison of Spatial Action Planning for Egocentric and Allocentric Spatial Strategies in Rats performing an Episodic Memory task with Miniscope Ca^{2+}imaging

Authors: *F. GOBBO[1], R. MITCHELL-HEGGS[1,2], D. TSE[1,3], N. GARCIA-FONT[1,4], S. S. SCHULTZ[2], R. G. M. MORRIS[1,4];

Abstract: *Aim*: A key question in spatial navigation is if, and how, hippocampal replay encodes a memory of previously visited space or a spatial action plan that informs decision-making. Furthermore, the use of different navigational strategies may change the role of hippocampal replay. This study uses endoscopic calcium imaging in the rat hippocampus to compare the neuronal representation of space and decision making in animals learning and retrieving different reward destinations in an episodic memory task using egocentric or allocentric navigational strategies.
Experiment: 10 WT male LH Rats performed variants of the everyday memory task designed to rely on egocentric or allocentric strategies (Broadbent et al Eur.J.Neurosc 2019). Neuronal activity was recorded from CA1 neurons expressing GCaMP6f with miniature microscopes using the Inscopix system (195 cells/animal, SEM 50.7). Rats learned to retrieve food during sample trials from one of six possible sandwells whose position changed every session and were tested for recall 60 min after learning. When recalling, animals entered the arena from four possible start locations, generating distinct origin-goal trajectory combinations. 27 training sessions were performed to ensure coherent, asymptotic performance, and tests conducted to confirm that animals were using an egocentric or allocentric strategy. Consecutive sessions were recorded using Ca^{2+} imaging for each strategy (sessions 28-34). First, we compared the neural representation of the arena space between the two strategies in terms of active place cell population, neural directionality and place field symmetry. We then confirmed reactivation of neurons representing destinations, and asked if the replayed content involves the goal or the trajectory. Furthermore, we compared the reactivation along the recalled trajectory with different and egocentrically similar -but allocentrically distinct- trajectories.
Implications: In both strategies we observed prospective replay encoding the animal's future trajectory, reward destination, and alternative possibilities. Our data provides new information on whether the prospective replay involves memory replay or action planning and hints at how these may differ between egocentric and allocentric navigational strategies.

Abstract: Even in familiar environments, discrete events/rewards happen that are the content of recency (or episodic) memory. Goal-oriented tasks offer an opportunity to understand how space is represented, and how this is stored and accessed during memory retrieval and planning. Spatial tasks can be solved using egocentric or allocentric coordinates (Packard & McGaugh, *Neurobiol.Learn.Mem.*1996). Using the everyday arena task paradigm (Bast et al,*J.Neurosci* 2005), we showed that hippocampal neural activity recorded before animals navigate reflects their intended destination or trajectory (Gobbo et al,*PNAS,2022*).
Here, we sought to dissociate the role of the hippocampus in allocentric vs. egocentric represention using behavioral and optogenetic techniques. Rats (n=10) were trained daily to find reward hidden in sandwells whose location changed daily, either with an allocentric protocol in which the reward was approached from different starting points in the same session, or with an egocentric protocol starting from a single start location. Learning occurred well in both protocols as shown in probe tests. Test sessions confirmed that removing extraarena cues caused performance to drop to chance for allocentric (56%) but not egocentric animals (96%). To test the requirement for hippocampal activity in the two tasks, we expressed the inhibitory opsin Jaws, or GFP in control animals (n=30). We confirmed the successful suppression of neuronal activity in a separate group of animals by means of electrophysiology. Hippocampal silencing during action planning caused a mild but significant drop in performance in allocentric but not egocentric animals. Silencing the hippocampus during the execution of the task further impaired the performance of allocentric animals. Animals performing the egocentric protocol, and controls, were unaffected by light stimulation.
Our data indicate that hippocampal activity during goal-directed navigation is required to form an action plan when allocentric representations are used, but not when navigation is based on egocentric representations. The performance of egocentric animals is likely mediated by neural activity that does not involve or need the hippocampus.

Title: Impaired spatial representation Dentate Gyrus in 5×FAD mice

Authors: *S. HAN, L. KOU, P. YUAN;
Inst. for Translational Brain Res., Fudan Univ., Shanghai, China

Abstract: One of the symptoms of Alzheimer's disease (AD) is impaired spatial memory. Ample evidence from previous research identified that a substrate for spatial memory can be the location-specific neuronal activities (place cells) in hippocampus. Place cells have been identified in subregions of hippocampus, including CA1 (Cornu Ammonis), CA3 and DG (Dentate Gyrus). A unique property of DG places cells is a stable spatial representation of the same place over days, whereas CA1 places cells dynamically remap on daily basis, suggesting that DG place cells could encode the stable components of spatial memory. However, DG place cells have not been studied in AD before and whether their impairment contribute to spatial memory dysfunction remains poorly understood. In this study, we performed single-cell calcium imaging of the granule cells in DG using a miniaturized microscope, while the mice ran through a linear track with water rewards at both ends. We imaged 5xFAD mice at the adult (6 mo) stage, as well as their age-matched litter-mate wild types. We found that 5xFAD mice showed impaired spatial representation in DG, including diminished number of place cells ($p = 0.048$) and a lower degree of spatial information ($p < 0.0001$). In addition, DG place cells in 5xFAD mice showed an increased probability of having multiple place fields. Importantly, we found that DG place cells in 5xFAD mice were less stable, as measured by inter-trial correlation of the neuronal activities. Furthermore, we developed a place cell emergence model using mutual inhibition among DG cells receiving inputs representing different spatial frequencies, and found that increased synchronized activities could result in the appearance of the specific abnormalities we observed in 5xFAD mice *in vivo*. Consistent with the model prediction, we observed more pronounced synchronized activity in 5xFAD mice. And eliminating correlated activity using a diagonal decoder increased the performance of predicting the animal's location using DG place cells in 5xFAD mice, indicating a detrimental effect of the synchronized activities for spatial representation. In conclusion, our results described a specific abnormality in the spatial representation of DG place cells in 5xFAD mice, and suggested that plaque-associated hyperactivities might give rise to this phenomenon.

Title: Impaired spatial encoding in transgenic A53T mice model of α-synucleinopathies

Authors: *M. AMIRI[1], D. SUN[2], C. FRENCH[1];
[1]Med., [2]Electrical and Electronic Engin., The Univ. of Melbourne, Melbourne, Australia

Abstract: A key feature of hippocampal CA1 neurons is their ability to spatially tune their dynamics within the boundaries of the observable environment. Considerable studies showed Alzheimer's disease pathology (amyloid-β and tau) negatively affect spatial encoding and memory. However, very little is known about the functional effect of intraneuronal α-synuclein inclusions pathology on neural activity underlie spatial encoding in α-synucleinopathies such as Parkinson's disease and Lewy body dementia. Here, we examined the neural calcium activity of hippocampal place cells in A53T mice expressing the A53T mutant form of human alpha-synuclein and compared the results to those detected in non-transgenic wild-type (WT) littermates (n = 6 in each group).To visualise neural activity in the hippocampus, we labelled pyramidal neurons in CA1 with GCaMP6f adeno-associated virus, and a gradient refractive index (GRIN) lens was implanted to relay the signal. We recorded calcium activity from CA1 place cells using head-mounted miniaturized fluorescent microscope "miniscope", while mice ran back and forth along a linear track environment. We then evaluated the neural dynamics of CA1 place cells, calcium event rate and amplitude (ΔF/F), along with spatial tuning properties. This study is the first (to our knowledge) in vivo calcium imaging from hippocampal neural population in an α-synucleinopathies mice model. Here we report that, A53T model displayed disturbed neural calcium homeostasis as indicated by a significant increase in the calcium event amplitude (0.05926 ± 0.002948 dF/F; mean ± SEM; $p < 0.0001$; KS-test) and calcium event rate activity (0.1982 ± 0.003168 Hz; $p<0.0001$; KS-test) compared to WT littermate (0.04199 ± 0.001549 dF/F, 0.1568± 0.003246Hz). Furthermore, CA1 place cells in A53T mice were less spatially tuned, contain less spatial information, and had a sparser and less stable place field map than those in WT animals. Specifically, the stability of place field map was degraded progressively across three consecutive days exploring in a familiar environment in A53T mice, while it was remained more stable in WT genotype. Overall, our findings suggest that pathological accumulation of α-synuclein leads to significant hippocampal functional deficits in terms of intrinsic neuronal network activity related to spatial coding. These impairments are plausibly attributed to calcium dysregulation, which is a result of the loss of synaptic output capabilities associated with α-synuclein accumulation.

Title: Active experience, not time, determines within day representational drift in dorsal CA1

Authors: D. KHATIB[1], A. RATZON[1], M. SELLEVOLL[1], O. BARAK[1], G. MORRIS[2], ***D. DERDIKMAN**[1];

Abstract: Memories of past events can be recalled long after the event, indicating stability. But new experiences are also integrated into existing memories, indicating plasticity. In the hippocampus, spatial representations are known to remain stable, but have also been shown to drift over long periods of time. We hypothesized that experience, more than the passage of time, is the driving force behind representational drift. We compared the within-day stability of place cells' representations in dorsal CA1 (dCA1) of the hippocampus of mice traversing two similar, familiar tracks for different durations. We found that the more time the animals spent actively traversing the environment, the greater the representational drift, regardless of the total elapsed time between visits. Our results suggest that spatial representation is a dynamic process, related to the ongoing experiences within a specific context, and is related to memory update rather than to passive forgetting.

Title: The influence of sensory experience and behavior on the representational drift in the hippocampus of mice

Authors: *J. Y. OH, J. R. CLIMER, H. DAVOUDI, D. A. DOMBECK;
Dept. of Neurobio., Northwestern Univ., Evanston, IL

Abstract: Representational drift has been shown in many brain regions, including place cell ensembles in the primary output structure of the mouse hippocampus, CA1. The slow changes over days in the representation of space observed in this region have been proposed to play a role in distinguishing experiences over time and continual learning. However, it is also possible that representational drift occurs as a result of changes in behavior or the sensory environment that have not been accounted for in previous measurements due to the difficulty in measuring and/or controlling sensory modalities such as odors. To address these possibilities, we trained mice extensively for stereotyped behavior and also designed a multisensory virtual reality system that is capable of precisely and stably controlling the animal's visual and olfactory environment across weeks. Using longitudinal two-photon imaging of CA1 place cells in mice, we first observed representational drift in a highly familiar visual-only environment without odor control. This drift was similar in magnitude and time course to the drift observed in experiments in real environments. We are now repeating these experiments while controlling the odor landscape to determine whether this leads to a reduction in the magnitude of drift. Our preliminary results suggest that representational drift is still present in this highly controlled multisensory environment, though possibly to a lesser degree than without odor control. These findings suggest that while CA1 representational drift may largely come from internally generated processes, variability in the sensory environment may also contribute and should be considered in future experiments.

Title: Spatial memory in individual and populations of neurons of the non-human primate hippocampus

Authors: *H. TAN[1], J. Y. X. CHENG[2], T. P. Y. NG[1], C. OWENS[1], C. LIBEDINSKY[1,3], S.-C. YEN[1,4];

Abstract: The non-human primate (NHP) hippocampus is known to encode location and heading, among other spatial variables. These are signalled exclusively, as well as in combination with each other, in single hippocampal neurons. With regards to location, neurons that signal occupied location (place cells), as well as viewed location (view cells), singly or jointly, have been found in some studies that did not control for the correlated sampling of the two variables. However, correlation of place and view is a common artefact arising from linear track environments or stereotyped movement patterns. Additionally, given that the visual field is highly dependent on the direction that the head is facing, head direction is also strongly correlated with viewed location. To resolve these dependencies, we sought to: 1) quantify mixed selectivity to place, view, and head direction; 2) assess the independence of spatial variables encoded by mixed selective cells, and their main and interaction effects; and 3) investigate how the signal from a population of neurons may support goal-directed navigation.
Among a preliminary sample of 32 hippocampal neurons analysed, 2 were mixed-selective to place, view, and head direction. Using a maximum likelihood approach to find the independent contributions of each variable, the cells retained mixed selectivity for all 3 variables. By conditioning the rate map of a second variable on the firing fields of a first variable, we found examples of non-linear conjunctive selectivity. Activity in the conditioned rate map within the firing field of the second variable exceeded the 95th percentile drawn from a pseudopopulation of locations of matching size outside the firing field. While cells selective to spatial variables were fewer than non-selective cells, they may not be the only contributors to accurate navigation. Decoding of population activity in a subset of 13 cells, including the 2 which were mixed-selective, showed that information gain on the goal identity was higher during the period of cue presentation, compared to during active navigation. This was true even of cells that did not show spatial selectivity.

Title: Three dimensional place cells in the marmoset hippocampus and frontal cortex

Authors: *C. WEI, J. XI, C. LIU, C. XU;
Inst. of Neurosci., Shanghai, China

Abstract: One-dimensional or two-dimensional spatial modulated cells have been thoroughly examined in over various brain areas such as hippocampus, yet, three-dimensional place cells remain less unclear. Recent studies in bat and rat hippocampus[1-2] have found the 3D place cells, which were modulated by the environment and locomotion. We addressed this question in freely moving marmosets by wirelessly recording single-unit activities of the hippocampus and frontal cortex, up to 256 channels simultaneously. Place cells detected in both areas uniformly represent and cover the entire space, while being influenced by experience and conjunctively encoding with other spatial information: locomotion speed and head direction. These results demonstrate that both the hippocampus and frontal cortex process the volumetric spatial information while marmosets are continuously moving in 3D space. *Reference:[1] Yartsev, M. Title: Encoding 2D space with extrinsic and intrinsic theta sequences: A hippocampus model

Authors: *Y. YIU[1,3], C. LEIBOLD[1,2];
[1]Fac. of Biol. & Bernstein Ctr. Freiburg, [2]BrainLinks-BrainTools, Albert-Ludwigs-Universität Freiburg, Freiburg, Germany; [3]Grad. Sch. of Systemic Neurosciences, Ludwig-Maximilians-Universität München, Munich, Germany

Abstract: Recollection of past events relies on our ability to recall a sequence of memories. It is believed that the hippocampus supports the representation of memory sequences, as evidenced by the observation that the sequential firing of place cells at the theta timescale (6-12Hz) can encode the behavioral sequence of traversing multiple locations, known as the theta sequence. However, in a 2D space, an 1D location-sequence can assume any arbitrary shape, raising questions about how the sequences of spatial memories can be propagated by a 2D topology of place cells. We therefore theorize that theta sequences propagate along two types of 1D manifolds in a 2D space. One is the online running trajectory driven by the external sensorimotor drive of animal movement, while the other is the associative location-sequence driven by intrinsic network connectivity, inspired by the rich recurrent connectivity in the hippocampal formation.

In this study, we simulated a spiking neural network consisting of two layers of place cells in a 2D space: cornus ammonis 3 (CA3) and dentate gyrus (DG). The sequences representing the running trajectory can be extrinsically coordinated by sensorimotor drive of the animal's movement via short-term depression mechanism. This mechanism temporarily reduces the recurrent input into the place cells behind the animal, thereby propagating the spike sequences forward in the direction of travel. On top of the extrinsic sequences, intrinsically driven sequences are generated by recurrent connectivity between CA3 and DG with fixed synaptic strengths. These sequences follow the direction of the DG-CA3 projections, and thus, are independent of the running trajectory. The two-layer structure allows for simultaneous propagation of both extrinsic and intrinsic sequences. The former encodes the running trajectory, while for the latter, we demonstrated that intrinsic sequences could function as stable landmarks of neural activity for spatial memory. The spike correlations of the intrinsic sequences remain unchanged regardless of running directions, enabling reliable decoding of spatial locations based on spike timing patterns. The inclusion of intrinsic sequences thus expands the dimensions of spatial encoding, which would otherwise be limited to running trajectory alone. Furthermore, our simulation results align with the properties of the experimentally observed theta sequences in terms of directionality of spike phases and correlations. Our model offers a mechanistic explanation for how 2D space can be encoded by 1D sequences and sheds light on how intrinsic hippocampal circuits represent spatial memory.

Title: Explaining the variability of artificial place field induction in a naturalistic model of hippocampal place field formation

Authors: *S. T. JONES[1], F. SAVELLI[2];
[1]Neuroscience, Developmental and Regenerative Biol., [2]Dept. of Neuroscience, Developmental and Regenerative Biol., Univ. of Texas at San Antonio, San Antonio, TX

Abstract: Entorhinal grid cells have been implicated in generating hippocampal place fields. Theoretically, place fields can be formed if synaptic plasticity, gated by postsynaptic activation, strengthens co-active grid inputs and heterosynaptically weakens silent ones (Savelli & Knierim, J Neurophy 2010). Artificial place fields can indeed be induced in experimentally controlled locations following transient postsynaptic activation of hippocampal cells via juxtacellular or optogenetic stimulation (Diamantaki et al Curr Bio 2016, Cell Rep 2018, McKenzie et al Neuron 2021). We asked if naturally occurring and artificially induced place fields can be explained by the same model. We simulated 100 place cells during a previously recorded 20 min foraging

session of a rat in a 76 cm-diameter cylinder. The juxtacellular stimulation protocol was transiently applied to all cells mid-session. We excluded 24 cells that spontaneously showed high levels of pre-stimulation activity in the locations where the animal dwelled during the stimulation. We then spatially correlated these locations with the post-stimulation rate maps of the remaining 76 cells. The resulting correlation distribution was bimodal, with the high-correlation mode representing 26 cells that remapped their place fields near the stimulated locations, and the low-correlation mode representing cells that remapped elsewhere or did not remap. To further assess the net effect of the stimulation, we repeated the identical simulation without applying the stimulation protocol. We then correlated post-stimulation rate maps from the stimulated vs. unstimulated simulation. The resulting correlation distribution was also bimodal: half of the cells showed low correlation, indicating divergence between the stimulated and unstimulated simulations, whereas the other half showed higher correlation, indicating negligible divergence. To evaluate the persistence of the changes induced by the stimulation, we repeated this analysis using a later post-stimulation epoch. We found that 10 out of 38 low-correlation cells moved to the high-correlation group. Hence stimulation had a temporary effect on some of the remapping cells. Our model explains the artificial induction of place fields and its variable success in multiple experimental studies. Successful creation of a place field might depend on sufficient coverage of the stimulated locations by a combination of spatial inputs that can be strengthened to maintain the place field. If grid inputs vary from cell to cell, the same location could be viable for creating a place field in some cells but not in others.

Title: Investigating the Functional Significance of Spatial Representations in Navigation and Extinction Learning

Authors: *B. GHAZINOURI[1], M. MOHAGHEGHI NEJAD[2], S. CHENG[1];
[1]Inst. for Neural Computation, Ruhr Univ. Bochum, Bochum, Germany; [2]Ruhr-University Bochum, Bochum, Germany

Abstract: Spatial navigation is crucial for the survival of animals. While there is substantial knowledge about neural representations of space, such as place cells (PC) and boundary cells (BC) in the hippocampus, their functional role in spatial navigation and learning has received limited attention. To address this open issue, we used closed-loop simulations of a spatial navigation task and extended a computational modeling toolchain for spiking neural networks.

The simulated task resembled the Morris watermaze, where an artificial agent had to find a hidden goal in an open-field environment. The model network consisted of PCs covering the environment, and BC representing the edges. The spiking activity of these cells was modeled as an inhomogeneous Poisson process and each PC or BC has its own firing field. This input was fed to 40 action selection neurons that each represents one direction of movement, distributed homogeneously across 360°. Therefore, the agent was able to move freely in any direction. If the agent enters the goal zone, learning is reinforced by potentiation of feedforward weights in a symmetric STDP learning rule with eligibility trace. As a result, the agent learned the path to the reward, i.e., it found the reward faster in later trials. (Ghazinouri et al. 2023). To differentiate between learning the most efficient path and the layout of the environment, we devised more complex tasks, including changing the starting point, moving the target (extinction learning), and implementing a T-Maze within an open field. In these tasks, we observed a nonmonotonic relationship between performance and a newly introduced variable called the overlap index. This index measures the overlap between neighboring place cells and reflects both place cell number and field size. In contrast, the Fisher information, which describes the informativeness of the place cell population about spatial location, best accounted for navigation performance in our model. We demonstrated that a symmetrical STDP learning rule performed better for simple tasks, while an asymmetrical learning rule was more effective for more sophisticated schemes. We conclude that efficiently encoding spatial information is crucial for navigation performance, as evidenced by the study's findings. Additionally, the research highlights the significance of synaptic depression in extinction learning. By investigating the effects of different learning rules and complex task variations, this study contributes to our understanding of how animals navigate their environment and adapt their behavior in response to changing circumstances.

Title: Gain modulation of place tuning by vasoactive intestinal peptide-expressing inhibitory neurons

Authors: *N. LENKEY, A. C. GARVERT, M. NEUBRANDT, K. VERVAEKE;
Univ. of Oslo, Oslo, Norway

Abstract: Inhibitory neurons control how principal neurons (PNs) integrate excitatory synaptic inputs into output firing rates. By controlling distinct subcellular domains, inhibition enables PNs

to perform various input-output computations. Gain modulation (multiplicative/divisive modulation) is among these fundamental cortical computations enabling PNs to adapt to different sensory input strengths and maintaining input tuning selectivity. While in sensory cortices, inhibitory neurons that express vasoactive intestinal peptide (VIP) control the gain of visual and auditory responses by disinhibiting PN dendrites (1, 2), the role of VIP cells in modulating spatial tuning remains unexplored. To address this, we studied the modulation of place tuning by VIP cells in area CA1 of the hippocampus and in the retrosplenial cortex (RSC), a major hippocampal target, where place-tuned neurons have recently been discovered (3).We used two-photon microscopy and Ca2+ indicators in head-restrained mice performing a goal-oriented spatial task, where mice run on a linear track enriched by tactile cues. First, we recorded the activity of VIP cells in RSC using VIP-Cre transgenic mice and Cre-dependent GCamp6s virus. Our results show that locomotion either activates or inhibits VIP cells, confirming previous work in the hippocampus and other brain areas. Next, to test how VIP cells affect place tuning of PNs, we crossed VIP-Cre mice with Thy1-GCaMP6s mice and used optogenetics utilizing red-shifted opsins (Cre-dependent ChrimsonR and ArchT virus) to up- or downregulate VIP cell activity while simultaneously imaging the activity of PNs. In RSC, we found a robust modulation of place tuning. Optogenetic activation of VIP cells strongly increases place cell responses. In contrast, inhibition of VIP cells decreases place cell responses without altering spatial selectivity, suggesting a disinhibitory role for VIP cells in this cortical circuit. Further analysis of the tuning curves confirms that VIP cells exert a largely multiplicative/divisive gain modulation on PN activity. Finally, we used Bayesian decoding models to show that spatial information significantly decreases when VIP cells are inhibited and increases when VIP cells are activated in RSC. Ongoing experiments explore whether VIP cells play a similar role in the hippocampus. Altogether, these data demonstrate the ubiquitous role of VIP cells in controlling gain in cortical circuits and highlight a key contribution to spatial coding in the cortex.

Title: Regulation of Place Cell Formation and Stability by OLM Inhibitory Interneurons in the Hippocampus

Authors: *M. UDAKIS, H. WEI ZHU, J. R. MELLOR;
Bristol Univ., Bristol, United Kingdom

Abstract: The hippocampus plays a crucial role in the processing of spatial information, underpinned by the formation of place cells that encode representations of space. The formation of place cells in the CA1 region depends on the synaptic plasticity of excitatory inputs from CA3, triggered by their coincident activity with entorhinal cortex layer III inputs via the temporoammonic (TA) pathway, leading to sustained dendritic depolarisations in the form of plateau potentials. However, the regulatory mechanisms underlying this plasticity process and its impact on place cells' stability is unclear. OLM interneurons selectively target distal dendritic regions where TA inputs are received, and their inhibitory synapses have been shown to undergo synaptic plasticity. Thus, we propose that OLM inhibitory interneurons by modulation of the impact of TA pathway inputs at both short and long timescales may play a role in regulating place cell formation and stability. To test this hypothesis, we employ a combination of in vitro and in vivo techniques, including optogenetics, to manipulate OLM interneuron activity and investigate their role in these processes. Using whole-cell patch clamp in mouse brain slices, we demonstrate that coincident activation of CA3 and TA inputs induces long-term potentiation (LTP) in CA3 but not in TA inputs, mimicking the plasticity observed during place cell formation. We find that OLM interneuron activation during plasticity induction inhibits CA3 LTP. Additional findings suggest this effect is mediated by OLM interneurons reducing dendritic non-linearities generated by stimulation of the TA pathway. To assess the impact of OLM activity on place cell stability, we utilise in vivo calcium imaging in mice to record CA1 place cell and OLM interneuron activity in familiar and novel environments. Miniscope experiments reveal that place cell representations remain stable across multiple sessions within a familiar environment but with a significant and well characterised drift, while global remapping occurs when exposed to novel environments. OLM interneuron activity was highly correlated with mouse velocity during exploration. To investigate the involvement of OLM interneurons in place cell remapping, we selectively activate these interneurons using optogenetics during environment exposures. We find enhancing OLM interneuron activity at specific regions of a familiar environment suppresses the expression of place cells without inducing remapping. Ongoing experiments aim to examine whether OLM interneuron activity is differentially regulated by exposure to novel environments and the impact this has on place cell remapping.

Title: A Dual-input Firing Rate Model for CA1 Place Cell Phase Precession and Theta Sequences

Authors: Y. LU[1], A. FERNANDEZ-RUIZ[2], *J. RINZEL[3];
[1]Courant Inst. of Mathematical Sci., New York Univ., New York, NY; [2]Neurobio. and Behavior, Cornell Univ., Ithaca, NY; [3]New York Univ. Ctr. for Neural Sci., New York, NY

Abstract: Hippocampal place cells, that fire when an animal enters a specific location in the environment, are believed to be crucial for spatial memory and navigation. During locomotion, hippocampal network dynamics are dominated by the theta rhythm. Place cell firing exhibits phase precession - its firing shifts to earlier phases of theta oscillation as an animal traverse the place field of that cell. Despite numerous theories attempting to explain the generation of phase precession, the underlying mechanism remains elusive. In this study, we investigate a dual-input model (Fernández-Ruiz et al, 2017) as a potential mechanism for CA1 place cell phase precession; it argues that the interplay of the strength and phases of location/time-dependent inputs from CA3 and entorhinal (mEC) areas accounts for the phase advance of spikes in CA1 place cells with respect to the theta rhythm. We applied a mean-field firing rate model to implement this idea. Our model considers an ensemble of CA1 place cells with identical place fields. We model the mean-membrane potentials in three compartments - soma, proximal dendrites and distal dendrites, the firing rate at soma and the mean synaptic output over the cells. With increasing CA3 input innervating the proximal dendrites and decreasing mEC input innervating the distal dendrites, the place cell firing rate in our simulation shows a phase precession in a range consistent with experimental observations. Moreover, we demonstrated that the rate coding predominantly relies on CA3 inputs (Zutshi et al, 2022). Additionally, we studied the role of local inhibition in CA1 and reproduce the alteration of rate and phase shifts observed with optogenetic silencing of CA1 PV+ cells (Royer et al, 2022). Our computational model provides supporting evidence for the dual-input hypothesis. Further, we extended the dual-input model to account for theta sequence generation: place-specific cell ensembles represent spatial trajectories in a compressed manner within a single theta cycle. With the extended model, we replicated phase precession of the one-ensemble model and incorporated a unique place field for each ensemble. We propose a potential mechanism for theta sequence generation by coordinating these place cell ensembles with local inhibition in CA1.

Title: Changes in ionic driving force at excitatory and inhibitory synapses in hippocampal place fields are counterbalanced by NMDARs.

Authors: *S. GRITZ[1], S. SENTHILKUMAR[1], A. D. MILSTEIN[2];
[1]Ctr. for Advanced Biotech. and Med., Rutgers Univ. Grad. Program In Neurosci., Piscataway,

NJ; [2]Ctr. for Advanced Biotech. and Med., Rutgers Univ. Dept. of Neurosci. and Cell Biol., Piscataway, NJ

Abstract: Place cells in hippocampal area CA1 exhibit spatially selective firing during spatial navigation. Underlying the increase in firing is a ~10 mV subthreshold membrane potential depolarization that in large part reflects an increase in the strength of excitatory synapses active within a cell's place field. Evidence suggests this increase in excitation arises during learning via long-term potentiation of AMPAR-mediated synaptic currents. However, as a place cell depolarizes, AMPARs lose ionic driving force as they approach their equilibrium potential (0 mV), while inhibitory GABARs increase driving force with increasing distance from their equilibrium potential (-70 mV). This predicts that even if AMPAR conductance increases in-field, and GABAR conductance stays equal at positions out-of-field and in-field, GABAR currents will increase in-field, while AMPAR currents will be blunted. However, recent in vivo experiments showed that optogenetic depolarization of place cells does not change the ratio of excitation to inhibition within a place field (Valero et al., Science, 2022). In that study, a simple model indicated that in order to explain the experimental data, synaptic inhibitory conductance would have to decrease dramatically from out-of-field positions to in-field. However, this model did not account for the presence of voltage-dependent NMDAR-type glutamate receptors at excitatory synapses in CA1 place cells. Here we examine the effects of NMDARs on the ratio of excitation to inhibition in hippocampal place cells and discuss its implications for the role of spatially biased synaptic inhibition in place field expression.

Title: Efficient sampling of nearby space by entorhinal-hippocampal sweeps

Authors: *R. J. GARDNER, A. VOLLAN, M.-B. MOSER, E. MOSER;
Kavli Inst. For Systems Neurosci., Trondheim, Norway

Abstract: Networks of entorhinal grid cells and hippocampal place cells generate anticipatory "sweep" trajectories during alert states, once per theta cycle (Vollan et al., same session). Each

sweep consists of a sequence of network activity representing an outgoing path, originating from the animal's present location and terminating in nearby space. The functional role of sweeps and their relationship to the external sensory environment have not been determined, however.
We used Neuropixels probes to record large-scale neural population activity in medial entorhinal cortex and hippocampus in freely moving rats. We then applied a latent-variable model (Wu et al. 2017) to the neural activity to infer the trajectories of sweeps. Like earlier studies (Johnson and Redish 2007, Kay et al., 2020), we found that sweeps alternately pointed to the animal's left and right side. However, while sweeps were formerly interpreted as expressions of navigational trajectories, we found that sweeps commonly point to unnavigable locations, outside opaque walls of an open-field arena and beyond edges of elevated running tracks. As well as spanning such unvisited locations in familiar environments, sweeps extended into unfamiliar space, raising questions about the function of sweeps during the first moments of exploration in a novel environment.
We hypothesized that sweeps, instead of representing possible behavioral paths, might serve to efficiently scan the entire environment. We therefore measured how quickly sweeps covered the binned 2D environment, and we compared this with the coverage rate of simulated sweep angles determined by various rules. We found that empirical sweeps covered space faster than all simulated strategies.
A biologically plausible strategy for maximizing environmental coverage is to maximize sampling of nearby space on a short time scale. We therefore asked what pattern of sampling directions would be chosen by an ideal agent tasked with sampling nearby space with optimal efficiency. Remarkably, the simulated agent chose alternating directions which closely resembled empirical sweep angles. Furthermore, in both the empirical data and in the simulation, the consistency of alternation was positively correlated with locomotion speed.
In conclusion, we find that sweep directions are suggestive of a neural algorithm for efficiently sampling nearby space.

Title: Ultraslow periodic sequences of neural activity in the medial entorhinal cortex

Authors: *S. GONZALO COGNO[1], A. LAUTRUP[1], H. A. OBENHAUS[1], R. I. JACOBSEN[1], S. ANDERSSON[2], C. CLOPATH[3], F. DONATO[4], M.-B. MOSER[1], E. I. MOSER[1];

Abstract: Brain function emerges from the dynamic coordination of interconnected neurons, often in the form of neuronal oscillations. While such oscillations are mostly studied at subsecond time scales, we reported previously[1,2] that neurons in medial entorhinal cortex (MEC) can organize their activity into minute-scale oscillations that manifest as periodic sequences of activity across neurons in the population. These ultraslow periodic sequences, recorded with calcium indicators while mice ran in darkness under a benchtop two-photon microscope, entrained nearly the entire entorhinal cell population and transcended epochs of locomotion and immobility. It remained to be determined, however, whether the periodic sequences took the form of travelling waves, mirroring properties of rhythms at subsecond time scales. Moreover, the functional role of the ultraslow periodic sequences was not established, and it remained an open question whether the sequences were expressed in spiking activity or if, instead, they reflected some unknown dynamics unique to calcium imaging. Here we show that the periodic sequences do not share features of traveling waves, with the activity of participating cells not moving smoothly across anatomical space. By creating a simple model, we further illustrate the potential role of the periodic sequences in facilitating certain patterns of neuronal activation in downstream structures, such as ramping or stochastic activity, that unfold at behavioural time scales. Finally, by performing large scale Neuropixels recordings in head-fixed mice during self-paced running in darkness, we found that ultraslow oscillations and periodic sequences are present also in spike activity from electrophysiology data. The organization of MEC activity into ultraslow sequences may facilitate the encoding of experience at behavioral time scales.

Title: A medial entorhinal microcircuit rhythmically scans nearby space

Authors: *A. VOLLAN, R. J. GARDNER, E. I. MOSER, M.-B. MOSER;
Kavli Institiute for Systems Neurosci., Trondheim, Norway

Abstract: The navigational abilities of mammals rely on spatial maps represented by position-tuned neurons in the hippocampal region. Constructing and using spatial maps likely require a representation of locations in the animal's surroundings. While it is simple to read out an animal's self-location from place- and grid cell activity, it is unclear how these cells represent locations in the space around the animal. Here we used Neuropixels probes to record neural activity from 100s-1000s of cells in the parahippocampus of freely moving or resting rats to determine how cells in the brain's navigation circuit map nearby space.

We first describe a novel "internal" direction (ID) signal, expressed by a dedicated set of theta-rhythmic directional cells in parasubiculum (ID cells). During locomotion, ID typically pointed to either side of the animal (~45° relative to head direction) and flickered rhythmically from right to left on alternate theta cycles.

We reasoned that ID would be well suited to steer spatial representations in particular directions in nearby space. By decoding position from the joint activity of co-recorded grid cells, we found that grid cells express "sweeps" - rapid trajectories traveling outwards from the animal's location once per theta cycle, as previously reported in place cells (Johnson & Redish 2007, Kay et al 2020). Remarkably, the direction of sweeps closely matched ID. Individual grid modules expressed co-aligned sweeps with lengths proportional to the grid module spacing. Place cells also expressed ID-aligned sweeps but were delayed by ~20ms relative to grid cell sweeps. ID and sweeps persisted and remained coupled in the absence of sensory inputs during REM sleep. During slow-wave sleep, ID-aligned sweep-like trajectories could be identified but their rhythmic nature was lost.

Lastly, we searched for a microcircuit that can generate sweeps from directional input. To this end, we identified putative monosynaptic connections between ID cells, conjunctive grid-ID cells, and pure grid cells using temporal cross-correlation. We found that ID cells projected to grid-ID cells with similar preferred directions. Grid-ID cells projected to pure grid cells with a slightly shifted grid phase. The direction of translation between the two grids closely matched the preferred direction of the presynaptic grid-ID cell. The observed tuning relationships are in line with continuous attractor network models of grid cells where directional input translates a bump of activity on the toroidal grid cell manifold. Based on our findings, we hypothesize that sweeps facilitate navigation by scanning the animal's surroundings (see Gardner et al, same session).

Abstract: Computations of the brain are thought to be performed in groups of neurons. However, defining such groups in large-scale recordings is challenging, in particular if the represented variable is not known. Here, the two main approaches in population analyses - studying neural correlations and population coding - are combined in a framework for finding neural ensembles and characterizing their function topologically. This exploits the complementary information found in the correlation structure and the neural state space and we reveal the topology in recordings of functional networks such as grid, head direction, place and orientationtuned cells, and expose a toroidal topology of ensemble activity during head-fixed wheel running in darkness [Obenhaus et al. 2022, Campbell et al, 2021]. Furthermore, we decode the internal dynamics and compare it to the external variable. The findings pave the way for studying mixed population recordings where the specificity of the cells is difficult to measure or unknown, either in simplistic experiments with high experimental control or during natural behaviors in heterogeneous environments.

Title: Event structure sculpts lateral entorhinal dynamics

Authors: *B. R. KANTER, C. M. LYKKEN, M.-B. MOSER, E. I. MOSER;
NTNU, Trondheim, Norway

Abstract: Our experience of the world is a continuous stream of events, things occurring at a particular time and place. How this flow of experience is parsed and organized impacts our perception and memory of such events, yet the neural mechanisms underlying this process are largely unknown. The lateral entorhinal cortex may play a key role due its convergence of multisensory inputs, its encoding of events and their temporal relationships, and its connections with the hippocampal memory system. Here, we simultaneously recorded hundreds to thousands of neurons from lateral entorhinal cortex (LEC), medial entorhinal cortex (MEC), and area CA1 of the hippocampus in freely behaving adult male rats as we manipulated event structure. In the absence of defined events, population activity in LEC, but not MEC or CA1, continuously drifted along a one-dimensional manifold without reversing direction. This drift was caused by slow dynamics in the firing rates of LEC neurons over the course of minutes. After learning a task with a single recurring event, LEC dynamics were constrained to a stable state space trajectory defined by the event, but the drift was maintained along an orthogonal axis. In a more naturalistic task with hierarchical event structure, stable trajectories for each level of the hierarchy were simultaneously encoded along separate coding dimensions. Finally, event boundaries caused discrete jumps in state space that were mechanistically distinct from drift. Together, these results provide a dynamical systems explanation of how events are encoded within a temporal context.

Title: Development of toroidal topology in the grid cells network

Authors: *M. GUARDAMAGNA[1], E. HERMANSEN[1], J. CARPENTER[1], C. M. LYKKEN[1], B. DUNN[2], M.-B. MOSER[1], E. I. MOSER[1];

Abstract: Grid cells are a fundamental anchor for the brain's spatial navigation system and provide a metric for the brain's spatial map. It has been recently discovered that at the network level these neurons organize on a toroidal manifold, irrespective of sensory inputs or behavioral states (Gardner et al., 2022), in agreement with continuous attractor theories for the formation and operation of grid cells. However, the developmental origin of the toroidal topology remains to be determined. Does it precede or follow the tuning of individual grid cells? Is the organization of the network learned from experience or is it experience-independent? We sought to study the developmental timeline of the torus, starting from the earliest indications of grid cell selectivity, and working our way back to postnatal day 10 (P10) - before pups can actively explore or open their eyes and before space is likely to be relevant for the animals. In the first set of experiments, we recorded the activity of thousands of medial entorhinal cells (LII and LIII) from P15, when rat pups start to explore outside of the nest (approximately two days after eye opening). Each experimental session consisted of a pre-sleep trial, followed by the exploration of a large arena (1x1m). Using cross-correlations between the firing activity of cell pairs to identify clusters and characterize the topological structure with persistent cohomology (Hermansen et al., 2022), we were able to find evidence of toroidal manifolds from P15, before any stable periodic tuning of individual grid cells. The torus exhibited adult-like characteristics from the first exposure to the experimental room, irrespective of the behavioral state (sleep or arena exploration). From P16-17 onward, we observed the gradual emergence of individual grid cells in the cell population from which the toroidal manifold was initially detected. Multiple grid modules could be identified in the population activity as early as P15. In a second round of experiments, we characterized the topology of medial entorhinal neurons at even earlier developmental stages. Starting from P10 - an age when eyes and ear canals are closed, and pups do not move much - we recorded up to 1000 cells in LII and LIII of the medial entorhinal cortex, while pups slept in a heat-controlled pot. We were able to consistently uncover clear toroidal topology, with stable tuning, as early as P11 (preceding many major developmental milestones) and we are currently exploring whether similar structure is present at P10. Our results reveal that spatial mapping has strong experience-independent components, rooted in the early postnatal organization of medial entorhinal cortex circuitry.

Abstract: Grid cells in the medial entorhinal cortex have spatial firing fields patterned in a hexagonal grid. These cells are organized into modules, defined by a common grid spacing and orientation. Within each module, the firing patterns of the cells are spatially offset from one another, i.e., every grid cell has a distinct phase. However, the extent of phase variation within grid modules is unknown. While some computational models of grid cells, such as continuous attractor networks (CANs), assume a uniform phase distribution, others, including feed-forward models, can function without this requirement and exhibit clustering of grid phases. Here, we analysed the phase dispersion of several hundreds of grid cells recorded simultaneously from a range of grid modules while rats were foraging in a square environment of up to 4x4 meters. We assessed the similarity of observed phase distributions to random uniform and non-uniform distributions using statistical tools including Ripley's L-function, SVMs, persistence homology and likelihood ratios. Accounting for the number of recorded neurons and phase estimation uncertainties, our analyses revealed that the phase distributions of most modules did not significantly differ from uniform distributions. Yet, some extreme cases such as very small spacing cells in a large environment showed significantly clustered phase patterns. Additionally, by projecting phases onto a torus using topological data analysis, we found that the spatial phase distributions matched that of the torus. These observations are in line with a key assumption of CAN models, but also suggest that for grid spacings that are small compared to size of the environment, other processes, similar to those of feedforward models, might be at play.

Title: Independent realignment of grid cell modules during hippocampal remapping

Authors: *C. M. LYKKEN, B. R. KANTER, A. NAGELHUS, M. GUARDAMAGNA, E. I. MOSER, M.-B. MOSER;
NTNU, Trondheim, Norway

Abstract: Grid cells in the medial entorhinal cortex (MEC) create a universal metric of space that may be a basis for environment-specific maps and memories in the hippocampus. Grid cells are organized into discrete modules: All cells within a module operate coherently, but it is thought that different modules could, under some circumstances, operate independently of each other. This independence may underlie the generation of unique hippocampal maps for each environment. However, experimental evidence for discordant responses among grid modules is limited, and it has never been shown in conjunction with place cell remapping. To test whether grid modules realign independently during place cell remapping between distinct environments, we chronically implanted Neuropixels probes in MEC and hippocampus in rats to simultaneously record multiple grid modules and place cells. We found that place cells exhibited robust and stable global remapping between rooms. There were only slight differences in rotation between grid modules, and their rotation was largely coherent with border and head direction cells. Despite this, each grid module shifted independently between rooms. The difference in the translation of grid modules was large, and the distance between them was similar to what is expected by chance. Further, this differential translation of grid modules was sufficient to produce remapping in a grid-to-place cell model. These findings are the first experimental evidence demonstrating that functionally independent grid cell modules may underlie hippocampal remapping.

Title: Investigating the septo-entorhinal cortex circuitry supporting spatial coding by grid cells.

Authors: *J. HERNÁNDEZ, B. GUTIERREZ-GUZMAN, H. DANNENBERG;
George Mason Univ., Fairfax, VA

Abstract: The septo-hippocampal circuitry, including the medial septum (MS), the hippocampus (HPC), and medial entorhinal cortex (MEC), provides a neural substrate for episodic memory and spatial navigation. Grid cells in the MEC, a functionally defined cell type that tessellating the environment by firing at multiple locations in space that fall on the vertices of equilateral triangles, have been hypothesized to serve path integration and memory-guided navigation. However, the circuit mechanisms that generate spatial periodicity in grid cell firing remain elusive. Previous experimental data using pharmacological inactivation of the medial septum (MS) demonstrate that a combination of theta (6 - 10 Hz)-rhythmic GABAergic, glutamatergic, or cholinergic input from septo-hippocampal projection neurons is essential for spatial periodicity in grid cell firing. However, how the three main cell types in the MS act synergistically to enable spatial periodicity in grid cell firing remains elusive. Furthermore, little is known about the time course of reduction in grid cell firing after inactivation of MS inputs. We here use temporally precise optogenetic inactivation of choline acetyltransferase (ChAT)+ cholinergic MS neurons, parvalbumin (PV)+ GABAergic MS neurons, and the whole MS in freely behaving mice to test the hypothesis that cholinergic modulation of weak theta-rhythmic input can rescue neural dynamics in the MEC and spatial periodicity in grid cell firing. Our preliminary results show that cell-type-specific silencing of individual populations of cholinergic or GABAergic MS neurons does not disrupt spatial periodicity in grid cell firing as observed with pharmacological inactivation of the whole MS. Our results will contribute to understanding the contribution of individual cell types in the MS and their interactions to spatial coding by grid cells in the MEC and to understanding the temporal dynamics in grid cell firing as a function of medial septal inputs.

Title: A neural sequence code of 2D trajectories explains spatial periodicity in grid cell firing

Authors: R. R.G.[1], G. A. ASCOLI[2], ***H. DANNENBERG**[2];
[1]Mathematical Sci., [2]Bioengineering, George Mason Univ., Fairfax, VA

Abstract: Grid cells, first discovered in the medial entorhinal cortex of freely foraging rats, fire at multiple locations in space that fall on a hexagonal lattice. The spatial periodicity in grid cell firing has been interpreted as a neural metric for space providing animals with a global coordinate system in navigating physical and mental spaces. However, recent experimental data have challenged this view of a global metric in favor of a more local computational function of grid cells. Moreover, the specific computational problem being solved by grid cells and how local computations result in the experimentally observed global firing pattern has remained largely elusive. We here provide mathematical proof that spatial periodicity in grid cell firing is implied by four simple axioms about a neural sequence code of trajectories in 2D space and that the hexagonal firing pattern of grid cells emerges as the most parsimonious solution to such a sequence code. We thereby provide a teleological cause for the existence of grid cells and reveal the underlying nature of the global geometrical organization in grid maps as a direct consequence of a simple local sequence code using a minimal number of neurons. Our results show that sequence coding of trajectories by grid cells provides a mechanistic explanation for how grid cells serve path integration. Moreover, a theory of sequence coding of trajectories by grid cells predicts and provides an intuitive explanation for many previously puzzling experimental observations of grid cell properties such as the rotation of grid maps against the walls of rectangular environments, the fragmentation of grid maps in 1D space, and rescaling of grid maps in response to changes in the environment. A neural sequence code of trajectories unifies two major theories in neuroscience, namely that cell sequences provide a neural syntax and that grid cells serve path integration, into one simple and intuitive theoretical framework.

Title: Cholinergic dynamics supporting exploratory behavior, learning, and recall of hippocampus-dependent memories

Authors: *F. FAROKHI MOGHADAM, B. GUTIERREZ GUZMAN, X. ZHENG, H. DANNENBERG;
George Mason Univ., Fairfax, VA

Abstract: In the hippocampal formation, cholinergic modulation supports the formation of spatial memories and cognitive functions that enable memory-guided navigation. The major

source of cholinergic innervation to the hippocampus is originated from the medial septum/diagonal band of Broca (MSDB). In particular, cholinergic dynamics have been hypothesized to facilitate changes in brain states supporting either learning or recall of spatial memories. However, recent experimental data from mice support an alternative hypothesis, namely that cholinergic dynamics are a function of movement activity. We therefore recorded and quantified cholinergic dynamics in freely behaving mice and tested the alternative hypotheses that cholinergic dynamics in the septo-hippocampal circuitry are primarily explained either by i) the speed of animal movement, ii) behavioral activities such as grooming or rearing, iii) hippocampus-dependent learning or recall of spatial memories, or a combination of these factors. We used a fiber photometry approach to monitor cholinergic dynamics on a sub-second timescale in freely behaving mice. In detail, we targeted Cre-dependent expression of a genetically encoded Calcium sensor (GCaMP) to choline acetyltransferase (ChAT)-positive septo-hippocampal projection neurons in ChAT-Cre mice. We monitored population activity of cholinergic projection neurons via a chronically implanted optical fiber targeting the MSDB. To quantify cholinergic dynamics as a function of hippocampus-dependent learning and recall, we recorded cholinergic activity in mice performing an object location memory task. Mice were video-tracked, and pose and exploratory behavioral activities of mice during the task were analyzed using deep learning approaches. Consistent with previous data, our results show that cholinergic activity increases as a function of movement speed and transiently increases during rearing. Preliminary data show a trend of higher cholinergic activity when the mouse is exploring the object at the novel location after correcting for the effects of movement speed and rearing. This finding is consistent with the hypothesis that acetylcholine supports the encoding of novel information. Quantifying temporal dynamics in cholinergic modulation will allow us to test long-standing hypotheses of cholinergic modulation of memory function. Furthermore, understanding the neurophysiology of cholinergic dynamics will help us understand and develop novel hypotheses on how changes in temporal dynamics in cholinergic modulation contribute to disease pathology in neurological disorders with cholinergic dysfunction.

Abstract: The medial entorhinal cortex (MEC) is crucial for spatial memory. It is also a major component of the hippocampal-entorhinal circuit that is hypothesized to form a “cognitive map” for memory-guided navigation. However, little is known about how the cognitive map in the MEC develops during learning and influences memory. By imaging MEC calcium dynamics while mice learned to pursue water rewards in a novel virtual environment for ten days, we discovered that during successful learning (good performers), the overall dynamics of the MEC map gradually became more spatially consistent and then stabilized. In contrast, mice with unsuccessful learning (poor performers) showed an MEC map with low spatial consistency that did not improve during learning. The largest difference in spatial activity consistency between the good and poor performers existed at cues before the reward and immediately before the reward, suggesting that modulating the MEC map consistency in these areas could affect reward-predictive behavior after spatial memory has already been established. To test this hypothesis, we optogenetically modulated the spatial consistency of the MEC map while mice pursued water rewards in a well-learned environment. In the good performers, stimulating the MEC at locations randomly distributed along the track prior to the reward impaired reward-predictive behavior, whereas mimicking the consistent activity at cues prior to the reward did not alter the behavior. In the poor performers, consistent optogenetic stimulation immediately before the reward improved reward-predictive behavior. This effect remained true when consistent stimulations just before the reward and at cues prior to the reward were combined, but not when the stimulation was only applied to the cue locations. Together, these results indicate that specifically reducing the spatial consistency of the MEC map interfered with spatial memory. In addition, consistent activity before the reward directly drives reward-predictive behavior, whereas consistent activity at cues is important for the map and supports reward-predictive behavior. In summary, our findings reveal the establishment of a spatially consistent cognitive map in the MEC during successful learning and indicate that the map is not simply passively shaped by upstream inputs, but that spatial memory is determined by the MEC map.

Title: Auditory spatial information shapes the MEC cognitive map during navigation.

Authors: *D. NGUYEN, G. WANG, Y. GU;
Natl. Inst. of Hlth., Bethesda, MD

Abstract: Navigation within laboratory settings is mainly studied through visual modality. But navigation in the natural world often requires the employment of multisensory information, for example: auditory information helps pry animals detect predator's movement so that they can escape from danger; olfactory information leads animals to food sources. Here we focus on auditory spatial information: how they are encoded in the brain during navigation and how this encoding is compared to that of visual information, which dominates the navigation of many animals. We investigated these questions in the microcircuit of the medial entorhinal cortex (MEC), a brain area that is heavily involved in spatial navigation. Calcium dynamics of the MEC were measured using two-photon imaging when mice navigated virtual linear tracks, where auditory and visual spatial cues could be flexibly controlled. We established an auditory virtual reality (AVR), in which mice only relied on auditory cues to determine water reward locations. During AVR navigation, MEC specifically encoded the most task-relevant auditory cues that were associated with reward location. This encoding developed with experience and was specifically associated with the successful determination of the reward. We further combined AVR with visual VR and found that in environments with only auditory or visual cues, which delivered equivalent spatial information, the MEC recruited separate cell populations to form different cognitive maps. Finally, when auditory and visual cues were both present in the same environment, the MEC used separate cell populations to encode auditory and visual cues. In summary, our study demonstrates that auditory spatial information shapes the MEC map, which is different from that of visual spatial information, indicating the MEC's capability to distinguish spatial cues in different sensory modalities.

Title: Stochastic resonance enhances signal propagation and velocity integration in a model grid cell network.

Authors: *D. GUPTA, I. SHAIKH, C. ASSISI;
IISER, Pune, India

Abstract: Grid cells in the MEC possess spatially periodic receptive fields that form a hexagonal lattice that tiles space. They maintain a constant orientation and phase relative to one another and are prime candidates for a neural coordinate system to map trajectories through space. Grid cell receptive fields remain stable despite sensory input noise, fluctuations in neuronal excitability, and the stochasticity of ion channel dynamics. In this study we use a biophysically realistic continuous attractor network model of grid cells to examine how it overcomes the deleterious effects of noise and may even use noise to form a robust spatial representation.
The network was built by connecting a simple network motif consisting of conductance based models of excitatory stellate cells and inhibitory interneurons. This motif behaved as a bistable system - an external perturbation was required to switch the activity of neurons. When we drove the bistable system using a 10 Hz oscillatory drive, akin to the theta drive from the medial septum, we found that specific levels of noise were required to cause periodic switching between the states of the network. Thus, the presence of noise could improve the system's response to weak or subthreshold oscillatory inputs, a phenomenon known as stochastic resonance. To construct a one dimensional attractor network, we connected the motifs into a ring. We introduced an asymmetry in the network such that the activity propagated in one direction when the stellate cells were stimulated. As before, interneurons received an oscillatory drive, and an additive noisy current. We found that the activity reliably propagated along the ring only at specific noise levels. We extended this network to a multi-bump attractor network to reproduce periodic grid fields. We found, this network could integrate 1D velocity inputs. However, the accuracy of the decoded trajectory peaked at non-zero levels of noise.
Our results suggest that the MEC network might rely on endogenously generated noise to uncover weak signals and maintain robust representations of spatial trajectories using stochastic resonance.

Title: Discrete modules emerge in a biophysically realistic grid cell network

Authors: I. SHAIKH, **S. NABAR**, *C. ASSISI;
IISER Pune, Pune, India

Abstract: Continuous attractor network (CAN) models with radially symmetric local excitatory connectivity and long-range inhibition generate hexagonal firing patterns that resemble the receptive fields of grid cells in the medial entorhinal cortex (MEC). Local excitation promotes the formation of activity clusters, while long-range inhibition prevents the spread of excitation beyond a specific range, resulting in a hexagonal grid-like structure. The distance between the vertices of this grid is determined by the extent of the inhibitory surround. In the MEC, grid cell spacing is not uniform along the dorsoventral (DV) axis, ranging from approximately 40 cm at the dorsal end to nearly 100 cm at the ventral end. Moreover, grid spacing changes in discrete steps forming distinct grid cell modules along the DV axis. Grid scales exhibit a geometric progression, with the ratio between successive scales falling between 1.4 and 1.7. CANs have effectively simulated this step-like progression and further refined the sequence of scale ratios. By gradually altering the spatial extent of inhibition along the DV axis in CANs, discrete jumps in spatial frequency occur, closely matching experimentally observed values. CANs typically consist of rate-based neurons that operate as linear dynamical systems with interactions following simple sigmoidal or rectification nonlinearities. In this study, we investigate the emergence of grid modules within a one-dimensional biophysically realistic network model composed of conductance-based stellate cells and inhibitory interneurons. All interactions between stellate cells are mediated by inhibitory interneurons. The interneurons mutually inhibit each other. Our findings recapitulate some of the results seen in rate-based CAN models - as the spatial extent of inhibitory interactions is continuously varied, grid cells segregate into discrete modules. The spatial scale associated with each module exhibits the same geometric progression observed in experimental studies. Gradients along the dorsoventral axis in the MEC are not restricted to the spatial extent of inhibition. Systematic changes in the frequency of subthreshold oscillation and resonance, input resistance, membrane time constants and synaptic integration properties of stellate cells are seen. These gradients are mainly attributed to changes in HCN channel conductance and a potassium leak current. Unlike rate-based CAN models, our model allows us to manipulate each of these parameters and explore their impact on the observed modularity in the network.

Title: Subthreshold dynamics shape grid cell activity in a biophysically detailed continuous attractor model

Authors: *I. SHAIKH, C. ASSISI;
IISER, Pune, India

Abstract: Grid cells in the Medial Entorhinal Cortex (MEC) fire when the animal is at the vertices of spatially periodic hexagonal lattices, which tile the two-dimensional range of the animal. Continuous Attractor Network (CAN) models explain how this pattern can emerge due to network interactions. Aside from a few exceptions, most models use rate-based neurons which are usually linear dynamical systems with interactions that follow a simple sigmoidal or rectification nonlinearity. Spiking CAN models typically consist of integrate-and-fire neurons. However, in contrast to these models, stellate cells in the MEC, putative grid cells, display a rich dynamical repertoire showing post-inhibitory rebound, depolarization sag, subthreshold oscillations, and resonant responses. Furthermore, several of these properties vary systematically along the dorsoventral axis of the MEC. It is unclear how these properties can contribute to the emergence of grid cell receptive fields.
We developed a CAN model of a grid cell network consisting of conductance-based stellate cells and interneurons. In addition to currents that contribute to spike generation, stellate cells have hyperpolarization-activated depolarizing currents (HCN) and a persistent sodium current. Inhibitory Interneurons receive a sinusoidal drive to model the theta drive from the medial septum. Stellate cells interacted only via an inhibitory intermediary, while inhibitory interneurons mutually inhibited each other and the stellate cells. We found that a center-surround connectivity led to periodic spatial receptive fields in one dimension and hexagonal fields in two dimensions. To track the movement of an animal, we introduced directional asymmetries.Our model was able to integrate complex trajectories accurately over several seconds and gradually drifted when external inputs were absent. Stellate cells in our model exhibit a depolarizing ramp, similar to that observed in grid cells when an animal first enters a receptive field. In the absence of lateral excitation from stellates, this ramp can be explained by inhibitory modulation in our model. We found that the first spike generated by a grid cell when the animal enters its grid field is a rebound spike, which occurs at a preferred phase of the theta oscillation. HCN knockout experiments show a clear expansion of grid scale and grid field sizes. Our model network replicates this observation. As expected from experiments, theta phase precession persists in absence of HCN. To our knowledge, this is the first biophysically detailed grid cell attractor model that uses realistic membrane currents to reproduce dynamics observed in experiments.

Title: Local activity principle as a normative theory on the emergence of grid cells

Authors: *M. S. GUINTO, J. YOSHIMOTO;
Dept. of Biomed. Data Sci., Fujita Hlth. Univ., Nagoya, Aichi, Japan

Abstract: Grid cells, which were first discovered in the entorhinal cortex of mammals, are normatively thought of as instrumental in spatial navigation because of their periodic firing characteristics as the animal traverses its surroundings. In recent years, converging evidence from etiological and teleological investigations of hexagonal grid cells indicate that they might arise from optimally efficient coding schemes, with several metabolic, sparsity, and nonnegativity constraints supporting the formation of regular lattices that approximate what has been observed in animal experiments. Here we introduce a normative theory that suggests how grid-like representations can also be seen as a consequence of the local activity principle, a circuit-theoretic concept introduced by Leon Chua in 1998. Past studies on the local activity principle, for which explicit mathematical criteria have been laid out, have shown deep connections with Turing's work on morphogenesis and provided a formal, quantitative characterization of Prirogine's "instability of the homogeneous." We demonstrate how the so-called "edge of chaos," a subset within the locally active regime, in state space (as opposed to anatomical space) contributes to the emergence of grid representations. By focusing on the importance of confined spheres of influence for efficient computation, this work supplements existing approaches that address the challenge of understanding the ontology and possible universality of grid cells in the cortex.

Title: Grid code for future spatial information in the entorhinal cortex

Authors: *A. OUCHI, S. FUJISAWA;
RIKEN, Saitama, Japan

Abstract: Although grid cells in the entorhinal cortex play fundamental roles in spatial navigation, how the entorhinal grid system support for planning a future traveling path is still to be elucidated. Here, we investigated the neuronal representation of current and future spatial information in the entorhinal cortex and hippocampal CA1, performing large-scale extracellular recordings from these brain areas of rats moving toward a destination in the square arena. In the entorhinal cortex, we found a subset of cells that have a grid representation of the space shifted

toward the traveling direction; firing rate maps of these cells did not show gridness based on current animal locations, but they displayed grid presentation when rate maps are estimated based on future animal locations. Furthermore, these travel-direction-shifted grid cells were firmly phase modulated by theta oscillations (5-12Hz), and the phase preferences of these cells differed from traditional grid cells in layers 2, 3, and 5. We hypothesize that these travel-direction-shifted grid cells underlie the mechanisms of spatial navigation for future travels in the network of the entorhinal cortical and hippocampus.

Title: Grid cells activity in a homing task requiring path integration

Authors: *J. PENG[1,2], B. THROM[1,2], T.-Y. YEN[1,2], M. NAJAFIAN JAZI[1,2], H. MONYER[1,2], A. KEVIN[1,2];
[1]Dept. of Clin. Neurobio., Heidelberg Univ., Heidelberg, Germany; [2]German Cancer Res. Ctr. (DKFZ), Heidelberg, Germany

Abstract: Converging evidence from experiments in both rodents and humans suggests that grid cells contribute to path-integration-dependent navigation. How grid cell activity might contribute to path-integration-dependent behavior has remained to be determined as grid cell activity has been studied mostly during random foraging or other behavioral paradigms with limited navigational demands. Here we recorded grid cell activity in freely moving mice performing a path integration task (AutoPI task) in which the mouse searched for a lever on an arena and returned to the home base to collect a reward. Surprisingly, grid cells did not have a stable periodic firing pattern during the task. Using a combination of single-cell analysis and grid-module-level decoding techniques, we found that error accumulated in the phase and orientation of the grid representation when mice navigated in darkness. Moreover, we often observed a translation of the grid pattern within trials, whereby the grid representation went from being anchored to the room reference frame to being anchored to a task-relevant, moving object. Despite this re-anchoring which caused discontinuity in integration of self-motion information by grid cells, we found that error accumulation in the orientation of the grid cell pattern predicted the homing direction of the mouse. Our findings provide novel insights into the function of grid cells in path-integration-dependent behavior.

Title: Robust Variability of Grid Cell Properties Within Individual Grid Modules Enhances Encoding of Local Space

Authors: ***W. REDMAN**[1], S. ACOSTA[2], X. WEI[3], M. GOARD[4];
[1]Univ. of California Santa Barbara, Santa Barbara, CA; [2]Univ. of California Santa Barbara Neurosci., Univ. of California Santa Barbara Neurosci., Santa Barbara, CA; [3]The Univ. of Texas at Austin, Austin, TX; [4]Univ. of California, Santa Barbara, Univ. of California, Santa Barbara, Santa Barbara, CA

Abstract: Grid cells in rodent medial entorhinal cortex are organized into discrete modules, characterized by similar grid spacing and orientation. This modularity has fundamentally shaped the way in which the functional role of these neurons has been interpreted in spatial navigation. In particular, because it has been assumed that the grid properties within module are identical, integration across multiple modules is necessary for accurate localization in space. However, the validity of this assumption has not been systematically tested. By analyzing recently recorded grid cell data, we find small yet robust variability in grid spacing and orientation within individual modules, on the order of centimeters and degrees, respectively. Computational modeling of synthetic grid populations with similar levels of heterogeneity reveals that single modules can encode information of local space with much higher accuracy. This challenges a long-held notion about the nature of the grid code and the necessity of multiple modules for spatial localization.

Title: Navigation in Abstract Cognitive Spaces Through Extraction of Low-DimensionalVelocity Signals from Non-Spatial Data for Grid Cell Integration

Authors: *A. IYER[1], S. CHANDRA[4], S. SHARMA[2], I. R. FIETE[3];
[1]MIT, Cambridge, MA; [2]Brain and Cognitive Sci., MIT, CAMBRIDGE, MA; [3]Ctr. for Learning and Memory, MIT, Cambridge, MA; [4]Massachussetts Inst. of Technol., Cambridge, MA

Abstract: Grid cells in the medial entorhinal cortex exhibit striking spatial representations during navigation. Recent studies have shown that grid cells are not limited to spatial navigation but also represent abstract cognitive spaces. Such spaces include a viewed cartoon image that is deformed along two abstract feature dimensions or an environment in which auditory pitch varies upon a lever press. Here, we hypothesize that the brain is able to quickly form representations of these abstract spaces by learning to extract a low-dimensional velocity signal during navigation through the space, and then piping this signal into grid cells, whose internal structure is then mapped onto the space through the operation of velocity (path) integration. We developed a computational model that takes in abstract time-varying inputs of distinct modalities and of vastly different statistics and dimensions, and extracts from these inputs low-dimensional velocity signals. The model does so by predicting the next state given past states (state transitions) and by applying a geometric consistency constraint in which movement along closed loops should result in the same state (loop closure), which is itself computed by the output grid cells. The model provides a computational hypothesis for how animals extract abstract velocities in diverse non-spatial contexts, leading to potential insights into how grid cells encode abstract cognitive spaces.

Title: Temporal regularities guide feature-based learning in complex reward environments

Authors: *A. YAZDANPANAH, M. C. WANG, M. P. BENZ, A. SOLTANI;
Dartmouth Col., Hanover, NH

Abstract: In naturalistic reward environments, people are constantly faced with the task of learning the values of multi-feature objects from limited feedback, a challenge referred to as the curse of dimensionality. To mitigate the curse of dimensionality, humans adopt different

strategies including feature-based learning which involves learning the value of informative features. Attention can bias this process by selecting a subset of those features for more efficient reward learning. However, it is currently unknown how attention is guided by certain characteristics of the environment to influence learning and decision making. One possibility is that the spatial and/or temporal patterns or regularities of features in the environment could deploy attention to guide learning similar to how perception is influenced by visual statistical learning (i.e., subtle statistical relationships among visual objects in space or time). To test whether regularities in the environment could guide attention for feature-based learning, we conducted an experiment in which human participants (N=57) learned about reward probabilities associated with 16 different visual stimuli, each with two features (shape and pattern), through reward feedback that followed selection between a pair of stimuli on each trial. To introduce temporal regularities of features that could guide attention, we interleaved choice/learning trials with bouts of trials in which participants were presented with a sequence of visual stimuli and were required to identify the next stimulus in the sequence. We implemented temporal regularities in only one of the two features (manipulated feature) of stimuli presented during the pattern-detection task. Importantly, both features were equally informative about the reward outcome and there was no overlap between the set of stimuli used in the learning and temporal pattern-detection tasks. We used a combination of model-free analyses and fit of choice data based on multiple reinforcement learning models to study the effect of our manipulation on feature-based learning. We found that participant's choice behavior and value estimations were both biased towards the manipulated feature (i.e., feature with regularity during the pattern-detection task). In addition, participants demonstrated a stronger tendency to learn about the manipulated feature of the unchosen option, which resulted in higher learning rates for the manipulated feature. Overall, our results show that the existing patterns of features in the environment could deploy attention to mitigate the curse of dimensionality by biasing reward-based learning toward such features.

Title: Neural Correlates of Motivational States that Bias Reinforcement Learning and Memory Formation

Authors: *A. H. SINCLAIR, Y. WANG, R. ADCOCK;
Psychology & Neurosci., Duke Univ., Durham, NC

Abstract: Motivation influences goals, decisions, and memory formation. *Imperative* motivation links urgent goals to actions, narrowing the focus of attention and memory. Conversely, *interrogative* motivation integrates goals over time and space, supporting rich memory encoding for flexible future use. Here, we investigated whether these motivational states engage distinct neural systems to influence learning and memory. In an fMRI study with human participants (N=44, ages 18-35, 25 women), we manipulated motivational states by randomly assigning participants to read one of two cover stories before a reinforcement learning task. The Imperative group imagined *executing* a museum heist, whereas the Interrogative group imagined *planning* a future heist. During the subsequent reinforcement learning task, participants repeatedly chose among four doors representing different museum rooms (choice phase). Choosing a door revealed a trial-unique painting and an associated reward value (feedback phase); rewards were later converted to bonus payments. Importantly, only the cover stories differed between groups; the reinforcement learning task was identical, and all participants had the same expectations about how and when bonus payments would be awarded. The next day, we conducted a surprise memory test on the paintings. Replicating our prior behavioral findings, we found that Imperative motivation enhanced short-term reward learning, increasing exploitative choices, points earned, and optimal choices. Conversely, Interrogative motivation enhanced long-term memory formation, increasing next-day recognition memory and recall of painting-value associations. fMRI data was preprocessed with fmriprep and analyzed with FSL. During the choice phase, striatal activation was greater in the Imperative group relative to the Interrogative group. During the feedback phase, activation in the hippocampus, ventral visual stream, and default mode network predicted subsequent memory. However, different motivational states were associated with distinct routes to memory formation. In line with theoretical predictions, amygdala activation drove memory in the Imperative group, but not in the Interrogative group. Overall, we demonstrate that motivational states impact whether or not memories are encoded successfully, the nature of memory representations (rich and associative vs. sparse and decontextualized), and the neural mechanisms that contribute to memory formation. Our findings offer broader implications for enhancing education, behavior change, clinical interventions, and communication.

Title: Information-seeking around aversive outcome anticipation

Authors: *I. AITSAHALIA[1,4], P. SEPULVEDA[2,4], S. DONG[5], R. CHEN[5], Y. CHAI[5], N. H. NAQVI[3], K. IIGAYA[2,4,3];
[1]Neurobio. and Behavior, [3]Psychiatry, [2]Columbia Univ., New York, NY; [4]Translational Imaging, New York State Psychiatric Inst., New York, NY; [5]Neurosci. and Behavior, Barnard Col., New York, NY

Abstract: Anticipating negative or uncertain outcomes can be a major source of anxiety and fear, especially among populations with psychiatric disorders. This aversive anticipation, called dread, can be formalized through anticipatory utility computation, a behavioral economic theory which provides a normative framework for analyzing the value from the anticipation of a future reward or punishment, in addition to the experience of reward or punishment itself (Berns et al., 2006; Loewenstein, 1987). While research has shown that advanced information of pleasant outcomes tends to boost positive anticipation (Iigaya et al., 2016; 2020), and therefore most people choose to receive information in behavioral paradigms, many studies have suggested heterogeneous impacts of advanced information about future aversive experiences on anticipatory feelings. For example, a classic study showed that patients waiting for medical operations experience greater fear if they receive more information about the operation in advance (Janis, 1958). Other researchers, however, suggest a large individual variation on the preference for advanced information.We extended a behavioral task (Bromberg-Martin & Hikosaka, 2009) to probe information-seeking behaviors in a dreadful context (Iigaya et al., 2016; 2020), while we recorded a variety of biophysical modalities, including heart-rate, skin conductance response, and pupil dilation, to validate this task. At the start of each trial, participants are presented with the probability of receiving punishment and the duration of the delay until they receive the outcome. They then choose between an "information" target to find out about the outcome, or a "no-information" target to simply wait for the outcome without knowledge. After the delay period the outcome is played for the participant: either punishment (a loud scream) or a neutral outcome, according to the probabilities presented. The aversive nature of the outcome was supported by participants' self-reports and physiological measures (increase in pupil area and skin conductance after the presentation of the scream). We found a wide range of information-seeking preferences, which were modulated by the delay and probability of the negative outcomes. Advance information about prospective outcomes impacted participants' experience, as reflected by a higher pupil sizes at the moment non-aversive outcomes were revealed. Our study suggests that information modulates the experience of dread, an important step into understanding critical disorders such as post-traumatic stress or anxiety disorders.

Title: Real-time visual attention training through closed-loop eeg neurofeedback

Authors: *M. NOROUZI[1], K. WELLINGTON[1], B. GARNEAU[1], R. ABIRI[2];
[2]Univ. of Rhode Island, [1]Univ. of Rhode Island, Kingston, RI

Abstract: Attention is the ability to process important information while dismissing distractions during a task. Visual attention involves finding a target among competing stimuli. Sustained attention, a cognitive skill, is the maintaining of focus over time. Our overall hypothesis is that a single neurofeedback training session can enhance this ability. In this study, we developed an innovative Python-based Brain-Computer Interface (BCI) that incorporates a Multi-Layer Perceptron (MLP) algorithm to decode brainwave patterns during a visual attention training task. This study processed scalp electroencephalography (EEG) signals in real-time via 8-channel and 16-channel wet-electrode systems. Our overall experiment involves three phases: open-loop pre-evaluation, neurofeedback training unique to the closed-loop, and open-loop post-evaluation. The first and third phases as open-loop forms have similar procedures. During the open-loop form, we primed participants to discriminate a sequence of composite images. Each image was a fair superimposition of a scene and a face image. The participants were asked to respond (with a push button) to the intended subcategory (e.g., indoor scenes) while withholding their responses for the irrelevant subcategories (e.g., outdoor scenes). We made use of data from four participants to develop the MLP model. This open-loop classification model demonstrated a commendable average classification accuracy of 91%. During the closed-loop form as a neurofeedback training phase, the composition and transparency of the sequence of blended images are adjusted using the open-loop model in the pre-evaluation phase and based on the participant's decoded attentional level toward a specific image category. We hope to expand the recruitment of human subjects for the closed-loop form and neurofeedback training. The results from such a neurofeedback platform will have a significant impact on developing low-cost and portable attention training systems for patients with attention deficits.

Title: Generalization in reinforcement learning and the role of sleep

Authors: *A. JASKIR, M. J. FRANK;
Cognitive & Psychological Science, Carney Inst. for Brain Sci., Brown Univ., Providence, RI

Abstract: When trained on specialized tasks, cutting-edge algorithms in deep reinforcement learning (i.e. learning through trial-and-error) can outperform human experts, but humans remain unsurpassed in quickly transferring learning between tasks with shared structure. For example, a musician trained on guitar can generalize a scale from one part of a fretboard to another and can apply this knowledge to speed learning to play a cello, despite differences in the desired song to play or the movements to achieve that song. Drawing upon recent work interfacing computer science and cognitive neuroscience (Lehnert et. al., 2020), we hypothesized that humans form "reward-predictive" state abstractions (RPAs) that support such transfer. RPAs are achieved by clustering situations which share analogous action-reward sequences (e.g., all fret positions on a guitar are reducible to twelve unique notes). Furthermore, we propose that sleep plays a constructive role in these abstractions in biological agents, whereby extensive rest allows for reprocessing and discovery of event similarities; this hypothesis draws upon the Complementary Learning Systems, a computational theory of memory consolidation in the hippocampus and cortex (McClelland et al, 1995; Singh et al, 2022). We developed a novel sequential decision-making task to test for RPA transfer. Specifically, participants in the Learning Block were asked to learn through trial-and-error which sequences of key presses lead to reward; the sequences share a hidden rule (uninstructed to participants) where pairs of keys can be arbitrarily exchanged in any sequence without affecting the resulting reward order and therefore are compressible. In the Generalization block, the sequence changed but the underlying hidden structure remained. Performance in the Generalization block would be enhanced if participants learn RPAs. Collecting participant data through the online platform Prolific, we demonstrate that human behavior reflects performance enhancements distinctive to RPAs. We further characterize the effects of sleep on this learning process and motivate the neural implications of these findings. This work provides insight into the flexibility of human cognition and the underexplored role of sleep in reward learning.

Title: Long-term credit assignment in humans critically depends on sequential structuring of events

Authors: *S. BRUINSMA, F. H. PETZSCHNER, M. R. NASSAR;
Neurosci., Brown Univ., Providence, RI

Abstract: To refine our future behavior, it is essential to learn whether past actions or events led to good or bad outcomes and assign credit accordingly. For instance, if you are feeling worse than usual today, identifying which actions or events (such as not getting enough sleep or skipping breakfast) may have contributed to that state can improve choices in the future. However, assigning credit is a notoriously difficult problem, especially when we want to consider the longer-term consequences of our actions. In the present study, we explored human credit assignment strategies through a novel behavioral paradigm where online participants (n=218) had to either observe or select activities with different short- and long-term pain-related consequences for an avatar and subsequently predict the impact of those activities on that avatar's pain level. Behavioral results suggest that when activities are randomized over time, participants tend to learn short-term consequences, but fail to learn long-term ones. However, learning of long-term consequences can be improved if activities are blocked in time, such that each activity is repeated multiple times in succession. Furthermore, when participants had the freedom to select activities, we identified a relationship between activity selection patterns and learning, where increased repetition in activity selection was related to a learned preference for activities that reduce long-term, but not short-term, pain. In order to understand the potential computations underlying participant behavior, we compared several computational models and found that standard model-free algorithms (i.e., temporal difference learning) fail to properly learn long-term consequences of activities in our task, whereas Bayesian models that take into account the causal structure of the environment effectively learn both short- and long-term consequences regardless of whether activities are repeated or not. Thus, neither model adequately aligned with participant behavior across different activity repetition patterns, suggesting the necessity to develop more refined models that account for constraints on human credit assignment. Overall, our results demonstrate that credit assignment critically depends on the order in which actions are selected, with repetitions aiding the learning of long-term consequences. This raises intriguing questions about whether individuals might deliberately repeat actions (i.e., perseveration) to enhance their ability to assess long-term consequences, warranting further exploration into how action selection and subsequent credit assignment may correlate with or predict real-world behavior.

Title: Neural representations of Bayesian learning process in dynamic Environment

Authors: *Y. ZHANG, X. WAN;
Beijing Normal Univ., Beijing, China

Abstract: In a dynamic environment, maintaining accurate beliefs requires the learning rate to beadjusted based on experiences. This means that while stable beliefs should be maintained even inthe presence of noisy data, they must remain flexible during periods of uncertainty or change.However, the underlying mechanism by which the brain implements such adaptive learningprocesses is not fully understood. To investigate this question, we conducted an experimentrequiring participants to predict the current value of a number based on previous feedbackinformation drawn from five normal distributions with different means but the same variances.Participants had to assess whether the fluctuations in the numbers were caused by noise or changesin the true value for accurate predictions. Combining computational modeling with MEG(Magnetoencephalography), we studied the neural processes involved in this task and found that aBayesian inference model best described and predicted participant behavior. The Bayesianinference-based learning process can be divided into two components: the stable update (model-freecomponent) and the dynamic adjustment based on the probability of environmental change (model-based component). During the feedback phase, an unsigned prediction error (UPE) was encoded inthe putative ACC (anterior cingulate cortex) Theta band (4-7 Hz) signal, which is believed to berelated to the model-based component of the learning process. In contrast, signed prediction error(SPE) was represented by Beta band (15-30 Hz) signals in the putative primary motor cortex (PMC)region during both the feedback and motor preparation and execution phases. While the beta bandsignals during motor preparation and execution were mutually decodable, the signal during thefeedback phase could not be decoded from the other two phases. This suggests that during thefeedback phase, the beta band signal in PMC may differ from the motion preparation and executionphases and may involve the stable update (model-free component) process of Bayesian updating.

Title: Attentional bias toward rewarding vs contextual cues in trauma exposed individuals

Authors: *C. SHARP[1], P. RJABTSENKOV[1], C. MARINO[1], Z. ALI[1], S. BAVDEKAR[1], E. PINEDA[1], A. LAZAROV[2], B. SUAREZ-JIMENEZ[1];
[1]Univ. of Rochester, Rochester, NY; [2]Tel-Aviv Univ., Tel Aviv, Israel

Abstract: Decreased pursuit and anticipation of rewards are common symptoms of trauma-related psychopathology. However, little is known regarding how trauma exposure may affect

attention allocation to conditioned reward cues. We used eye-tracking to examine how trauma exposure affects attention to rewarding versus contextual cues from a virtual reality (VR) reward conditioning task. Trauma exposed (TE) and non-trauma-exposed (HC) participants completed an eye-tracking task before and after the VR reward conditioning task. During the eye-tracking task, participants freely viewed matrices of pictures of the conditioned reward stimuli (MN) and the surrounding environment (CX) from the VR task. We compared participants' total dwell time and number of first fixations on each cue type as measures of attentional bias. While not statistically significant, our preliminary data show that HCs' percentage of first fixations on CX images increased from pre-task to post-task while in TEs this decreased from pre-task to post-task. However, while HCs' percentage of total dwell time on CX images was higher than that of TEs at both pre-task and post-task, percentage of total dwell time on CX images did not increase from pre-task to post-task in either HCs or TEs.The directionality of our preliminary findings suggests that trauma exposure may bias attention toward valenced cues and away from contextual cues during one's initial scanning of an environment. This attentional bias toward valenced cues may serve as a signature for trauma exposure that could be targeted for treatment.

Title: Striatal involvement in reward processing in the human infant brain

Authors: *J. E. TRACH[1], T. S. YATES[1], D. CHOI[1], L. BEHM[1], C. T. ELLIS[4], S. D. MCDOUGLE[1,2], N. B. TURK-BROWNE[3,2];
[1]Dept. of Psychology, [2]Wu Tsai Inst., [3]Yale Univ., New Haven, CT; [4]Dept. of Psychology, Stanford Univ., Stanford, CA

Abstract: The ability to learn from positive and negative feedback is an essential cognitive capacity throughout life but perhaps especially when first learning to make sense of the world during early development. Behavioral work suggests that even very young human infants can use reward feedback to learn and guide their behavior to maximize the reward (i.e., positive feedback) they receive from their environment. However, it is unknown how the infant brain learns from and processes rewards. Prior research in adults and adolescents suggests that regions of the striatum may be involved. At the same time, human infants are extremely altricial and it remains unclear whether this reward processing system is present or mature early in

development. Furthermore, methodological challenges have limited the study of subcortical structures in infants, which cannot be resolved with traditional infant neuroimaging techniques such as EEG and NIRS. Recent advances have made it possible to conduct fMRI studies in awake and behaving infants. We thus used fMRI to measure whole-brain activity during an infant-friendly reinforcement learning paradigm. Infants were presented with two solid color shapes, one associated with a high reward probability (80%) and the other with a low reward probability (20%). One shape was randomly selected on each trial, and then converted to an outline that revealed either a rewarding stimulus (dynamic smiley face) or no outcome. Infants who had a minimum of 20 trials during which they were looking at the screen and not moving their head excessively were included in further analyses. Data collection is ongoing and so results are preliminary. We have so far extracted fMRI activity from three ROIs in the basal ganglia (bilateral accumbens, caudate, and putamen) during the reward period. This analysis revealed preliminary evidence of increased activity to rewarded versus nonrewarded trials in bilateral caudate and a trend in the same direction in bilateral accumbens. This aligns with past research in adults and provides initial support for the involvement of the striatum in reward processing during infancy. In planned analyses, we will leverage the computational framework of reinforcement learning to relate reward prediction error (the learning signal in reinforcement learning) to striatal activity and examine value representations in other regions of the brain, namely the medial prefrontal cortex. Overall, this work marks a promising step in our understanding of reinforcement learning in the infant brain.

Title: Midbrain signaling of identity prediction errors depends on orbitofrontal cortex networks

Authors: *Q. LIU[1], Y. ZHAO[1], S. ATTANTI[2], J. L. VOSS[3], G. SCHOENBAUM[1], T. KAHNT[1];
[1]Natl. Inst. of Drug Abuse, Baltimore, MD; [2]Mayo Clin. Alix Sch. of Med., Scottsdale, AZ; [3]Dept. of Neurol., Chicago, IL

Abstract: Previous work has shown that the lateral orbitofrontal cortex (OFC) represents expectations about the identity of rewards and that the dopaminergic midbrain responds to reward identity prediction errors (iPE, i.e., value-matched violations of reward identity

expectations). We hypothesized that the lateral OFC directly contributes to the computation of iPEs in the midbrain by signaling reward expectations. To test this, we used network-targeted transcranial magnetic stimulation (TMS) to modulate activity in the lateral OFC network. Healthy human subjects (N=31, 11 males) performed a trans-reinforcer reversal learning task during functional magnetic resonance imaging (fMRI) in two sessions (order counter-balanced); once after sham stimulation and once after continuous theta burst stimulation (cTBS). Stimulation coordinates in the lateral prefrontal cortex (LPFC) were individually selected based on maximal resting-state fMRI connectivity with seed regions in the lateral OFC. The task required subjects to learn associations between visual cues and equally-valued food odor rewards. Unpredictably for the subject, these associations were reversed multiple times throughout the task, eliciting iPEs. Functional connectivity between the lateral OFC and the rest of the brain was significantly reduced after cTBS relative to sham in the first block of the experiment, validating our network-targeted stimulation procedure. Relative to sham, cTBS impaired behavioral performance in the first block of the task, and disrupted representations of expected reward identity in the lateral OFC. Importantly, fMRI responses to iPEs in the midbrain were significantly modulated by OFC-network targeted cTBS relative to sham. These results suggest that neural representations of expected outcome identity in the lateral OFC directly contribute to signaling of iPEs in the midbrain, presumably by providing the predictions necessary for computing the error signal. Taken together, our findings support a model in which midbrain iPEs are generated by comparing incoming sensory information with identity expectations represented in the OFC.

Title: Differential neuronal activity in the mPFC and Nucleus Accumbens during habituation to rewards

Authors: *I. ALLIENDE[1], J. VALDES[2];
[1]Facultan de Medicina, [2]Univ. de Chile, Santiago, Chile

Abstract: The reward system plays a crucial role in processing stimuli with motivational valence and goal-directed behaviors. Dopamine (DA) is one of the main neuromodulators associated with this system, being released from the ventral tegmental area (VTA) to limbic areas such as the nucleus accumbens (NAc) and cortical areas such as the medial prefrontal cortex (mPFC).

Microdialysis studies have demonstrated that novel and unpredictable motivational stimuli increase DA release in the mPFC and NAc when a highly hedonic reward such as chocolate is consumed. However, upon subsequent exposure to the stimulus, the levels of DA released in the NAc decrease compared to the first exposure. This phenomenon is called "habituation" and has been described specifically for the NAc-shell, an area highly responsive to rewarding stimuli, while the mPFC and NAc-core do not show this habituation. Other studies in animals where the mPFC is injured have shown that this structure, especially in its infralimbic portion (IL), is necessary for the occurrence of the habituation phenomenon. Also studies in addicted animals show that the habituation of NAcc to natural rewards under drug abuse is suppressed, instead the mPFC shows a decrease in DA release.
Together, these findings suggest a possible mechanism where the IL-mPFC would have an inhibitory controller role over the NAc-shell that is altered under conditions of addiction. However, the available results are studied by microdialysis, which shows changes in DA release, but there are no studies that account for changes in the neuronal activity of the circuit involved, which help us understand this phenomenon.
In my PhD thesis I employed in vivo free-motion electrophysiology to record the activity of neurons in the IL-mPFC and NAc-shell during a habituation protocol to natural rewards.Furthermore, I am currently conducting experiments on animals addicted to amphetamines to compare both conditions. The results reveal that the habituation is associated with changes in neuronal activity patterns, increasing the IL-mPFC activity and decreasing the NAc activity. We observed that in IL pyramidal cells, the repeated administration of chocolate doesn't generate significant changes in the number of excited cells, but it does generate an increase in the frequency of excited cells. On the other hand, in the MSN putative NAc cells, the same protocol generates a decrease in excitatory activity in relation to the number and frequency. These results emphasize the presumed inhibitory role of IL on NAcc in the occurrence of the habituation phenomenon, providing key information to elucidate the changes in neuronal activity that occur in response to rewards.

Title: Functional language mapping with stereo-EEG

Authors: *L. FANDA[1], J. MONNEY[1], F. ARTONI[1], P. MEGEVAND[2];
[1]Univ. de Genève, Genève, Switzerland; [2]Neurol. Dept., Geneva Univ. Hosp., Geneva, Switzerland

Abstract: In epilepsy surgery, functional language mapping (FLM) plays a key role in individualizing cortical resections and limiting their potential negative consequences on language functions. Despite the growing popularity of stereo-EEG, FLM with stereo-EEG electrodes is not a standardized procedure. Here, we systematically assessed cortical responses to simple language tasks in patients undergoing stereo-EEG monitoring.Three basic tasks were used to examine language-related cortical activity: picture naming, auditory naming, and sentence completion. Thus far, 7 patients participated in the study at Geneva University Hospitals' Epilepsy Monitoring Unit. Preprocessing included applying a high-pass filter at 1Hz, a line noise comb notch filter, and rejecting epochs with significant residual artifacts. For each presentation modality, baseline-normalized, event-related spectral perturbation (ERSP) and event-related potentials (ERPs) were computed. These measures were time-locked to the delivery of the stimulus and time-warped to account for varying stimulus durations and realign response events. A significance threshold of 95% was applied to each frequency with respect to its relative baseline (pre-stimulus). The ERP and ERSP preliminary analysis revealed significant functional response on 7.5% of channels per patient, i.e., 9, 5, and 6 channels on average respectively for visual naming, auditory naming, and sentence completion. We detected 4 typical response patterns with respect to baseline: stimulus/response evoked ERPs combined with ultra-HF (150-300 Hz) power decrease, broadband frequency (2-300 Hz) power increase with decay towards the end of the stimulus presentation, HF (50-150 Hz) power increase combined with LF (2-20 Hz) power decrease during stimulus presentation, and anticipatory pre and post HF power increase. These distinct patterns suggest the involvement of several distinct cortical processes. Our functional mapping protocol allows for assessing language function by analyzing cortical responses to visual and auditory inputs. Further work will probe the correspondence between stereo-EEG, fMRI and direct electrical stimulation-based language mapping, and establish the clinical relevance of the various response patterns.

Title: Mapping cortical representations of experiential and distributional semantics for concrete and abstract concepts

Authors: *C. LIU, G. XUE;
Beijing Normal Univ., Beijing, China

Abstract: Recent studies have differentiated two types of semantic information, including the experiential semantics (i.e., information about perceptual, affective, spatio-temporal, and other features of human experience) or distributional semantics (i.e., information about statistical co-occurrence of words), yet the neural representations of these information are unclear. In particular, it is still debated whether the two kinds of semantics are complementary, or the experiential semantics can completely cover the other one. We hypothesized that the concreteness of the stimuli plays a key role and may solve this contradiction, such that concrete concepts involve more perceptual experiences and are better captured by experiential semantics, whereas abstract concepts are learned through language and are better represented by distributional semantics. To test this hypothesis, we collected functional MRI data from 24 participants. Participants judged the familiarity of 420 words (roughly half concrete and half abstract), each for four times. We created the neural representational similarity matrix of the words in each of 200 subregions across the whole brain by calculating the Pearson correlation between the activation patterns (i.e., Neural RSM). Similarly, the experiential and distributional semantic representational similarity matrices (i.e., semantic RSM) were created with the human-rated features of words or word vectors from a word2vector model, respectively. Spearman correlations were conducted between the neural RSMs and semantic RSMs. Partial correlation analysis revealed that when all words are included, both experiential and distributional semantics had unique contributions to the neural RSM and they played a complementary role. The semantic representations were found in a widespread, left-lateralized network. Supporting our hypothesis, experiential and distributional semantics made more contribution to the neural representations of concrete and abstract words, respectively. These results suggest that semantic representations in human brains include both feature-based experiential semantics and association-based distributional semantics that contribute differentially to concrete and abstract words.

Title: Mapping cortical language representation during real-time natural dialogues

Authors: *Z. ZADA, S. A. NASTASE, S. SPEER, L. MWILAMBWE-TSHILOBO, L. TSOI, S. BURNS, U. HASSON, D. TAMIR;
Princeton Univ., Princeton, NJ

Abstract: How is language encoded in the brain during everyday conversations? Typical studies of the neural basis of language present subjects with predetermined, isolated words or sentences, and do not consider the role of spontaneous language production or interactive conversational dynamics. Here, we aim to address both gaps and map brain areas involved in both speech production and comprehension during natural dialogue. We developed a hyperscanning paradigm to collect fMRI data in 30 dyads (60 human subjects) as they freely discussed 10 topics across 5 runs. Topics were presented as a starting point, but each dyad was free to pursue the discussion in different ways. fMRI data were preprocessed using fMRIPrep and spatially downsampled to 1,000 parcels. To characterize the linguistic content encoded in each parcel, we estimated parcel-wise encoding models to predict held-out BOLD signals during speech production or comprehension from word embeddings extracted from the GPT-2 language model. To account for turn-taking during natural conversations, we split the regressors into different subsets for speaking and listening, and fit both submodels jointly using banded ridge regression; this allows the model to learn different weights for each process, and allows us to quantify the relative contribution of each submodel. Then, we correlated the actual and predicted BOLD activity for left-out runs in each parcel, quantifying the extent of linguistic content in the signal. We found strong encoding performance bilaterally in the somatomotor, premotor, and superior temporal cortex (Fig. 1). When evaluated separately, speech production more strongly recruited the somatomotor cortex, while speech comprehension more strongly recruited the superior temporal cortex. These brain maps concur with existing research on the functional role of language areas, but extend them to a naturalistic setting and with an explicit language model. Our findings lay the foundation for assessing brain-to-brian coupling between speakers and listeners in the embedding space.

Title: Right-hemisphere functional connectivity increases in proportion to lesion size after left-hemisphere stroke

Authors: *N. VLADYKO[1], A. T. DEMARCO[1], P. E. TURKELTAUB[1,2];
[1]Georgetown Univ. Med. Ctr., Washington DC, DC; [2]MedStar Natl. Rehabil. Hosp., Washington DC, DC

Abstract: Aphasia is an acquired language disorder that often results from a stroke to left-hemisphere (LH) language areas. Stroke may alter brain activity and functional connectivity (FC) in lesioned and spared areas after a LH stroke. Changes in connectivity may be important for aphasia outcomes at the chronic stage of recovery. However, the findings on the influence of the LH stroke on the RH FC diverge: some find an increase in contralesional FC at the chronic stage, while others report a decrease or no difference compared to controls. Our study examined the relationship between lesion size and contralesional FC. We hypothesized that larger LH lesions would produce greater increases in RH FC relative to small lesions. In this study, 78 chronic LH stroke survivors (35 F, mean age = 60.91; mean days post-stroke = 1592; median lesion size = 80.125 cc) and 72 demographically matched controls (36 F; mean age = 61.1) were included. All participants completed a 14.5-minute movie-watching fMRI scan. After standard pre-processing, FC was calculated for all 246 Brainnetome parcels for each participant. Correlations between lesion size and RH edges revealed that larger LH lesions corresponded to greater FC of many RH edges. Next, we median-split the stroke group based on lesion size (small lesion: n=37, mean lesion size = 31.23 cc; large lesion: n=38, mean lesion size = 177.48 cc), and compared each group to controls using edgewise t-tests. Both groups showed increased RH intrahemispheric FC relative to controls, however, the increase was greater for the large lesion group compared to the small lesion group. Both groups showed reduced interhemispheric FC compared to controls. These findings contribute to the understanding of functional reorganization in the RH after LH stroke and reveal an increase in the RH FC at the chronic stage. The next steps will be to determine if the spatial pattern of RH FC increases relates to lesion location and if FC changes contribute to behavioral aphasia outcomes.

Title: Scaling laws for language encoding models in fMRI

Authors: *R. J. ANTONELLO, A. VAIDYA, A. G. HUTH;
Univ. of Texas, Austin, Austin, TX

Abstract: Representations from transformer-based unidirectional language models are known to be effective at predicting brain responses to natural language. However, most studies comparing language models to brains have used GPT-2 or similarly sized language models. Here we tested whether larger open-source models such as those from the OPT and LLaMA families are better at predicting brain responses recorded using fMRI. Mirroring scaling results from other contexts, we found that brain prediction performance scales log-linearly with model size from 125M to 30B parameter models, with ~15% increased encoding performance as measured by correlation with a held-out test set across 3 subjects. Similar log-linear behavior was observed when scaling the size of the fMRI training set. We also characterized scaling for acoustic encoding models that use HuBERT, WavLM, and Whisper, and we found comparable improvements with model size. A noise ceiling analysis of these large, high-performance encoding models showed that performance is nearing the theoretical maximum for brain areas such as the precuneus and higher auditory cortex. These results suggest that increasing scale in both models and data will yield incredibly effective models of language processing in the brain, enabling better scientific understanding as well as applications such as decoding.

Title: Differentiating reading gains in children with attention deficit hyperactivity disorder and children with reading difficulties using fMRI data

Authors: *T. HOROWITZ-KRAUS[1], M. KHASHAB[2], S. GANAIEM[3], R. FARAH[2], J. FOTANG[4], K. ROSCH[4];
[1]Technion, Baltimore, MD; [2]Technion, Haifa, Israel; [3]Technion, Haifa, Israel, Israel; [4]Kennedy Krieger Inst., Baltimore, MD

Abstract: Reading is defined as the ability to decode printed text to sounds in the spoken language and comprehend it semantically. This ability also relies on different cognitive sub-processes and executive functions (EF), which contribute to the reading process. Dyslexia, or Reading Difficulties (RD), is a neurodevelopmental disorder affecting 15% of children

worldwide. This disorder is highly comorbid with attention-deficit/hyperactivity disorder (ADHD). Children with RD+ADHD demonstrated greater reading and EF challenges than those with RD-only. The goal of the current study is to determine the effect of EF-based reading intervention on behavioral and neurobiological correlates for EF among 8-12 y.o. English-speaking children with RD+ADHD (n=18), RD-only (n=18) and typically developing children (n=18). Behavioral and neurobiological data were collected from all participants before and after eight weeks of training with the EF-based reading computerized program. Functional MRI data were collected using 5 minutes of resting state condition, pre and post-intervention.Separate 3 Group (RD+ADHD, RD-only, typical readers) x 2 Test (Pre, Post-intervention) repeated measures ANOVA were conducted for reading and EF measures. Functional connectivity matrices within and between EF networks, including the cingulo-opercular (CO), fronto-parietal (FP), ventral and dorsal attention networks (VAN, DAN) were defined and compared between the participants and conditions. Prediction models connecting behavioral and neurobiological changes were conducted as well using regression analysis.Training had different effects among the three groups. While typical readers showed the highest scores in reading and EF measures, children with RD+ADHD showed significantly greater gains in comparison to children with RD-only in reading (reading fluency, rate and comprehension) and EF measures (switching, inhibition and working memory). Furthermore, greater changes in functional connectivity following the intervention, mainly between FP and DAN, were found among children with RD+ADHD and RD-only, with a significant decrease in functional connectivity of FP-DAN found in the RD+ADHD group. Changes in FP-DAN significantly predicted changes in naming abilities following training across all groups.The current study's results strengthen the role of EF in the reading process. It also supports the differences, both behaviorally and neurobiologically, in EF among children with RD-only and those with RD+ADHD. In an attempt to get closer to a precision-education approach, a differential intervention for these groups may be indicated.

Title: Maternal COVID-19 Infection Impacts the Intergenerational Transmission of Cognitive Functioning in the Postpartum Period: Results From the COVID-19 Mother-Baby Outcomes Initiative

Authors: *J. M. WARMINGHAM, V. CHAVES, A. LAVALLEE, M. HUSSAIN, G. KURMAN, M. KYLE, D. DUMITRIU;
Dept. of Pediatrics, Columbia Univ. Irving Med. Ctr., New York, NY

Abstract: Children's cognitive and language development in the first six months of life depends on parental support and interaction. Maternal COVID-19 infection during the perinatal period has the potential to alter maternal cognitive and executive functioning, which may influence infant cognitive and language development among children born during the pandemic. **Aims**: Identify the influence of COVID-19 infection on a mother's performance in verbal IQ, executive functioning, and cognitive domains, and test associations between maternal cognitive functioning and infant communication and cognitive skills. **Methods**: Participants were mother-infant dyads (n=283) enrolled in the COVID-19 Mother Baby Outcomes (COMBO) Initiative. Of those enrolled, 32.3% (n=91) of mothers had COVID-19 prior to delivery. At 6 months postpartum, mothers and infants participated in a virtual research visit (via Zoom). Mothers completed performance-based assessments of executive functioning (Trail Making Test A & B), verbal IQ (American National Adult Reading Test), and cognitive functioning (MoCA-blind). With the instruction of a research assistant via zoom, mothers guided infants through the Developmental Assessment of Young Children (DAYC-2) for 6-month-olds. **Results**: Maternal COVID-19 infection was associated with lower maternal cognitive functioning (*B*=-.129, *p*=.019) and lower executive functioning (*B*=.156, *p*=.018) when controlling for sociodemographic factors, including education. Among mothers without COVID-19 infection, higher maternal verbal IQ was associated with higher scores on infant scores on expressive language (*r*=.21, *p*=.005), communication (*r*=.15, *p*=.047), and infant cognition (*r*=.24, *p*=.002). In the COVID-positive group, maternal verbal IQ was not associated with infant development (*p*s>.05). In models adjusted for sociodemographic factors and child age, higher maternal verbal IQ was associated with higher scores in the domains of infant cognition (*B*=.19, p=.005), expressive language (*B*=.198, *p*=.005), and communication (*B*=.15, *p*=.034). Neither maternal executive functioning nor cognitive functioning (MoCA score) were associated with infant development scores (*p*s>.05). In adjusted models predicting infant development, there were no significant interactions between maternal COVID-19 infection and maternal cognitive functioning (*p*s>.05). **Summary:** COVID-19 infection is associated with lower postpartum maternal executive and cognitive functioning and attenuation of intergenerational transmission of cognitive functioning. Maternal verbal IQ was most strongly associated with infant development outcomes at 6 months old.

Title: Longitudinal Associations Between Maternal Cognition and Infant Cognition in a Subsample of the COVID-19 Mother Baby Outcomes (COMBO) Initiative

Authors: *V. CHAVES, M. KYLE, J. WARMINGHAM, A. LAVALLEE, I. AHMED, S. HYMAN, G. ATWOOD, G. KURMAN, D. DUMITRIU;
Columbia Med. Ctr., New York, NY

Abstract: Background: Maternal verbal cognition and caregiving behavior is associated with many facets of infant development in the first two years of life. However, evidence of longitudinal associations between maternal cognition and caregiving behavior with infant development is scarce, particularly among infants born during the pandemic. **Aim of the study:** Determine the potential predictive power of maternal verbal cognition and maternal sensitivity on communication, fine and gross motor, problem solving and personal social development at 18 months old, as well as the impact of SARS-CoV-2 infection on maternal verbal cognition. **Methods:** The sample is composed of mother-infant dyads (n=146) enrolled in the COVID-19 Mother-Baby Outcomes (COMBO) Initiative. Of those, 44.5% (n=65) had a history of SARS-Cov-2 infection perinatally. Maternal sensitivity was coded from a diaper change paradigm recorded via video visit (Zoom) at 4-months postpartum. Maternal cognition was measured at 9-months postpartum with the American National Adult Reading Test (AMNART) via video visit (Zoom). Finally, infant development was measured at 18-months via maternal report using the Ages and Stages Questionnaire, 3rd edition (ASQ-3). **Results:** Maternal COVID-19 infection was associated with lower maternal verbal cognition (r=0.22, p=0.049) but not infant development outcomes. Maternal verbal cognition was not associated with infant cognitive development. However, verbal cognition was a significant predictor of infant's communication (r=0.32, p=0.009) and fine motor (r=0.31, p=0.01) scores. Greater maternal sensitivity was associated with lower infant fine motor scores (r= -0.51, p=0.01). When controlling for covariates, such as baby gender, medical coverage, and ethnicity, maternal sensitivity was not associated with infant development. Higher maternal verbal cognition was associated with higher fine motor scores (B=0.38, p=0.035) but not other child development outcomes at 18 months. **Conclusion:** We assessed the longitudinal associations between maternal cognition and sensitivity on infant's cognitive development in a subset of mother-infant dyads enrolled into the COMBO Initiative. Surprisingly, coded sensitivity at 4 months was related to lower fine motor scores at 18-months in unadjusted but not adjusted models. Notably, maternal COVID-19 infection was associated with lower scores on maternal verbal fluency. Maternal verbal cognition was a significant predictor of infant's communication in unadjusted models and fine motor in the adjusted model, suggesting that maternal verbal abilities are important to promote development in the first 2 years of life.

Title: The effect of white matter-hyperintensities on aphasia outcome in post stroke patients

Authors: *N. NAJIB[1], D. MORALES-SANZ[3], A. DEMARCO[3], P. E. TURKELTAUB[2]; [1]Neurol., [2]Neurol. Dept, Georgetown Univ., Washington, DC; [3]Georgetown university, Washington, DC

Abstract: Small vessel ischemic disease (SVID) is a multifactorial finding that can manifest as white matter hyperintensities (leukoaraiosis) in brain MRIs. Following stroke, several studies suggest that SVID may be a contributing factor to aphasia severity, in addition to other predictors like age, time since stroke, and lesion size. One challenge in studying the importance of SVID in post stroke aphasia is that there are several qualitative rating scales available to measure the severity of leukoaraiosis. Yet, it is unknown whether different rating scales perform similarly or not. Here, we attempt to replicate prior findings that presence and severity of leukoaraiosis contributes independently to post-stroke aphasia, comparing common leukoaraiosis rating scales. Participants included 70 patients (29 F, 41 M) with chronic left hemisphere stroke, who underwent a neuroimaging battery as part of ongoing research at Cognitive Recovery Lab, including high resolution T1 and T2-FLAIR-weighted scans. In order to measure the leukoaraiosis, scans were visually inspected and the right brain hemisphere only was scored on three different qualitative scales: 1- Fazekas Deep White matter hyperintensities (DWMH, Fazekas et al. 1987) ranged from 0 to 3, 2- Fazekas Periventricular Hyperintensities (PVH, Zimmerman et al. 1986) ranged from 0 to 3, 3- Manolio ranged from 0 to 9 (Manolio et al. 1994). The Western Aphasia Battery-Revised (WAB) was used to quantify aphasia severity. We constructed regression models predicting each WAB measure (WAB Aphasia Quotient (AQ)and the four subscores) based on each of three different scales for SVID. All models included lesion size (mean:107.2 cc, SE: 93.4), age (mean: 61.4 years, SE: 11.3) and months since stroke (mean: 57.6, SE: 64.7) as additional predictors. There were negative effects of leukoaraiosis on different measures of the WAB-AQ, with a reduction of 21 points for patients with grade 3 of Fazekas scales (both DWMH and PVH) compared to patients with grade 1 Fazekas scales). There was no effect of Manolio scale scores on WAB scores. The results for sub-scores were similar in terms of statistically significant effects, but different in magnitude. Lesion volume was inversely related to all WAB scores. Months since stroke was positively related to some WAB scores. Severity of aphasia after stroke relates to severity of both deep and periventricular leukoaraiosis based on the Fazekas scales but not Manolio scale. Objective quantitative measures of leukoaraiosis should be investigated, as they may provide greater fidelity than rating scales and could reveal more specific relationships between white matter disease severity and aphasia outcomes.

Title: Cross-linguistic differences in neural encoding and processing of stop consonants: the impact of language experience on attention allocation

Authors: *A. OLIVEIRA[1], Y. KOTHARI[1], T. BLODER[2], Y. SHINOHARA[3], V. SHAFER[1], P. CUNHA[1];
[1]The Grad. Center, CUNY, New York, NY; [2]Catholic Univ. Eichstätt-Ingolstadt, Eichstätt, Germany; [3]Waseda Univ., Tokyo, Japan

Abstract: This study aimed to investigate the impact of language experience on the neural encoding and processing of stop consonant speech sounds. While previous research indicated minimal differences in P1 and N1 amplitude and latencies, recent studies have suggested that bilingual or nonnative experience may induce an Nd effect (Datta et al., 2020). The Nd effect refers to heightened negativity in the Auditory Event-Related Potential (AEP) when attending to a stimulus compared to ignoring it. Yet, it remains unclear whether the Nd effect is influenced by bilingualism itself or the nonnative nature of the target speech sounds. Thus, the present study examined cross-linguistic disparities in AEPs to three types of stop consonants: short lag [pa], pre-voiced [ba], and long lag aspirated [p^ha]. Participants included English monolinguals, Hindi, Spanish, and Portuguese bilingual listeners. All language groups shared the [pa] phoneme, while Hindi and English included [p^ha], and Portuguese, Spanish, and Hindi included [ba]. Electroencephalogram (EEG) data were collected from 42 participants (approximately 10 per group) using 17 scalp electrodes, with a sampling rate of 1000 Hz and a low-pass filter set at 100 Hz. Participants ignored the speech stimuli and watched a muted movie. The data were cleaned and re-referenced to Oz. Results revealed greater negativity in P1 and N1 amplitudes for bilingual participants compared to monolinguals (by approximately 2 μV). Moreover, P1 latencies were approximately 20 ms earlier for bilinguals compared to monolinguals. These findings suggest that bilingual listeners allocate attention differently when processing speech stimuli.

Title: Effect of the temporal processing on the time course of effective connectivity for understanding implicit intention of a speaker in discourse.

Authors: *S. TOKIMOTO[1], N. TOKIMOTO[2];
[1]Mejiro Univ., Tokyo, Japan; [2]Shobi Univ., Saitama, Japan

Abstract: In everyday speech, speakers often communicate their intentions implicitly by indirect expressions (e.g., interrogatives to request something, "Can you reach the salt?"). The speaker's implicit intention is assumed to be derived by pragmatic inference, but the details of this inference are unknown. To discuss the neural mechanisms of the inference, we analyzed the EEG associated with the understanding of a speaker's implicit intentions in discourse, paying attention to temporal processing. Experimental discourses with three speakers were manipulated by two factors: (1) the context to derive a speaker's intention from to be explicit or implicit. With the implicit context, higher-order inference is assumed; and (2) a speaker's intention referring to past or future behavior. EEGs of 24 Japanese native speakers were recorded during the auditory comprehension of the discourse by 64 electrodes on the scalp. We placed 34 regions of interest (ROIs) in the brain, referring to recent fMRI studies on understanding indirect utterances and episodic memory retrieval. After the source localization of the EEG, we examined information flow between the 34 ROIs by calculating partial directed coherence (PDC) for the theta, alpha, beta, and gamma bands every 200 ms after the onset of a critical word, at which the speaker's intention (Yes or No) was recognized. To examine the effect of context implicitness on the inference, we calculated the difference in PDC between explicit and implicit conditions for past and future discourse, respectively. As a result, a significant directed network and its time course for four EEG bands were depicted as a manifestation of the contextual effect. The significant PDC differences corresponding to the contextual implicitness were both positive and negative, indicating that higher-order inference should be understood not only as an increase in information flow, but also as a decrease. Significant PDC differences were observed between multiple ROIs up to 900 ms after the critical word in past discourse, but up to 500 ms in future discourse, suggesting that the time course of the two processing were different with each other. Furthermore, the ROIs that functioned as hubs in past discourse were right inferior frontal gyrus (IFG, BA 47), left IFG (BA 10), left caudate, right insula (BA 13), and left medial prefrontal cortex whereas in future discourse they were left cingulate gyrus (BA 31), left IFG (BA 47), left middle temporal gyrus (BA 21), left superior frontal gyrus (BA 10), left fusiform gyrus (BA 20), and right precuneus (BA 19), suggesting that apparent formal similarity in inference differs significantly in terms of the network of neural activity.

Title: Investigating the neural architecture of speech processing pathways

Authors: *P. NIKOLOV[1], J. LIN[1], C. CORNELL[1], K. YOON[1], S. KIM[1], P. COX[2], S. DAMERA[3], J. RAUSCHECKER[1], M. RIESENHUBER[1];
[1]Georgetown Univ. Med. Ctr. Interdisciplinary Program In Neurosci., Washington, DC; [2]Neurosci., Lehigh Univ., Bethlehem, PA; [3]Children's Natl., Washington, DC

Abstract: Introduction:In current “dual-stream” models of language processing in the brain, speech perception and speech production are thought to be subserved by the anteroventral and dorsal streams, respectively. Computational models of speech processing (“internal forward and inverse models”) propose dynamic interactions of neural representations involved in speech perception and speech production. Yet, despite their importance for speech processing and acquisition, these interactions are still poorly understood. Motivated by a computational model (internal model) framework, we investigated neural signal dynamics and selectivity in an EEG experiment (N=20) involving the use of stimuli optimized to differentially activate perceptual and articulatory neural representations.
Methods:Our preliminary analyses are based on a sample of 20 healthy L1-English speaking adults who completed speech perception and production tasks while their neural activity was recorded using a 64 channel Biosemi Active2 EEG system. A novel aspect of our experiment was the design of stimulus sets optimized to differentiate perceptual (‘percDiff’) and articulatory (‘prodDiff) neural representations. Overt production onset times were determined by three expert manual raters. EEG data were preprocessed using EEGLAB. Using FieldTrip, cluster-based permutation statistics were run using a cluster-identification threshold of 0.01. Overt production was analyzed from 200 to 120ms prior to acoustic production onset, and perception data were analyzed from 0 to 300ms post-stimulus onset.
Results and Discussion: Perception task: Preliminary results reveal three distinct and significant clusters when listening to percDiff word pairs; around 150ms over central channels we found a cluster ($p = 0.009$) that showed larger differences between the percDiff but no significant difference for prodDiff word pairs. Later, at 210 and at 240ms over central/parietal channels we found two distinct clusters, ($p=0.028$ and $p=0.015$, respectively) that did show a significant difference between prodDiff as well as percDiff pairs. For the prodDiff case, we found one significant cluster ($p=0.015$) between 210-240ms that showed significant difference between prodDiff word pairs overt frontal channels.These results are compatible with model predictions of an initial perceptual processing of auditory signals, followed by sensorimotor transformations via the parieto-frontal dorsal stream.Overt production task: Ongoing analyses are investigating signal flow across the hypothesized two processing streams and the transformation between perceptual and articulatory representations.

Title: Effects of Second Language Learning with a Cartoon Cloze Test Examined by EEG Functional Connectivity Analysis

Authors: *N. NAGAIGUCHI[1], S. YAZAWA[3], K. HIRAKI[3], S. SHIMADA[2];
[1]Meiji Univ., Hino-shi, Japan; [2]Meiji Univ., Kawasaki-shi, Japan; [3]Grad. Sch. of Arts and Sci., The Univ. of Tokyo, Tokyo, Japan

Abstract: The Cloze Test is a type of fill-in-the-blank test in which blanks are placed in sentences and is an efficient method for assessing language proficiency. The test is expected to improve language proficiency by guessing a word from the preceding and following sentences. Nowadays, e-learning (studying with tablets, smartphones, etc.) and fun materials like manga, are integrated in the field of education. In this study, we examine the effects of the second language learning training using the Cartoon Cloze Test app by measuring the changes in brain activity. 24 healthy males and females (mean age 23.5 ± SD 4.29) whose second language was English participated in the experiment. The participants' brain activity was measured using electroencephalography (EEG) while solving English tasks before and after a one-month training period (pre- and post-test). The training consisted of English composition and the Cartoon Cloze Test in which blanks were provided in the cartoon dialogues. In the pre- and post-tests, the participants had to answer two types of Cloze Tests: the multiple-choice test, in which they had to select the answer from a list of choices, and the fill-in-the-blank test, in which they had to enter the appropriate word. Functional connectivity analysis was conducted based on the EEG data measured during the pre- and post-tests. The calculated connectivity was compared between the pre- and post-tests. In addition to the tests, a test measuring the individual's overall English proficiency was administered before and after the training. The test scores measuring overall English proficiency and the fill-in-the-blank test showed a statistically significant improvement in the post-test. In the post-test, the EEG analysis showed a significantly higher connectivity in the left frontal lobe for both types of the Cloze Tests. Moreover, there was a significantly higher connectivity between the left frontal and right temporal lobes only for the fill-in-the-blank test. The left frontal lobe is related to analyzing vocabulary, while the right temporal lobe is related to analyzing grammar. Unlike the multiple-choice test, the fill-in-the-blank test requires participants to guess the appropriate word for the blank from the context and to change the word form according to subject, tense, etc. by themselves. Therefore, the training may have improved the bilateral connectivity related to analyzing vocabulary and grammar. These findings suggest that training with the Cartoon Cloze Test enhances functional connectivity in the brain regions related to syntactic parsing and semantic decision, and improves proficiency in the fill-in-the-blank test and overall English test.

Title: Dynamics of discourse comprehension: real-time neurobiological insights from fused fMRI/EEG analysis

Authors: *M. HONG, K. ABOUD;
Vanderbilt Univ., NASHVILLE, TN

Abstract: Approximately 43 million U.S. adults struggle with basic text comprehension. Despite a wealth of research exploring the neural underpinnings of reading disorders in children, reading comprehension in adults remains under-studied. This study fills the gap, applying high-resolution fused MRI-EEG analysis to identify neural mechanisms underlying reading comprehension in adults with varying range of reading abilities. We examined typical adults as they read medical passages in the MRI, and in a separate session, while EEG data was collected. Joint Independent Component Analysis (ICA) revealed comprehension variations associated with differences in network exchanges related to word reading and oral language between groups with lower and higher reading comprehension abilities, with early and late signals involved. These exchanges interacted with executive function regions, aligning with the Simple View of Reading model. This study underscores the complexity of neural network interactions in adult reading comprehension and suggests potential avenues for developing targeted interventions catered to adults with varying levels of reading comprehension ability. This investigation offers crucial contributions to our understanding in the field of neuroscience and brain-based reading comprehension interventions.

Sch. of Med., New York City, NY; [7]Sch. of Engin. and Applied Sci., Harvard Univ., Boston, MA

Abstract: Humans effortlessly transduce the continuous acoustics of speech into rich linguistic meaning during everyday conversations. In this study, we leverage 100 hours (half a million words) of spontaneous open-ended conversations and concurrent high-quality electrocorticography recordings to decipher the neural basis of real-world speech production and comprehension. By capturing unconstrained conversations in real-world settings, we encompassed the richness and diversity of human speech production and comprehension. Employing Whisper, a deep multimodal speech-to-language model, we developed electrode-wise encoding models capable of accurately predicting neural responses to both acoustic and semantic aspects of speech, with single-electrode correlations up to 0.5 in precentral gyrus and superior temporal gyrus and 0.35 in inferior temporal gyrus. We uncover a distributed cortical hierarchy in speech and language processing, with sensory and motor regions involved in speech processing and language areas engaged in semantic and contextual processing. Moreover, we identify distinct regions responsible for speech production and comprehension. Our findings demonstrate mixed selectivity in most electrodes, indicating overlapping processing of speech and linguistic content, as well as speech production and comprehension. Notably, our encoding model allowed us to track processes of speech planning for the first time. We observed a temporal gradient of information processing, where encoding in high-level brain areas such as inferior temporal gyrus ($M = -480$ ms, $SD = 284$ ms) peaked before motor areas ($M = -305$ ms, $SD = 391$ ms, $t(80) = -1.95$, $p < 0.05$) and auditory areas ($M = -250$ ms, $SD = 307$ ms, $t(48) = -2.72$, $p < 0.005$) during production. This study offers a comprehensive account of the unfolding neural responses during fully natural, unbounded daily conversations. By leveraging a multimodal deep learning approach, we highlight the power of deep learning in unraveling the neural mechanisms underlying natural language processing in the human brain. Our research provides valuable insights into the unique complexity and dynamics of human speech processing, contributing to our understanding of language in real-world contexts.

Title: The effect of prosody on figurative language comprehension: the case of albures

Authors: *E. RUIZ ALANIS, A. REYES-AGUILAR;
Sch. of Psychology, Natl. Autonomous Univ. of Mexico, Mexico City, Mexico

Abstract: A set of elements that permit the non-literal interpretation of a speech act are necessary for understanding figurative speech. *Albur* (*albures* in plural) is a word play with scatological or sexual connotations that is typical of Mexican Spanish. Prosody is a key element of *albures* because it makes it easier to interpret them in a non-literal manner.To better understand the influence of prosody in the comprehension of *albures*, we performed a behavioral test to validate a set of stimuli (*albures*) for their further use in an MRI protocol to understand the neurocognitive basis of albur comprehension. Participants watched a video with either 37 or 38 stimuli, and were instructed to hit the space bar each time they recognized an *albur*. Because of the distinctive intonation of albures, we observed that the stimuli with the highest rate of detection contained the most salient prosodic cues. However, only slightly, the detection was also influenced by facial and hand gestures. Additionally, we found that the stimuli can be split into two categories: *albures* that depended on morphological reanalysis, which were the ones with the highest detection rate, and *albures* that relied on polysemy.

Title: Differing contributions of acoustic parameters to sound-symbolic associations for shape- and size-optimized pseudoword sets

Authors: *S. NAYAK[1], S. LACEY[1], L. NYGAARD[2], K. SATHIAN[1];
[1]Penn State Col. of Med., Hershey, PA; [2]Psychology, Emory Univ., Atlanta, GA

Abstract: Sound-symbolism is the idea that there is a non-arbitrary relationship between the meaning of a word and its sound. It has been most commonly studied using pseudowords signifying shape or size. Previously, we analyzed the contributions of the acoustic parameters of a set of 537 consonant-vowel-consonant-vowel (CVCV) pseudowords, created from phonemes with established sound-symbolic shape associations and thus optimized for the shape domain, to their ratings on a rounded/pointed scale (Lacey et al., Cognitive Science, 2020). Here, we extended this analysis to a new set of 638 CVCV pseudowords optimized for sound-symbolic size associations. This new set was created using the same phonemes as the prior set but included three additional vowels with established size associations; each pseudoword in the new set contained one of these vowels in the first, second, or both vowel positions. Participants listened to the pseudowords and rated them on scales capturing the categorical opposites of the shape (rounded, N=30; pointed, N=27) or size (small, N=28; big, N=29) domains. We measured both vocal (mean pitch, pitch standard deviation, pulse number, fraction of unvoiced frames [FUF], jitter, shimmer, mean autocorrelation, mean harmonics-to-noise ratio [HNR], and duration) and spectro-temporal (speech envelope, spectral tilt, and fast Fourier transform [FFT]) acoustic parameters. Vocal parameters were compared to ratings using correlations (Bonferroni-corrected for 9 tests), and spectro-temporal parameters were compared to ratings by computing correlations (Bonferroni-corrected for 3 tests) between the respective representational dissimilarity matrices (RDMs). For the shape-optimized set, all vocal parameters, except for mean pitch, contributed significantly to their shape ratings, but none contributed to their size ratings. For the size-optimized set, all vocal parameters, except for mean pitch, again significantly contributed to shape ratings; but, importantly, duration, FUF, jitter, mean autocorrelation, and mean HNR were significantly correlated with size ratings. All three spectro-temporal parameters contributed significantly to both shape and size ratings in both pseudoword sets. These results indicate the differing contributions of acoustic parameters to sound-symbolic associations of pseudowords for the size and shape domains.

Title: Acoustic stimulus parameters underlying sound symbolism in words and pseudowords

Authors: *J. DORSI[1], S. LACEY[2], L. NYGAARD[3], K. SATHIAN[2];
[1]Pennstate Col. of Med., Hershey, PA; [2]Penn State Col. of Med., Hershey, PA; [3]Psychology, Emory Univ., Atlanta, GA

Abstract: Sound symbolism, the idea that words sound like their meanings (e.g., "knife" *sounds* pointy; "ball" *sounds* round), has mainly been studied in the context of pseudoword ratings for dimensions such as roundedness or pointedness. However, sound symbolism in real words is still not well understood. Here, 24 participants (20 female) rated the *sounds* of real words and pseudowords on a "very round" to "very pointy" scale. We used 160 real words (nouns selected from the list of Sidhu et al., Psychonomic Bulletin & Review, 2021, ranging from very round [e.g., "olive"] to very pointy [e.g., "fork"]) and two classes of non-words: 320 consonant-vowel-consonant-vowel (CVCV) pseudowords created from phonemes with established sound-symbolic associations for shape, and 160 'derived' pseudowords created by replacing some of the phonemes of the real words to make highly word-like pseudowords (e.g. “usive” from “olive” & “foft” from “fork”). We tested the correlations between participants’ round/pointy ratings and twelve different acoustic stimulus parameters: three spectro-temporal (speech envelope, fast Fourier transform [FFT], and spectral tilt); and nine related to voicing (duration, mean pitch, pitch standard deviation, pulse number, fraction of unvoiced frames [FUF], jitter, shimmer, mean autocorrelation, and harmonics-to-noise ratio [HNR]). For the CVCV pseudowords, we found strong and significant correlations between representational dissimilarity matrices (RDMs) of ratings and the spectro-temporal properties of FFT and speech envelope, replicating prior findings (Lacey et al., Cognitive Science, 2020), and a weaker but still significant correlation with spectral tilt. For the real words and the derived pseudowords, the correlations between RDMs of rating and all three spectro-temporal parameters were small, challenging the import of these parameters on shape ratings for these stimuli. For the CVCV pseudowords, we replicated the significant correlations reported by Lacey et al. (2020) for pulse number, FUF, jitter, shimmer, mean autocorrelation, and HNR. The derived pseudowords had largely similar correlations with ratings for these vocal parameters. Importantly, these vocal parameters also correlated significantly with ratings of the real words. These results suggest that physical properties of the speech signal influence how round/pointy real words sound, offering key support for sound symbolism in real language.

Title: Acoustic parameters underlying sound-symbolism in English nouns: a machine learning approach.

Authors: *V. KUMAR[1], J. DORSI[3], S. LACEY[2], L. NYGAARD[4], K. SATHIAN[5];
[1]Neurol., [2]Penn State Col. of Med., Hershey, PA; [3]Neurol., Pennstate Col. of Med., Hershey, PA; [4]Psychology, Emory Univ., Atlanta, GA; [5]Neurol., Milton S. Hershey Med. Ctr. & Penn State Col. of Med., Hershey, PA

Abstract: Sound symbolism refers to the non-arbitrary association between the sound of a word and its meaning (e.g., pseudowords like "lomo" and "teke" sound rounded and pointed, respectively). Previously, using the machine learning "K-nearest neighbors" (KNN) algorithm, we found a combination of acoustic parameters that strongly predicted how rounded/pointed a set of 537 consonant-vowel-consonant-vowel (CVCV) pseudowords sounded. However, it remains unclear whether these acoustic properties also mediate sound-symbolic associations found in natural language (e.g. for real words such as "balloon" and "spike"). Unlike pseudowords, measuring sound symbolism in real words is confounded by semantic knowledge; listeners might indicate that "balloon" *sounds* round because they know it refers to a round object. To understand what acoustic features effectuate sound-symbolic associations in real words, we selected 160 nouns (from the list of Sidhu et al., Psychonomic Bulletin & Review, 2021) that ranged in ratings of meaning from very round (e.g. "olive") to very pointy (e.g., "fork"). Next, we created a set of 160 pseudowords by altering the selected real words to make word-like pseudowords ("derived pseudowords"; e.g. "usive" & "foft"). Finally, we chose 320 CVCV pseudowords from our prior work. We asked 24 participants (20 female) to rate the sounds of all our stimuli on a "very rounded" to "very pointy" scale. We used the KNN algorithm to identify the optimal combination of parameters that predicted sound ratings for each stimulus type. The parameters were the same acoustic properties examined in our prior work: three spectro-temporal (fast Fourier transform [FFT], spectral tilt, speech envelope) and nine related to voicing (harmonics-to-noise ratio [HNR], pulse number, fraction of unvoiced frames [FUF], mean autocorrelation [MA], shimmer, jitter, mean pitch, pitch standard deviation [PSD], and duration). The best parameter combination differed by stimulus type, but with some notable similarities, e.g. FFT, FUF, and HNR were part of the optimal model for all three stimulus types. Finally, we used the optimal KNN model for the derived pseudowords (comprising FFT, FUF, MA, & HNR) to generate predicted sound ratings for the real words. We found that these predicted sound ratings correlated with a measure of the roundedness/pointedness of each word's *meaning* (Sidhu et al., 2021). Using parameters important for predicting the ratings of *pseudoword sounds* makes this analysis unconfounded by any semantic bias. This correlation suggests that words do sound like their meanings, supporting the central claim of sound symbolism.

Title: Natural and artificial metacognition in humans and Large Language Models

Authors: *S. YOSHIZAWA[1], K. MOGI[2];
[1]Physics, Tokai university, Hiratsuka city, Japan; [2]Sony Comp Sci. Lab., Sony Comp Sci. Lab., Shinagawa-Ku, Japan

Abstract: In recent years, various AI systems, generative AIs in particular, have made significant progresses. Comparison with humans is important in assessing the ability of AI (Turing 1950), enhancing alignment of AI with humans (Yudkowsky 2016), and facilitating human collective intelligence (Woolley et al. 2010). One of the Large Language Models, Chat Generative Pre-Trained Transformer (ChatGPT, OpenAI 2023) has been examined regarding its cognitive capabilities. In false-belief-tasks (Baron-Cohen 1992) related to the theory of mind (Baron-Cohen et al. 1995), ChatGPT performs robustly in comparison with humans in in-context learning. (Kosinski 2023, Moghaddam 2023), while its vulnerabilities have been reported (Dsiri 2022). ChatGPT is based on the Transformer architecture (Vaswani et al. 2017), a variation of artificial neural networks. Metacognition in neural networks has been discussed in a "what they know and what they do not know" context (Clark and Karmiloff-Smith 1993, Fleming 2021). Confidence judgments on a particular knowledge is a typical example of metacognition. (Kepecs and Mainen 2012). Here we examined the generic metacognitive abilities of Large Language Models, by analyzing the confidence judgments of ChatGPT. We used the retrospective confidence judgments (RCJs) (Hart 1965) to make comparisons between typical human subjects and ChatGPT. We designed the task with different degrees of uncertainty based on the “Uncertainty Response (UR)” paradigm (Smith and Washburn 2005), which has been used to measure metacognition in animals with quantitative evaluation of the subjects' confidence rates under variable contexts such as “post-decision wager” paradigms. (Persaud 2007). As ChatGPT is context-sensitive and order-sensitive, a robustness check was conducted to evaluate the degree of genericity and universality of the responses of the generative AI to prompts. Based on the results, we analyze the metacognitive capabilities of the currently available Large Language Models such as ChatGPT. We make comparisons with human metacognitive abilities subserved by neural networks including medial and lateral prefrontal cortex, precuneus, and insula (Vaccaro and Fleming 2018). Finally, we discuss the role of language in artificial and natural intelligence, considering the related brain circuits involved in the latter (Fernandez-Duque et al. 2000).

NanoString Technologies, Inc., Seattle, WA

Abstract: The brain is complex and heterogeneous where cell function and cell-to-cell communication are critical for rapid and accurate performance. The ability to explore protein-driven activities at high resolution within the spatial context of their immediate environment is critical to gain comprehensive pictures of brain development, activity, aging, disease or dysfunction, and inflammatory responses. Many existing approaches for high-plex single-cell spatial proteomics face issues around simplicity, speed, scalability, and big data analysis. Here, we present an integrated workflow that addresses key concerns around high-plex proteomics. The CosMx™ Spatial Molecular Imager (SMI) and AtoMx™ Spatial Informatics Platform comprise an end-to-end workflow that efficiently handles highly multiplex protein analysis at plex sizes exceeding 68 targets. The CosMx protein assays use oligonucleotide-conjugated antibodies, that are detected using universal, multi-analyte CosMx readout reagents. The CosMx Mouse Neural Cell Typing and Alzheimer's Pathology panel is optimized to comprehensively profile neural cell lineages across the brain as well as the progression of Alzheimer's disease (AD). Furthermore, 80% of the antibodies making up both panels are cross-reactive with human tissue antigens. The AtoMx spatial informatics platform provides full analysis support, including whole-slide image viewer, and methods for performing built-in or fully customizable analyses for cell typing, ligand-receptor analysis, neighborhood analysis and spatial differential expression. The CosMx protein assay reagents were validated on the FFPE adult mouse brain, mouse embryo, and Alzheimer's positive human brain. We used the CosMx Mouse Neural Cell Typing and Alzheimer's Pathology panel with the CosMx SMI to identify multiple neuronal subtypes, different reactive states of astrocytes and microglia, cell degeneration and proliferation. In a single-cell exploration of mitochondria, we noted distinct patterning of key immune targets based on their immediate microenvironment. Additionally, evaluated the co-expression patterns and activation states of microglia within 200 µm from the amyloid plaque and tau tangles. CosMx SMI is a high-plex spatial multi-omics platform that enables the detection of > 68 proteins at subcellular resolution. In combination with the high-plex CosMx Mouse Neural Cell Typing and Alzheimer's Pathology panel, we present a flexible and scalable informatics platform, a robust solution for comprehensive neural and disease phenotyping that captures the complexity of neuronal and glial cellular activity with full spatial context.

Title: High-plex in situ proteogenomic profiling of human brain sections with spatial molecular imaging

Authors: *A. HECK, K. YOUNG, A. ROSENBLOOM, A. WARDHANI, M. WALTER, G. ONG, R. KHAFIZOV, M. KORUKONDA, Z. LEWIS, T. PHAN-EVERSON, S. BONNETT, C. WILLIAMS, P. DANAHER, R. LIU, J. CEJA NAVARRO, C. KANG, J. REEVES, G. GEISS, D. W. RUFF, J. M. BEECHEM;
NanoString(R) Technologies, Seattle, WA

Abstract: Spatially resolved transcriptomics and proteomics work in concert to create a full biological picture, including cell function, cell activity and cell-to-cell communication. The ability to profile numerous RNAs and proteins on the same tissue section in spatial context is especially advantageous for dissecting neurobiological mechanisms that are largely dependent upon spatial relationships.
Here, we demonstrate the “proteogenomic” capability of the CosMx™ Spatial Molecular Imager (SMI), a single-cell spatial biology platform that leverages the cyclic in situ hybridization chemistry to enable high-plex detection of RNAs and proteins at subcellular resolution. In this proteogenomic assay, 40+ proteins and 6,000 RNAs are targeted on the same FFPE human brain section, delivering highly quantitative results. The 40+ target proteins focus on neural cell typing

and neurodegenerative disease pathology (including amyloid precursor protein, amyloid beta, and phosphorylated tau variants) and are labeled with oligonucleotide-conjugated antibodies. These antibodies are detected via several rounds of reporter-probe binding and fluorescence imaging on the SMI instrument. The same brain section undergoes hybridization with probes targeting 6,000 RNAs that cover broad biological areas and emphasize neuroscience. The >4,900 neuroscience-related genes targeted cover >80 pathways and enable robust neuronal and glial cell typing as well as exploration of key ligand-receptor interactions. As RNA and protein SMI assays utilize the same reporter chemistry, RNA detection occurs on the SMI instrument using the same readout reagents. The SMI proteogenomic approach uses high-plex protein data from a large area of tissue to identify smaller regions of interest on the same slide for 6,000-plex RNA profiling, which offers a more comprehensive view of the cell functions and states observed in the protein assay.
Furthermore, this proteogenomic approach enables enhanced cell segmentation accuracy. The abundant cellular information from the protein data can be used alongside a new cell segmentation framework that leverages data from morphology staining (i.e. GFAP, IBA1, NeuN or OLIG2, and S6) and the 40+ different proteins measured by the SMI platform. Thus, by combining the high-plex neuro protein and RNA assays, we achieve unparalleled cell segmentation, enabling better assignment of transcripts to cells and opening numerous avenues for biological inquiry. We ultimately demonstrate the use of CosMx SMI to create a spatial cell atlas of the brain, define neighborhoods, and probe numerous pathways and cellular phenotypes.

Abstract: The human brain features long-ranging complexities where critical cell function and cell-to-cell communication take place over relatively large interstitial distances and far from the cell somas. The ability to explore protein-driven activities at high resolution, within the spatial context across a large environment and passing through multiple microenvironments, allows a comprehensive picture of brain biology to emerge and is applicable to a myriad of open questions regarding brain development, activity, aging, and neurodegeneration. The CosMx™ Spatial Molecular Imager (SMI) efficiently handles highly multiplex protein analysis on FFPE tissues at > 68-plex. The CosMx protein assays use oligonucleotide-conjugated antibodies that are detected using universal, multi-analyte CosMx readout reagents. Standard CosMx SMI assays make use of standard glass microscope slides with attached flow cells, with 300 mm^2 of the imaging area. The flow cell is mounted within an observation chamber fitted with control valves to precisely deliver cell preparation and analyte detection reagents, and a high-resolution fluorescent microscope linked to a high-capacity data collection computer for further computational analysis of captured images. However, the size, complexity, and heterogeneity of the human brain from one area to another further drive the need to sample much larger tissue sections. Here we demonstrate a novel Large Surface Area flow cell with > 1,600 mm^2 of the imaging area, representing a > 5-fold increase in the imaging area. To enable this large imaging surface area, we developed a custom flow cell larger in size than standard glass slides and optimized the flow-cell design and reagent-delivery conditions to ensure uniform reagent delivery throughout the large-sized samples being analyzed. Combining the Large Surface Area flow-cell imaging capabilities with our human-specific > 68-plex CosMx SMI Human Neural Cell Profiling and Alzheimer's Pathology Protein Panel, we demonstrate spatial imaging of key neural cell typing (GFAP, Iba1, NeuN), and disease-specific targets (APP, Amyloid Betas, Tau), and key post-translational modifications. Advanced neuronal segmentation algorithms allow for specific tracing and segmentation of single neurons, including axons, across hundreds of micrometers of space. The ability to image and evaluate 5-fold larger sections of human brain tissues with unparalleled spatial context and high-plex analyte content allows the grander scale of disease anatomy and processes to be cataloged with exquisite precision and accuracy.

Title: A Flexible and Cost-Effective Method for Generating Custom 10x Beads to Capture Neuronal Splicing Events at Single Cell Resolution

Authors: K. IRWIN[1], I. SINHA[1], K. BOWDEN[2], P. C. WONG[3], ***J. LING**[1];
[1]Johns Hopkins Sch. of Med., Baltimore, MD; [2]Johns Hopkins Univ., Baltimore, MD; [3]Johns Hopkins Sch. of Med., Sch. of Med., Baltimore, MD

Abstract: Droplet-based RNA sequencing methods, such as the 10x Genomics platform, have revolutionized our ability to profile human tissues at single cell/nuclei resolution. However, 10x single nuclei RNA sequencing (snRNAseq) is currently limited to 5' or 3' capture and is unable to directly target the middle portions of mRNA transcripts. Internal sites of mRNAs contain many features that are relevant to disease such as alternative splicing variants. Our lab has developed a method that can generate gel beads that are coated with both poly(dT) oligos and targeted capture oligos (TaCOs), all of which contain cell barcodes and unique molecular identifiers. By designing TaCOs to anneal directly adjacent to internal sequences of interest, TaCO-Seq can profile any portion of an mRNA transcript. Meanwhile, the remaining polyT probes ensure that simultaneous capture of gene expression is unaffected. TaCO beads are compatible with 10x Genomics Chromium X controllers and can integrate seamlessly with downstream sequencing and analysis pipelines.
As a proof-of-concept, our lab has used TaCO-Seq to capture TDP-43-associated cryptic exons in human brain samples from ALS-FTD and identified differential cryptic exon burden in different cell types. Detection of splicing at single nuclei sequencing will help us clarify the genetic and environmental factors that underlie the onset and progression of TDP-43 cryptic exons in neurodegenerative diseases. Furthermore, TaCO-Seq is a highly flexible and cost-effective method that can be generalized for single cell targeting of any sequences in the genome or transcriptome. We believe TaCO-Seq will be a useful tool to study alternative splicing in the fields of neuroscience, oncology, and the broader research community.

Title: Spatial validation of Evercode™ split-pool combinatorial barcoding with RNAscope™ multiplex assay in adult mouse brain cryosections

Authors: *A. SAPRE[1], S. DESHPANDE[2], S. MARRUJO[1], M. SAMBHI[2], L.-C. WANG[2], G. DEMIRKAN[1], M. SRINIVASAN[2], A. ROSENBERG[1];

Abstract: Single nuclei RNA sequencing (snRNA-seq) using Evercode™ combinatorial barcoding is a powerful tool to capture transcriptomes from up to 1 million nuclei to identify both known and novel cell types. Capturing cellular heterogeneity is important for complex tissues such as the mammalian brain where there are defined cell-cell interactions within brain structures. However, traditional snRNA-seq sacrifices spatial information due to the dissociation of samples into single nuclei suspensions. Complementing snRNA-seq with RNAscope™ RNA in-situ hybridization (RNA-ISH) can provide an understanding of the spatial organization of transcriptomes and the ability to visually validate snRNA-seq findings.
To show the power of these complementary techniques we performed both Evercode™ snRNA-seq and RNA-ISH from alternating sagittal sections from a frozen, healthy, adult-mouse brain. First, we developed a protocol to extract nuclei from multiple cryosections to perform nuclei fixation. Fixed nuclei were processed with Evercode™ WT v2 and a subset of barcoded nuclei were sequenced resulting in transcriptomes from 13,800 nuclei with 2,300 median genes/cell. Using this snRNA-seq dataset, we selected a set of highly expressed and differentiating genes to perform RNAscope™ on adjacent sections for granule, Purkinje, oligodendrocyte precursor (OPC), endothelial, glutamatergic, and GABAergic cells. To validate and spatially confirm the presence of these cells, we used the RNAscope™ Multiplex method to detect cell-type markers determined by snRNA-seq and previously established canonical markers. From colocalization patterns, we observed a remarkable concordance of gene expression between snRNA-seq and RNA-ISH, exhibiting both cell specificity and brain region specificity.
In the snRNA-seq dataset, *Car8* was a highly specific and differentiating marker for Purkinje cells, representing only 0.5% of all cells processed. Using RNAscope™ LS Multiplex, we validated *Car8* to be uniquely specific and concordant with *Calb1*, another canonical marker for Purkinje cells. Similarly, we determined *Pde1a* as a marker for glutamatergic cells by snRNA-seq which was found to have region specific co-expression with *Slc17a7* in the cortical layers. Moreover, we determined *Vcan* as a specific marker of OPCs and OPC-like cells by snRNA-seq, which was found to co-localize with *Pdgfra* and both datasets revealed a subset of OPC-like cells that were *Vcan*+ and *Pdgfra*-. These examples highlight the power of complementing snRNA-seq and spatial RNA-ISH techniques to validate biologically relevant findings and understand region specific gene expression.

Title: Improving Yield and Cell Type Diversity in Single Nuclei RNAseq Studies

Authors: *D. J. ACRI[1], L. DABIN[2], R. MUSTAKLEM[3], J. KIM[4];
[1]Stark Neurosciences Res. Institute, Indiana Univ. Sch. of Med., Indianapolis, IL; [2]Indiana Univ., [3]Indiana Univ., Indianapolis, IN; [4]Indiana Univ. Sch. of Med., Indiana Univ. Sch. of Med., Indianapolis, IN

Abstract: Single cell assays for DNA, RNA, and protein provide a rapidly expanding toolkit for understanding neurobiology. These new technologies have made it possible to test new hypotheses concerning rare cell types, cellular responses to disease, and cell-specific mechanisms. However, the accessibility of these types of studies is limited by the cost and quality of cells that can be isolated intact from the dense interconnected cellular matrix of the brain. To overcome this technical hurdle, one popular approach has been to isolate out nuclei from frozen tissue for transcriptomic profiling, termed single nuclei RNA sequencing (snRNAseq). While isolating out nuclei, the presence of ambient RNA and cellular debris can introduce technical artifacts and affect the quality of sequencing. For droplet-based microfluidic systems, this is especially important as debris can clog instruments and lead to the loss of multiple samples. Additionally, the presence of debris can lead to unintentional overloading and the presence of doublets. Therefore, the goal of our study is to test publicly available protocols for efficiency, cost, yield, and overall quality of the data using 10xGenomics Single Cell Gene Expression profiling method. In this study, we directly compare several centrifuge-based and machine-assisted protocols to isolate nuclei from the cortex of 6-month-old wild-type mice. Across all samples, we observed that the presence of debris significantly decreased yield in terms of total nuclei recovered and reads past quality control for ambient RNA via SoupX pipeline. Directly comparing between technologies, we found that centrifuge-based isolation protocols were cost-effective but were significantly variable in total nuclei recovered. In contrast, machine-assisted isolation protocols that did not require staining were the most time-efficient and were able to capture a wider diversity of cell types. Finally, ex-vivo activation of several glial cell types was found to be modulated by the protocol used to isolate nuclei. This study provides valuable benchmarking of cost, time, and quality control metrics associated with nuclei isolation for snRNAseq.

Sch., Boston, MA; [6]Broad Inst. of MIT and Harvard, Cambridge, MA

Abstract: While somatic variants have been heavily studied in tumors, their prevalence and significance to other diseases, and in healthy individuals, are less well-understood. Our lab and others revealed that somatic mutation is a widespread phenomenon throughout normal brains. Human neurons each contain 100 or more clonal somatic single nucleotide variants (sSNV) at birth, acquired during prenatal development, and gain 15-20 additional sSNVs arising per year per genome. Despite being the main source of genetic diversity between cells within an individual, the patterns and mechanisms by which somatic variants form in different brain cell types as well as their functional impact are not well understood. Typical methods for detecting somatic variants in single cells do not provide simultaneous gene expression, cell type, or chromatin state information. In order to bridge somatic variant calling, gene expression, and epigenetics we developed the Duplex-Multiome method. In Duplex-Multiome, a strand-tagging step is added to construction of 10X Single Cell Multiome ATAC + Gene Expression libraries. Consensus between both strands of tagmented DNA, or duplexes, can then be applied to single cell ATAC-seq libraries to filter out artifacts created by PCR and sequencing error while maintaining true somatic variant calls. Duplex-Multiome was performed on three post-mortem cortical brain samples ranging from gestational week 14 to 51 years of age, generating data in >10,000 single nuclei representing 13 different cell types. Requiring duplex consensus reduced variant calls likely to be artifacts by up to 10-fold, as well as eliminated mutational signatures resulting from sequencing error. Duplex consensus somatic variant calls further fit known contributors to somatic variation in the human brain such as the clock-like mutational signatures SBS1 and SBS5. Variant calls could be also assigned to cell type as determined by multimodal clustering of single cell ATAC + Gene Expression data. Duplex-Multiome thus enables association of somatic variants with cell type and gene expression in the human brain at a much larger scale than previously possible.

Title: Determination of cell type specific variant burden in a somatic SLC35A2-associated drug resistant focal epilepsy case reveal variant enrichment in non-neuronal cell types

Authors: *D. LAI[1], M. GADE[1], B. E. PORTER[2], E. L. HEINZEN[1];
[1]Univ. of North Carolina, Chapel Hill, NC; [2]Stanford Univ., Stanford Univ., Stanford, CA

Abstract: Germline genetic variants in *SLC35A2*, a Golgi-localized, UDP-galactose transporter essential for cellular glycosylation, have been implicated in one type of congenital disorder of glycosylation associated with intractable seizures and X-linked developmental and epileptic encephalopathy. Recent evidence has recognized somatic, loss-of-function *SLC35A2* variants as an important contributor to drug resistant neocortical epilepsy and in mild malformation of cortical development with oligodendroglial hyperplasia in epilepsy (MOGHE). However, the specific cell types harboring *SLC35A2* variants remain largely under investigated. In this study, we demonstrate cell type specific variant burden in human somatic mosaic brain tissue can be determined using SoMoSeq (Somatic Mosaic tissue Sequencing); a modified G&T-seq method that enables parallel genotyping and full-length cDNA sequencing from single nuclei. Resected brain tissue was obtained from a male with drug resistant focal epilepsy harboring a pathogenic *SLC35A2* variant (c.C435A:p.Y145X) and an age-matched pediatric stroke case (control). Total nuclei were isolated, immunostained with an anti-NeuN antibody and underwent fluorescence-activated nuclei sorting. Forty-six NeuN+ and 46 NeuN- single nuclei were sorted into each well of a 96-well plate along with two mini-bulk (n=50 nuclei) and two blank wells. We collected twenty-four 96-well plates, for a total of 1104 NeuN+ nuclei and 1104 NeuN- nuclei, for SoMoSeq processing where DNA and RNA were physically separated for genotyping and full-length cDNA generation, respectively. We observed a genotyping dropout rate of 39% (857/2208) and a doublet rate of 0.5% (11/2208). Of those that genotyped (n=1340), 92% genotyped as wild-type and 8% genotyped as variant positive (variant allele fraction, VAF = 8%). This VAF is concordant with that in bulk tissue, which was determined as 10% using digital PCR. Interestingly, variant positive nuclei are more prominent in NeuN- (13.5%) compared to NeuN+ (3%) populations, suggesting that the variant is preferentially enriched in non-neuronal cell types. We have selected all *SLC35A2* variant harboring cells (n=91), matched variant negative cells (n=213), and stroke control (n=37) for cDNA library preparation and sequencing on the Illumina NovaSeq6000 to a targeted depth of 8-10 million reads per cell. Analysis of transcriptomic data to robustly classify the specific cell types harboring the *SLC35A2* variants is currently ongoing. This study demonstrates the successful application of SoMoSeq to human somatic brain tissue, providing a powerful tool to quantify cell type specific variant burden.

Title: Investigating Neuroinflammation in the human brain tumor microenvironment using a novel rna-protein co-detection assay

Authors: A. DIKSHIT[1], S. DESHPANDE[1], L.-C. WANG[1], G.-A. KIM[1], J. YU[1], **D. WAKHLOO**[1], *J. PULLIAM[2], M. SRINIVASAN[1];
[1]Advanced Cell Diagnostics, a Bio-Techne brand, Newark, CA; [2]Bio-Techne, Rockville, MD

Abstract: Glioblastomas are one of the most aggressive forms of brain tumors characterized by distinct genetic and molecular signatures. The progression of these tumors as well as their response to therapy is impacted by the complex tumor-immune interactions in the microenvironment. Compared to other solid tumors, the role of immune cells in progression, invasion and prognosis is not well studied for CNS tumors. Assessing unique features of the brain tumor microenvironment requires a multi-omic strategy to identify unique immune cells infiltrating the tumor and their dynamic interactions with other cells within the tumor. Using the flagship single-cell spatial RNAscope technology, target gene and protein expression can be visualized to characterize cell types and tissue neighborhoods. Here, we demonstrate a novel method for the simultaneous detection of RNA and protein using a modified co-detection assay. With this novel TSA amplification-based co-detection assay we visualized a few combinations of 3 RNA and 3 protein marker panels on human FFPE normal brain and brain tumor tissues. Antibodies targeting key immune cell markers such as CD8, IBA1 and CD68 were used. In addition, neuronal and morphology marker antibodies for PanCK and NeuN were included in the panels. RNA probes targeting chemokines and cytokines such as CXCL10, IFNG, TNFA, CXCL2. IL-6 were also used in the panels. Immune cells infiltrating the brain tumor tissues were characterized by studying co-expression of key RNA and protein markers. The tumors demonstrated infiltration of immune cells such as T cells, microglia and macrophages represented by expression of CD8, IBA1 and CD68 protein markers. In addition, expression of cytokines was used to assess the activation status of these immune cells which is an important indicator for potential success of certain therapeutic interventions. Distinct differences in neuroinflammation signatures were also observed between the normal and tumor brain tissues. The assay offers a powerful technique for visualizing target RNA biomarkers in specific cell-types identified by cell-marker protein expression. This is a valuable tool for multiomic analysis and accurate interrogation of complex tissues such as the brain to obtain insights into novel prognostic and therapeutic biomarkers.

Title: High-plex analysis of expression profiles in human frontal cortex following ischemic stroke at single- cell resolution by spatial molecular imaging

Authors: *O. HO-SHING, M. PATRICK, C. WILLIAMS, A. WARDHANI, C. PHAN, S. ILCISIN, O. APPELBE, S. HE, H. ZHAI, J. LYSSAND, V. DEVGAN, M. RHODES, J. BEECHAM;
NanoString Technologies, Seattle, WA

Abstract: Stroke is ranked as the fifth leading cause of death and the principal cause of long-term disability for adults in the United States. Ischemic stroke occurs due to a blockage or rupture in blood vessels, leading to critical loss of oxygen and glucose to the brain. This triggers the release of free oxygen radicals, disruption of the blood-brain barrier, and ultimately the death of neuronal tissue (infarction). The progression of neural damage after ischemic stroke is mediated through the interaction of immune cells, glial cells, surviving neurons, and the surrounding extracellular matrix. Therefore, a deeper understanding of the impact of ischemic infarction on long-term neuronal function requires a high-resolution analysis of interactions between these spatially and functionally distinct cell types. Here we evaluate the differential expression in the frontal cortex of ischemic stroke patients compared to non-infarct areas, utilizing the CosMx™ Spatial Molecular Imager (SMI). SMI uses high-plex in situ imaging chemistry to provide high-throughput and high-sensitivity single-cell analysis of RNA and marker proteins. The CosMx™ SMI 6,000-plex assay targets critical genes involved in metabolic (>20), immunological (>70), and neurobiological (>80) pathways, providing a comprehensive investigation of single-cell expression in normal and neurodegenerative brain tissue. We characterize the loss of neuronal function in peri-infarct cortical tissue and elucidate post-infarction mechanisms within glial and immune cell types in the surrounding extracellular matrix. We find that peri-infarct cortical regions initiate regulatory expression profiles distinct from non-infarct regions, demonstrating higher integration of astrocytic processes, spatially identified throughout the tissue by immunohistochemical marker GFAP. We also distinguish the extent of the peri-infarct border and find a decrease in typical neuronal signaling pathways within surviving neuronal cells, but a persistent increase in immunological and inflammatory pathways. Altogether, these data demonstrate that spatially characterizing astrocytic and neuronal pathways in post-infarction tissue provides a granular examination of neurodegeneration. These findings may facilitate targeted cell type-specific therapies for patients following ischemic stroke injury. The CosMx™ 6,000-plex assay allowed us to simultaneously visualize RNA transcripts and relevant protein analytes at a single-cell level, providing a quantitative multiomic approach to surveying the heterogeneous environment of brain tissue. Title: Multimodal profiling of neurons in 3D human cortical organoids using patch-seq

Authors: ***E. BAT-ERDENE**[1], A. J. BORELAND[1], R. GABRIEL III[1], J. LIU[2], A. KREIMER[2], Z. P. PANG[1];
[1]Dept. of Neurosci. and cell biology, Child Hlth. Inst. of New Jersey, Rutgers Robert Wood Johnson Med. Sch., New Brunswick, NJ; [2]Dept. of Biochem. and Mol. Biol., Robert Wood Johnson Med. Sch., Piscataway, NJ

Abstract: The progress in understanding the pathophysiology of mental disorders is hampered by the lack of an integrative understanding of diverse cell types in human brain. Brain neurons exhibit diversity in gene expressions, morphology, and electrophysiology. However, it has been technically difficult to investigate all aspects of neuronal diversity in the same cells. We hypothesize that electrophysiological (and possibly morphological) features of human neurons can be predicted by single-cell transcriptomic profiles. Therefore, the aim of this study is to construct a comprehensive cell atlas of human neurons from 3D brain organoids using multimodal analyses. We used 3D cortical organoids derived from human induced pluripotent stem cells (hiPSC). Patch-seq combining patch-clamp recording, biotin staining, and single-cell RNA sequencing provided a morpho-electric annotation of most transcriptomically defined neural cell types. The electrophysiological features include cell membrane properties, resting membrane potential, action potential, after hyperpolarization potential, postsynaptic currents and, Na+ and K+ whole-cell currents. The morphological features include the soma, dendrites, axon, and axon terminals.We profiled more than 100 human neurons with electrophysiology and single-cell RNA sequencing using SMARTSeq with excellent quality control. The profiles include 3000 to 10000 unique genes from one cell. The neural clusters represented distinct subtypes, including upper and deep cortical neurons, progenitors, and radial-glial cells. Our results suggest that neuronal types in the neocortex represent a diverse pool of cells that consists of distinct non-overlapping subtypes. Ongoing experiments will significantly increase the number of cells with complete profiles to enrich the database.

Abstract: The human cerebral cortex is composed of billions of morphologically and functionally distinct neurons. These neurons are produced in an organized fashion during development. The neocortex is a 6-layered laminar structure, with a precise anatomical organization ensuring proper function. Each layer is comprised of distinct populations of neurons distinguished by differences in size, shape, connectivity, and gene expression. The complex cognitive functions of the adult neocortex depend on the precise emergence of these properties during development. Elucidating the molecular mechanisms that regulate human neocortical development has been a challenge for many years. Development of the neocortex requires an orchestration of a series of processes including the appropriate generation, migration, positioning of the neurons, acquisition of layer-specific transcriptional hallmarks, and formation of precise axonal projections and networks. Over the past years, fate-mapping, genome-wide analysis, and transcriptome profiling has been used to characterize this neocortical cellular diversity. In our pilot study, we apply the 6000-plex NanoString's CosMx™ SMI, a spatial molecular imaging platform to detect RNA and protein markers in situ at single-cell and subcellular resolution. The pre-defined content from the 6000-plex panel has comprehensive coverage of genes and pathways. The assay utilizes standard IHC-grade antibodies or in situ RNA hybridization probes that are covalently linked to small (~20nm) high information content single-molecule imaging barcodes. The platform's ability to perform high-plex multi-omic imaging with sub-cellular resolution allows the visualization and quantification of targeted RNA and proteins directly from tissue samples. Using second trimester primary brain samples, focusing on the neurogenic and gliogenic periods, we visualize known and novel patterns of RNA transcripts across cell types. We identify transcripts involved in cell-cell interactions, synaptogenesis and cortical layering spanning cortical laminae. Using this platform reiterates fundamental differences between neurogenic and gliogenic radial glia, excitatory neurons, and other cell types, highlighting differences in local transcription between the two significant time periods, across the germinal zones and cortical plate

Abstract: Recent advances in transcriptomic studies of the human cortex have provided a universal framework to explore cell type diversity in the brain. Among these cell types, cortical excitatory neurons are known by their signature dendritic arbors, with a pronounced apical dendrite, which compartmentalize and integrate synaptic input to compute and ultimately translate signals to downstream neurons. Using Patch-seq sampling, which facilitates the collection of morphology, electrophysiology, and transcriptomic data from the same neuron, we investigated the morphoelectric and transcriptomic properties of human cortical, intratelencephalic (IT)-projecting excitatory neurons in Layer 4 through 6 (L4-6). IT neurons serve as the recipients of thalamocortical projections and are responsible for cortico-cortico feedback. They also have diverse transcriptomic properties and map to fourteen different IT transcriptomic types based on a reference taxonomy (Hodge et al 2019) and can be roughly aggregated based on their laminar position into L4 IT, L4/5 IT, L4/5 Near Projecting (NP), L5 IT, L6 IT and L6 IT Car3 types. Here we evaluated whether the transcriptomic diversity of these neurons, which account for over half (14 out of 24) of the excitatory transcriptomic types in the taxonomy corresponds to distinct morphoelectric properties. Our findings reveal differences in the tendency of apical dendrites to reach layer 1, apical dendrite orientation, and somato-dendritic morphology across transcriptomic types. We also see subtle shifts in dendrite and soma distribution patterns of different L4 IT transcriptomic types. These patterns suggest that cortical inputs to these neurons are highly topographic. The electrophysiological properties of these neurons also vary in a layer-specific and depth-dependent manner. In summary, the combined transcriptomic and morphoelectric properties of these neurons offer insights into how different

IT neuron types may contribute to the flow of information across cortical circuits within the human cortex.

Title: Spatial Transcriptomic Profiling of the human and mouse retina Prepared with the CryoJane Tape Transfer System using GeoMx DSP and CosMx SMI Spatial Analysis

Authors: *Y. LIANG;
NanoString Technologies, Seattle, WA

Abstract: Spatial Transcriptomic Profiling of the Human and Mouse Retina Prepared with the CryoJane Tape Transfer System using GeoMx DSP and CosMx SMI Spatial Analysis
Yan Liang[1], Charlie Glaser[1], Wei Yang[1], Su Ma[1], Bela Anand-Apte[2], Vera L. Bonilha[2], Sujata Rao[2], William Horrigan[2], Joseph Beechem[1]
[1]NanoString® Technologies, Seattle, WA, USA[2]Dept. of Ophthalmology, Cole Eye Institute, Cleveland, OH, USAThe goal of the study is to identify key transcriptomic markers in the retina by profiling retina layers using spatial transcriptomic analysis at cellular and subcellular levels. Additionally, transcriptomic results from each layer are compared to identify layer-specific characteristics. Human and mouse retina samples, prepared as fresh and fixed frozen, are analyzed using the GeoMx® Digital Spatial Profiler (DSP) with the Mouse Whole Transcriptome Atlas. Furthermore, FFPE mouse retina samples are analyzed to characterize transcriptomic profiles at single-cell and subcellular resolutions on CosMx™ Spatial Molecular Imager (SMI) using the 1,000-plex Mouse Neuroscience Panel.Retina is using Cryo-Jane Taper Transfer system and mounted on adhesive-coated slides using an adhesive tape. This method is used to secure fragile frozen tissue, such as the retina. Human and mouse samples were stained for immunofluorescence microscopy with antibodies that target NF-H, GFAP and NeuN for GeoMx DSP and 18s rRNA, amyloid-beta and GFAP for CosMx SMI. Staining allows for the identification of structural layers in the retina and regions of interest for spatial profiling. On DSP, each sample had three ROIs in each photoreceptor, inner nuclear, and ganglion cell layers, and then, photocleaved oligonucleotides from probes were collected and sequenced for readout. For SMI data analysis, six field of views were placed on each section to cover most regions of multiple layers.Using GeoMx DSP, ~6,000 genes were detected in human retina samples, and approximately 500 genes were detected between the photoreceptor and inner nuclear

layer.CosMx SMI results show we were able to identify cell types (e.g. amacrine, horizontal cell, bipolar cell, ganglion cell) and cell-specific markers for outer nuclear layer, inner nuclear layer and ganglion cell layer. Data between GeoMx DSP and CosMx SMI showed high concordance, identifying multiple biologically relevant genes in each layer. Overall, our data demonstrate that GeoMx DSP and CosMx SMI can identify distinctive, biologically relevant genes in the retina as specifically targeting different morphological structures. In addition, we show the validity of the CryoJane Tape Transfer System using GeoMx DSP and CosMx SMI RNA-based assays.

Title: Chromatin organization of retinal development at the single-cell level

Authors: *V. TRINH[1], C. P. SANTIAGO[1], R. P. CARMEN[1], D. T. KIM[2], J. P. LING[1], S. BLACKSHAW[1];
[1]Johns Hopkins Univ., Baltimore, MD; [2]Aarhus Univ., Aarhus, Denmark

Abstract: The spatial organization of chromatin in the nucleus dictates gene expression, where interacting elements, such as enhancers and promoters, are situated in close proximity. These configurations can be measured through chromatin conformation capture (3C) and genome-wide Hi-C studies, which have revealed changes in chromatin architecture during lineage commitment, cell differentiation, and neural development. Large-scale changes in chromatin structure, therefore, play an important role in altering gene expression systems and cellular functions. The retina has long been used as a model for studying neurogenesis because it is an easily accessible extension of the CNS. However, since rod photoreceptors make up ~80% of cells in the murine retina, single-cell genomics is necessary to study low-abundance cell types. The Blackshaw Lab has developed an atlas of mouse retinogenesis at the single-cell level using scRNA-seq and scATAC-seq at multiple time points throughout retinal development. Hi-C and single-cell Hi-C has also been conducted in the retina, however, the previous studies only focused on rod photoreceptors and had sparse data on low-abundant cell types. Multiomic studies that correlate different genomic modalities allow for a more comprehensive understanding of gene regulation. Overall, there lacks a single-cell system that unifies measurements in chromatin organization with transcriptomic and other epigenomic modalities. To capture both 3D genome organizational and transcriptomic data in individual cells, we adapt the Hi-C protocol for use in a multiomic, droplet-microfluidic single-cell system. We demonstrate that our droplet-based single-cell Hi-C + RNA-seq protocol is able to capture and correlate DNA contacts and RNA profiles of cells. The method will enable the analysis of local and large-scale chromatin

conformational changes associated with cell type-specific gene expression changes in retinal cells and other heterogeneous tissues.

Title: Spatial and Single-Cell Multiomics of the Mouse Retina Reveals Cellular and Tissue-Level Changes Induced by Spaceflight

Authors: *J. PARK[1], E. OVERBEY[1], J. KIM[1], S. GAENSAN[1], A. KLEINMAN[1], J. PROSZYNSKI[1], G. INGHIRAMI[1], W. YANG[2], C. GLASER[2], Y. LIANG[2], X. W. MAO[3], J. BEECHEM[2], C. MASON[1];
[1]Cornell University: Weill Cornell Med. Col., New York, NY; [2]NanoString Technologies, Seattle, WA; [3]Loma Linda Univ., Loma Linda, CA

Abstract: Spaceflight causes a variety of physiological changes, including vision impairment known as spaceflight-associated neuro-ocular syndrome (SANS). Possible causes include radiation exposure, microgravity, and changes in intracranial venous flow. SANS can lead to optic disc edema, posterior globe flattening, chorioretinal folds, and hyperopic shifts. These changes pose a risk to astronaut health and will likely require mitigation for long-duration spaceflight missions.
To fully understand the pathogenesis of SANS, we profiled gene expression and chromatin profiles of mouse retina from the Rodent Research-6 (RR-6) mission, which flew on the International Space Station (ISS) for 29 days and was harvested after 4 days of return in 2017. Using the NanoString GeoMx® Digital Spatial Profiler, tissue architectures were characterized by Nf-H, GFAP, CD31, and Cyto13 staining to collect whole transcriptome profiles of distinct regions within the mouse retina, including lens, corneal stroma, ganglion, inner nuclear, outer nuclear, photoreceptor, and retinal pigment epithelium. Based on these region-specific expression profiles, the NanoString CosMx™ Spatial Molecular Imager with CosMx RNA Assays are currently being implemented to define associated receptor-ligand and cell-cell interactions.
To match the spatial findings to a complete cellular profile, we utilize 10X Genomics Multiome single-nuclei RNA- and ATAC-sequencing from the opposite (left) eyes that were preserved flash frozen. By integrating multimodal sequencing data with spatially resolved transcriptomics

data, we present a multimodal atlas of mouse retina and demonstrate the impact of spaceflight in a tissue microenvironment and cellular level. Our analysis is ongoing, and we expect to highlight perturbed pathways, including those involved in photoreceptor cell degeneration. We also expect to find molecular targets and insights related to countermeasures for SANS, which will be crucial in preparing and protecting astronaut vision for future spaceflight missions.

Abstract: Recent years have seen extraordinary advances in synaptic-resolution connectomics using electron microscopy (EM). Despite enabling high fidelity reconstruction of synaptic connections, EM connectomics is not intrinsically robust to errors that may arise from tracing, sectioning, and imaging and lacks molecular details that define circuit function, such as ion channels and receptors. Here, we report progress on an effort to achieve scalable synaptic-resolution connectomics combining expansion microscopy, a recently-developed optical super-resolution imaging technique, with multiplexed antibody staining and cellular barcoding. With this approach, we are able to map nanoscale cell morphology and achieve rich *in situ* molecular annotation of cell type markers and synaptic proteins. This method should facilitate reconstruction of synaptic connections and make tracing error-robust via the input of cellular barcodes. Scaling properties for barcoded connectomics suggest the potential to eventually

overtake electron microscopy in volumetric reconstruction speed by 1 to 2 orders of magnitude while also delivering molecular annotations.

Title: Patch-seq technique: the method, parameters, and adaptations for optimal single neuron characterization

Authors: *K. NASIROVA, K. BLAKE, A. MCCUTCHEON, K. HADLEY, R. MANN, B. PAWAR, R. RAJANBABU, M. VANNESS, S. VARGAS, M. CLARK, J. GLOE, W. HO, N. DEE, K. SMITH, J. TING, R. DALLEY, E. LEIN, H. ZENG, T. JARSKY, S. SORENSEN, B. KALMBACH, B. R. LEE;
Allen Inst., Seattle, WA

Abstract: Patch-seq is a technique (Lee, Budzillo, et al. eLife 2021) that collects electrophysiological, transcriptomic, and morphological (MET) data from a single neuron. This multimodal characterization has been instrumental in defining the phenotypic properties of transcriptomic types across regions and species. As we have expanded to different species and brain regions, we have identified and optimized the key parameters to obtain high quality multimodal data from diverse cell types. These parameters include cell/slice health evaluations, an automated electrophysiology acquisition software package with custom modules, and adaptive nucleus extraction methods. Additionally, we have identified decision points in the Patch-seq process depending on the dataset to be acquired. For example, if the goal is to obtain electrophysiology and transcriptomics data (ET), the extraction/retraction period is more simplistic; however, if the goal is to obtain electrophysiology, transcriptomics and morphology

(MET), extra time and a more cautious pipette retraction is needed to preserve the somatic membrane for morphological evaluation. To improve the specificity of Patch-seq targeting, we utilized various forms of genetic tools to target specific cell types. For the mouse neurons, genetic tools such as Cre-lines, retro-orbital injections and intracranial injections of retrograde tracing were utilized to target cell types or projection neurons. For human and non-human primate, we optimized a culture paradigm to extend the use of each case and the opportunity to apply enhancer adeno-associated viruses (AAVs) to label and target cells in a cell type specific manner (Lee, Dalley, et al., BioRxiv 2022). The Patch-seq protocol, its key parameters, and much of the data collected by our team are publicly available. The aim of this project is to assist the larger scientific community in Patch-seq experiments with the hope to foster a collective effort to understand the multimodal properties of neurons across regions and species.

Title: The transcriptomic and spatial organization of telencephalic GABAergic neuron types

Authors: *C. T. J. VAN VELTHOVEN, M. KUNST, D. MCMILLEN, C. LEE, J. CAMPOS, J. CLOSE, S. DANIEL, B. LONG, J. MALONE, N. MARTIN, A. RUIZ, N. VALERA CUEVAS, C. PAGAN, L. KRUSE, J. WATERS, L. NG, K. A. SMITH, B. TASIC, Z. YAO, H. ZENG;
Allen Inst. for Brain Sci., Seattle, WA

Abstract: The telencephalon consists of an intricate set of structures that are required for some of the most complex and evolved functions of the mammalian brain. Gamma-aminobutyric-acidergic (GABAergic) cells form a very heterogeneous population of neurons throughout the telencephalon that play a crucial role in regulating the activity of neuronal networks. Recently, we generated a comprehensive, high-resolution transcriptomic and spatial cell type atlas for the whole mouse brain (Yao et al 2023). We leveraged this atlas to conduct an in-depth analysis of the transcriptomic diversity and spatial organization of GABAergic neuronal types in the mouse telencephalon. We analyzed ~615,000 GABAergic neurons from cerebral cortex, including isocortex, hippocampal formation, olfactory areas, and cortical subplate, and the cerebral nuclei

including striatum and pallidum. The neurons were clustered into 5 classes, 52 subclasses, 219 supertypes, and 1051 cell types. The classes and subclasses are mostly defined by their developmental origin and spatial location. Within this dataset, we identified a large set of highly distinct cell types as well as continuous molecular gradients within and across different regions. The discrete and continuous gene expression diversity collectively shape the cellular diversity that underlie the diverse function of the many regions and neural circuits in the telencephalon.

Title: Analysis of neural activity in molecularly defined cell types in the mouse frontal cortex

Authors: *T. WANG[1], A. SINGH[1,2], K. DAIE[2], K. SVOBODA[2];
[1]Janelia Res. Campus, Ashburn, VA; [2]Allen Inst. of Neural Dynamics, Seattle, WA

Abstract: Neuronal cell type classification has been revolutionized by advances in genomics. It is now possible to profile the mRNA repertoire of individual cells and cluster populations of cells into ‘transcriptomic cell types’ (t-types). Individual brain regions can contain dozens of t-types. Large-scale functional imaging experiments have revealed diverse patterns of neural activity during behavior. The correspondence between t-types and behavior-related activity patterns is largely unknown. To establish this correspondence we developed FIRE (functional imaging registered to gene expression) to link transcriptomic identity with neuronal activity. Mice were trained to perform a sensory discrimination task that required short-term memory. Anterior lateral motor (ALM) cortex is necessary for this task. ALM neurons exhibit persistent activity that predicts upcoming movements (i.e. a neural correlate of motor planning), in addition to activity related to sensory stimuli, movements, rewards and other behavioral parameters. Population calcium imaging was performed using two-photon microscopy over the course of several weeks in excitatory (Slc17a7-cre, Emx1-cre, Rbp4-cre) and inhibitory (Vgat-cre) GCaMP-expressing transgenic lines. After in vivo imaging, thick (300 um) brain slices were cut and aligned to the imaged volume with single-cell precision. We performed RNA fluorescence in situ hybridization coupled with expansion microscopy (EASI-FISH). This approach relies on the hybridization chain reaction to generate bright fluorescent punctae corresponding to individual

mRNA molecules that can be resolved and counted. To rapidly image large sample volumes, we built a custom multispectral selective plane illumination (i.e. 'lightsheet') microscope that enables the simultaneous detection of 7 dyes species. We have also developed a multi-stage computational pipeline to efficiently process the resultant TB-scale raw image datasets. Finally, we analyzed the extent to which t-types statistically explain the diverse response patterns observed across thousands of neurons. Defining cell type-specific behaviorally-related signals is a necessary step towards understanding how computation is implemented in neural circuits.

Abstract: To systematically understand age-induced molecular changes, we performed spatial transcriptomics of young, middle-aged, and old mouse brains and identified seven transcriptionally distinct regions. All regions exhibited age-associated upregulation of inflammatory genes and downregulation of genes related to synaptic function. Notably, aging white matter fiber tracts showed the most prominent changes with pronounced effects in females. The inflammatory signatures indicated major ongoing events; microglia activation, astrogliosis, complement activation, and myeloid cell infiltration. Immunofluorescence and quantitative MRI analyses confirmed physical interaction of activated microglia with fiber tract and concomitant reduction of myelin in old mice. Machine learning algorithms identified transcription factor networks driving these changes. Our study provides a resourceful dataset of spatially resolved transcriptomic features in the naturally aging murine brain encompassing three age groups, and both sexes. The results link previous disjointed findings and provide a comprehensive overview of brain aging identifying fiber tracts as a focal point of inflammation.

Title: Spatial multiomic evaluation reveals the expression profiles of subpopulations of microglia within differing microenvironments of the mouse brain

Authors: *C. PHAN, O. HO-SHING, A. ROSENBLOOM, C. WILLIAMS, J. REEVES, C. KANG, O. APPELBE, H. ZHAI, V. DEVGAN, M. RHODES, J. BEECHEM; NanoString Technologies, Inc., Seattle, WA

Abstract: Spatial multiomic profiling of the brain has the potential to augment our understanding of the nervous system with unprecedented detail, allowing researchers to profile thousands of targets at subcellular resolution. Investigations of this magnitude previously relied on a combination of immunohistochemistry and fluorescence-activated cell sorting or single-cell sequencing to understand the biology, but each of these approaches only captures individual aspects of the tissue structure and molecular biology happening within each cell. For high-plex spatial approaches to be successful, they require accurate localization of profiled targets, high enough target coverage to understand the underlying biology, and the ability to accurately capture the structure of cells in which these targets are found. The CosMx™ Spatial Molecular Imager (SMI) allows researchers the ability to examine the expression of 1,000 RNA targets and 64 proteins at a time at subcellular resolution.

In this study, we focus on microglia as these are a particularly challenging cell type to profile accurately but are critical as they are the brain's tightly regulated macrophages involved with brain development, neuronal maintenance, as well as pro- and anti-inflammatory activities. Microglia are both motile and are defined by complex cellular morphology with branching processes, and thus, these cells represent a key class to model, but one which is easily misinterpreted.

In the coronal and sagittal sections profiled here, we demonstrate that the CosMx SMI is able to successfully segment distinct microglial cells, which enables investigation of the substantial cellular diversity not just between brain regions but based on individual cell-to-cell interactions within the local microenvironment. Furthermore, distinct protein and gene expression profiles of these diverse activities can be mapped back to their location in tissues with single-cell precision, including the ability to trace morphological distributions of critical protein markers such as P2ry12, TMEM119, CD68, DAP12, and CD11b within individual glial processes.

As the RNA panel used covers 1,000 curated targets for neurobiology, we can explore novel insights based on complex spatial evaluation of expression data including cell typing, signaling pathway analysis, ligand-receptor analysis, and cell type co-localization. Identifying the differential expression of certain targets amongst different subtypes of cells will provide insights into the potential discovery of new biomarkers and targets for future therapeutics.

Title: Single-cell rna sequencing of cd45+ cells reveal an increased in lyve1+ macrophages in hind paws of diabetic mice

Authors: *V. PHAM, J. NICHOLS, R. MAHALINGAM, A. SHEPHERD;
Symptom Res. CAO, MD Anderson, Houston, TX

Abstract: Diabetic peripheral neuropathy (DPN) is one of the most common complication of diabetes. Symptoms of DPN can include tingling, numbing and burning sensation in the fingertips or toes. Based on previous studies, DPN involves a complex interaction of several factors such as hyperglycemia, dyslipidemia, microvasculature dysfunction, oxidative stress and inflammation. Immune cells, especially macrophages, have been shown to have pathological functions in DPN. Therefore, this study focused on performing an in-depth analysis of leukocytes, with specific attention to macrophages, in the microenvironment of the distal foot to determine potential pathological mechanisms that might affect the distal nerve endings of the hind limbs. We collected hind paws from male $Lepr^{db/db}$ and $Lepr^{wt/wt}$ (WT) mice aged up to 12 weeks (young mice) or 21 weeks (aged mice). After obtaining a single cell suspension from the hind paws of these mice, fluorescent staining and cell sorting was used to isolate $CD45^{+}$ cells for single-cell RNA sequencing. These sequences were integrated into clusters based on their similar biological state and annotated based on differential gene expression. Supervised subclustering of the "macrophage" cells was performed based on Lyve1 and MHCII expression to isolate cells with distinct functional roles. Histology was also performed using Lyve1 co-stained with CD68 and IBA1 antibodies in order to quantify $Lyve1^{+}$ macrophages. Using MHCII expression, we formed 4 groups that designate as $Lyve1^{+}MHCII^{HI}$, $Lyve1^{+}MHCII^{LO}$, $Lyve1^{-}MHCII^{HI}$, $Lyve1^{-}MHCII^{LO}$. We examined these 4 types and found an increase in $Lyve1^{+}MHCII^{LO}$ in aged $Lepr^{db/db}$ that did not occur in the other 3 samples and an overall decrease in the percentage of $Lyve1^{+}MHCII^{HI}$ and $Lyve1^{-}MHCII^{HI}$ in aged $Lepr^{db/db}$ sample. We also noticed that $Lyve1^{+}MHCII^{LO}$ cells upregulate pathways of vasculature development and mobility while the other 3 groups are more proinflammatory or activated immune response. This result would suggest a transition from a pro-inflammatory M1 phenotype to an anti-inflammatory M2/angiogenic phenotype in aged $Lepr^{db/db}$. Histology also showed an increase in mean intensity of Lyve1 in macrophages present in the foot pads of young and aged $Lepr^{db/db}$ mice as compared to WT mice from both age groups. Pearson's correlation showed that aged $Lepr^{db/db}$ have a greater overlap of Lyve1 with CD68/IBA1 compare to both young and aged WT. Based on these findings it is clear that there is a substantial difference between immune cells in the foot pads of WT and $Lepr^{db/db}$ and the immune response evolves as the mice age.

Abstract: The mouse brain comprises tens of millions of neurons and nonneuronal cells organized into numerous circuits and structures that are responsible for complex behaviors and neurological functions. Advances in single-cell technologies have led to the discovery of thousands of brain cell types. However, our understanding of the gene regulatory programs in these cell types is still limited. Here we report a comprehensive atlas of candidate cis-regulatory DNA elements (cCREs) in the adult mouse brain, generated through examination of the chromatin accessibility in 2.3 million individual brain cells from 117 anatomical dissections. The atlas includes 1.3 million cCREs and their chromatin accessibility across 602 distinct brain cell populations, adding over 640,000 new cCREs to the most recent such annotation in the mouse genome. The mouse brain cCREs are moderately conserved in the human brain. The mouse specific cCREs, in particular those identified from a subset of cortical excitatory neurons, are strongly enriched for transposable elements, suggesting a potential role for transposable elements in the emergence of new regulatory programs and neuronal diversity. Finally, we infer the gene regulatory networks in over 200 subclasses of mouse brain cells, and develop deep learning models to predict, from DNA sequence alone, the activities of gene regulatory elements in different brain cell types. Our results provide a resource for analysis of cell-type-specific gene regulation programs in both mouse and human brains.

Abstract: The mammalian brain is composed of millions to billions of cells that are organized into numerous cell types with specific spatial distribution patterns and structural and functional properties. An essential step towards understanding brain function is to obtain a parts list, i.e., a catalog of cell types, of the brain. Here, we report a comprehensive and high-resolution transcriptomic and spatial cell type atlas for the whole adult mouse brain. The cell type atlas was created based on the combination of two single-cell-level, whole-brain-scale datasets: a single-cell RNA-sequencing (scRNA-seq) dataset of ~7 million cells profiled, and a spatially resolved transcriptomic dataset of ~4.3 million cells using MERFISH. The atlas is hierarchically organized into four nested levels of classification: 32 classes, 306 subclasses, 1,045 supertypes and 5,200 clusters. We systematically analyzed the neuronal, non-neuronal, and immature neuronal cell types across the brain and identified a high degree of correspondence between transcriptomic identity and spatial specificity for each cell type. The results reveal unique features of cell type organization in different brain regions, in particular, a dichotomy between the dorsal and ventral parts of the brain: the dorsal part contains relatively fewer yet highly divergent neuronal types, whereas the ventral part contains more numerous neuronal types that are more closely related to each other. We also systematically characterized cell-type specific expression of neurotransmitters, neuropeptides, and transcription factors. The study uncovered extraordinary diversity and heterogeneity in neurotransmitter and neuropeptide expression and co-expression patterns in different cell types across the brain, suggesting they mediate a myriad of modes of intercellular communications. Finally, we found that transcription factors are major determinants of cell type classification in the adult mouse brain and identified a combinatorial transcription factor code that defines cell types across all parts of the brain. The whole-mouse-brain transcriptomic and spatial cell type atlas establishes a benchmark reference atlas and a foundational resource for deep and integrative investigations of cell type and circuit function, development, and evolution of the mammalian brain.

Abstract: In recent years the advent of single-cell RNA sequencing (RNAseq) technologies gave scientists an unprecedented ability to define cell types by their gene expression profiles. However, the spatial information retained does not go beyond broader brain regions, and finer details (i.e. subnuclear or layer-specific localization and gradients) are lost in the dissociation process. Spatial transcriptomics has the potential to fill in this gap by mapping of cell types defined by a transcriptomic atlas to the location of individual cells within a histological section. The Allen Institute recently generated a transcriptomic atlas of cell types for the entire mouse brain. To further our understanding of cell type distribution within the brain we generated a spatial transcriptomics dataset covering the entire mouse brain using the commercial MERFISH platform MERSCOPE. Here we describe our workflow of processing these data from experimental outputs to cells mapped to the reference taxonomy and aligned to the Allen Institute Common Coordinate Framework (CCF). Furthermore, we will present preliminary analysis on how these data can be used to quantify the distribution of cell types across the brain and describe the complexity of brain regions with respect to cell type distribution.

Abstract: Many cephalopods camouflage, evading predators and surprising prey by matching their appearance to their surroundings. This behavior requires animals to observe their environment, process texture information, and reproduce a matching texture on their skin. Not only is this behavior a remarkable feat of visual perception, but the lineages giving rise to cephalopods and vertebrates diverged very early during animal evolution, providing a fascinating opportunity to study the convergent evolution of sensory computations. In addition, the camouflage output is realized by a unique motor system operating at single-cell resolution, providing insight into ultra-fine motor control. While the brain areas involved in camouflage have been coarsely mapped, the cell types underlying the behavior remain largely unknown. To understand the genetic basis of camouflage in the European cuttlefish *Sepia officinalis*, we are assembling the genome of an adult cuttlefish using various sequencing techniques. Using the genome as a reference, we profile the cell type diversity in the cuttlefish brain using single-nucleus RNA sequencing, enabling evolutionary comparisons to different cephalopod and model species. Further, we visualize the cell types by mapping the spatial expression of marker genes using *in situ* hybridization and spatial sequencing methods to generate a comprehensive molecular map of the cuttlefish brain. Ultimately, we aim to inform physiological studies of the identified cell types in order to link their molecular profiles to their role in camouflage behavior.

Title: Single-cell transcriptomic analysis on the cerebellum of mice with the 16p11.2 microduplication mutation

Authors: *K. D. TISON[1], H. HALVERSON[2], M. GAINE[3], K. PARKER[4], A. WILLIAMS[2];
[2]Dept. of Psychiatry, Iowa Neurosci. Inst., [1]Univ. of Iowa, Iowa City, IA; [3]Pharmaceut. Sci. and

Exptl. Therapeutics, Col. of Pharm., [4]Dept. of Psychiatry, Iowa Neurosci. Inst., Univ. of Iowa, Iowa City,, IA

Abstract: Schizophrenia (SCZ) is a complex genetic disorder and mutations such as the copy number variant 16p11.2 microduplication (16p11.2dup) can cause SCZ. 16p11.2dup is associated with microcephaly, suggesting that the duplicated genes are involved in neurodevelopment. Computational analysis of publicly available bulk RNA-seq data from mice with 16p11.2dup shows significant transcriptional dysregulation in the cerebellum, but the specific cell types affected are unknown, and there are no published analyses of cerebellum-dependent behaviors in this mouse line. Therefore, we performed delay eyeblink conditioning, which is a cerebellum-dependent form of learning, as well as single nucleus RNA-seq, to address these knowledge gaps. We observed that 16p11.2dup mice show impaired learning ($p<0.01$) and conditioned response timing ($p<0.05$) compared with WT littermates. We also performed single nucleus RNA-seq using the 10X Genomics 3' expression kit on the whole cerebellum of male and female 16p11.2dup mice and WT littermates. Using the R package toolkit Seurat, we will cluster nuclei with similar gene expression profiles which is crucial for unraveling the cellular heterogeneity present in the cerebellum. Dimensionality reduction techniques, such as PCA and t-SNE, will be used to look at the dataset in a lower-dimensional space. By condensing the complex gene expression data, these techniques will allow for the identification of patterns and relationships among the different cell populations. Overall, our data show that 16p11.2 dup is associated with a deficit in cerebellum dependent behavior. The single nucleus RNA-seq data will help specify which cerebellar cell types are most affected by 16p11.2dup and may accelerate the discovery and development of new diagnostic and therapeutic strategies for schizophrenia.

Title: Development of a miniaturized microscope for two-photon lifetime imaging in freely behaving mice

Authors: *T. SALEMI[1], L. YAN[1], Y. NAKAHATA[1], L. CHEN[2], R. YASUDA[1];
[1]Max Planck Florida Inst. for Neurosci., Jupiter, FL; [2]Inst. of Mol. Medicine, Peking University, Beijing, China, Beijing, China

Abstract: Intracellular signaling plays a critical role in synaptic plasticity, learning, and memory. However, a tool to monitor neuronal signal transduction with subcellular spatial

resolution in freely behaving animals is lacking. Fluorescent resonance energy transfer (FRET) based biosensors, in combination with 2-photon fluorescence lifetime imaging (2pFLIM), provide means to monitor conformational changes or translocation of donor and acceptor fluorescent protein as a proxy for intracellular protein dynamics in live brain. Here, we developed a miniaturized 2-photon head-mounted microscope to perform in vivo FRET-FLIM (mini-2pFLIM). The 4g body of the mini-2pFLIM did not impair the ability of the animal to locomote. Using a genetically encoded calcium indicator (GCaMP6s) we were able to image a field of view of 350um x 350um with a sufficient resolution to image the soma and dendrites in freely moving animals while performing calcium imaging and reliably measuring the lifetime of the excited state. An electrotunable lens enabled us to image the supragranular layers within a range of 200 um of depth. Next, we used in-utero electroporation to sparsely transfect layer 2/3 pyramidal neurons in the mouse somatosensory cortex with an improved mEGFP-based FRET biosensor (2dvCamuiα) able to report Ca2+/calmodulin-dependent protein kinase II (CaMKII) activation. The fluorescence of mEGFP in the 2dvCamuiα-expressing neurons had a significantly shorter lifetime of the excited state and a higher degree of cell-to-cell variability compared to cells expressing mEGFP alone. These results demonstrate that our system can efficiently measure FRET at subcellular resolution in freely moving animals. Future work will aim to apply this mini-2pFLIM in different behavioral paradigms to clarify the spatiotemporal dynamic of CaMKII activation in freely behaving animals during plasticity, memory formation and learning. Our system will allow to image a wide variety of other biosensors during naturalistic behaviors in mice and has thepotentiall to reveal the complex intracellular protein machinery that regulates neuronal steady state and plasticity.

Title: Ten color identification within miniscope acquired functional imaging reveals mPFC coding of social identity

Authors: *M. L. PHILLIPS[1,2], N. T. URBAN[2], T. SALEMI[2], R. YASUDA[2];
[1]ZEISS Res. Microscopy Solutions, Loxahatchee, FL; [2]Max Planck Florida Inst. for Neurosci., Jupiter, FL

Abstract: Current capabilities of state-of-the-art in vivo imaging during freely moving behavior can record two, spectrally distinct, fluorophores. This severely limits the number of cell types identifiable in a functional imaging experiment. Here we present a pipeline that enables the distinction of nine neuronal subtypes from regions defined by behaviorally relevant cells during *in vivo* GCaMP imaging. These subtypes are identified utilizing unique fluorophores that are co-expressed with GCaMP, unmixed by multispectral lambda imaging on a confocal, and spectral fingerprints co-registered with functional data obtained on miniaturized microscopes. Using this method, we recorded pyramidal neurons in the medial prefrontal cortex categorized by projection region during a freely moving social memory task. As neural activity in each category was concurrently imaged, we can determine which projection neurons most preferentially encode identity versus novelty/familiarity and what types of social behaviors are most important for this distinction. This method will not only increase efficiency for calcium imaging experiments by enabling nine neuronal populations to be investigated simultaneously but also enhances the statistical power of the results by utilizing within subject comparisons.

Title: Co-registering ten genetically expressed fluorophores during in-vivo GRIN lens imaging

Authors: ***N. T. URBAN**[1], M. L. PHILLIPS[3,2], T. SALEMI[2], R. YASUDA[2];
[1]Imaging Ctr., [2]Max Planck Florida Inst. for Neurosci., Jupiter, FL; [3]ZEISS Res. Microscopy Solutions, Loxahatchee, FL

Abstract: By imaging genetically expressed calcium sensors in the brain, we can simultaneously record and correlate the activity of hundreds of neurons with observable behavior. Using head-mounted miniscopes enables this without restricting the animal's free movement, at the expense of image quality and versatility. Multicolor imaging, in particular, becomes a challenge, even more so when using GRIN lenses to image deeper within the brain. But without the ability to use additional fluorescent labels to identify specific cell types, genetic traits, or connectivity within the brain, we are left with frightfully little knowledge about the neurons whose activity we are

trying to interpret.
Recent dual-color miniscopes are capable of visualizing one additional color alongside GCaMP, but adding a third or more colors seems elusive. It is possible, however, to circumvent these limitations and restore full multicolor capabilities by supplementing functional miniscope data with a single, multispectral volumetric image taken with a confocal microscope. By creating a high-resolution, multicolor map of the visible neurons, we can identify which were active during behavior, along with any secondary labels they might be expressing. Furthermore, by combining multispectral lambda-detection with excitation multiplexing, we can differentiate fluorophores based on both their emission and their excitation spectra. This opens up the use of spectrally adjacent fluorescent proteins, allowing more fluorescent labels to be used simultaneously.
Even though GRIN lenses notoriously complicate multicolor imaging by inducing a multitude of spatial and chromatic distortions, these aberrations are highly reproducible and can be precisely measured, allowing them to be overcome. We characterized the aberrations of the most common GRIN lenses used for miniscope imaging, and used these corrections to image with wavelengths across the visible spectrum, and co-register each color channels in x,y, and z with high accuracy. Finally, we used an upright Zeiss LSM 980 to image the mPFC of head-fixed mice, expressing nine spectrally distinct fluorescent proteins alongside GCaMP. After co-registering the miniscope and confocal images, we measured the multispectral fingerprint of each active neuron in order to detect and identify secondary fluorophores. This technique allows us to not only overcome the optical limitations on spatial resolution and volumetric imaging, but to further allow the simultaneous recording of multiple neuronal subtypes at once, enabling the direct comparison of activity patterns during behavior.

Title: Evaluation and characterization of Styrylbenzene analogue-K114 and its use for high contrast and resolution fluorescent localization of plaques in rodent and plaques and tangles in human brain tissue

Authors: *S. SARKAR[1,2], S. PADALA[2], J. B. RAYMICK[3];
[1]Neurotoxicology, Natl. Ctr. for Toxicological Research/ US FDA, Little Rock, AR; [2]Neurotoxicology, Natl. Ctr. for Toxicological Res., Jefferson, AR; [3]Neurotoxicology, Natl. Ctr. For Toxicology, Jefferson, AR

Abstract: Plethora of studies showed utilities of several chemical dyes due to their affinity to bind amyloid abeta to show plaques under light or fluorescence microscope, and some of them show affinity to bind and neurofibrillary tangles (NFT) at the end of 19th century. However, only few of them has the propensity to bind both senile plaques (SP) and neurofibrillary tangles (NFT). In our current study, we have modified the method of K114 staining procedure and our modified method yielded substantial improvement in the labeling of plaques and tangles in the human brain. Additionally, our modified method could detect SP in rodent brains in 15 min and NFT in human brains within 20 min. We have also compared whether different drying methods or mounting medium can affect the resolution and contrast of the plaque and tangle staining in the brain. To further evaluate the target of the modified K114, we performed double labeling of K114 and abeta antibodies raised against three different epitopes. Our results demonstrated that modified K114 can be used as a very sensitive dye to detect various forms of senile plaques in the brain. Regarding detecting tauopathy in the AD brain, we have used five different phosphorylated Tau to understand the potential binding targets. We have found more than 80% hyperphosphorylated Tau against AT8, PTau and TNT1 colocalized with K114 labeled tangles, whereas more than 70% of the hyperphosphorylated Tau colocalized with modified K114 tangles. On the other hand, more than 90% of the plaques that are stained with abeta MOAB-2 were colocalized with modified K114. Our results indicate that modified K114 could be used as a valuable tool which can be used to detect AD pathologies in human and rodent brains with high contrast and resolution relative to other conventional fluorescence markers.

Title: Three-dimensional visualization and quantitative analysis of retinal degeneration for hereditary retinal dystrophies with retina-PACT

Authors: *Z. WANG, J. B. TREWEEK;
USC, Los Angeles, CA

Abstract: Retinal neurodegenerative diseases which are often distinguished by dysfunction or loss of cell subsets, are the leading cause of vision deficits. However, the genetic and pathological heterogeneity of retinal dystrophies complicates the development of effective treatments. Royal College of Surgeons (RCS) rat model serves as a powerful tool for investigating the pathogenesis of retinitis pigmentosa, characterized by loss of photoreceptor (PR) cells, and for testing candidate therapies for their ability to slow or reverse degeneration. To accelerate and improve these preclinical studies, we developed a novel tissue clearing technique (retina-PACT or rPACT) to enable high-resolution visualization of intact retinas by light sheet

fluorescence microscopy (LSFM), avoiding tissue damage and loss of 3D-constructional information. In addition to rendering retinas optically transparent, rPACT protects the 3D architecture and laminar structure of retinas, permitting researchers to evaluate topographical differences in retinal degeneration. Because rPACT supports immunolabeling and high-resolution imaging at depth, it enables the quantification of major pathological signs of retinal degeneration across all retinal layers at multiple positions. A semi-automated computational pipeline was created to facilitate quantitative analysis for whole-retina datasets. Greater PR cell loss was found at positions close to the optic nerve, suggesting that the progression of degeneration originated from the central retina. Compared to PR cells, slower degeneration of bipolar cells indicated that their degeneration progressed from outer to inner layers. Evidence of dendrite withdrawal of bipolar cells prior to their significant cell loss hints at the potential importance of synaptic connectivity for cell survival. The outward migration of glial cells from ganglion cell layer, which has been observed in previous studies, was confirmed in rPACT-cleared RCS rat retinas. But more interestingly, our results revealed an earlier onset of gliosis in female RCS rats relative to male counterparts. In addition to these sex differences, although the spatial uniformity of retinas was demonstrated at postnatal day 21 (P21), position-related disparities of degeneration were found at P49 and P60, uncovering the spatial heterogeneity in the progression of retinal degeneration. This work demonstrates the utility of rPACT in granting researchers access to high-quality, whole-retina image datasets for quantitative evaluation, either to forward vision research more broadly or to characterize dynamic developmental and disease processes of retina.

Title: Ultramicroscopy of human tissue

Authors: *H.-U. DODT[1,2], J. A. OAKES[1,2], C. FUCHSSTEINER[2], M. FOROUGHIPOUR[1], M. FOROUGHIPOUR[1], K. BECKER[1], S. SAGHAFI[1];

Abstract: Ultramicroscopy has been used very successfully to investigate chemically cleared mouse brains. However its application to human tissue has been hampered by difficulties to

obtain specific cellular staining. The use of endogenous fluorescent marker is not possible in humans and staining with antibodies is difficult due to diffusion problems. Furthermore standard clearing protocols like 3DISCO take weeks to months to clear human tissue. Notoriously difficult is clearing of tumors due to their high cell density. We therefore developed in the last years a new clearing protocol, pathoDISCO, which allows clearing of tumor tissue in the centimeter range within days[1]. This method uses boosted autofluorescence for cellular visualization but does not yet provide specific subcellular staining. We found specific fluorescent stainings for cytoplasm and nuclei which also survive our harsh tumor clearing. Interestingly modern stainings were very sensitive to our active clearing with a chemical reaction. So we had to resort to simple chemical stainings developed long time ago which were more stable. Applying suitable image processing we could generate Hematoxilin/Eosin (HE) stained like images of various human tissues. With our ultramicroscope volume recordings of pathology cassette sized tumor pieces of 4 mm thickness could be obtained with subcellular resolution. Our single optical sections provide a resolution and appearance equivalent to histological slides but now for whole tissue volumes. We were able to specifically stain cytoplasm, cell nuclei, collagen and blood vessels. The ability to stain blood vessels in tumors like glioblastoma offers a completely new parameter for malignancy staging in pathology. Standard histological sections can not provide this information as blood vessels appear in these sections only as rings or stripes. Thus with our 3D recordings the important aspect of neovascularisation can be quantified and may be used in future as predictive marker. We applied our technology to various neuronal and non neuronal tumors. We are confident that this approach will open up completely new ways for diagnostics in pathology. Inst., Weill Cornell Med., New York, NY; [4]Ctr. for Biologic Imaging, Univ. of Pittsburgh, Pittsburgh, PA

Abstract: An interplay of genetic factors and experiences shape a network of nearly 200 billion cells in the human brain making up who we are. Recent advances in tissue clearing, immunostaining and high-speed microscopy have opened up the possibility of imaging all of these cells throughout the entire human brain. However, transcriptomic studies have revealed that cells in the brain belong to numerous subtypes. To label each cell-type individually would require hundreds of antibodies. Limitations on the number of secondary antibodies and fluorophores that can be imaged in parallel would require laborious repeated imaging rounds and computationally expensive registration of images between each staining round, making the task of imaging an entire human brain, let alone many brains, nearly impossible. A smaller number of specific antibodies could be used, but data would then only cover a small number of cell types, overlooking the complexity of distributions and differences between individual cell types throughout a sample. To overcome these problems, we devised a combinatorial coding framework to resolve many cell types with a limited subset of antibodies. This approach recognizes that relative amounts of select proteins in each cell may be sufficient to encode a much larger number of cell types. Human and mouse brain transcriptomic datasets provide the opportunity to predict how many cell-types could potentially be resolved using subsets of expressed genes. Data-driven analysis can predict optimal marker combinations, while modeling can predict the number and range of cell types that could be resolved using a given subset of genes (e.g. constrained antibody availability). We also recognized that wider coverage may be achieved by pooling multiple antibodies into a reduced number of spectral channels. Pooling can be guided by consideration of the hierarchical nature of cell type taxonomies. For example, if markers in one spectral channel define whether a detected cell is a neuron (e.g., NeuN), an interneuron marker (e.g., GAD1) can be pooled with a microglia marker (e.g., Iba-1) in a second spectral channel. An independent nuclear marker can be used to locate all cells within the sample in order to extract each cell's 'proteomic code'. This approach has been tested by imaging mouse brain samples with 7 antibodies pooled into 4 spectral channels (plus a 5th nuclear label channel). This 'compressed sensing' approach to large-scale immunohistochemistry holds the potential to resolve hundreds of cell types within the whole human brain with highly feasible single-round staining and high-speed 9-color spectrally multiplexed acquisition.

Title: Ultraplex microscopy: Serial multiplexing of molecular labeling techniques and imaging modalities using ultrathin sections

Authors: *J. PEREZ-GARZA[1], Z. DEANE[2], G. RAIMONDI[3], J. OREA[3], R. TRIPP[4], E. GASTEYER[5], I. CHARLES[3], M. P. KENNY[3], L. OSTROFF[3];

Abstract: The molecular organization of cells and tissue is challenging to study due to the inefficiency of multiplexed molecular labeling methods and the limited options for combining staining and imaging modalities in a single specimen. Here we present ultraplex microscopy, a versatile strategy that combines ultrathin sectioning with reversible embedding to allow multiplexing of molecular probes, staining protocols, and imaging methods with subcellular resolution. We show that 50 nm-thick sections of brain tissue are compatible with immunofluorescence (IF), fluorescence in situ hybridization (FISH), histological staining, and direct imaging of fluorescent reporter proteins, as well as imaging by brightfield, epifluorescence, super-resolution, and electron microscopy. We also demonstrate the use of click chemistry on ultrathin sections to detect metabolic labeling of RNA as well as immunoreagents. Arbitrary combinations of staining and imaging methods can be applied to serial sections from a single tissue sample to allow multiplexed labeling and imaging at the subcellular level, bypassing incompatibilities between reagents and protocols. High-resolution molecular detection is possible, as ultrathin sectioning enhances spatial resolution and signal-to-noise relative to standard preparations for light microscopy, while reversible embedding permits molecular labeling, most notably of mRNA, that is impossible on conventional resin sections. Labeling is performed using routine protocols for standard fixed tissue sections, and no custom or specialized regents are needed. Samples as large as an intact rat brain can be embedded and sections are shelf-stable, so a single sample can be used for many experiments across time to allow collection of rich multimodal datasets.

Title: Microwave-assisted acceleration of protein retention expansion microscopy in neural tissue of Xenopus laevis tadpoles

Authors: M. R. BULLARD[1], N. B. QUAICOE[1], D. A. ADAMS[1], A. JIN[1], J. M. LIN[1], *H. HE[2];
[1]Biol., Georgetown Univ., WASHINGTON, DC; [2]Biol., Gorgetown Univ., Washington, DC

Abstract: Protein retention expansion microscopy (pro-ExM) retains genetically-encoded fluorescent proteins or antibody-conjugated fluorescent probes in the fixed tissue and isotropically expands the tissue through a swellable polymer network to allow nanoscale (<70 nm) resolution on diffraction-limited confocal microscopes. Despite numerous advantages pro-ExM brings to biological studies, the complete protocol is time-consuming and can take multiple days to complete. Here, we adapted the pro-ExM protocol to the brain tissue of *Xenopus laevis* tadpoles and significantly accelerated the workflow using a commercially available specialized microwave processor. Microwave radiation has long been successfully used to accelerate and, in some case, enhance various steps of the conventional immunohistochemistry (IHC) and electron microscopy (EM) protocols, from fixation to antibody incubation. With automated pulse duration and wattage control, as well as precise temperature-regulation, microwave-assisted processing can effectively facilitate the diffusion of reagent molecules in the tissue in aqueous solutions, while preventing overheating hot spots inside the specimen. We tested the feasibility of microwave-assisted expansion microscopy using vibratome sections (40-80um) of tadpole brain tissues, and successfully reduced the hours-long Acx incubation (>6hr) and protease digestion (8-13 hr) steps to <30 minutes, making it possible to finish the entire pro-ExM protocol within a day. In addition to the significantly accelerated processing time, our microwave-assisted pro-ExM protocol maintains the superior resolution and signal-to-noise ratio of the original pro-ExM protocol, which we verified with cytoskeletal and synaptic markers. Furthermore, microwave-assisted pro-ExM protocol consistently yielded higher expansion factor, suggesting that microwave radiation may also facilitate the expansion process, aside from the increased diffusion rate. With appropriate adjustment of the microwaving parameters (wattage, pulse duration and interval, and number of cycles), this protocol can be adapted to other model organisms and tissue types and would greatly increase the efficiency of pro-ExM experiments.

Abstract: Cells are not uniformly distributed in the human cerebral cortex. Rather, they are arranged in a regional and laminar fashion that spans a range of scales. We present an innovative imaging and analysis pipeline to construct a reliable cell census of human Broca's area. Magnetic resonance imaging (MRI) is used to establish a macroscopic reference coordinate system of laminar and estimated cytoarchitectural boundaries. Cell counting is obtained with a digital stereological approach performed on the 3D reconstruction of the sample at cellular resolution using a custom-made inverted confocal light-sheet fluorescence microscope (LSFM). Mesoscale optical coherence tomography (OCT) is used to register the distorted histological cell typing obtained with LSFM to the MRI-based atlas coordinate system. The result is an integrated high-resolution cellular census of Broca's area within a whole-brain reference space atlas. In particular, a whole hemisphere is first imaged at 150 µm isotropic resolution with a 7 T MRI, and then Broca's area is dissected out. The block is cleared with TDE for 500-µm in-depth imaging with OCT. The system is equipped with a custom-made vibratome that enables serial sectioning of the block after each acquisition. The resulting slabs are treated with the SHORT method for immunofluorescence staining and optical clearing. LSFM imaging allows obtaining 3D reconstruction of the slabs with an isotropic resolution of 3,3 µm. Finally, digital stereology is performed to obtain the count of various neuronal markers.

Title: Assessment of multiplexed quantitative ability of in situ hybridization chain reaction based upon fluorescent intensity and mRNA grain count correlation

Authors: *V. KUMAR[1], D. M. KROLEWSKI[2], M. FOLTZ[2], H. AKIL[2], S. J. WATSON[3]; [2]Univ. of Michigan, [1]Univ. of Michigan, Ann Arbor, MI; [3]Univ. of Michigan, Michigan Neurosci. Inst., Ann Arbor, MI

Abstract: The cost effectiveness of in situ hybridization chain reaction (HCR) compared to other multiplexing in situ hybridization approaches (e.g., RNAscope) makes it a desirable method for RNA expression analysis. However, variations in the individual probe binding and the extent of linear chain amplification, can influence both the fluorescence intensity and the mRNA grain (copy number) count. Such variations could become more prominent in mammalian brain tissues, particularly in the postmortem human brain tissues where disease conditions can alter the RNA integrity and thus the overall binding sensitivity of probes. Here, we assess the multiplexed quantitative ability of HCR for mRNA analysis in multiple cell types in fresh-frozen brain tissue, and explore key factors including the choice of fluorophores, tissue preparation, experimental conditions, and imaging parameters which critically determine the overall sensitivity and effectiveness of the HCR quantitation. Using multi-round HCR, we analyze *Vglut1*, *Gad2*, *Fgf12* transcripts based upon fluorescence intensity and grain count estimation. These genes under basal conditions in rat brain, represent a dynamic range of expression pattern in terms of cell number and mRNA copies. Our preliminary tests for *Fgf12* and *Gad2* suggest a linear association between voxel intensity and grain counts for hairpin concentration range 2-30 nM and incubation times 1-2 hrs. Thereafter, increasing the number of probe pairs, longer hairpin incubation times and/or higher concentrations appears to yield brighter and larger spots which fail to resolve properly, thus, inversely effects the segmentation of individual grains particularly in high grain density (subcellular) locations. We further explore and highlight the key factors which determine consistency, sensitivity, and optimum signal to noise ratio, essential for both qualitative and quantitative analysis. Based upon our observations, choice of fluorophore (AlexaFluor-647 or -546 vs. AF-488) hairpin conjugates, tissue fixation (fresh frozen vs.

perfused) and the abundance of transcript level (grain density and cell number) critically determines the effectiveness of the HCR for accurate grain counting with respect to the mRNA expression. For example, *Gad2* in fresh-frozen tissues and *Npy* when detected with AF-647 or -546 consistently showed biologically accurate cell counts in comparison to perfused tissues using AF-488 or -405, respectively. Similarly, genes with high density of grains such as *Sst* present challenge to accurately resolve individual grains and count despite using low concentration of hairpins (0.6nM to 1.25nM) or fewer probe pairs (1-2 pairs).

Title: Pku tag, a genetically-encoded shape tag for light and electron microscopy

Authors: *R. SUN, L. WANG, Y. HU, Y. LI;
Peking Univ. Sch. of Life Sci., Beijing City, China

Abstract: The neural network in the brain is composed of hundreds or thousands of neuronal types with different morphology, electrophysiological activity and gene expression profiles. In order to dissect the large number of neuronal types in the brain, understand their gene expression and connectomic characteristics, and explore the role of these neurons in complex animal behavior, a sufficient number of tags are needed for both optically cellular labeling under light microscopy (LM) and ultrastructural labeling under electron microscopy (EM). However, tags that currently exist are still limited, constraining our understanding of the immense diversity of neuronal types. Here, we have developed a series of new genetically-encoded tags, named PKU (Polymer King-size Unit) tags, which make use of the polymerization of self-assembling proteins to generate easily visible and distinguishable shapes to encode diverse cell type identities. By combining the multi-shape PKU tags with fluorescent colors and subcellular localizations, we have further expanded the number of labeling tags. We also demonstrated that the combinations of tags could, in principle, expand the labeling patterns to up to thousands of types, far exceeding the number of known neuronal types. Additionally, shape tags are suitable for neuronal circuit tracing between multiple brain regions. Finally, to test whether PKU tag could be used as a versatile tag for brain connectomic studies in EM, we fused APEX2, a genetically-encoded EM reporter, with distinct PKU tags. The results showed that PKU tags could preserve their distinct shape features under extreme fixation condition of EM and could be used to tag multiple neurons as a “brainbow” for EM.

Abstract: Light sheet fluorescence microscopy (LSFM) is a versatile imaging technique used for live and fixed samples, particularly for high-resolution mapping of large cleared intact organs. However, existing high-performance LSFM implementations are often prohibitively expensive and lack scalability needed for high-throughput applications. Here, we introduce a low-cost and highly scalable framework, called projected Light Sheet Microscopy (pLSM), while maintaining high imaging quality. By leveraging consumer-grade off-the-shelf components, including pocket laser projectors, inexpensive CMOS cameras, Nvidia nano board, and optimized optical paths, pLSM offers comparable imaging performance to high-end systems at just one twentieth of the cost. One of pLSM's key strengths lies in its over-the-network control architecture and compatibility with various sample types, including brains cleared with multiple tissue clearing methods as well as live imaging application. The plug-and-play architecture and remote operability from anywhere, make pLSM highly scalable for high-throughput imaging applications. We demonstrate pLSM’s capabilities by performing high-resolution, multi-color imaging of intact whole mouse brains and post-mortem human brain samples cleared using various methods. Moreover, we showcase its potential for comprehensive phenotyping by quantitative mapping of the brain-wide distribution of entire dopamine system in mouse brain. Overall, the open access pLSM framework has the potential to further democratize LSFM and facilitate greater scalable access to high-resolution light sheet microscopy.Figure. (a) 3D model of the pLSM system. (b) pLSM control architecture. (c) High resolution pLSM imaging of TH+ dopamine neurons in intact mouse brain followed with quantitative mapping by brain-wide neuron segmentation. (d) Region-specific dopamine neuron counts comparison between pLSM and COLM (a high-end system). A high degree of agreement achieved.

Abstract: Inhibitory interneurons are hypothesized to play critical roles in cortical circuit operations such as spatial summation, prediction, and attention. Specific classes of interneurons may also be involved in controlling oscillatory dynamics. These neurons can now be precisely studied in transgenic mice and other genetically accessible species using light sheet microscopy. However, in classical primate histology, anatomical analysis is done by slicing. This

permanently deforms the sample orthogonal to the slicing plane, making analysis possible in only one plane per sample. Light sheet microscopy works by loading in specific antibodies into delipidated tissue, and imaging is performed non-destructively in three dimensions. This technique has been mostly applied to small brains (e.g., mouse brains, ~0.4 cm3). The size, scarcity of primate tissue, and the lack of methodological validation have mostly prevented primate researchers from using light sheet imaging. We seek to validate the methodology of light sheet microscopy for high-throughput anatomical imaging for the three main classes of inhibitory neurons (Parvalbumin-PV, Calbindin-CB, and Calretinin-CB positive interneurons) in the macaque brain. In two rounds, we performed staining and imaging of neurons expressing fluorescent markers for NeuN (a non-specific indicator for neurons) and PV, followed by CR and CB in the same block (7mm x 11mm x 8mm) of macaque parietal cortex. Antibody penetration and expression in the tissue was high and approximately uniform in the tissue for Neun, CB, and CR, but weak for PV. We developed an automated cell counting pipeline which avoids the drawbacks of manual counting. For this analysis we used LIP as our region of interest. We used MATLAB functions to run edge detection on the 3D matrix, followed by pixel-connectivity on the binary output to identify potential neurons. We used volume and solidity (measure of roundness) statistics to differentiate neurons from noise. We validated the automated statistics by overlaying the computer generated centroids on the raw data, and adjusted thresholds to obtain the best match. Finally we compared the laminar profile of CB+, CR+, and PV+ interneurons from light sheet to classical histological cell counting. In both datasets we found expression of CB/CR was high in superficial layers (with a peak in layer 2), and PV expression peaked in middle layers. This demonstrates the feasibility of light sheet microscopy and automated cell counting to study the composition of inhibitory neurons in the non-human primate brain. This will lead to both increased throughput of data collection, as well as enabling discovery of new neural patterns.

Abstract: The world health organisation (WHO) indicates that about half a billion of people suffer from disabling hearing loss. The most common form is sensorineural hearing impairment, which arises from degeneration or dysfunction of cochlear cells (World report on hearing, WHO, 2021). Novel therapeutic strategies involving gene or cell therapies, aimed at restoring hearing (Wolf et al., 2022; Ma et al., 2019) necessitate unbiased quantification of targeted cells in the intact cochlea. This becomes challenging, especially when there are more than hundreds of targeted cells present.

Our group is developing optical cochlear implants, where the cochlear neurons (spiral ganglion neurons, SGNS) are optogenetically modified and tagged by a fluorescent protein to further investigate the transduction rate by immunohistochemistry (Hernandez et al., 2014; Wrobel et al., 2018; Huet et al., 2021). Since each cochlea contains thousands of SGNs, we have developed a pipeline to fully automate cell quantification based on volumetric imaging of intact cochleae by light sheet fluorescence microscopy.

Previously, we developed a semi-automatic approach using Arivis Vision4D based on automatic seed finding and watershed-based algorithm to segment SGNs of intact mouse cochleae and estimated the performance evaluation based on the F1 score (~0.97). However, this approach was time consuming, dependent on sample quality and required manual inputs (Keppeler et al., 2021).

In this study, we are developing a fully automatic segmentation approach based on the machine learning algorithm-Stardist (Schmidt et al.,2018; Weigert et al.,2020). This technique uses a convolutional neural network to predict cells shaped as star convex polyhedrons, considering the object probability and star-convex distances. From the data obtained from the previous semi-automatic approach, we cropped out 21 smaller sections of images and their corresponding segmented results as annotations, to generate the first model. Despite the very small number of training data used to generate this model, we achieved a high F1 score of 0.91. However, several rounds of training cycles are required to increase the quality of predicting SGNs. We will employ the NAPARI framework to combine the first model's predictions and incorporate manual corrections, optimizing the precision of the SGN quantification. In this poster, we would discuss the methodology, recent findings, and prospects of fully automated quantification of SGNs. The use of such tools based on machine learning algorithms contributes to the advancement of hearing research and the development of innovative therapeutic approaches to deafness.

Title: The Laminar Distribution of Inhibitory Cell Types in Macaque Cortex and its Implications for Hierarchical Information Processing

Authors: *M. J. LICHTENFELD[1], A. G. MULVEY[1], H. NEJAT[1], Y. XIONG[1], B. M. CARLSON[1], B. MITCHELL[1], D. MENDOZA-HALLIDAY[2], P. D. MENG[1], R. DESIMONE[2], A. MAIER[1], J. H. KAAS[1], A. BASTOS[1];
[1]Psychology, Vanderbilt Univ., Nashville, TN; [2]McGovern Inst. for Brain Res., MIT, Cambridge, MA

Abstract: The Canonical Microcircuit (CMC) has been hypothesized to be the fundamental unit of information processing in laminar cortex. Each CMC contains (with some variation) each of the six cortical layers along with their specific cellular characteristics and organization. Importantly, the characteristic oscillatory activity spanning across the CMC is produced by interplay between GABAergic inhibitory interneurons and excitatory neurons. However, the anatomical and physiological basis of the CMC has primarily been established in excitatory neuron anatomy and neurophysiology. We sought to describe the laminar distribution of inhibitory cell types across the cortex, and in this work, we investigate the role of inhibitory cells in producing laminar electrophysiology. Brain tissue was collected from six macaques. Electrophysiology was performed in six macaques using laminar probes placed perpendicular to the cortical sheet. Anatomy and electrophysiology were collected in 11 distinct cortical areas spanning the cortical hierarchy: Primary visual cortex (V1), V2, V3, V4, lateral interparietal cortex (LIP), medial superior temporal cortex (MST), medial temporal area (MT), 8A/FEF, TEO, premotor cortex (PMD), and lateral prefrontal cortex (LPFC). Additional anatomical data was collected in two areas: 7A and dorsal prelunate (DP). We stained representative slices for Parvalbumin (PV), Calbindin (CB), and Calretinin (CR) positive neurons, which comprise the three main inhibitory cell types found in macaque cortex. Nissl and NeuN staining were also performed to provide contextual information about laminar position. We found a significant laminar structure of PV+, CB+, and CR+ neurons across the cortical hierarchy and across animals. PV+ neurons consistently peaked in layer 4, and CB+ and CR+ neurons peaked in layer 2 and upper parts of layer 3. We further found a consistent relationship between the laminar distribution of these inhibitory neurons with power in the local field potential. PV+ distributions correlated positively with theta (4-8 Hz) and gamma (40-150 Hz) oscillations. CR+ and CB+ neuron distributions correlated negatively with theta, alpha (8-12 Hz), and beta (15-30 Hz) oscillations. Additionally, CR+ neurons were found to significantly increase in proportion moving up the hierarchy, while CB+ neurons significantly decreased. These findings, of patterns

of inhibition across cortex and their alignment with laminar neurophysiology at specific frequencies, provide a richer functional and anatomical basis for the CMC as the fundamental unit of information processing.

Abstract: Recent advances in tissue processing, labeling, and fluorescence microscopy are providing unprecedented views of the structure of cells and tissues at sub-diffraction resolutions and near single molecule sensitivity, driving discoveries in diverse fields of biology, including neuroscience. Biological tissue is organized over a wide range of spatial scales. Understanding cellular function and multi-cellular organization often requires simultaneous probing of tissue architecture over scales of nanometers to centimeters. Harnessing molecular imaging across three-dimensional samples on this scale requires new types of microscopes with larger fields of view and working distance, as well as higher imaging throughput. We present a new expansion-assisted selective plane illumination microscope (ExA-SPIM) with diffraction-limited and

aberration-free performance over a large field of view (85 mm^2) and working distance (35 mm). Combined with new tissue clearing and expansion methods, the microscope allows nanoscale imaging of centimeter-scale samples, including entire mouse brains, with high isotropy, no sectioning, and at speeds approaching 1 gigavoxel/sec. We illustrate ExA-SPIM by reconstructing individual neurons, including complete axonal arbors across the entire mouse brain, imaging xfp-expressing cortico-spinal neurons in the macaque motor cortex, and tracking axon pathways in the human white matter fluorescently labeled for heavy chain neurofilaments.

Title: Bone tissue clearing reveals new neuronal structures in teeth and jawbones

Authors: *Y. YUN[1], S. KANG[2], J.-Y. PARK[3], H. CHOI[1];
[1]Seoul Natl. Univ. Col. of Med., Seoul, Korea, Republic of; [2]Dent. reserch institute, Seoul, Korea, Republic of; [3]Oral Maxillofacial Surgery, Seoul Natl. Univ. Col. of Dent., Seoul, Korea, Republic of

Abstract: As the demand for dental work such as tooth extraction and implant surgery increase, trigeminal nerve injuries are becoming more common. Despite efforts to generate microscopic images of the nerves in dental pulp using conventional neurohistological analysis, the whole maxilla and mandible visualization in a whole, undamaged tooth has remained a technically challenging task. The neural architecture of the branch of the peripheral nerve that travels through the alveolar bone where the teeth are rooted is unknown in particular. In this study, we developed a quick and easy technique that combines decalcification, tissue clearing, immunohistochemistry, confocal microscopy, light-sheet fluorescence microscopy, and quantitative analysis of full-thickness bowel for high-resolution 3D imaging of the mouse maxilla and mandible. In order to explain the neural network and offer novel insights into neuronal anatomy, statistical techniques and three-dimensional image reconstruction were applied. The findings of this investigation supported the idea that at least 40% EDTA for two weeks was necessary for the complete decalcification process. After 16 hours of electrophoretic tissue clearing mode and another 14 hours of immersion in SDS buffer at 60°C, the overall structural details and staining properties were at their best. We were able to see the mouse mandible and maxilla in three dimensions at the macroscale-level, as well as the dental pulp's whole peripheral nerve branch that runs through the alveolar bone. When examined using a 10x objective lens, full-thickness mandible pictures might reach sizes of 8 x 3 x 1 mm^3. Quantitative data for the maxilla and mandible revealed comparatively distinct features. In conclusion, the developed techniques could be able to offer a thorough 3D view of the nerve fibers found in soft tissues surrounded by hard tissues. By giving a 3D image of numerous immune cells in an intact mouse maxilla and mandible, this technique could be used to facilitate a variety of research methodologies on neural-immune interaction.

Abstract: Neuropathological assessment of the effect of toxic compounds on the central and peripheral nervous systems requires classification and quantification of a variety of anatomical and histological endpoints. Many of these methods require time-consuming, manual measurements subject to considerable variability within and between raters. Automated deep learning-assisted digital image analysis provides an opportunity to decrease turnaround time for these studies and increase the precision of the data. At Charles River, we have validated a method of generating qualified algorithms, which leverages the depth of expertise from our wide field of pathologists across the globe and our own team of developers. This approach is very efficient and flexible enough to create and adapt algorithms on a study-by-study basis. Here, we show qualification data demonstrating the predictive strength and statistical power of automated methods for brain region and nerve fiber segmentation relative to the traditional, manual measurements used for assessing trophic effects of toxicants in several brain regions and peripheral, myelinated fibers.

Two photon calcium imaging is widely used for recording neural activity in the living mammalian brain. However, extending high-speed two-photon imaging to 3-dimensions has proven difficult. In conventional 2-photon microscopy studies which are confined to 2D, imaging can only capture in-plane structures and usually focus on imaging somatic activity. While dendritic segments may be visible in 2D images, it is almost impossible to relate their activity to specific cells, or to simultaneously record the activity of multiple soma and their dendrites in parallel. Meanwhile, attempts to image activity throughout complex 3D dendritic projections have needed significant and precise a-priori knowledge, and are sensitive to natural movements. Here, we demonstrate that two-photon light-sheet microscopy offers unique advantages for high-speed, volumetric functional brain imaging, even in the scattering in-vivo mouse brain. We describe and characterize a two-photon version of swept confocally aligned planar excitation microscopy (2P-SCAPE), a single-objective light sheet approach capable of high-speed volumetric imaging to depths exceeding 400 microns below the cortical surface. 2P-SCAPE can achieve near-isotropic sampling of large volumes spanning depth ranges of over 300 microns at up to 20 volumes per second. Recordings of in-vivo GCaMP activity at cellular resolution in awake mice capture neural activity in apical dendrites and soma in awake behaving mice. Our results demonstrate that a single-objective two-photon light-sheet is a powerful alternative to point-scanning two-photon for high-speed volumetric imaging of mouse brains.

Title: Vascular Network Analysis across the Whole Mouse Brain via Light-sheet Microscopy and AI-Based Image Analysis

Authors: *K. MINATOHARA[1], K. SUGAWARA[2], M. OITATE[1];
[1]Daiichi Sankyo, Tokyo, Japan; [2]LPIXEL Inc., Tokyo, Japan

Abstract: In this study, we performed fluorescent staining and light-sheet microscopy imaging of cleared mouse brain to acquire fluorescently labeled vascular images throughout the whole brain. Furthermore, we established a method for vascular image analysis using AI, successfully achieving vascular image analysis across the whole brain. First, fluorescent labeling of blood vessels and tissue clearing of mouse brains were visualized by light-sheet microscopy. This technique allowed us to capture the vascular network of the whole brain with high spatial resolution. The acquired images enabled the observation of both the overall brain structure and the detailed morphology of individual vessels. Specifically, we extracted 3D features from the vascular data, enabling the characterization of complex vascular structures throughout the brain. Furthermore, we developed a machine learning model that required minimal annotation for training. This model effectively registered and aligned the vascular structures in the 3D brain volume, enabling accurate visualization and analysis of vascular network across the whole brain. Our results demonstrate the effectiveness of combining fluorescent labeling and imaging of the whole-brain vasculature in cleared mouse brains, highlighting the potential of this novel approach. Additionally, the AI-based vascular image analysis method represents a groundbreaking advancement for 3D analysis of the whole-brain vasculature. Through this study, we aim to disseminate knowledge of this innovative approach for vascular analysis in cleared mouse brains, providing researchers with new insights and prospects in brain vascular research.

Abstract: At the very basis of all physiological research is the ability to image the anatomy of the tissue in question, facilitated by the tools available. Each organ system has its own defined structure corresponding to its functionality which gives rise to the need to image these systems in an unbiased and complete manner. Analysing large volumes of organ tissue, however, remains a palpable challenge within science. Despite the variety of sample preparation and imaging techniques, many require complex protocols and expensive equipment and reagents as well as being limited by the size of the sample able to be acquired as a whole. Organ systems and, specifically, neuronal circuits often extend beyond this limited data field. Here we present a pipeline that utilizes the resolution capabilities of fluorescent expansion microscopy techniques, in which the sample is physical and isotopically enlarged, and targets of interest are fluorescently labelled using assorted techniques, creating the data field. Adding to the pipeline is customized dual-sided light sheet microscope capable of imaging large samples, made from standard optical equipment, along with targeted data acquisition software which specifically targets the data field. The large sample chamber and the choice of different refractive index matching solutions provide the grounds for imaging at several resolutions, from the sub-micron to the mesoscale. Since the samples are able to undergo various rounds of testing under different expansion factors, a hierarchal approach can be employed: first imaging at low resolution in order to acquire the entire data field and proceeding to increase the resolution and reducing the data field to image finer structures at higher-resolution.The physical capabilities of the system facilitate the imaging of neuronal morphology and extended to the central nervous system. Moreover, this system has the potential to extend to other large tissue volumes, providing the basis for further anatomical research. The fundamental goal of this pipeline is to stay within the parameters accessible to most laboratories in terms of cost and the ability to be replicated, fulfilling the ultimate goal of expanding knowledge and enhancing opportunities for the research community.

Abstract: During Deep Brain Stimulation (DBS) surgery for Parkinson’s Disease (PD), it is critically important to accurately place the electrodes within specific deep brain targets, such as the subthalamic nucleus (STN). Current methods of evaluating electrode position in the operating room include: 1) microelectrode recordings, which increase the risk of intracranial hemorrhage and often require the patient to be awake during invasive brain surgery, and 2) intraoperative imaging, which has a limited resolution. Our group proposes to use two-photon microendoscopy to perform high resolution, real-time imaging along the surgical trajectory through a narrow stereotactic cannula to assist with neuronavigation and detect blood vessels using Second Harmonic Generation (SHG). Here we show that conventional, two-photon microscopy and several rudimentary image classifiers can be used to distinguish the human STN from the surrounding tissue due to the spatial distribution of autofluorescence. We also develop a 186 mm long and 1.2 mm diameter microendosocpe composed of Gradient Refractive Index (GRIN) lenses. This device has a magnification of ~2.8X, a field of view of ~180 microns, and a

resolution of 0.86 microns and 9.6 microns in the lateral and axial directions, respectively. The prototype was used to image endogenous autofluorescence and blood vessels in *ex-vivo* human brain tissue. We also report on our progress towards a second-generation prototype.

Title: The Expression Profile Of Selected Class A, B And C Orphan GPCRs And CNS Localizations

Authors: *S. MAJUMDAR[1], Y.-T. CHIU[1], N. SCIAKY[1], D. KOCAK[1], W. WANG[2], Z. WU[2], K. HUA[1], J. ENGLISH[3], J. IRWIN[4], B. ROTH[1];
[1]Pharmacol., The Univ. of North Carolina-Chapel Hill, Chapel Hill, NC; [2]Cell, Developmental and Regenerative Biol., Icahn Sch. of Med. at Mount Sinai, New York, NY; [3]Biochem., Univ. of Utah, Salt Lake City, UT; [4]Pharmaceut. Chem., Univ. of California San Francisco, San Francisco, CA

Abstract: Containing more than 800 members, G protein coupled receptors (GPCRs) represent the largest class of membrane proteins in the human genome. It is estimated that 20-30% of FDA approved drugs target GPCRs making them the largest druggable family in the genome. However, the endogenous ligand/function remains unknown for more than 100 orphan GPCRs (oGPCRs). GPCRs are expressed in every major organ system in the body. Located in the cell membrane, GPCRs transduce extracellular signals into important physiological effects. Upon ligand dependent activation of a GPCR, signal transduction involves binding to and stimulating heterotrimeric G protein dissociation which in turn couples to various downstream effectors that modulate secondary messenger signaling molecules including cAMP, IP3, Ca^{+2} and others. Human GPCRs are classified into five major families: Rhodopsin (Class A), Secretin and Adhesion (Class B), Glutamate (Class C), and Frizzled/taste receptors 2 (TAS2). This study focuses on characterizing some selected understudied members of class A, Class B and class C GPCRs namely Gpr173, *MTNR1B, Adgrb2, Adgra3 and GprC5b* . For this study we generated CRISPR GPCR-*Cre* mouse lines (i) *Gpr173* (*Gpr173-EGFP-CT-IRES-ERT2-Cre*), (ii) *Gprc5b* (*Gprc5b-Ires-Cre*), (iii) Ar2 (*Adgrb2-EGFP-CT-IRES-ERT2-Cre*), (iv) Gpr125 (*Adgra3-mGL-CT-IRES-Cre*) as well as *Flpo* mouse line (v) *Mtnr1b* (*Mtnr1b-mCherry-Ires-Flpo*). The

Cre^{ERT2}mouse line is then crossed with reporter *Ai9-TdTomato* (Td-Tomato) mouse line. The animals were treated with tamoxifen (150mg/kg) for 4 days between postnatal (P) days 39 and 42 after which 22 different organs were harvested on P56. The *Gprc5b* mouse line was crossed with *Td-Tomato* mouse line and the *Mtnr1b* mouse line was crossed with *FRT-EGFP* mouse line. For *Gprc5b*, tissues were harvested on p56 and on p120. Histological analyses were performed to identify tissue-specific distribution of the Td-Tomato and EGFP reporter. Here we show the whole-body organ screening of *Gpr173*, *Mtnr1b* and *Gprc5b*. All results will be available on AMIS (http://amis2.docking.org/). AMIS is an open resource for mouse imaging data generated by NIH Commonfund Program for Illuminating Druggable Genome (IDG) that provides access to whole body distribution of understudied genes via engineered mouse lines. Following the tissue-specific distribution profile, multiplexing IHC was employed for further analysis to identify downstream signaling pathways. This would add to the knowledge and establish oGPCRs as suitable therapeutic targets.

Abstract: In a human brain around 200 billion cells are working together shaping who we are. Grasping their complex organization, even in a single brain remains a major challenge. Advances in tissue clearing provide a window onto cells inside of intact brains, and have recently been optimized for clearing and immunostaining human brain tissue. However, imaging cleared tissues on the scale of the whole human brain presents many challenges, with conventional methods likely to require many months or years of acquisition time per brain. Here, we present a complete imaging and analysis pipeline developed specifically to achieve high-throughput, multispectral imaging of entire, cleared and immunolabelled human brains at cellular resolution for cell-type atlasing with acquisition times of less than 2 weeks. Our human brain optimized light-sheet (HOLiS) microscopy system is a form of oblique-plane single objective light-sheet, capable of imaging 5mm thick, optically cleared, complete coronal sections of human brain. By imaging thick sections, we can reduce tissue deformations and cut-edge effects, although this necessitated novel optical solutions to enable implementation of a long working distance, multi-immersion primary objective lens. Another feature of HOLiS is its ability to image multiple spectral channels in parallel to enable multiplexed antibody labeling of the different cell-types. Combining multiple laser lines for simultaneous excitation, emitted fluorescence is spectrally divided by our novel 4-way image splitter for simultaneous detection of currently 5 spectral channels with the capacity for 9 channels imaged in parallel. The 5^{th} channel images a nuclear dye, providing fiducials for every cell. Although spectrally multiplexing adds complexity, it greatly accelerates HOLiS acquisition time and reduces data processing burden. Using ultra-fast cameras, we acquire multi-spectral images up to at 0.75 mm^3/s with micron sampling translating to image an entire human brain in < 2 weeks. At modest sampling density and 9 spectral channels, the data of a single human brain scan is expected to exceed 3 PB, imposing constraints on transfer, storage, data pre-processing, and accessibility. We developed a parallelizable analysis pipeline which locates every nucleus, and extracts cell-type information from the spectral channels to provide compressed point-cloud representations of the data that can be quantitatively analyzed, shared and compared between brains. These rich datasets can be clustered to explore cell type distributions and used to guide more complex feature-based analysis, neuroanatomical segmentation and efficient visualization of raw data.

Title: In vivo microscopy of peripheral nerve regeneration

Authors: *I. LUZHANSKY[1], E. ANISMAN[1], D. HUNTER[2], S. ZHANG[1], D. PATEL[1], R. PEREZ[1], N. SYED[1], A. AHMED[1], M. MALIK[1], J. BONNER[1], E. FERIA[1], B. KHAN[1], L. COHEN[1], B. COHEN[1], S. LEE[1], D. BROGAN[1], M. D. WOOD[2], M. Y. BEREZIN[1]; [1]Washington Univ. in St. Louis, Saint Louis, MO; [2]Surgery, Washington Univ. Sch. of Med., Saint Louis, MO

Abstract: Visualization of axons, Schwann cells, and other intraneural cells in peripheral nerve injury models will facilitate investigation of the mechanisms of nerve regeneration. Here, we introduce a technique for chronic high-resolution microscopy of a murine peripheral nerve trunk. We surgically displace the biceps femoris to expose up to 5 mm of the sciatic nerve around the trifurcation and implant a transparent, flexible, sutureless skin-embedded optical window. This enables chronic observation of the sciatic nerve for more than 8 weeks with negligible impact on behavior and nerve function. We also developed an optically friendly nerve repair conduit to enable intravital monitoring of regeneration in a peripheral nerve transection repair model with up to 6 mm gap. Using our system in transgenic mice with fluorescent protein-expressing axons, Schwann cells, or vascular endothelial cells, as well as exogenously introduced fluorescently labeled fibrin and dyes to label myelin and vasculature, we observed a variety of cellular-scale events in uninjured nerve and in nerves post-injury via two-photon confocal microscopy. We successfully captured fascicle-specific Wallerian degeneration, Schwann cell differentiation, angiogenesis, and growth cone-led axonal elongation. We also visualized the in-vivo formation of a tissue cable across the nerve gap and intraneural fibrin degradation and collagen formation. In summary, we demonstrate a longitudinally intravitally imageable small-mammal model of major peripheral nerve injury. This model can be applied to elucidate molecular healing mechanisms by facilitating measurement of migrational and morphological dynamics in injured nerve within the same animal over time.

Title: Spatiotemporal backpropagation patterns of human single unit waveforms revealed by intraoperative high-density Neuropixels recordings

Authors: *D. MESZENA[1], A. C. PAULK[1], W. MUÑOZ[2], I. CAPRARA[2], M. JAMALI[2], B. F. COUGHLIN[1], C. WINDOLF[3], E. VAROL[4], Z. M. WILLIAMS[2], S. S. CASH[1];

Abstract: High-density laminar silicon probes have been widely used in rodent electrophysiology but were virtually absent from human research until recently. Clinical research devices have so far been able to detect single-unit activity (SUA) with a poor spatial resolution (due to large inter-contact distances) or they have been limited to recording only the low-frequency component of the extracellular neural activity (local field potentials). We pioneered a rare opportunity to test state-of-the-art silicon probes (namely the custom-designed, backside-thickened Neuropixels 1.0-S probes) in the operation room setting during resective surgeries in the cases of tumors or epilepsy or the implantation of a deep brain stimulator (DBS) in patients with Parkinson's disease. These probes feature hundreds of closely packed active contact sites enabling for multi-channel oversampling of extracellular SUAs. Spatiotemporally resolved morpho-electric properties of single units allow us for sophisticated clustering of neural cell types. We focus on a particular spatial feature of cortical neurons called the backpropagating action potential (bAP). Intracellular spikes can propagate backward along the somatodendritic axis. This phenomenon can also be detected extracellularly on spike-triggered averages (STAs) of the corresponding SUAs after spike sorting. These bAPs have been observed in rodents (using standard Neuropixels 1.0 probes) in vivo with distinct spatiotemporal patterns across brain regions, putative cell types, and morphological orientations. By using algorithms and criteria from published rodent literature, we report the first in vivo evidence for human neural action potential backpropagation from awake and anesthetized human patients. Interestingly, the appearance of human bAP did not depend on the spike amplitude, firing frequency, or spike count of the clustered SUA, but was correlated with the cell type. Putative cell types were predicted by their peak-to-trough ratio on the channel with the largest amplitude. Our preliminary results on the detection of multi-channel bAP patterns have shown consistency with the rodent findings, as we were able to identify canonical regular spiking (RS) putative principal cells expressing reliable bAPs (over 5 vertical channels, or over 100 μm), as well as fast-spiking (FS) putative interneurons which completely lack this spatial propagation. These results highlight the importance of high-density sampling in translational human in vivo recordings for disentangling cell types and morphological contributions to the local neocortical microcircuit.

Title: Extracting cellular spike activity from synchronous measurements of electrical and chemical neural signals

Authors: *U. AMJAD[1], J. CHOI[1], D. J. GIBSON[2], A. M. GRAYBIEL[2], H. N. SCHWERDT[1]; [1]Dept. of Bioengineering, Univ. of Pittsburgh, Pittsburgh, PA; [2]McGovern Inst. for Brain Res. and Dept. of Brain and Cognitive Sci., MIT, Cambridge, MA

Abstract: Dopamine plays an important role in synaptic plasticity and modulating neural activity (i.e., spike activity). Such synaptic plasticity is thought to underly many forms of learning. However, the role of these neuromodulators in regulating plasticity has yet to be fully explored in behaving animals. Measurements of synchronous dopamine and neural spike activity are needed to precisely examine how dopamine shapes neuroplasticity during learning. We previously demonstrated concurrent recording and analysis for local field potentials and dopamine in behaving non-human primates (Schwerdt et al., 2020); however, these methods did not naturally extend to extracting concurrent neural spike activity and dopamine. Artifacts introduced into the electrophysiological (EPHYS) recording by our neurochemical recording technique, fast scan cyclic voltammetry (FSCV), hinder concurrent analysis. FSCV applies a small periodic voltage (every 100 ms) to the implanted carbon fiber electrode to induce redox reactions of surrounding electroactive molecules, such as dopamine, which then produce a measurable current that is proportional to the dopamine concentration. However, the applied FSCV voltage couples directly to neighboring implanted EPHYS electrodes in the form of an artifact due to the brain's conductive properties. Artifact noise can be erroneously labeled as spikes using standard thresholding and clustering-based spike sorting methods. Consequent analytical measures, like spike firing rates, are then susceptible to error and misrepresentation of the actual neural environment. We developed an automated algorithm capable of interpolating away FSCV artifacts from raw EPHYS waveforms in the time-domain to reliably extract spike firing data. We compared spike sorting with and without interpolation by calculating a percent

spike recovery (%PSR) on spike timestamps. %PSR was 87.35% of the spikes (with a std:7.59%, n=6, 3 sessions, 2 channels/session). FSCV artifacts were simulated on isolated EPHYS signals (without concurrent FSCV) to make these calculations. The algorithm was tested on multi-modal FSCV-EPHYS recordings where we were able to successfully isolate and identify task-modulated neural units in the primate striatum in combination with dopamine signals, allowing us to directly compare neuronal spike and dopamine activity during online behavior. This work paves a way forward for extracting meaningful interactions between striatal dopamine and neural spike activity overtime.

Title: Spatiotemporal profile of extracellular action potentials in posterior parietal cortex area LIP of the macaque monkey

Authors: P. THIRUNAVUKKARASU[1], *M. PARE[2];
[1]Dept Biol, York Univ., Toronto, ON, Canada; [2]Dept Biomed & Mol Sci., Queens Univ., Kingston, ON, Canada

Abstract: Extracellular spike waveforms recorded from neurons are known to reflect the intracellular process of action potential generation through the activation and inactivation of ion channels. The variability between the shape of spike waveforms is thought to be a direct result of the differential ion channel expression between these subtypes. In cerebral cortex, spike waveforms recorded from pyramidal neurons are known to be ‘broader’ than the ‘narrow’ spike waveforms exhibited by fast-spiking interneurons. To capture this temporal variability in primarily biphasic waveforms, where a negative deflection occurs before a positive deflection, researchers have used the spike width—the time between the trough and peak of the waveform. However, this uni-dimensional approach often fails to discriminate putative interneurons from pyramidal neurons and to account for further nuanced classes of neurons. Here we report on our efforts to refine classification approaches by examining the spatiotemporal profile of action potentials recorded from neurons within the lateral intraparietal (LIP) area in one rhesus monkey. We refined the standard approach to calculating the template mean waveform. We aligned each individual waveform, not on the time of the trough, but on the maximum of the first derivative between the trough and peak, which corresponds to the instance of maximum change in voltage of the waveform. Using unsupervised classification with both timing and relative amplitude

measures, we derived a three-class provisional model comprised of one narrow-spike class robustly separated from two broad-spike classes. Consolidating this classification, we identified a phenomenon observed exclusively in all broad-spike neurons, a knee-like change in the voltage close to the waveform peak. In addition, narrow-spike neurons were characterized by high firing rates, more irregular firing, and generally lacking bursting. While displaying converse firing statistics from narrow-spike neurons, there was no identifiable difference in the discharge properties between the two identified broad-spike classes. Nevertheless, several waveform features involving the knee-like change were highly discriminating between these two classes. Moreover, the class with the broader spikes exhibited more highly unusual, W-shaped troughs (observed in 15% of the sample), which has been associated with multiple Na+ influxes thanks to larger dendritic tree arborization. This novel analysis provides a fresh perspective and new tools to help identify distinct spatiotemporal and functional signatures of three different types of cortical neurons.

Title: Longitudinal electrophysiological assessment of visual ability in mice

Authors: *R. D. LAMPRECHT[1,2], Y. ZHAO[2], M.-F. FONG[2];
[1]Biomed. Engin., Georgia Inst. of Technol., Atlanta, GA; [2]Coulter Dept. of Biomed. Engin., Georgia Tech. and Emory Univ., Atlanta, GA

Abstract: Over the past few decades, mice have emerged as a premier model for studying visual cortical function. To evaluate visual ability, experimental designs often employ behavioral assessments which either require extensive training and may drive unintended cortical plasticity, or rely on subcortical reflexes rather than cortical processing. To circumvent these limitations, one method for evaluating cortex-dependent visual ability is to measure the response in the primary visual cortex (V1) to precisely-timed visual stimuli. Here we present a low-cost, extensible pipeline for longitudinal monitoring of V1 responses. Our system leverages Bonsai Rx, an open-source programming language, to develop a suite of tools for the presentation of visual stimuli and synchronization with electrophysiological data recorded via the Open Ephys acquisition system. Using these tools, we mapped receptive fields and quantified spatial acuity, contrast sensitivity, and orientation selectivity in V1 of mice across a range of developmental ages (P23-P120). We demonstrate that this platform can reliably track visual cortical responses

using the local field potential recorded via chronically-implanted electrodes over months. Finally, we highlight the extensibility of this platform to include other forms of data acquisition (e.g. video, motor tracking, pupil monitoring, calcium imaging, high channel count electrophysiology) and real-time stimulation (e.g. optical, electrical, auditory). This work may be of interest to researchers seeking to build simple and affordable systems for measuring visual ability in mice over time, with the potential to scale to more complex experimental paradigms.

Abstract: Neurons in the central nervous system exhibit diverse electrophysiological, morphological, and molecular characteristics. These diverse neurons form neural circuits that underlie a variety of brain functions and behaviors. The physiological properties of neurons are influenced by their molecular properties. However, methods for comprehensively analyzing these properties at multiple levels from a single neuron have not been established. To address this issue, we developed an experimental technique to analyze gene expression profiles of a hippocampal neuron recorded from *in vivo* conditions by integrating existing techniques including *in vivo* juxtacellular recording, cell labeling, brain slicing, patch clamping, and single-cell RNA sequencing. In detail, a juxtacellular recording of spike patterns from a neuron is performed from the hippocampus in a living mouse. Subsequently, a soluble fluorophore, Alexa

488/594 hydrazide, is electroporated into the recorded neuron for cell labeling. Acute hippocampal slices with a thickness of 200 μm are prepared from the mouse. In the slice, the labeled neuron is visualized and collected using a glass pipette under a microscope. Finally, a single-cell RNA sequencing is performed from the collected cell to identify its gene expression profiles. The accuracy of our methods was confirmed by comparing spike patterns and cellular localization with expression levels of marker genes in individual neurons. So far, we performed electrophysiological recordings and gene expression analysis from forty hippocampal CA1 neurons recorded under urethane anesthesia. By focusing on spike patterns related to hippocampus sharp wave ripples, a transient local field potential signal representing synchronous spikes of a large number of neurons, we are now analyzing a relationship between the degree of participation of individual neurons into sharp wave ripples and their gene expression profiles. Our method is useful to elucidate molecular mechanisms linked to physiological signatures of neurons.

Title: Automated high throughput patch clamp studies of Piezo1 channel

Authors: S. PAZ[1], ***D. NAGY**[2], S. KARATSIOMPANI[3], J. KEFAUVER[4], R. PAK[5], D. SAUTER[2];
[1]Univ. of East Anglia, Norwich, United Kingdom; [2]Sophion Biosci., Bedford, MA; [3]Sophion Biosci., Copenhagen, Denmark; [4]Univ. of Geneva, Geneva, Switzerland; [5]Scripps Res., La Jolla, CA

Abstract: Piezo ion channels convert mechanical stimuli into various biological activities through a process called mechanotransduction. Piezo1 and Piezo2 were identified in 2010 as molecular mediators of the mechanically activated current found across multiple cell types. While the main function of Piezo2 is the mediation of gentle touch sensation, Piezo1 has functions in numerous physiological processes, including sensing shear stress of blood flow for proper blood vessel development, regulating urinary osmotic pressure, controlling blood pressure and exercise performance. Previous studies have shown that over 25 mutations in Piezo1 cause human disease. However, most mutations have yet to be extensively studied. Piezo1 is activated through cell membrane deformations caused by mechanical forces, such as osmotic pressure, fluid shear stress, substrate stiffness, and confinement. Known stimuli activating Piezo1 *in vitro*

are shear stress, as well as the indentation of a cell with a glass probe and membrane stretching. In this study, we aimed to develop a feature to perform Piezo1 experiments on a high throughput automated patch clamp platform. The stimulus applied here was shear stress produced by liquid flow injection containing Yoda1, the Piezo1 agonist, at 26 and 30 °C. Fluid flow shear stress is achieved by applying a defined solution flow through the microfluidic recording chamber, creating a uniform shear force for the study's cells. In addition, Yoda 1 slows the inactivation phase of transient currents, enabling better detection of Piezo1-mediated mechanically induced responses. HEK293T cells stably expressing mPiezo1-GFP fusion protein and HEK cell line lacking Piezo1were used to develop the assay and ensure the specificity of Piezo1 responses. We demonstrated the feasibility of mechanically stimulating Piezo1 using the high-speed liquid handling feature (or standard speed) in the Qube384 platform using either Yoda1 at 5 µM or 10 µM. Success rate of over 80% was achieved using Yoda1 10 µM and shear stress of 5 dyne/cm^2 regardless of the temperature (26/30°C) with an amplitude current around -2 nA. Importantly, no current response was observed in the HEK cell line lacking Piezo1. In addition, we evaluated whether responses could be observed by repeated stimulation. Indeed, a 20-minute wait time between stimulations allowed us to obtain current responses of similar amplitude. Our results demonstrate the Qube384 is capable of characterizing Piezo1 in vitro. These assays open the door to a new set of features that allow the identification of antagonists at Piezo1 in the presence of Yoda1 using automated high throughput electrophysiology platforms.

Title: Operationalization of long-duration patch clamp recording of striatal medium spiny neurons in juvenile and old mice

Authors: *X. ZHAN[1,2], S. M. JOHNSON[1], R. MARGOLIS[2];
[1]Physiol. and Biophysics, Howard Univ., Washington, DC; [2]Psychiatry and Behavioral Sci., Johns Hopkins Sch. of Med., Baltimore, MD

Abstract: Long-duration recording of ion currents in brain slices has been challenging. Several efforts to extend the duration of recordings have been made in the past few decades, including the introduction of NMDG (*N*-Methyl-D-glucamine), HEPES, sucrose, and choline-based cutting solutions. Despite these improvements, long-duration recording has proven elusive, especially for brain slices from older animals. In this study, we attempted to develop a protocol to increase the duration of slice recording by focusing on depolarization dependent after hyperpolarization (AHP), and low-voltage threshold activated Ca currents in striatal medium spiny neurons. We induced I_{AHP}, and low-voltage threshold activated Ca dependent currents, using a hyperpolarization prepulse of -105 mV. In comparison to previous protocols, 1) lactate was used in the cutting solution (in mM: NMDG, 102; HEPES, 20; $NaHCO_3$, 26; NaH_2PO_4 1.25; KCl, 2.5; $MgSO_4.7H_2O$, 10; $CaCl_2$, 0.5; Na-L-ascorbate; 5; Na pyruvate, 3; Thiourea, 2; glucose, 20, at 4^oC, pH 7.4) and recording perfusate (in mM: NaCl, 124; KCl, 2.1; $MgSO_4.7H2O$, 1; $CaCl_2$, 2; KH_2PO_4, 1.2; $NaHCO_3$, 20; glucose, 10; Na-HEPES, 4; Sodium lactate, 1; Sodium pyruvate, 2; Sodium ascorbate, 0.4; pH 7.4, at room temperature); 2) R-CPP, a NMDA blocker, was used only in the recovery solution: 3) the intracellular Ca level was 5 mM. The currents were significantly greater than the currents induced without a prepulse or in a lower intracellular Ca level (0.25 mM). In young mice, the recorded currents were stable for up to nine hours after the slice was prepared. Stable recordings of three hours were achieved in mice as old as twelve months in both C57BL/6 and heterozygous JPH3 knockout mice (JPH3 KO). No significant run-down was observed even in JPH3 KO mice with partially compromised function of junctophilins, a critical protein for homeostasis modulation. These modifications, by preserving the physiological health of brain slices for as long as nine hours after slice preparation, will facilitate investigation of neural plasticity, pharmacological studies, and aging.

Title: Patch clamping video game: An interactive simulation to teach and train electrophysiology students

Authors: *N. J. MALTA[1], C. VAN ZYL[1], A. DUNNUM[1], W. D. HUNT[1], M. ROWAN[2], M. STIMBERG[3], R. BRETTE[3], C. R. FOREST[1];

Abstract: Patch clamping is a well-established technique in electrophysiology for investigating the electrical properties of neurons and other cells. Unfortunately, the equipment required for patch clamping is often large, expensive, and limited in availability, making it challenging to teach and train students on the technique. Further, the hardware and software components involved in this technique have a steep learning curve for new researchers. There is a need to expose and engage many hundreds of learners each year to this gold-standard technique.
To address this barrier, we introduce a user-friendly software simulation, a video game, that emulates the process of working with a patching rig, providing an accessible learning tool for students interested in exploring this technique.
The software offers a virtual environment that replicates key aspects of patch clamping procedures. Users can establish gigaseals, break into cells, and take simulated electrical recordings. Further, the software replicates various failure modes encountered during real experiments, like pipette tip clogging, breakage, and variations in resistance between different tips.
Through the utilization of this software, in experiments with dozens of users in lab and course environments we record telemetry data to observe common challenges faced by novice patchers. By tracking the performance improvements of users over time, we demonstrate the effectiveness of our simulation-based approach in facilitating skill development and improving understanding of patch clamping techniques.
By providing an accessible and free solution, our simulation software aims to empower students to explore and gain familiarity with patch clamping. It serves as a valuable educational tool that bridges the gap between theoretical knowledge and practical experience, enabling students to enhance their understanding of the technique and its applications.

Title: Low noise, high-throughput patch clamping with microfabricated quartz electrodes

Authors: *C. P. VAN ZYL[1], M. C. YIP[1], R. E. PERSZYK[2], B. YANG[1], M. M. GONZALEZ[1], S. F. TRAYNELIS[2], C. R. FOREST[1];
[1]Georgia Inst. of Technol., Atlanta, GA; [2]Dept Pharmacol, Emory Univ. Sch. of Med., Atlanta, GA

Abstract: Single-ion channel recordings are critical to understanding fundamental activities and behaviors of individual cells, such as electrophysiological response to drug exposure or functional information about neuronal synaptic transmission. Patch-clamping is the gold-standard, Nobel-prize-winning technique and highest precision method to facilitate single-cell or ion channel electrical recordings through contact between a glass micropipette electrode and cell membrane. However, it remains a low-throughput technique, as the process of sealing onto the cell membrane (and even touching any organic membranes) leaves organic debris within the electrode, preventing its reuse. In addition, high-resolution, single channel recordings require meticulous attention when patching to eliminate sources of noise and tedious repetition to obtain a single ion channel in a patch recording. Patch electrodes pulled from quartz glass have reduced electrical noise and isolate electrical signals more effectively than their more widely-used borosilicate glass counterparts. Electrode cleaning for reuse and electrode polishing are novel techniques applied to borosilicate electrodes to increase throughput and reduce noise. However, the application of these techniques to lower-noise quartz electrodes has yet to be attempted and would enable higher resolution and throughput of patch clamp experiments. Thus, we have demonstrated more efficient and accurate recordings of cell activity by applying electrode microfabrication and detergent-based cleaning techniques to quartz electrodes. First, we demonstrate the efficacy of cleaning quartz electrodes by successfully collecting greater than ten consecutive patch clamp recordings per single electrode. Then, we show increased gigaseal resistance and reduced noise recordings near the system limitations (i.e. baseline noise of patch clamp electronics) through the use of quartz electrodes with flat, sub-nanometer annular tip openings microfabricated using a focused ion beam. This combination of quartz electrodes, detergent-based cleaning, and electrode microfabrication can be readily applied to high-precision single-ion channel recordings and will advance the field of patch clamp electrophysiology by simultaneously increasing the quality and throughput of experiments at a lower cost per attempt.

Title: Fluorescent-guided automated patch clamp electrophysiology to systematically study Parvalbumin interneurons in Alzheimer's Disease

Authors: *M. M. GONZALEZ[1], B. MAGONDU[2], M. J. ROWAN[3], C. R. FOREST[1]; [1]Woodruff Sch. of Mechanical Engin., [2]Coulter Dept. of Biomed. Engin., Georgia Inst. of Technol., Atlanta, GA; [3]Dept. of Cell Biol., Emory Univ. Sch. of Med., Atlanta, GA

Abstract: Alzheimer's disease (AD) is a neurodegenerative disorder characterized by progressive cognitive decline, affecting millions worldwide. Understanding the underlying mechanisms of AD is crucial for the development of effective therapeutic interventions. Tau and amyloid beta are key hallmarks of AD, however the underlying cause of cognitive decline and memory impairment remains elusive. As a result, alternative hypotheses regarding the cause of cognitive decline in AD are gaining attention. Namely, cognitive decline in early Alzheimer's disease (AD) may be attributed to disrupted neuronal circuits rather than the accumulation of amyloid plaques or tau tangles. Initial findings indicate that circuit hyperexcitability precedes plaque formation in AD mouse models. The dysregulation of GABAergic interneurons, specifically parvalbumin-expressing interneurons, is believed to contribute to circuit dysfunction. The spatial and temporal progression of interneuron dysregulation in AD is still largely unstudied. To effectively investigate the intrinsic properties of PV interneurons with precise spatial and temporal resolution, patch clamp electrophysiology is the recommended approach. However, manual patch clamp experiments are known for their low throughput and labor-intensive nature. To overcome these limitations, we have developed an automated patch clamp rig, known as the patcherBot, which enables automated fluorescent-guided patch clamp recordings. To demonstrate the utility of this technology, we focused on investigating the role of PV interneurons in a human amyloid precursor protein model of AD (hAbeta^{SAA}, Jax Strain #034711) and corresponding control strain (B6J hAbeta, Jax Strain #033013). To measure the intrinsic properties of PV interneurons, we utilized an adeno-associated virus (Addgene Plasmid #135631) to tag these neurons with green fluorescent protein (GFP). Utilizing the advanced capabilities of the enhanced patcherBot, we conducted 50 automated patch clamp recordings over several days on GFP-tagged interneurons derived from the lateral entorhinal cortex and somatosensory cortex of 2-month-old subjects. In this study, we present the intrinsic properties of these PV interneurons and highlight the invaluable contribution of automation in systematically investigating Alzheimer's Disease. The automation employed in this study will greatly accelerate our comprehension of the specific role played by PV interneurons in AD, offering the potential to unveil innovative therapeutic targets and strategies for alleviating cognitive decline.

Title: Why do networks need Excitation-Inhibition balance? A representation capacity perspective

Authors: *Q. WANG[1], M. A. POWELL[4], E. W. BRIDGEFORD[2], J. VOGELSTEIN[3]; [1]Neurosci., [2]Biostatistics, [3]Biomed. Engin., Johns Hopkins Univ., Baltimore, MD; [4]Mathematical Sci., United States Military Acad., West Point, NY

Abstract: Why do brains have inhibitory connections? Why do brains need Excitation-Inhibition (E-I) balance to avoid disorders like Schizophrenia and Autism Spectrum Disorders? Do feedforward deep neural networks also need E-I balance? We propose an answer from the perspective of representation capacity. We believe representing functions is the primary role of both (i) the brain in natural intelligence and (ii) deep networks in artificial intelligence. Our answer to why there are inhibitory/negative weights is: to represent more functions. We mathematically prove that, in the absence of negative weights, neural networks with non-decreasing activation functions are *not* universal approximators. We also provide insights on the geometric properties of the representation space that non-negative networks cannot represent. Our answer to how networks benefit from E-I balance is: to represent functions more efficiently. We mathematically prove that, when a fixed ratio of inhibition is allowed, neural networks of infinite size *are* actually universal approximators; However, the farther this ratio deviates from balance, the more resources neural networks waste on silent neurons and monotone neurons: when excitation ratio is low, networks tend to form silent neurons that are always quiescent regardless of how strong the input may be; when excitation ratio is high, networks tend to form monotone sub-networks that can only represent simple functions. Given an E-I ratio of the entire network, we mathematically deduce individual neuron's synaptic input E-I ratio distribution and quantify the probability of silent and monotone unit formation. In short, when networks are not E-I balanced, they cannot make efficient usage of the available neurons to represent complex functions, as many of the neurons are quiescent (low-E) or can only represent simple functions (high-E). Apart from theoretical derivations, we also experimentally demonstrate that 1) even feedforward deep neural networks need balanced E-I ratio to achieve better performance, and 2) the majority of state-of-the-art pre-trained deep neural networks have balanced E-I ratio. We expect these insights will yield a deeper understanding of inhibition and E-I balance that leads to more efficient machine learning and better solutions for disorders associated with E-I imbalance.

Title: Spatial planning in the presence of positional uncertainty

Authors: *M. SALMASI, M. SAHANI;
Gatsby Computat. Neurosci. Unit, Univ. Col. London, London, United Kingdom

Abstract: Spatial navigation is conducted through combining path integration signals with incoming sensory modalities. The noise and intrinsic ambiguity of the sensory signals together with the noisy path integration system lead to positional uncertainty. To behave optimally in a navigation task, the animals/agents should take into account the uncertainty of the input signals, and infer a distributional belief about their location. Different frameworks have been suggested for the representation of distributional beliefs in the brain, such as sampling, probabilistic population codes, and distributed distributional codes (DDC). However, it remains unclear how the brain represents positional beliefs and how the hippocampus employs these representations to perform spatial planning. DDC suggests that a probability distribution is represented by the expected values of some encoding functions. We assume that given the history of sensory observations and efference copies of the motor commands, the posterior distribution over the location is represented by the DDC values. We have previously shown that the animal can update the DDC values recursively and conduct probabilistic localization and structural learning. Here we show how spatial planning can be performed using the codes of uncertainty. After learning the transition structure of the environment, the value iteration algorithm can be used to derive the optimal value function for each location in the environment. In the absence of positional uncertainty, the animal could follow the action that maximizes the value at each location and reach the desired goal. However, the true location is a latent variable, and the animal has only access to the DDC values of the posterior distribution over the location. We show that for each action, a weighted sum of the DDC values provides the expected value of that action, and by choosing the action corresponding to the highest expected value function, the animal can find an effective policy for planning. The simulations confirm that by following this DDC-based policy, the animal can take the positional uncertainty into account and reach the goal efficiently. Our results provide a general framework for planning under uncertainty and can be employed beyond spatial planning to any action selection task in which there is uncertainty about the task's (latent) variables.

Title: Deriving causal relationship in resting state functional connectivity using SSFO-based optogenetic fMRI

Authors: *X. HAN[1], S. R. CRAMER[2], N. ZHANG[1];
[2]Biomed. Engin., [1]The Pennsylvania State Univ., State College, PA

Abstract: The brain network has been extensively studied as a collection of brain regions that are functionally interconnected. However, the study of the causal relationship in brain-wide functional connectivity, which is central to brain function, remains challenging. Here we combined stabilized step-function opsin (SSFO)-based optogenetics with fMRI in a resting-state rodent model to study how a local increase of excitability affects brain-wide neural activity and resting-state functional connectivity (RSFC). We further examined the feasibility of using this method to infer the causal relationship in the brain network based on the modulated RSFC. When the dentate gyrus (DG) was sensitized by SSFO activation, we found significantly changed brain activity and connectivity in several brain regions associated with the DG, particularly in the mPFC. To derive the directional information in these connections, we incorporated Pearson's correlation and partial correlation analyses in a graphic model. Our causal inference result shows an 85-100% accuracy rate compared to the directional information based on anatomical tracing data. This study established a system to investigate the relationship between local region activity and RSFC modulation and provide a way to analyze the underlying causal relationship between brain regions.

Title: A mean-field approach to modeling energetic efficiency and non-deterministic signaling outcomes in cortical neural networks

Authors: *E. A. STOLL;
Western Inst. for Advanced Study, Denver, CO

Abstract: Mean field theory has been usefully employed to model probabilistic coding in cortical neural networks [Gabrie, 2020]. This methodology allows an exploration of the solution space, leading to the selection of an optimal system state from a probability distribution [Mei et al., 2019]. At the mean field limit, the network achieves a fixed state, where excitatory and inhibitory contributions are balanced, so that fluctuations dominate network level dynamics [Brunel, 2000]. As a result, applications of mean field theory have promoted a better understanding of how spontaneous membrane potential fluctuations influence signaling outcomes [Geisler et al., 2005] and how stochastic events shape network-level dynamics [Bandyopadhyay et al., 2022]. Yet a mechanistic connection between noisy coding and energy efficiency in cortical neurons has remained elusive.
This report presents a thermodynamic basis for mean-field theory, with the Hamiltonian being modeled not only as a computational quantity but also as an energetic quantity. In this approach, cortical neurons integrate upstream signals with random electrical noise to generate a physical quantity of information. This complex-valued probability distribution is then reduced as the trial Hamiltonian is resolved. As information is compressed, free energy is released, driving a shift in the neuronal membrane potential. Here, the optimal neuronal ensemble to encode the state of the surrounding environment is also the most energy-efficient solution, since the extraction of predictive value from a thermodynamic quantity of information both maximizes energetic efficiency and drives a system-wide non-deterministic computation.

Title: Dendrites increase computational efficiency in physically constrained neural networks

Authors: *E. H. S. TOLOZA[1,3], M. T. HARNETT[2];
[1]MIT, Brookline, MA; [2]McGovern Inst. for Brain Res., MIT, Cambridge, MA; [3]Harvard Med. Sch., Boston, MA

Abstract: Unlike traditional artificial neural networks, biological networks must overcome energetic and spatial costs associated with sampling inputs in physical space. Specifically, the number of possible synaptic connections per unit volume should strongly influence how different types of networks are functionally organized. We constructed recurrent neural networks consisting of either rate-based or biophysically-realistic spiking units trained via gradient descent

and subjected them to synapse sampling limits. We discovered that the addition of dendrites enhances performance across a range of tasks that represent different classes of computation, but only under realistic spatial constraints. Using intuitive models of network energy and physical volume, we identified specific parameter spaces where dendrites represent an energetically and/or spatially efficient means to increase the computational power of a network. Our results provide a new general principle for explaining why some biological networks favor fewer principal neurons with extensive dendritic trees (e.g. cortex) while others favor an increased number of neurons with little to no dendritic arborization (e.g. cerebellar granule cells).

Title: Graph Theory Based Parcellation of Brain Networks

Authors: *K. XHINDI[1], J. C. NINO[2], M. FEBO[3];
[1]Biomed. Engin., [2]Material Sci. and Engin., [3]Psychiatry Dept., Univ. of Florida, Gainesville, FL

Abstract: The identification and characterization of modules in functional brain networks can be approached through two methodologies: community-finding algorithms and parcellation from functional Magnetic Resonance Image (fMRI) analysis. Both methodologies seek to uncover the organization of the brain, yet they differ in their utilization of methods and models. Community-finding algorithms are founded on graph theory principles and aim to identify communities of highly interconnected brain regions within a graph. Parcellation from fMRI analysis, on the other hand, employs statistical methods to identify brain regions exhibiting similar patterns of activation in response to a specific task. 128 human derived functional connectivity graphs were initially parcellated from the original methodology of the data by Schaefer et al, 2017.The current study evaluates the quality of the partitions derived from Louvain's Algorithm, k-means, and Principal Component Analysis by using mathematical measures such as modularity, Normalized Mutual Information (NMI), Surprise and Conductance Values. Furthermore, In Alzheimer's Disease (AD) and Cognitive Normal (CN) Groups, nodes are assigned different roles based on their within-module degree (Z) and participation coefficient (P), which measure connectivity within modules and link distribution among different modules.Louvain and PCA algorithms show higher NMI and surprise values compared to the Schaefer algorithm, indicating stronger agreement and statistical significance in their community structures, while Spectral and k-means algorithms exhibit the highest maximum values of conductance, reflecting more cohesive and well-defined communities. Based on the P and Z score combination the CN Group has 29 nodes with different functions as compared to the AD counterparts, with more than 50% of them being assigned to connecter nodes in the CN Group.The graph theory-based parcellation

approach offers several advantages for analyzing brain connectivity compared to other algorithms as shown by improved metric score. By applying graph partitioning algorithms, such as Louvain, k-means, and PCA it may enable the identification of distinct regions or communities within the brain network as well as difference in organization between AD and CN Groups.

Title: The scale-invariant covariance spectrum of brain-wide activity

Authors: *Z. WANG[1], W. MAI[2], Y. CHAI[1], K. QI[1], H. REN[1], C. SHEN[1], S. ZHANG[1], G. TAN[1], Y. HU[2], Q. WEN[1];
[1]Univ. of Sci. and Technol. of China, Hefei, China; [2]The Hong Kong Univ. of Sci. and Technol., Hong Kong, Hong Kong

Abstract: The structure of high-dimensional neural activity plays a pivotal role in various sensory and behavioral processes. Here, we analyze whole-brain calcium activity in larval zebrafish (huc:h2b -GCaMP6f), captured by fast light-field volumetric imaging during hunting and spontaneous behavior. We find that brain-wide activity is distributed across many principal component dimensions described by the covariance spectrum. Intriguingly, this spectrum shows an invariance to spatial subsampling: That is, the distribution of the eigenvalues of a smaller and randomly sampled cell assembly is statistically similar to that of the entire brain. We propose that this property can be understood in the spirit of multidimensional scaling (MDS), whereby pairwise correlation between neurons can be mapped onto a distance function between two points in a low-dimensional functional space. We numerically and analytically calculate the eigenspectrum in our model and identify three key factors that lead to the experimentally observed scale invariance: (i) the slow decay of the distance-correlation function, (ii) the higher dimension of the functional space, and (iii) the heterogeneity of neural activity. Our theory can quantitatively recapitulate the scale-invariant spectrum in zebrafish data, as well as two-photon and multi-area electrode recordings in mice. Furthermore, fitting the model to the experimental data uncovers a reorganization of neurons in the functional space when the zebrafish is engaged in hunting behavior. Our results therefore provide new insights and interpretations of brain-wide

neural activity and offer clues about circuit mechanisms for coordinating global neural activity patterns.

Title: Balancing stable and unstable synapses for continual learning in deep neural networks

Authors: *S. CHO[1], S. BAEK[1], S.-B. PAIK[2];
[1]Dept. of Bio and Brain Engin., [2]Dept. of Brain and Cognitive Sci., Korea Advanced Inst. of Sci. and Technol., Daejeon, Korea, Republic of

Abstract: Modern deep neural networks (DNNs) can perform various tasks at the human level (Kiela, 2021). However, most DNNs encounter a critical issue when learning multiple tasks, known as catastrophic forgetting; at a certain point, the network drastically loses the ability to process old information while learning new tasks (McCloskey, 1989), which is not observed in human brains. On the other hand, when multiple items are memorized in the brain, a characteristic phenomenon known as the serial position effect is observed in which items learned first (primacy effect) and last (recency effect) are memorized better than those trained in between (Atkinson, 1968). Previous studies proposed that the serial position effect can arise in a network composed of two distinct types of synapses, stable and unstable types, where stable synapses consolidate their weights only when they change significantly, while unstable synapses change their weights freely (Lee, 2020). Importantly, it was reported that control of the ratio of stable and unstable synapses enabled the network to memorize both previously learned and newly learned information. Here, by advancing this notion, we show that the implementation of both stable and unstable synapses in DNNs can induce the serial position effect, with minimizing catastrophic forgetting to enable continual learning. Specifically, we trained AlexNet to classify images of different objects while the composition of stable and unstable synapses in the network was varied. As a result, we found that the model with only unstable synapses showed recency effect while the model with only stable synapses showed primacy effect. The model with both types of synapses showed evidence of the serial position effect in which both recency and primacy effects appeared. Moreover, we found that the model with both types of synapses could learn significantly more items than conventional DNNs, which show only recency effect. As the

number of sequentially learned items was increased, the model with only stable synapses failed to learn new items at a certain threshold, suggesting that its memory resources were overloaded. Similarly, the model with only unstable synapses failed to retain old items at a certain point, revealing catastrophic forgetting. In contrast, the model with both stable and unstable synapses maintained the serial position effect by learning new items while retaining old ones simultaneously, adaptively redistributing its memory resources. Overall, our results demonstrate that the coexistence of stable and unstable synapses in DNNs enables human-like flexible memory resource allocation, suggesting a possible solution for catastrophic forgetting.

Abstract: The primary visual cortex is one of the most well understood regions supporting the processing involved in sensory computation. Historically, our understanding of this part of the brain has been driven by describing the features to which individual neurons respond. An alternative approach, made possible by the availability of high-density neural recordings, has suggested that neural activity is often constrained to low dimensional representations, known as neural manifolds. However, responses in visual cortex seem to have very complex and nonlinear structure and the neural manifold they generate remains elusive.
In this work, we apply a precise quantification of the structure of such neural manifolds and address some of the problems the community has to face when conducting topological data analysis on neural data. We do this by analyzing publicly available two-photon optical recordings of primary mouse visual cortex in response to visual stimuli with a densely sampled rotation angle. Since the set of rotations of two-dimensional objects lives on a circle, one would hypothesize that they induce a circle-like manifold in neural activity. We discovered a circle-like neural manifold in the population activity of primary visual cortex, supporting the manifold hypothesis. To achieve this, we applied a shortest-path (geodesic) approximation algorithm for computing the persistent homology groups of neural activity in response to visual stimuli. It is

important to note that the manifold is highly curved and standard Euclidean approaches failed to recover the correct topology.
Furthermore, we identified subpopulations of neurons which generate both circular and non-circular representations of the rotated stimuli, with the circular representations being better for angle decoding. We found that some of these subpopulations, made up of orientationally selective neurons, wrap the original set of rotations on itself which implies that the visual cortex also represents rotations up to 180 degrees.
Given these results we propose that population activity can represent the angle of rotation of a visual scene, in analogy with how individual direction-selective neurons represent the angle of direction in local patches of the visual field. Finally, we discuss some of the obstacles to reliably retrieving the truthful topology generated by a neural population.

Abstract: The rodent barrel cortex processes information from whisker stimulus. The cortical structure and cell-type specificity strongly impact the network dynamics of the barrel cortex. However, the mechanisms of how structural details and cell-type specificity impact the network dynamics are not fully understood. We asked whether a connectomically constrained rate model can interpret the role of the cell-type specificity of the barrel cortex dynamics. To answer this question, we simulated the stabilized supralinear network (SSN) rate model and the spiking network activity of approximately 4000 leaky-integrate-and-fire (LIF) neurons. The parameters of SSN and LIF neurons were based on biologically plausible data for each specific cell type. We found that the SSN rate model and LIF network activity were consistent with each other, which showed that our approximation of population rate is biologically constrained. The connectivity from the excitatory neural population changed the amplitude of the dynamics, while connectivity from the inhibitory neural population changed the dynamic's amplitude and width. We conclude

that a connectomically constrained SSN rate model can explain the cell-type-specific network dynamics. Furthermore, the connectivity from excitatory and inhibitory neural populations has a different impact on the network dynamics. We can now use the model to derive predictions for future experiments and identify cell-type-specific activity patterns that contribute to sensory perception.

Title: Adaptive coding efficiency in neural populations with gain modulation

Authors: L. R. DUONG[1,2], ***D. LIPSHUTZ**[2], D. J. HEEGER[1], D. B. CHKLOVSKII[2,3], E. P. SIMONCELLI[1,2];

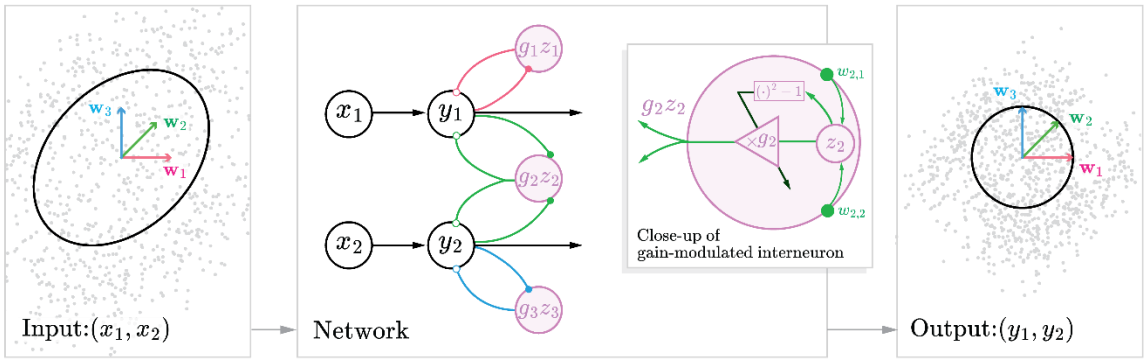
Abstract: Efficient transmission of sensory information from dynamic environments necessitates systems that rapidly and reversibly adapt to changes in sensory statistics. Individual neurons in a variety of early sensory areas have been shown to rapidly adapt their input-output gains to normalize the variances of their responses. At the neural population level, neurons rapidly adapt to decorrelate, or whiten, their responses; however, the mechanism for decorrelation is not known. Existing models rely on synaptic plasticity mechanisms, which are unlikely to operate as transiently or reversibly as gain modulation. Here, we propose a novel circuit model which uses single neuron adaptive gain modulation to decorrelate population response.



Our model is derived from a novel objective, which reformulates whitening of neural responses in terms of the variances of a fixed *overcomplete* projection of the neural responses. Optimization of this objective yields an online algorithm that maps onto a recurrent neural network comprised of primary neurons, gain-modulating local interneurons and fixed synaptic weights. Each interneuron receives weighted inputs from the primary neurons, adjusts its input-output gain based on the variance of its input and feeds back onto the primary neurons, whitening their outputs. Our framework can be generalized to handle biophysical constraints that improve robustness of the network to ill-conditioned inputs, and we demonstrate its use in whitening local image patches using convolutional weights. We also consider a multi-timescale extension of our circuit model in which the synapses learn on a slow timescale. In this case, gains rapidly adapt to changing sensory statistics whereas synapses slowly adjust to learn invariant features of the sensory statistics.

Abstract: Neocortex is composed of spiking neuronal units interconnected in a sparse, recurrent network. Spiking activity in such a network of neurons supports computations which transform sensory input to appropriate behavioral output. In this study, we use biofidelic, task-optimized spiking neural network (SNN) models to evaluate how recurrent networks of spiking units change to achieve task computations. Networks are composed of excitatory and inhibitory units randomly interconnected with likelihoods and strengths matched to mouse neocortex. We employ a task that requires a binary report of moving visual stimuli, analogous to tasks that mice perform. We find that, through training, SNNs selectively adjust firing rates in response to the stimulus input, and that excitatory and inhibitory connectivity between input and recurrent layers change in accordance with rate modulation. Input channels that exhibit bias to one specific input

developed stronger connections to recurrent excitatory units during training, while channels that exhibit bias to the other input developed stronger connections to inhibitory units. Furthermore, recurrent inhibitory units which were tuned to one input strengthened their connections to recurrent units of the opposite tuning. The convergence of trained network models on the specific pattern of cross-tuned inhibition highlights the significance of interneurons and their connectivity pattern in local circuit computations within neocortex.

Title: Investigating Multi-Feature Structure Learning in Recurrent Neural Networks for Visual Predictive Inference

Authors: *A. P. RASHED AHMED[1], T. SERRE[2], M. R. NASSAR[3];
[1]Neurosci., [3]Metcalf Hall, [2]Brown Univ., Providence, RI

Abstract: Flexible behavior depends critically on recognizing environmental changes and rapidly updating relevant internal representations. However, inferring which internal representations should be updated in high-dimensional real-world environments can be a difficult problem. Here we explore the computational basis of human flexibility in adapting to environmental cues through a novel visual predictive inference task called the Bouncing Ball task. Our task involves bouncing ball stimuli with separate color and velocity dimensions that undergo occasional discrete changepoints. The goal of the task is to predict the future position and color of the ball based on current observations, where the position is always observable, but the color is occluded in a specific region. By manipulating the degree of coupling between velocity and color changes, we investigate two conditions requiring different gating strategies to achieve optimal performance. In the independent condition, where the features change independently, disentangled feature representations are necessary to avoid interference. However, in the contingent condition, color changes co-occur with velocity changes, requiring coupled resetting of the features while maintaining independent representations of the features themselves. To explore the computational learning of these strategies, we trained three recurrent neural network (RNN) models: a vanilla RNN, a Long Short-Term Memory (LSTM) network, and a Hierarchical Multiscale-LSTM (HM-LSTM). Both LSTM variants models achieved optimal performance in the independent condition, demonstrating successful learning of disentangled representations. However, none of the models performed optimally in the contingent condition, exhibiting significant positional jitter following color changes. Separately,

the vanilla LSTM slightly outperformed the HM-LSTM on both conditions, indicating that the additional gates of the HM-LSTM are not well-suited for this task. Our findings suggest that the models successfully learn disentangled representations when explicitly required but struggle with contingently changing features, which lead to significant shifts in internal state representations upon color changes and impacting position predictions. We propose potential solutions, including adding representational constraints to promote disentangled representations and the refinement of boundary gates to provide more precise reset signals. Going forward, we plan to employ a wider battery of computational models and adapt the task for human participants.

Title: Ai alignment and Goodhart's rule.

Authors: *Y. TAMORI[1,2], K. MOGI[3];
[1]Grad. Sch. of Arts and Sci., The Univ. of Tokyo, Meguro-ku, Japan; [2]Neurocreative Laboratory, NPO, Tokyo, Japan; [3]Sony Computer Sci. Labs., Tokyo, Japan

Abstract: With the advancement of artificial intelligence systems, alignment between AI and humans (Gabriel 2020) is becoming an important research theme, from Large Language Models (Open AI 2023), generative AI (Walters and Murcko 2020), to self-driving cars (Badue et al. 2021). Reinforcement learning from human feedback (RLHF) (Griffith et al. 2013) is an attempt to facilitate alignment with humans through the learning process. One of the limits of AI is the inability to be flexible in the application of evaluation function, or to think "outside the box". When considering collective intelligence among humans (Woolley et al. 2010), or one augmented by AI, it becomes important to consider the merits and shortcomings of AI, including rigidity of evaluation function. Goodhart's law (Goodhart 1975) states that "when a measure becomes a target, it ceases to be a good measure". Originally proposed in the context of monetary policy, it is increasingly perceived to be of general relevance when it comes to problems of decision making and choice (Manheim and Garrabrant 2021). Here we investigate the relevance of Goodhart's law in AI alignment with humans, and collective intelligence between humans. The key assumption is that the validity of Goodhart's law comes from interactions from multiple agents. The human society, to which Goodhart's rule was originally applied, is where interaction between multiple agents naturally occur. AI alignment is in a sense collective intelligence of AI and humans (Przegalinska 2023). Evaluation function defined for a human, or an AI, ceases to be a good measure when applied to the interaction between agents, human or AI, when the reinforcement loop becomes intersubjective. We give a coherent model of the interaction between humans and AI, and a group of humans. In the model, we show that,

under certain conditions, there always exists a Hebbian interaction matrix for prompt-response transactions given a posteriori. The interaction matrix representing Goodhart's rule is embedded in its resolution matrix. Therefore, AI alignment could be partially solved by an algorithm that finds "Goodhart transactions" through introspective simulations using AI-derived strategies. Based on the results, we discuss brain areas possibly involved in flexible alignment. Context-dependent value perception in the orbitofrontal cortex (Elliott et al. 2008, Vlaev et al. 2011) and related areas such as the medial prefrontal and cingulate cortex (Pischedda et al. 2020) and the hypothalamus (Ogawa et al. 2022) are analyzed.

Title: Unveiling the Complexity of Cortical Folding: Introducing a Novel Graphical Representation Pipeline

Authors: ***L. ZHANG**, X. YU, Y. LYU, D. ZHU;
The Univ. of Texas at Arlington, Arlington, TX

Abstract: The folding patterns of cerebral cortex, characterized by distinctive convex gyri and concave sulci, present challenges in their quantitative modeling due to their complex and variable nature. In a previous study by Chen et al. (2017), an attempt was made to address this gap by developing a computational framework called GyralNet. This framework employed the watershed algorithm (Bertrand (2005)) to model cortical architecture from a graph perspective. However, GyralNet has certain limitations. Firstly, it relies solely on gyral altitude, resulting in limited anatomical description capability. Secondly, the flooding process used in GyralNet stops prematurely after reaching a predefined threshold, leaving a significant portion of the gyral crest area, and making the identification of the major gyral skeleton more challenging. To overcome these limitations, we introduce a novel computational pipeline that offers two key contributions. Firstly, this pipeline integrates multiple measures of folding patterns, enabling a comprehensive description of the cerebral cortex. Secondly, instead of using a predefined threshold to terminate the flooding process, our pipeline adopts a completed flooding strategy, where the flooding process continues until different water sources meet. As a result, the remaining gyral crest area is significantly reduced, facilitating the identification of the gyral skeleton in these narrower regions. Moreover, by eliminating the reliance on a uniform threshold, our approach minimizes the impact of cross-subject variability. We evaluated the proposed pipeline using multiple

datasets, encompassing over 2,000+ brains. The results demonstrate the efficacy of our approach in accurately quantifying and analyzing cortical folding patterns. Fig. 1(A) illustrates the key steps of our proposed pipeline and Fig. 1(B) shows a randomly selected subset of obtained results.

Title: Handling missing MRI data in brain tumors classification tasks based on synthetic images by GAN model vs. conventional solutions

Authors: *Y. MOSHE[1], Y. BUCHSWEILER[2], M. TEICHER[3], M. ARTZI[4];
[1]Bar ilan Univ., Petak tikva, Israel; [2]Tel Aviv Univ., Tel Aviv, Israel; [3]Gonda Brain Res. Ctr., Ramat-Gan, Israel; [4]Tel Aviv Sourosky Med. Ctr., Tel Aviv, Israel

Abstract: Deep learning (DL) is widely used for lesion segmentation and classification based on multiparametric MRI. However, in the real-world, data often has missing values. In this study we evaluated the use of synthetic images generation vs. other solutions for handling missing MRI data in brain tumor classification tasks.The study include 224 patients: 37 with low grade glioma (LGG), and 187 with high grade gliomas (HGG). Three Pix2pix GAN models were trained separately on the local institutional dataset, to generate T1WI, T2WI and FLAIR images. Resnet152 was used for classification between LGG and HGG. Inference of the classification model was performed on the local and the public BraTS datasets, and on different scenarios of input data: replacing missing images by generated images; duplication of existent images; and usage of black images. The similarity between the generated and the original images were evaluated using the Peak-Signal-to-Noise-Ratio (PSNR), and the Structural-Similarity-Index-Measure, (SSIM). Classification results were evaluated using accuracy and F1 score. High similarity was obtained between the generated and the original images with mean PSNR and SSIM = 35.65 and 0.91. Regarding the inference of classification results on missing data, the classification model used synthetic images to produce the highest results with mean accuracy level of 0.91 for the generated images, 0.85 for duplication of existent ones, and 0.77 for use with black images. A similar hierarchy of results was obtained on the BraTS dataset. Using the generated images, we have demonstrated the feasibility for inference on newly acquired data with local institutional dataset and public dataset with cases of missing data. Additionally, we have demonstrated the stability and generalization ability of the model while remaining consistent with the public dataset.

Abstract: Brains are embodied. Many fundamental questions remain unanswered: How is neural information encoded and communicated? How does the system correct for environmental perturbations? How do passive biomechanics affect the neuronal control of behavior? This leads to the foundational question: **How do nervous systems control and execute interactions with the environment?** Our international Network of interdisciplinary research groups (IRGs), which incorporates modelers, engineers, and experimentalists, is exploring the *Communication, Coordination, and Control of Neuromechanical Systems* (**C^{3}NS**).As an animal's length-scale and behavioral time-scale changes, the relative importance of forms of energy also changes. We have created a framework that quantifies the changes in these forms of energy and enables us to predict control and responses to perturbations. Thus, we have chosen to study three different groups of animals that exemplify these different dominant energy regimes.IRG1 is developing the framework as well as tools and technologies that are broadly applicable to neuromuscular modeling. IRG2, by focusing on legged locomotion in adult *Drosophila melanogaster*, investigates the effect of scale and speed in a system dominated by viscous forces. IRG3, by focusing on feeding in the soft-bodied marine mollusk *Aplysia californica*, investigates the effect of changing size in a system dominated by elastic forces. IRG4, by focusing on legged locomotion in mice, rats, cats, and dogs, investigates the effects of changing size and joint parameters on dynamic control in systems in which inertial forces increasingly dominate.

Title: Sensory and working memory information representation in neural systems near oscillatory instabilities

Authors: *W. NESSE[1], K. CLARK[2], B. NOUDOOST[2];
[1]Mathematics, [2]Opthamology, Univ. of Utah, Salt Lake Cty, UT

Abstract: We studied a dynamical neural model near an oscillatory instability to understand how the relative oscillatory phase and mean activity of the system work in tandem to represent and transmit information, as well as how such representations can be modulated by global top-down working memory-like signals. We establish that sensory input discrimination based on the relative oscillatory phase of neural field model (i.e. a phase code) is enhanced by working memory signals; whereas, concomitant rate coding of sensory input is reduced. While statistical discrimination via phase coding is far more effective than rate coding, we also study how information carried by a rate code may serve an important role in transmitting information beyond local sensory networks, as well as coordinating downstream computations. The goal is to address the dilemma of why rate-based coding exhibits only weak sensory discriminability and weak changes in response to working memory- or attention-like signals, and fails to account for observed behavioral benefits of these cognitive functions. We specifically propose a dual phase-plus-rate code that utilizes a phase code for maintaining the sensory representation, and rate code means of transmission. By segregating the role of phase versus rate code, our model reveals the utility of concomitant encoding of information by a dual code.

Title: Genes regulating cytoskeleton organization identified as neuro-common drivers of blood NfL change rate and disease-specific clinical progression in AI driven digital twins

Authors: X. SHEN[1], D. SHOKEEN[1], O. ISACSON[2], ***R. HARRISON**[1], S.-Y. SHIN[1], J. LATOURELLE[1];
[1]Aitia, Somerville, MA; [2]Neuroregeneration Res. Inst., McLean Hosp. / Harvard Med. Sch., Belmont, MA

Abstract: Elevated Neurofilament Light Chain (NfL) is commonly observed in neurodegenerative disorders (NDs), including AD and PD, and is widely recognized as a potential biomarker (Khalil et al. 2018). A recent study suggested that the rate of change in blood

NfL may be a better predictor of AD progression than the absolute NfL at baseline (Preishe et al. 2019). Here we use causal AI based digital twins to identify genes and pathways driving the rate of change in blood NfL robustly across AD and PD.
Two digital twins, each comprising of sets of Bayseian network models were built; one connecting 59k clinical and multi-omic variables measured in 317 subjects from the ADNI study, and the other connecting 38k variables in 514 subjects of the PPMI and Genetic cohort study. We performed ~18k counterfactual *in silico* experiments on digital twins and identified 20 overlapping genes driving the rate of change of blood NfL in both models. These 20 genes, quantified at the blood transcript level, explain 3% of the variance of the NfL change rate in the AD train dataset, adjusting for age, sex and APOE4 genotype ($p=0.07$); and 2% in the PD train dataset adjusting for age, sex, and pathogenic variants ($p=0.03$).
Pathway enrichment analyses found the 20 overlapping genes significantly overrepresented in gene sets known for the regulation of cytoskeleton organization ($p < 0.0002$). We next identified all additional drivers of NfL change rate in either PD or AD represented in these genes sets to create disease-specific cytoskeleton gene signatures and evaluate their effect on clinical disease progression. The 24 total PD-related cytoskeleton genes were shown to drive motor decline in the PD cohort, measured as rate of change in UPDRS III score ($p=0.04$), while the 28 AD-related cytoskeleton genes strongly affected cognitive decline, measured by the rate of change in CDR-SB score ($p=0.006$) in the AD train dataset. The AD related signature was validated in an independent out-of-sample AD dataset (ANMerge, $p=0.02$).
Causal network based digital twins provided evidence that AD and PD may share common genes and pathways causally affecting a neuro-common biomarker as well as disease-specific progression rates. Our finding that genes driving the NFL change rate are involved in the mechanism underlying the regulation of cytoskeleton organization is consistent with the fact that the cytoskeleton disorganization in neurons is a known early pathogenic event in multiple NDs and observed along with the excessive extraneuronal abundance of NfL. The findings of this study suggest further investigation of cytoskeleton genes for potential novel therapeutic strategies to slow disease progression may benefit multiple NDs

Title: Interpreting Neural Computation via Sequential-Autoencoders with Injective, Nonlinear Readouts

Authors: *C. VERSTEEG[1], A. R. SEDLER[3,4], J. D. MCCART[3,4], C. PANDARINATH[5,2]; [1]Emory Univ., Decatur, GA; [2]Dept. of Neurosurg., Emory Univ., Atlanta, GA; [3]Wallace H. Coulter Dept. of Biomed. Engin., [4]Ctr. for Machine Learning, Georgia Inst. of Technol., Atlanta, GA; [5]Wallace H. Coulter Dept. of Biomed. Engin., Emory Univ. / Georgia Tech., Atlanta, GA

Abstract: In light of recent advances that have dramatically increased the number of neurons that can be simultaneously recorded from the brain, we need new computational tools that can mine these datasets for interpretable explanations of neural computation. One promising approach has emerged from the field of machine learning, where the dynamics of artificial neural networks - the rules that dictate how their activity develops over time - can give insight into how thel networks perform cognitive tasks. However, because the dynamics of biological neural circuits cannot be directly observed, we need computational models that can approximate them from recorded neural activity. Recently developed Sequential Auto-Encoders (SAEs) model neural activity with lower-dimensional latent dynamics that are embedded into higher-dimensional neural activity. Unfortunately, existing SAEs have shortcomings that limit their interpretability, leading to inferred dynamics that are unnecessarily complex or unrepresentative of the underlying system. In this work, we solve this problem with recently developed invertible neural network architectures, creating a new model called ODIN (Ordinary Differential equations auto-encoder with Injective Nonlinear readout). We first demonstrate that ODIN can extract more interpretable dynamics from realistic synthetic spiking datasets than alternative models, including more accurate recovery of latent activity (mean Latent R2 of 0.93, 0.70 for ODIN, Linear-readout model, respectively), and better robustness to hyperparameter choice. Next, we apply this model to real neural datasets recorded from behaving monkeys, including motor cortical activity from a reaching task with obstacles (Maze) and frontal cortical activity from an interval timing task (ITT). We show that ODIN fit to the Maze dataset can achieve state-of-the-art reconstruction performance while using far fewer dimensions than alternative models (~10 vs. >25 for ODIN, alternative model, respectively), enhancing the interpretability of the latent representations. We also demonstrate that ODIN confirms previous findings in the ITT dataset, namely, that precisely tuned neural dynamics build a timing circuit. However, unlike the approaches used to analyze these data previously, ODIN has an explicit dynamics model that can predict how the neural circuit will generalize to untested conditions. Overall, this new computational method will help us to translate large neural datasets into an understanding of how computation is built by the brain.

Title: Categorical Invariant Generative Model (CIGMO): Deep Generative Learning Inspired by Primate Higher Vision

Authors: *H. HOSOYA;
ATR, Kyoto, Japan

Abstract: In this study, we propose a novel learning model called the Categorical Invariant Generative Model (CIGMO), drawing inspiration from the modular architecture of the primate visual system, which employs multiple cortical regions to encode invariant features specific to diverse object categories. Current deep generative models capture either the view variation or the categorization of object images, with scarce research targeting the integration of both structures in a single framework. To address this gap, CIGMO was designed to learn and encode three latent factors from a dataset of general object images: category, shape, and view. Overcoming challenges associated with unsupervised learning, we employed group-based weakly supervised learning as an 'inductive bias', allowing the model to learn separate shape and view representations from object images. We further extended this approach by introducing multiple modules of shape representations and creating mechanisms to specialize each shape representation to a particular object category while disentangling it from the view representation. Empirical investigation of CIGMO demonstrates its representational advantages. The model successfully solved the invariant clustering problem, discovering categories of object shapes in an unsupervised manner despite significant variation in object views. Quantitative performance surpassed various previous methods, including state-of-the-art invariant clustering. Further, our category-specialization approach enhanced the learned shape representation's capacity for multiple tasks, including one-shot identification and shape-view disentanglement in multiple criteria. Thus, CIGMO offers a novel learning approach to represent object images, providing more precise information for downstream tasks than typical approaches. This enhanced understanding of object image representation not only enhances our understanding of neural encoding mechanisms but also informs the development of advanced object recognition systems.

Title: Large-scale brain signatures of fluid dynamics and responsiveness linked to consciousness

Authors: *M. BREYTON, J. FOUSEK, P. SORRENTINO, G. RABUFFO, L. KUSCH, S. PETKOSKI, V. JIRSA;
Aix-Marseille Univ., Marseille, France

Abstract: Neural bases of consciousness have been explored through many different paradigms and the notion of complexity emerged as a unifying framework to characterize conscious experience. To date, the perturbational complexity index (PCI) performs best to assess consciousness through brain stimulation. However, the mechanisms underpinning this complexity remain unclear and reliable metrics on spontaneous activity are still missing. In this study, we explore brain responsiveness and resting-state activity through large-scale brain modelling with The Virtual Brain (TVB) and prove that complexity and consciousness are directly associated with a fluid dynamical regime (Fig 1). This regime corresponds to a specific set of parameters in the model associated with non-trivial spontaneous activity. Fluidity is reflected in the dynamic functional connectivity, calculated as the variance of its upper triangular part. Other metrics: Lempel-Ziv (LZ) complexity, the size of the functional repertoire (SFR), and the busting potential (BP) can also capture this dynamic in synthetic data. We validated our findings on a cohort of 15 subjects (spontaneous EEG recordings and maximum PCI values) under anesthesia and wakefulness. In this empirical data, PCI is systematically higher during wakefulness than under anesthesia for Xenon (N=5) and Propofol (N=5) drugs, but not for Ketamine (N=5). Metrics on spontaneous activity revealed that *fluidity* is also systematically higher during wakefulness than anesthesia (not for Ketamine) with a classification accuracy of 100%. Results for LZ complexity, the SFR and BP are similar. We demonstrated that the symmetry breaking caused by the connectome is sufficient for setting the global working point of the brain, allowing the generation of complex behavior in different paradigms: rest and stimulation. In the future, the imperfect separation of groups for some of the metrics could be improved by personalized brain modelling and including more realistic parameters in the models such as neuromodulatory pathways to improve explanatory power.

Title: Temporal variability of brain-behavior relationships in functional connectivity

Authors: *S. A. CUTTS, E. CHUMIN, R. F. BETZEL, O. SPORNS;
Indiana Univ., Bloomington, IN

Abstract: Title: Temporal variability of brain-behavior relationships in functional connectivity
Introduction: Most work on functional connectivity (FC) in neuroimaging data preference longer scan sessions or greater subject count to improve reliability of brain-behavior relationships or predictive models. Here, we investigate whether systematically isolating moments in time can improve brain-behavior relationships and outperform full scan data. We perform optimizations using a temporal filtering strategy to identify time points that improve brain-behavior relationships across 58 different behaviors.
Methods: We analyzed functional brain networks from resting state fMRI data of 352 healthy subjects from the Human Connectome Project. Templates were created to select time points with similar patterns of brain activity. Optimizations were performed to produce templates for each behavior that maximize brain-behavior relationships from reconstructed functional networks (Fig

1A).

Results: Results for the behavioral measure "working memory" are shown in Fig 1B-D. Optimization templates filtered time points with stronger behavioral relationships (Fig 1B) and brain-behavior correlation maps that transferred to held out test subjects (Fig 1C,D). With 10% of scan data, optimized templates of select behavioral measures (Fig 1E) achieved greater magnitude of brain-behavior correlations and greater transfer across groups of subjects than full FC.

Conclusions: We show that for a subset of behaviors, brain-behavior relations and reliability can be improved above full FC using only a fraction of neuroimaging data. Selectively filtering time points may allow for development of more targeted FC analyses and increased understanding of how specific moments in time contribute to behavioral prediction.

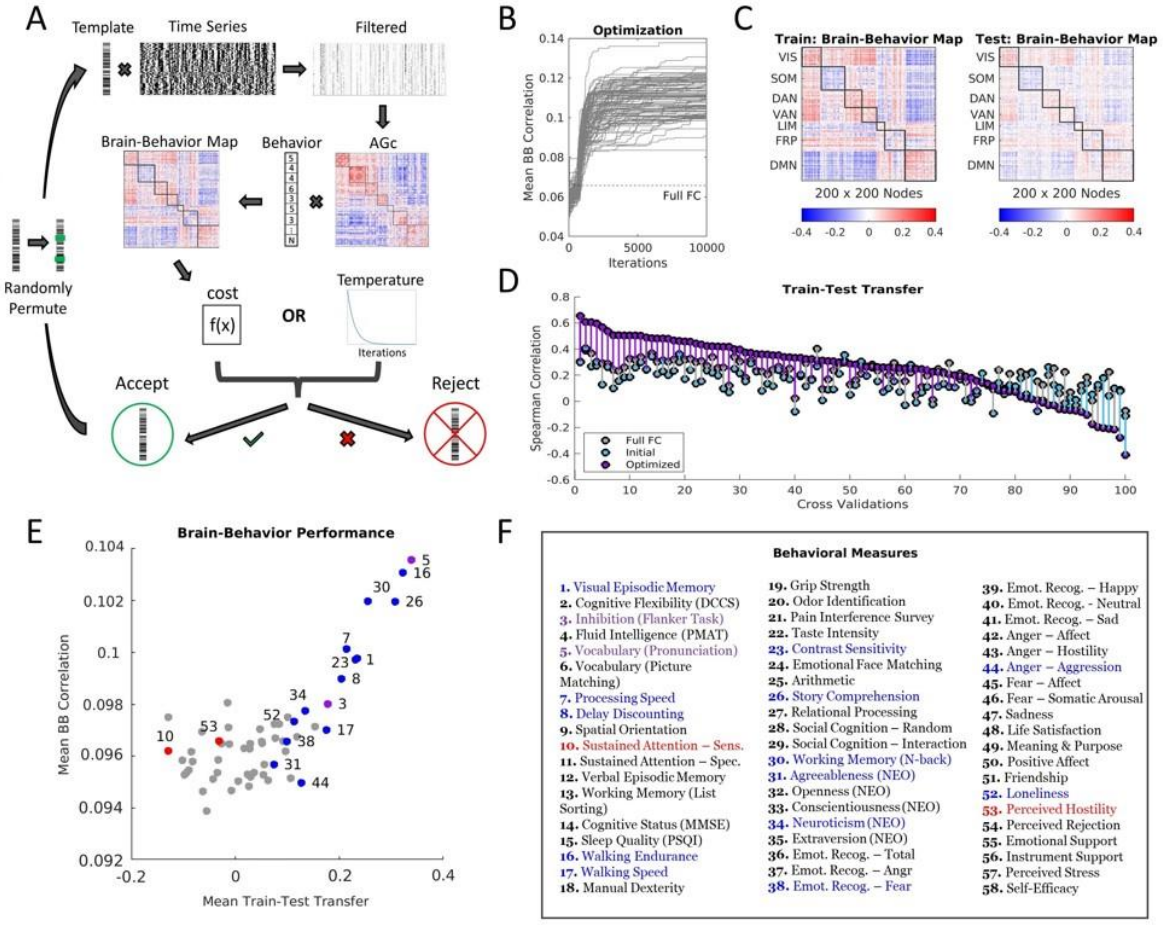

Figure 1. **(A)** Optimization pipeline utilizing filtering approach. The optimization is initialized with a random binary template and adjusted across 10,000 iterations to maximize behavioral relations. The agreement across binarized z-scored time series of brain regions is nearly identical to functional connectivity (FC; r = 0.96) and non-contiguous filtered frames produce a matrix similar in structure to FC, here referred as AG components (AGc). Normalized mutual information is used to compare the current template to each time step and filter the top 10% of frames with highest similarity. An AGc was created from the selected frames and each edge was correlated to behavioral scores across subjects. This produced a brain-behavior correlation map for the selected template that the optimization used to compare and improve the template pattern. **(B-D)** Example results for 'working memory'. **(B)** Improvement in behavioral correlations across each iteration of the optimizations for 'working memory' (computed on 100 separate cross validations) compared to average FC. **(C)** Average across the brain-behavior correlation maps for training (left) and testing (right) subjects. Black lines denote boundaries of functional networks. **(D)** Transfer of results across training and testing subjects of the cross validations were estimated based on Spearman correlation between train and test brain-behavior correlation maps. Optimized results (purple), initial randomized template (blue), full FC (gray). **(E)** Summary results across all behaviors showing behavior correlation magnitude and transfer between training and testing sets. Optimizations that significantly outperformed full FC ($p<0.01$) for train-test transfer (blue), magnitude of behavior correlations (red), both (purple). **(F)** List of behavioral measures.

Abstract: Recent advances in large scale neuronal recordings have achieved recordings from thousands up to a million neurons simultaneously taking neuroscience to the Big Data world. The thinking has traditionally been that the dimensionality of brain activity is minimally as high as the number of neurons in the brain. This has led to the notion that a Zebrafish or fly brain will have a complexity of ~100,000 dimensions. Here in the present work we will show that using nonlinear approaches that are not based on correlation for the analysis of whole brain activity in zebrafish larvae and drosophila, one finds that the dimensionality of brain activity is much lower than thought <20 even when Takens embeddings tend to overestimate dimensionality by 2n+1 where n is the real dimensionality. Neuronal activity dynamics can be described well on the surfaces of low dimensional manifolds. This approach has allowed us to estimate the dimensionality of whole brain activity at single neuron resolution showing that the majority of neurons in the brain operate in the low dimensional regime. Using these Takens embedding theorem based methods has allowed us to perform causal inference across the brain of such model organisms up to single neuron resolution that allow the creation of predictive models of behavior based on brain activity and ultimately create models of brain activity that predict behavior at single neuron resolution as well as the accompanying motor behavior of the animals.

Title: A multi-scale robust coding system in biology: the grid cells

Authors: *A. WINN[1], I. DAUBECHIES[1], S. CUI[2], C. L. CHARIKER[1];
[1]Duke Univ., Durham, NC; [2]Univ. of Chicago, Chicago, IL

Abstract: The parametrization of spatial location within the brain has been studied extensively in several species; in rats and mice, researchers have observed dedicated neurons in the entorhinal cortex that use an implicit multiresolution parametrization. In particular, these grid neurons have the following special properties: 1) each neuron activates when the animal is located in a particular region of physical space, which is called the neuron's receptive field; each neuron's receptive field consists of circular regions that are arranged in a triangular lattice on the plane; 3) grid neurons can be grouped into modules where the receptive fields are translates of one another; 4) there are about 5-10 modules with geometrically increasing lattice spacing and a fixed orientation offset between subsequent modules. We study mathematically the corresponding location-encoder design, in terms of its resolution, coverage, and robustness. The values of the parameters that optimize for these criteria are remarkably close to the empirically observed ones. This presents a biological example of a multi-scale, robust encoding system with rotation.

Title: Advancing Neuromorphic Design Through Biophysical Understanding of Neuronal Computational Complexity

Authors: *C. J. HARPER, A. KUMAR;
Univ. of California, Berkeley, Berkeley, CA

Abstract: How do we get computers to work like brains? Brains were optimized by evolution under space, weight and power (SWAP) constraints, similar to neuromorphic systems. The dominant paradigm in neuromorphic computing is use of simple neuron models. However, brains use complex neurons which are highly sophisticated computing elements. Our hypothesis is that

circuits composed of complex neurons are capable of performing sophisticated computations with fewer neurons than those containing simple neurons. However, our neuroscientific understanding of the biophysical determinants of single-neuron computational complexity is nascent. This gap impedes our design of neuromorphic systems and understanding of neurological disorders arising from disruption of those biophysics.
We leveraged natural occurring biophysical variability of 169 cortical neuron types, modeled by Blue Brain Project. We examined 'intrinsic complexity' by analyzing spatio-temporal Vm profiles in response to somatic current injection. We deployed PCA to determine dimensionality across neurons. This revealed that excitatory neurons were higher dimensional than inhibitory neurons, and that Ih currents, which are known to impart non-trivial Vm dynamics, were most important. We deployed Dynamical Components Analysis, which quantifies intrinsic dimensionality and computational complexity using predictive information (PI). Initial results indicate morphologically complex neurons have higher dimensionality. A more nuanced picture was observed when individual neuron PI was examined: simpler neurons could have more complex dynamics. Across excitatory neurons, PI increased monotonically with cortical layer (i.e., L2/3< L4<L5<L6). As neurons in different layers perform distinct computations, this suggests single neuron specializations for those computations. Finally, we modeled neurons as bilinear systems, facilitating explicit calculation of PI as a quantifier of I/O transformation complexity, which forms a pivotal aspect of our hypothesis. Together, our work provides a theoretically grounded measure of single neuron computational complexity, and leverages the naturally occuring design space to understand the biophysical determinants of computation towards SWAP efficient neuromorphic systems.

Title: A characterization of brain modular structure based on higher-order functional interactions

Authors: *M. PUXEDDU[1], T. VARLEY[4], M. POPE[2], O. SPORNS[3];
[2]Indiana Univ., [3]Olaf Sporns, [1]Indiana Univ., Bloomington, IN; [4]Indiana University, Bloomington, Bloomington, IN

Abstract: Brain functional connectivity can be modeled as a network of brain regions and their interactions. Network analyses revealed key topological features of brain networks, including modular structure [1]. So far, modules in the brain have been identified through algorithms accounting only for pairwise interactions among brain regions, which provide modules of highly interconnected nodes. Recently, higher-order interactions and multivariate measures of information are receiving more attention as playing a key role in complex systems such as the

brain. Thus, network neuroscience is moving into the development of tools able to infer the topology of brain networks considering higher-order dependencies [2].
Here, we propose a new algorithm for community detection in brain functional networks that capitalizes on these developments. Known that the redundancy in a subset of nodes is the information that is carried by all the elements [3], we aim to find modules composed by nodes whose activity is maximally redundant. We developed an algorithm that uses Total Correlation (TC) as a measure of redundancy, and, starting from a random partition, iteratively reassigns nodes to modules to maximize the sum of the TC of nodes constituting individual modules (Figure). Thus, the brain is divided into optimally redundant modules.
Running the algorithm on a group-averaged network estimated from the HCP [4], we identified modules that only partially match those found with conventional algorithms that maximize an edge-based modularity function [5]. This result suggests the existence of unexplored topological properties of brain functional networks that are revealed by multivariate measures of information. Further analysis will elucidate the role that they play in human cognition and behavior.

Title: Optimal control of spiking neural networks

Authors: *T. COSTA, J. R. CASTIÑEIRAS, A. RENART;
Champalimaud Fndn., Lisboa, Portugal

Abstract: The ability to efficiently control a recurrent circuit would facilitate computation generically, but optimal control is technically difficult, so applications of optimal control to circuit dynamics have mostly been restricted to linear networks and quadratic costs. Here, building on our previous work on control-limited decision-making [Castiñeiras, J. R., & Renart, A., bioRxiv, (2022)], we developed a mathematical framework for the optimal control of activity in recurrent networks of spiking neurons with a stochastic spiking threshold under arbitrary costs. In our framework, which is fully event-based and operates in continuous time, the uncontrolled dynamics of the network imposed by the connectivity is viewed as the passive policy in a KL control framework [Todorov, E., PNAS, 106, 11478 (2009)]. We define a notion of reward over network states through low-dimensional projections of neural activity, as in brain-machine interface experiments, and find the policy that maximizes future expected reward subject to a KL control cost. The optimal control law takes the form of an additive synaptic input to the recurrent input from the uncontrolled network. This control input depends on the Value function of the problem, which is obtained by solving a Bellman Equation that can be expressed as a system of nonlinear ordinary differential equations, and is thus tractable. Our work opens the door to a principled understanding of how activity in recurrent circuits can be adequately shaped by inputs from other brain areas, or by experimental manipulations.

Title: Self-organized critical dynamics improve the performance of deep neural networks

Authors: *S. VOCK[1], C. MEISEL[2];
[1]Neurol., Charite Universtätsmedizin Berlin, Berlin, Germany; [2]Charité Universitätsmedizin, Berlin, Germany

Abstract: Deep Learning has made a large impact in industry and research. However, training a deep neural network (DNN) can be challenging due to instabilities in the training process, leading to slow learning and suboptimal results. A theory-driven understanding of the conditions and control of DNNs is still missing. Recent research has indicated that critical phase transitions play a crucial role in optimal information processing in biological and artificial neural networks. We apply this concept to DNNs using adaptive self-organized criticality (aSOC), which is considered a plausible mechanism by which networks can be autonomously organized towards criticality through adaptive changes of their synaptic weights. By identifying the links between dynamics and performance, we aim to improve the understanding of information processing in neural networks, and ultimately enhance the computational properties of deep learning systems.Specifically, we first characterize the dynamics of DNNs using the Lyapunov Exponents and the dynamic range of the network, two well-established indicators of critical phase-transitions in dynamical systems. Next, we introduce aSOC to DNNs, allowing us to study the impact of a simple, local rule-set: Quiet nodes grow links and active nodes lose links. The neurons thereby adaptively strengthen and weaken randomly selected incoming connections based on a preset threshold for activation. Finally, we apply aSOC alongside with gradient descent: While aSOC drives the system to criticality, gradient descent learns the representations. We here use the MNIST dataset, which is widely applied for training and testing in the field of machine learning.We demonstrate that the critical state in fully-connected DNNs is characterized by disappearing Lyapunov Exponents and a maximal dynamic range, which has been questioned in previous investigations. By using aSOC during training, the entire DNN exhibits robust self-organization towards criticality. To investigate performance improvements, we study the effect of gradient descent alongside aSOC on a state-of-the-art DNN from the literature trained on the MNIST dataset. The results show faster learning, improved resilience against random weight initializations, and performance increases of up to 90% accuracy.In conclusion, our work explores the use of aSOC in DNNs and its effect on dynamics and performance. The results provide general insights into the dynamics of neural networks and show promising improvements in training DNNs. While we focus on fully-connected DNNs, future work may extend investigations toward other networks and different machine learning approaches.

Title: Creating spike sorting reference data using high-density electrode arrays

Authors: *J. COLONELL[1], S. CHEN[1], C. MANAGAN[1], R. ARRUDA[1], N. A. STEINMETZ[2], T. D. HARRIS[1];
[1]Janelia Res. Campus, Ashburn, VA; [2]Dept. of Biol. Structure, Univ. of Washington, Seattle, WA

Abstract: There is a critical need for spike sorting reference data to quantify and optimize spike sorter performance. Simultaneous recordings from extracellular probes and a juxtacellular or intracellular patch are the gold standard, but only provide data for a single cell in the ensemble of recorded units. In this study we performed multiple recordings across five brain regions in mouse using Neuropixels Ultra probes, which have 10X the site density of standard Neuropixels 1.0 probes. Higher site density improves spike sorting accuracy in two ways: (1) Detection on more sites creates higher signal to noise in template matching and (2) Denser sampling improves spike localization. This high accuracy sorting combined with manual curation to identify units with unimodal distributions in the high-density feature space provides a set of known spike times and labels for an average of 14 +/- 8 units/recording (N=33 recordings). Spatial resampling of the high-density data accurately reproduces the result that would be measured with a probe with standard site density, including real noise and background activity. The manually verified high-density sorting results serve as reference data to measure sorting accuracy of the standard density data, in which the spikes have on average lower SNR and poorer localization precision. Relative to simultaneous patch recordings, this method produces substantially higher yield of verified high-quality sorted spikes from simple and easily replicable data collection, while being limited by the accuracy of the initial sorting of the high-density data. We demonstrate the use of this reference data, which will be publicly available, in a parameter optimization study of Kilosort.

Abstract: Using different computational techniques, it is possible to analyse neural oscillations in order to understand the relationship between brain activity and cognitive processes. Considering that processing those bio-signals is a complex and time-consuming task, we develop a new graphical user interface, named BOARD-FTD-PACC, using MATLAB (The Mathworks, Inc.). That software was designed to facilitate visualization and quantification of neurophysiological recordings in different set-ups (i.e. intracellular and extracellular recordings with or without stimulation). BOARD-FTD-PACC provides different methods to analyzing post-synaptic responses and neural oscillatory data, mainly cross-frequency analysis such as phase-amplitude coupling (PAC) and phase coherence. At difference of most programs for analyzing synaptic activity, BOARD-FTD-PACC includes three methods for PAC quantification and four methods for power spectral analysis. This interface is a flexible and user-friendly tool that can be used by users without advance background in programing or computer science. In the present work, we show recordings derived from in vivo experiments in the thalamus, cortex, and hippocampus, illustrating the use of this graphical user interface.

Title: Deepregfinder: deep learning-based regulatory elements finder

Authors: *A. RAMAKRISHNAN[1], G. WANGENSTEEN[3], S. KIM[3], E. J. NESTLER[4], L. SHEN[2];
[1]Neurosci., [2]Icahn Sch. of Med. At Mount Sinai, New York, NY; [3]Brown Univ., Providence, RI; [4]Icahn Sch. Med. At Mount Sinai, New York, NY

Abstract: DNA regulatory elements (DREs) are genomic regions that play a crucial role in controlling gene expression by interacting with chromatin and DNA binding proteins. Promoters are DREs located proximal to the transcriptional start sites (TSSs) facilitating transcription initiation. Enhancers are cell-type-specific DREs that can act over long distances to stimulate gene expression. They coordinate with promoters via formation of DNA loops to mediate gene expression. Identifying enhancers at a genomic scale is crucial as changes in enhancer activity can give rise to diseases. DREs exhibit unique histone mark binding patterns which can be captured by high-throughput ChIP-seq experiments. However, a simple rule-based method often fails to account for the variations and noises among all the DREs at different locations on the

genome, the total number of which is estimated to be in the order of millions. machine learning models can be trained on known enhancer/promoter sites using histone mark ChIP-seq data as input and predict enhancers/promoters at other genomic regions. Several machine learning methods have been developed to predict DREs across the genome. But existing methods are often difficult to use, especially in preprocessing the raw data to be ready for consumption by the models. To this end, we have developed a highly customizable program named DeepRegFinder, which automates the entire process of data processing, model training and prediction. We have employed two deep neural network architectures - convolutional and recurrent neural networks - for model training and prediction. Additionally, DeepRegFinder can categorize enhancers and promoters into active and poised states, making it a unique and valuable feature for researchers. We conducted a comparative analysis of DeepRegFinder against five established methods, namely RFECS, eHMM, PREPRINT, EP-DNN, and ChromHMM. Our method demonstrated consistently higher precision and recall in comparison to existing algorithms for enhancer and promoter prediction across multiple cell types. Moreover, our pipeline is modular and eliminates the tedious steps involved in preprocessing, making it easier for users to apply on their data quickly. Finally, we demonstrated that the deep learning models, without any explicit programming, can learn to discern characteristic patterns of histone marks associated with different types of DREs such as active enhancers, poised promoters, and genomic backgrounds. This was accomplished through exploiting the interpretability of the first convolutional layer.

Title: Recording the 3D locations of EEG scalp electrodes using an ordinary cell phone camera

Authors: *S. SHIRAZI, S. MAKEIG;
Swartz Ctr. for Computat. Neurosci., Univ. of California San Deigo, La Jolla, CA

Abstract: Growing evidence supports the need for individual subject scalp electrode locations to perform source-resolved EEG brain imaging. Using 3D head surface scanning to record these locations reduces the acquisition time compared to sequential position-measuring systems, thereby maximizing participant engagement during the recording. However, current (photogrammetric) 3D scanner systems and attachments may be comparatively expensive (>$1000) and may require bright, uniform lighting conditions. Here we tested advanced light-based 3D scanning technologies that are more affordable and less sensitive to lighting

conditions: (1) using a currently recommended 3D scanner (*Occipital Structure.io*); (2) using an iPhone (> v10) 'Face unlock' 3D camera; (3) using a more affordable (~$250) smartphone 3D-scanning attachment (*Creality Ferret*), and (4) using an ordinary smartphone camera to capture 2D images of the participant head surface, then combining them using available software to reconstruct a 3D head surface mesh. **Method**. We used each method to scan a mannequin head wearing a BioSemi EEG scalp cap three or more times. To determine scan quality, we quantified the resolution and noise levels of the 3D scans. As a measure of ***spatial resolution***, we used normalized mean edge length, the mean length of the head mesh edges normalized by the cube root of the mesh volume. This measure captures the average granularity of the 3D scan while considering the object scale. To quantify a ***local mesh noise*** score for the 3D head meshes, we first identified each four mesh nodes adjacent to each other (i.e., mesh neighborhood). We then applied Principal Component Analysis (PCA) to find the best-fitting plane. The distance of each node in the neighborhood to the plane was used to quantify the degree of local mesh irregularity. The standard deviation of these values, normalized by the mean edge length, provided a local noise score for the scan. **Results**. For all four methods, both measures were stable across repeated scans (within-scanner variations < 10% of resolution or noise score), and local mesh noise scores were comparable (0.12-0.19). *Ferret* scanner meshes had the best resolution (0.006, iPhone: 0.011; *Structure*: 0.020; smartphone: 0.020). Reducing the room light level showed the *Ferret* scanner and ordinary smartphone camera to be the least sensitive to the light level. **Conclusions.** The results suggest that affordable, state-of-art scanning - including 3D scans composed from standard 2D camera images - is a viable approach to EEG electrode 'digitization', in particular where cost, space, and/or lighting conditions limit the use of more elaborate and expensive photogrammetric methods.

Title: The SSVEP toolbox: a GPU-accelerated toolbox for SSVEP feature extraction

Authors: *D. COMADURAN MARQUEZ[1], J. J. NORTON[2], E. KINNEY-LANG[1], H. HABIBZADEH[3];
[1]Univ. of Calgary, Calgary, AB, Canada; [2]Natl. Ctr. for Adaptive Neurotechnologies, Albany,

NY; [3]Office of Res. and Development, Stratton VA Med. Hosp., State Univ. of New York, Albany, Albany, NY

Abstract: We present the Steady-State Visual Evoked Potential (SSVEP) Toolbox, an open-source, Python-based, multithreaded, and graphical processing unit (GPU)-accelerated data analysis toolbox for SSVEP feature extraction and classification. SSVEPs, the brain's response to flashing lights, are widely used in brain-computer interfaces (BCIs) for communication and control. Over the past 25 years, many methods have been developed to extract SSVEP features from EEG. The SSVEP Toolbox provides easy-to-use implementations of three feature extraction methods—filter bank canonical correlation analysis (fbCCA), minimum energy combination (MEC), and multivariate synchronization index (MSI). The toolbox was developed in Python 3.9.16. Validation was done using a classification analysis on the SSVEPEXO dataset (3 targets, 12 participants, 8 EEG channels, 256 Hz sampling rate). Classification accuracies for were compared to the classifier suggested in the dataset website (i.e., Riemannian geometry (RG) with logistic regression). The classification results for fbCCA (81.3 +/- 10%), MEC (74.7 +/- 13.5%), and MSI (75 +/- 17.4%) are on par or exceeding the RG classifier (72 +/- 12%). The CPU (2.89 +/- 0.03 sec) and GPU (2.34 +/- 0.03 sec) implementations had similar runtimes for the complete dataset. To further test the timing of the tool, the first two subjects of the Wang2016 dataset were used. This dataset was selected as it has a higher target and electrode count (i.e., 40 targets, and 64 channels). With the Wang2016 dataset, the GPU (3.43 +/- 0.11 sec) version vastly outperformed the CPU (70 +/- 1.21 sec) implementation. The SSVEP Toolbox implements CPU and GPU-accelerated versions of three families of SSVEP feature extraction methods and demonstrated their use in a classification analysis. The GPU outperforms the CPU implementation for the Wang2016 dataset. With further development and release to an open-source repository (e.g., GitHub), the toolbox could accelerate the development of SSVEP-based BCIs. We will optimize the remaining feature extractions methods for the GPU, validate the toolbox using multiple other datasets, demonstrate the use of the toolbox in ensemble classifiers, and integrate the toolbox with BCI2000 to enable GPU-accelerated real-time feature extraction of SSVEPs. Acknowledgments: We thank ACHRI, NVIDIA Corporation, NIH Grant P41 EB018783, Resources at the Stratton VA Medical Center, and NSERC CREATE for the funding of this work.

Title: Enabling Integrity and Metadata Provenance for Neuroscience Artifacts Using Open Science Chain

Authors: *S. SIVAGNANAM[1,3], S. SAKAI[2], K. LIN[1], F. GARZON[1], S. YEU[1], K. YOSHIMOTO[1], K. PRANTZALOS[4], A. MAJUMDAR[5], S. SAHOO[4], W. LYTTON[3]; [1]UCSD, La Jolla, CA; [2]San Diego Supercomputer Ctr., UCSD, San Diego, CA; [3]SUNY Downstate Hlth. Sci. Univ., Brooklyn, NY; [4]Case Western Univ., Columbus, OH; [5]Univ. of California San Diego, LA JOLLA, CA

Abstract: Neuroscience generates vast amounts of experimental and imaging data in various formats, which play a crucial role in developing data-driven computational models to understand neuronal and network functions. Researchers working with these extensive multimodal datasets need techniques to maintain data integrity, especially when building upon prior research conducted by other scientists. When scientific datasets evolve or are reused to create derived datasets, it is crucial to securely preserve the integrity, metadata, and provenance to prevent unintended or malicious alterations during the process. Open Science Chain (OSC) provides a cyberinfrastructure platform where the integrity information about scientific dataset is stored and managed in a consortium blockchain. Other researchers can independently verify authenticity of scientific data using the information stored in the blockchain and provide feedback when the data cannot be validated. OSC allows researchers to store the cryptographic hash of the data as a manifest in the blockchain along with the metadata. When updates are made to a dataset or data collection in OSC, all metadata changes, including the SHA256 checksum for every file in that data collection, are tracked in the blockchain, enabling users to view a detailed, immutable history of that dataset over time. Neuroscience researchers, especially those involved in collaborative research will benefit from using the OSC to track the dataset that maybe generated and maintained at various locations. Members of research labs will benefit from tracking the provenance of data produced and referenced during different stages of research by various members. OSC aims to enhance data sharing and reproducibility in the neuroscience community by increasing confidence in the scientific results. API-based integrity services are being developed to generate and verify the integrity information of scientific data for data-driven research platforms and hubs. The poster presentation will discuss the integration of OSC with Neuroscience Gateway to capture the provenance metadata corresponding to the components for reproducibility.

Title: An approach for reliably identifying high-frequency oscillations and reducing false positive detections

Authors: Y. ZHOU[1], J. YOU[1], U. KUMAR[2], X. TAO[1], S. A. WEISS[6], A. BRAGIN[2,3], J. ENGEL[2,4,3,5], C. PAPADELIS[7], ***L. LI**[1,2];
[1]Univ. of North Texas, Denton, TX; [2]Dept. of Neurol., [3]Brain Res. Inst., [4]Dept. of Neurobio., [5]Dept. of Psychiatry and Biobehavioral Sci., Univ. of California Los Angeles, Los Angeles, CA; [6]Dept. of Neurol., State Univ. of New York Downstate, Brooklyn, NY; [7]Cook Children's Hlth. Care Syst., Fort Worth, TX

Abstract: Aiming to improve the feasibility and reliability of using high-frequency oscillations (HFOs) for translational studies of epilepsy, we present a pipeline with features specifically designed to reject false positives for HFOs to improve the automatic HFO detector.We presented an integrated, multi-layered procedure capable of automatically rejecting HFOs from a variety of common false positives, such as motion, background signals, and sharp transients. This method utilizes a Time-Frequency Contour approach that embeds three different layers including peak constraints, power thresholds, and morphological identification to discard false positives. Four experts were involved in rating detected HFO events that were randomly selected from different posttraumatic epilepsy (PTE) animals for a comprehensive evaluation.The algorithm was run on 768 hours recordings of intracranial electrodes in 48 PTE animals. A total of 453,917 HFOs were identified by initial HFO detection, of which 450,917 were implemented for HFO refinement and 203,531 events were retained. Radom sampling was used to evaluate the performance of the detector. The HFO detection yielded an overall accuracy of 0.95±0.03, with precision, recall, and F1 scores of 0.92±0.05, 0.99±0.01, and 0.94±0.03, respectively. For the HFO classification, our algorithm obtained an accuracy of 0.97±0.02. For the inter-rater reliability of algorithm evaluation, the agreement among four experts was 0.94±0.03 for HFO detection and 0.85±0.04 for HFO classification.Our approach shows that a segregated pipeline design with a focus on false positives rejection can improve the detection efficiency and provide reliable results. This pipeline does not require customization and uses fixed parameters, making it highly feasible and translatable for basic and clinical applications of epilepsy.

Title: Solving the spike sorting problem with Kilosort

Authors: M. PACHITARIU[1], S. SRIDHAR[2], ***J. PENNINGTON**[3,4], C. STRINGER[1];
[1]Janelia Res. Campus, Howard Hughes Med. Inst., Ashburn, VA; [2]Dept. of Opthalmology, Univ. Med. Ctr. Göttingen, Göttingen, Germany; [3]Janelia Res. Campus, Ashburn, VA; [4]Washington State Univ., Vancouver, WA

Abstract: Spike sorting is the computational process of extracting the firing times of single neurons from recordings of local electrical fields. This is an important but hard problem in neuroscience, complicated by the nonstationarity of the recordings and the dense overlap in electrical fields between nearby neurons. To solve the spike sorting problem, we have continuously developed over the past eight years a framework known as Kilosort. This paper describes the various algorithmic steps introduced in different versions of Kilosort. We also report the development of Kilosort4, a new version with substantially improved performance due to new clustering algorithms inspired by graph-based approaches. To test the performance of Kilosort, we developed a realistic simulation framework which uses densely sampled electrical fields from real experiments to generate non-stationary spike waveforms and realistic noise. We find that nearly all versions of Kilosort outperform other algorithms on a variety of simulated conditions, and Kilosort4 performs best in all cases, correctly identifying even neurons with low amplitudes and small spatial extents in high drift conditions.

Abstract: Aims: Behaviors are encoded by neural circuits that are widespread within the brain and change with age and experience. Immunodetection of the immediate early gene c-fos has been successfully used for decades to reveal neural circuits active during specific tasks or conditions. Our aims here is to develop a workflow that circumvents classical temporal and spatial limitations associated to c-fos quantifications.
Method: We used a new genetic TRAP method combining Cre-dependent tdTomato expression under c-fos promoter with Fos immunohistochemistry, allowing visualization and direct comparison of neural circuits activated at different times or during different tasks. By using open-source softwares (i.e. Qupath and Abba), we established a workflow that optimize and automate cell detection, cell classification (e.g. Fos vs. Fos/tdTomato) and whole brain registration.
Results: We demonstrate that this automatic workflow, based on fully automatic script, allows accurate cell number quantification with minimal interindividual variability. Further, interrogation of brain atlases at different scales (from simplified to detailed) was achieved allowing gradually zooming on brain regions to explore spatial distribution of activated cells. Then, we illustrated the potential of this approach by comparing patterns of neuronal activation in various contexts (e. g. different vigilance states, complex behavioral tasks ⋯). Finally, we explored programs (e.g. BrainRender) for intuitive representation of obtained results.
Conclusion: Altogether, this automated workflow allows a fast and accurate analysis of whole brain activity pattern at the cellular level, in various contexts.

Abstract: DANDI (http://dandiarchive.org) is a cutting-edge platform for neurophysiology research. By serving as a multi-species data archive, a collaboration space, and a computational platform, DANDI enables researchers to access the resources they need to support both computational and experimental neuroscience.DANDI datasets use a consistent layout based on the BIDS standard and common metadata structures to promote easier comprehension of included data. The infrastructure of the platform is built using open-source technologies and is hosted in the cloud, available to researchers who wish to use the platform to search, visualize, compute, collaborate, and coordinate their neurophysiology research projects while promoting FAIRness and efficiency.As of May 2023, DANDI boasts an impressive archive of over 500+TB of data from more than 293 datasets, spanning multiple species (C elegans, zebrafish, mice, rats, fruit flies, non-human primates, and humans) and from multiple recording modalities. The archive includes intracellular, extracellular, and behavioral timeseries from electrophysiology, optophysiology, and optogenetic experiments, as well as multimodal MRI, OCT, SPIM, ECOG, and immunostaining data from human ex vivo brain tissue samples. With over 6000 experiment participants and 890+ registered users worldwide, DANDI is the largest neurophysiology archive available.DANDI is dedicated to making data and software for neurophysiology research more FAIR (Findability, Accessibility, Interoperability, and Reusability). The platform provides user-friendly tools for data submission and access, a Jupyter-based computation hub for raw data introspection, data analyses, and integration with other analytic platforms and services. DANDI uses the BRAIN Initiative community data formats and standards such as NWB and BIDS and works closely with the community to expand these standards to neurophysiology and microscopy. The platform has an application programming interface server to attract scientists/developers to interact with the archive programmatically and has contributed to community efforts to provide efficient access to larger datasets in the cloud.With DANDI, researchers can now share, collaborate on, and publish citable datasets, which will significantly increase the rigor and reproducibility of cellular neurophysiology research. DANDI is a powerful resource that is transforming the field of cellular neurophysiology research, enabling researchers to work together more effectively and efficiently, and ultimately driving groundbreaking discoveries that will advance our understanding of the brain.

Title: Automating multi-probe insertions to improve the efficiency and reproducibility of electrophysiology experiments

Authors: *K. J. YANG[1], D. BIRMAN[1], I. BRAIN LABORATORY[2], N. A. STEINMETZ[1]; [1]Univ. of Washington, Seattle, WA; [2]Intl. Brain Lab., Seattle, WA

Abstract: Achieving consistent targeting of multiple simultaneous probes during electrophysiology experiments is a challenging and time-consuming process. Even with a planned insertion trajectory, experimenters still have to go through a lengthy process of positioning and inserting each probe. Electrophysiology experiments are increasingly focused on brain-wide coverage, requiring three or more simultaneous probes motivating researchers to accelerate their processes to reduce the duration of the experiment and the corresponding stress levels of their subjects. To improve the efficiency and reproducibility of multi-probe electrophysiology experiments, we developed two frameworks: a communication platform to allow software control of hardware micro-manipulators and an automation platform to perform multiple synchronous probe insertions. Each existing manipulator platform has proprietary software for programmatic control, which are rarely cross-platform and often expose inconsistent interfaces. To standardize manipulator communication, we developed a Python server that acts as a generic cross-platform application programming interface (API). This platform ensures that client applications only need to interface with one API to be compatible with many different manipulator platforms connected across various computer operating systems. Building on top of this communication platform and an existing trajectory planning tool, Pinpoint, we next developed a system that automates the insertion process for multiple probes, saving time. The automation system provides three guarantees for researchers: first, that probes will reach their intended targets without manually-introduced errors in targeting; second, that experiments can be repeated exactly to improve reproducibility; and third, that movement speeds are limited to low levels for reduced tissue damage. Because our software drives multiple probes simultaneously, complex multi-probe insertions are more manageable. Taken together, these open-source tools for communicating with hardware manipulators and automating multi-probe insertions enable the next generation of reproducible, high-efficiency, brain-wide electrophysiology data collection.

Title: Intraoperative refinement of human Neuropixels recordings

Authors: *Q. GREICIUS[1], *Q. R. GREICIUS[2], D. XU[3], J. E. CHUNG[4], E. F. CHANG[4]; [2]Neurolog. Surgery, [1]Univ. of California San Francisco, San Francisco, CA; [3]Univ. of California, San Francisco, Univ. of California, San Fransisco, San Francisco, CA; [4]Univ. of California, San Francisco, San Francisco, CA

Abstract: Recent work has demonstrated the feasibility of intraoperative use of Neuropixels probes to obtain high-density recordings of single-unit activity in human cortex. These data promise large scale studies of the fundamental computational units underlying complex human behaviors like speech and language processing. However, data acquisition in operating rooms poses a set of unique challenges due to the clinical constraints placed on the recording site and duration. Unlike the deployment of Neuropixels probes in model organisms, intraoperative recordings must be completed in a single session, within the span of 15-20 minutes. Furthermore, probes are placed within the pre-identified resection margins, and only a subset of this tissue may have intact function, let alone task-relevant activity. Accordingly, it is crucial to the yield of these experiments to be able to rapidly assess the quality of a recording site within the first few minutes of insertion so that a new site and/or task may be selected if the observed task-relevant activity in the tissue is poor. We present here a cross-platform, open-source application for real-time processing and visualization of data from Neuropixels probes using the latest version of the C++ API for SpikeGLX. With support for simultaneous recording from multiple probes, this toolset includes a map of all spiking activity over the length of each probe, spike-waveform displays for each channel, and event-triggered rasters and peristimulus time histograms for each channel that can be time-locked to a variety of custom event subtypes. Although development of this application was motivated by our group's intraoperative visualization needs, the functionality it offers is likely to be useful for guiding and troubleshooting recordings in more general contexts. The real-time spike map, in particular, will enable experimenters to make three valuable estimates at a glance: the overall level of activity in a region, the anatomical positioning (inferred from changes in spiking patterns along the shank), and the extent of tissue motion relative to the shank.

Title: Sharing analysis-ready human electrophysiology data on NEMAR/OpenNeuro using Hierarchical Event Descriptors (HED)

Authors: *S. MAKEIG[1,2], A. MAJUMDAR[3], A. DELORME[4], D. TRUONG[4], K. ROBBINS[5]; [1]Swartz Ctr. for Computat. Neurosci., La Jolla, CA; [2]Inst. for Neural Computation, [3]San Diego Supercomputer Ctr., [4]Swartz Ctr. for Computat. Neurosci., Univ. of California San Diego, La Jolla, CA; [5]Univ. of Texas at San Antonio, San Antonio, TX

Abstract: As ML/AI tools increasingly show the potential of finding and exploiting hitherto hidden structure in large collections of diverse data, NIH and other research funding agencies are increasing requirements, standards, and infrastructure for freely sharing experiment data in facilities that allow (1) search for data of interest that is stored in an analysis-ready format, (2) tools for analyzing the search-identified data, and (3) ready access to sufficient compute power to perform advanced analyses of both small and large data collections. Further, (4) analysis of very large data collections should avoid the need to download the data. We propose the term 'Integrated Data, Tools, and Compute Resource' (datcor) for such facilities and here describe NEMAR.org, a portal to shared human 'neuroelectromagnetic' (NEM) brain data (EEG, MEG, iEEG) shared publicly through OpenNeuro.org. NEMAR stores a copy of the growing number of OpenNeuro NEM datasets (currently >200 and >20TB, with >10,000 participants) and now offers data search, quality estimates, and visualizations. It also enables search-identified data to be analyzed without need for download using the high-performance computing resources of the Neuroscience Gateway (nsgportal.org). NEMAR/OpenNeuro datasets are stored in BIDS formats. Analysis-ready data requires detailed descriptions of experiment events using a common language. NEMAR and BIDS use the system of Hierarchical Event Descriptors (HED) under development since 2011 (hedtags.org). Here we demonstrate use of NEMAR and HED for creating, sharing, discovering, and analyzing NEM data.

Title: Automating the modeling of single cell neurons

Authors: *V. OMELYUSIK, T. BANKS, D. FAGUE, S. NAIR;
Dept. of Electrical & Computer Engin., Univ. of Missouri, Columbia, Columbia, MO

Abstract: Neurons perform synaptic integration of the stimuli they receive on their synapses using a complex set of intrinsic conductances that seemingly work in coordinated groups. However, prevalent single cell modeling techniques do not consider such potential interactions. A recent paper suggesting possible grouping of currents into distinct modules associated with specific neurocomputational properties suggests that the process of selection of model parameters could be simplified (Alturki et al., 2016). That hypothesis led to the development of design methodology that simplified the biophysical conductance-based cell design process by allowing the designer to focus on specific attributes of the cell one at a time: starting with passive properties, moving to baseline firing dynamics, then adding features such as burst firing and low- and high-threshold oscillations. By separating the cell design process into these stages, parameter selection can be simplified due to decreased interaction between the distinct current modules. The present study uses these findings to build an automatic optimization pipeline termed Automatic Cell Tuner (ACT) that generates conductance estimates from neurons' biological data. The pipeline is simulation-based; it trains a predictive model on voltage data simulated by a black-box simulator to estimate conductance values which could have generated external target data. Designed with flexibility in mind, it allows for usage of arbitrary models and feature generation. Our default implementation incorporates a shallow neural network to take advantage of fast gradient-based optimization. We embed the segregation approach by applying the ACT to voltage regions specified in the approach. We utilize the hierarchical current structure of the regions, i.e., that each new region introduces a new current set active for all further regions, to sequentially estimate conductance values in a compartmentalized manner. Preliminary results on regular spiking and bursting cells showed the segregation method outperforms estimation on the full voltage trace in terms of our composite quality metric. We are presently extending the methodology to complex multicompartment cells.

Abstract: To preserve scientific data created by publicly and/or philanthropically funded research projects and to make it ready for exploitation using recent and ongoing advances in advanced and large-scale computational modeling methods, publicly available data must use in common, now-evolving standards for formatting, identifying and annotating should share data. The OpenNeuro.org archive, built first as a repository for magnetic resonance imaging data based on the Brain Imaging Data Structure formatting standards, aims to house and share all types of human neuroimaging data. Here, we present NEMAR.org, a web gateway to OpenNeuro data for human neuroelectromagnetic data. NEMAR allows users to search through, visually explore and assess the quality of shared electroencephalography (EEG), magnetoencephalography and intracranial EEG data and then to directly process selected data using high-performance computing resources of the San Diego Supercomputer Center via the Neuroscience Gateway (nsgportal.org, NSG), a freely available web portal to high-performance computing serving a variety of neuroscientific analysis environments and tools. Combined, OpenNeuro, NEMAR and NSG form an efficient, integrated data, tools and compute resource for human neuroimaging data analysis and meta-analysis.

Abstract: High-density electrophysiology probes have opened new possibilities for systems neuroscience in human and non-human animals, but probe motion (or drift) while recording poses a challenge for downstream analyses, particularly in human recordings. In the action potential (AP) band, probe motion can cause neurons to drift across channels, and similar drift occurs for the potentials studied in the local field potential (LFP) band, so that motion estimation is a critical preprocessing step which enables downstream analyses to account for and control the possible confounding effects of the relative motion of the probe and brain tissue. Here, we improve on the state of the art for tracking this drift with an algorithm termed DREDGe (Decentralized Registration of Electrophysiology Data), with four major contributions. First, we extend previous decentralized methods to operate within and across frequency bands, leveraging the LFP in addition to spikes detected in the AP band. Second, we show that the LFP-based approach enables registration at sub-second temporal resolution. Third, we introduce a faster than real-time online motion tracking algorithm, allowing the method to scale up to longer and higher resolution recordings, which could facilitate real-time applications. Finally, we improve the robustness of the approach by accounting for the nonstationarities and artifacts that occur in real data and by automating parameter selection. These findings are robustly validated in large scale experiments in humans, mice, and non-human primates (NHPs), including repeated validation and comparison against competing algorithms in tens of mouse and human datasets and a proof-of-concept demonstration in NHP of a new method enabled by DREDge: localization of the probe during insertion.

Title: Sanpy: an open-source whole-cell electrophysiology analysis pipeline

Authors: *R. H. CUDMORE, L. GUARINA, J. T. LE, T. N. GRIFFITH, L. F. SANTANA; Physiol. and Membrane Biol., Univ. of California - Davis, Davis, CA

Abstract: Whole-cell recording is a gold-standard technique for interrogating the biophysical properties and mechanisms of single cell function. With continued advances in genetic, pharmacological, and computational tools, the utility of this technique will continue to grow well into the future. A major bottleneck in the interpretation of this critical data is the lack of community based open-source software tools for its analysis. Here, we present SanPy, a Python-based open-source and freely available software pipeline for the analysis and exploration of whole-cell current- and voltage- clamp recordings. SanPy provides a computational engine with an application programming interface allowing it to be programmatically scripted. Using this engine, we have developed a cross-platform desktop graphical user interface that does not require programming experience. A key benefit of SanPy is that it provides one-click downloads of this desktop application. SanPy is designed to extract parameters from current-clamp recordings of action potentials including threshold time and voltage, peak, half-width, and interval statistics. In addition, SanPy extracts parameters from a range of voltage-clamp protocols. SanPy is built to be fully extensible by providing frameworks for the addition of custom file loaders, analysis, and graphical user interface plugins. A key feature of SanPy is its focus on quality control and data exploration. In the desktop interface, all plots of the data and analysis are linked allowing simultaneous data visualization from different dimensions with the goal of obtaining ground truth analysis. We provide documentation for all aspects of SanPy including several use cases and examples. To test SanPy, we have performed analysis on current- and voltage- clamp recordings from neurons and cardiac myocytes. Taken together, SanPy is a powerful tool for whole-cell analysis and effectively lays the foundation for future extension by the scientific community.

Title: Novel parameterization of event-related potentials: a step towards characterizing the biophysical origins

Authors: *M. PRESTON[1], D. CELLIER[2], E. KOSIK[2], P. SEYFOURIAN[5], L. CLAAR[6], L. MARKS[6], C. KOCH[6], I. REMBADO[6], B. VOYTEK[2,1,3,4];

Abstract: Event-related potentials (ERPs) are foundational in linking human electroencephalography (EEG) to cognition and disease. For decades, systematic variation in ERP timing and amplitude have been linked to various perceptual and cognitive states, and have been leveraged in clinical applications ranging from anesthesia to brain-computer interfaces. Despite their wide adoption and utility, the biophysiological origins of ERPs remain largely unknown. Here, we test the hypothesis that early visual evoked potentials are driven by thalamic excitatory projections to input layers of primary visual cortex (V1). We make use of large scale single-unit and local field potentials (LFP) recordings using Neuropixels probes in head-fixed mice targeting the visual thalamic nuclei and V1, in conjunction with biophysically informed models. We also introduce a novel ERP parameterization approach that quantifies each ERP waveform in terms of its onset, amplitude, time-to-peak, duration, and peak-sharpness. Using simulated LFP and our novel ERP parameterization approach, we demonstrate that visual evoked potentials are driven by thalamocortical excitatory postsynaptic currents (EPSPs). These currents, which have a sharp temporal onset and slower decay, integrate such that when thalamic spikes are temporally aligned, the resulting V1 ERP is sharper and has a larger magnitude. When thalamic spikes are more temporally variable, the resulting EPSPs in V1 integrate into a slightly smoother ERP. These results further our understanding of the ERP origins and their biophysical interpretability.

Title: Decodanda: a Python toolbox for decoding and geometrical analysis of neural data.

Authors: *L. POSANI, S. FUSI;
Columbia Univ., New York, NY

Abstract: Neural decoding is a powerful tool to obtain insight into which variables of the external world are represented in the activity of a population of neurons, with broad applicability that spans from basic research to clinical applications such as brain-computer interfaces. Additionally, neural decoding has recently emerged as a tool to unveil the geometrical properties of neural representations, offering computational insights into the collective activity of neurons. Here we introduce Decodanda (https://www.github.com/lposani/decodanda), a Python toolbox for geometrical decoding of population activity. Decodanda exposes a series of functions for decoding and geometrical analysis of neural data, such as CCGP and parallel score, and automates essential data management and balancing practices such as trial-based cross-validation, a null model for statistical significance, pseudo-population pooling, and cross-variable balancing. Decodanda is agnostic to the specific classifier used for decoding, and its APIs are designed to expose a user-friendly and highly customizable syntax that allows researchers to build custom analysis pipelines using its functions as building blocks. Here, we give an overview of the design principles of Decodanda and its use cases in neuroscience research.

Title: Neuroscience Data Interface calculators: a motif for writing small analysis applets that are easy to learn, reuse, and test

Authors: *A. LEPSKY, R. WANG, X. CHENG, N. LASKY-NIELSON, R. GONG, C. JOHNSON, R. RODRIGUEZ, S. D. VAN HOOSER;
Brandeis Univ., Waltham, MA

Abstract: Advancements in data-driven fields such as neuroscience depend critically on small custom analysis programs. Many of these programs are developed in individual labs and suffer from minimal and narrowly scoped testing, poor documentation, and a dependency on particular file formats or data organization. Even when they are shared openly on sites such as GitHub, these programs can be difficult to reuse due to the issues above. To address this challenge, we have developed an applet motif for the Neuroscience Data Interface (NDI) called calculators. NDI provides a platform-independent, searchable database of documents containing all raw data and analyzed data for an experiment. Calculators access these databases and search for document types that they can operate on, eliminating the need to wire or pipe calculators together. In order to make them intuitive for new users, calculators produce only one type of output document, contain documentation in specific places, and override only 4 functions while leaving the rest as is. Importantly, calculators also must be able to generate several self-test cases, evaluate that the results produced are within tolerance of the expected results, and, if the user requests, show the actual and expected results graphically. The calculator motif allows users to quickly understand and trust calculators written by labs or groups. Users can then integrate these community-tested programs into analysis pipelines - sets of calculator objects along with any modifying parameters of calculator operations. We show examples of calculators for the visual system that compute tuning curves for orientation, direction, contrast, spatial, temporal frequency, and speed.

Title: Universal Renderer for Neuroscience: interactive 3D rendering for electrophysiology and neuroimaging in the browser, on desktops, and in virtual reality

Authors: *D. BIRMAN[1], J. SCHOCH[1], I. BRAIN LABORATORY[2], N. A. STEINMETZ[1]; [1]Univ. of Washington, Seattle, WA; [2]Virtual Entity, Virtual, United Kingdom

Abstract: Modern large-scale electrophysiology and neuroimaging techniques are generating unprecedented amounts of data. Exploring these data in their original anatomical context depends on the existence of easy-to-use and powerful 3D visualization tools. To solve this problem, we have developed an open-source software package, the Universal Renderer Creating

Helpful Images for Neuroscience (Urchin), that can visualize anatomically registered data from a variety of input sources in the space of common reference atlases. Our rendering package is platform-agnostic, working equally well as a standalone desktop application, in a virtual reality headset, or as a website. When running in a web browser, the renderer requires no installation and allows users to build complex 3D renderings in seconds. Users send data to the renderer through an application programming interface (API), using simple commands to pass information about their 2D or 3D scene. The visuals that the renderer can create include: brain regions rendered as opaque or transparent 3D objects, simple or complex 3D models such as spheres to represent neurons, probes, or neuron morphology, videos of neuroimaging data projected onto 3D surfaces, volumetric data such as MRI images, and 2D accents such as lines and text. Visualizations can be exported as high quality static images or videos from one or more camera angles. Unlike existing rendering packages intended for neuroscience, our software is interactive and allows users to explore their data in 3D space using keyboard and mouse interactions, or in virtual reality. This interactivity is not limited to simple scenes: by taking advantage of a powerful existing video game engine (Unity), our 3D renderer can support extraordinarily complex interactive scenes and at 60 hz we are able to display real-time firing rate data from up to 100,000 neurons overlaid on hundreds of individual brain regions. To demonstrate the power of Urchin we have developed several applications using the renderer, including a virtual reality experience in which participants explore a 30,000 neuron electrophysiology dataset, an online data viewer where users can explore 2D and 3D views of the mouse brain with per-region analysis results overlaid, and other interactive data viewers. Urchin makes it possible for neuroscientists to build powerful interactive explorations of their three-dimensional datasets with minimal effort and to share these easily with colleagues over the internet.

Title: Methods for semi-automated parcellation of the globus pallidus internus for localizing neurophysiological activity and deep brain stimulation leads

Authors: *B. POBIEL[1], K. J. O'NEILL, III[2], R. PATRIAT[3], T. PALNITKAR[2], H. BRAUN[4], O. SOLOMON[2], S. ALBERICO[2], M. HILL[2], B. MOHANTY[3], D. L. BAUER[3], B. PARKS[5], J. VITEK[2], N. HAREL[6], J. E. AMAN[3];
[1]Dept. of Neurol., Univ. of Minnesota, Twin Cities, Minneapolis, MN; [2]Dept. of Neurol., [3]Univ. of Minnesota, [4]Dept. of Radiology, Univ. of Minnesota, Minneapolis, MN; [5]Univ. of Minnesota, Univ. of Florida, Minneapolis, MN; [6]Univ. of Minnesota Syst., Univ. of Minnesota Syst., Minneapolis, MN

Abstract: Background: Historically, atlas-based stereotactic coordinates or qualitative 2D brain slices have been used to localize sites of neurophysiological activity or deep brain stimulation (DBS) leads within the internal segment of the globus pallidus (GPi). These approaches have limited spatial resolution and lack patient specificity. This project creates a reproducible, semi-automated method for parcellating the GPi in Cartesian 3D space using models previously generated by our team. This approach allows comparison across patients and can be used to generalize findings relating to localizing DBS leads and pathophysiological biomarkers in Parkinson's disease (PD) and dystonia patients.
Methods: In 3DSlicer™ an axial AC/PC plane is constructed from the anterior/posterior commissure (AC/PC). The segmented GPi volume is exported, and a C++ script generates a least-volume, axis-agnostic bounding box around GPi. The GPi volume, bounding box, AC/PC plane, and reconstructed lead and/or microelectrode positions are imported into Unity™. The AC/PC plane is fixed to an XY plane of a new coordinate system. The GPi bounding box is used to determine a longitudinal axis of the GPi and the axis is used to transform the GPi to the XY and ZY planes. A new plane-aligned bounding box is created and divided into dorsal/ventral aspects and anterior/central/posterior thirds. A series of planes are generated along the longitudinal axis and the centroid of the GPi is found in each plane to divide the GPi into mesial/lateral halves, creating 12 total subsections (e.g., posterior dorsolateral). Using collision detection, the intersections of lead contact positions and microelectrode sites are determined algorithmically and compared with patient-specific neurophysiology and/or clinical outcomes.
Results: One patient has been studied using this method. The segmented lead position was determined quantitatively to fall within the central portion of the GPi, with the therapeutic stimulation contact in the dorsal region spanning the mesial-lateral midline, facing in the posterior direction. The patient showed a 59% improvement in their total UPDRS-III score from this active contact location.
Conclusion: This methodology will be expanded to a larger study designed to localize DBS leads and distribution of neurophysiological activity in the GPi. Correlating these data with clinical outcomes in PD and dystonia will help determine optimal locations for lead placement and for localizing phenotype-specific biomarkers.

Title: Simplifying the conversion of neurophysiology data to NeurodataWithoutBorders format

Authors: G. FLYNN[1], ***C. BAKER**[2], R. LY[3], O. RUEBEL[4], B. DICHTER[5];
[1]CatalystNeuro, Los Angeles, CA; [2]CatalystNeuro, South Bend, IN; [3]Lawrence Berkeley Natl. Lab., [4]Oliver Ruebel, Lawrence Berkeley Natl. Lab., Berkeley, CA; [5]CatalstyNeuro, Benicia, CA

Abstract: Neurodata Without Borders (NWB) is a data standard that packages neurophysiology data with the metadata necessary for reanalysis. The NWB format allows data to be human- and machine-readable, and will enable data to be aggregated across many labs. The neuroscientists who want to use NWB have diverse data formats, and many of them have limited programming experience. To approach this problem, we have developed the NWB Graphical User Interface for Data Entry (GUIDE) to provide a simple entrypoint to the NWB ecosystem for any lab interested in adopting the standard.
Researchers must often convert their data from common proprietary formats such as Intan, SpikeGLX, TIFF, ABF, etc. It can be challenging to map these different data formats, each with its own unique structure, to NWB. This challenge has been overcome with the use of NeuroConv, a library for automatically handling the data mapping for 40+ proprietary formats spanning the modalities of intra- and extra-cellular electrophysiology, optical imaging and behavior. However, the use of NeuroConv requires experience with Python and is poorly suited for potential users that are unfamiliar with programming.
This initial release of NWB GUIDE is a cross-platform desktop application that walks users through all the requirements for converting their data to the NWB format and uploading datasets to the DANDI Archive. NWB GUIDE streamlines the data conversion experience, walking users through input file specification, metadata extraction and curation, efficient handling of large datasets, and finally uploading to the DANDI Archive. We look forward to working with members of the NWB community to test and improve the platform based on user needs and feedback.

Title: Advancements in the Neurodata Without Borders Software Ecosystem for Neurophysiology

Authors: *R. LY[1], C. BAKER[2], M. AVAYLON[1], G. FLYNN[2], B. DICHTER[2], O. RUEBEL[1]; [1]Lawrence Berkeley Natl. Lab., Berkeley, CA; [2]CatalystNeuro, Benicia, CA

Abstract: The Neurodata Without Borders (NWB) format standardizes how neurophysiology data and associated metadata are stored, and the NWB software enables researchers to easily access and save data in NWB. By standardizing neurophysiology data, NWB enables researchers to more fully extract return-on-investment from neurophysiology experiments. To lower the barrier of adopting NWB, we have made significant enhancements to the core NWB software tools, supported the integration of NWB with a wide array of powerful tools and technologies, and expanded NWB training efforts to reach a broader international neuroscience community.
We have enhanced PyNWB to allow users to read and write NWB data in Zarr, a modern, cloud-efficient storage format for chunked, compressed, N-dimensional arrays. To ensure FAIR data use, we have added support in NWB for linking neurophysiology metadata with persistent identifiers in external resources, such as ontologies and online databases. We have made enhancements to NeuroConv, a software suite for converting neurophysiology data from 40 popular raw acquisition data formats to NWB, and to NWB Inspector, a tool for assessing the quality of NWB files based on compliance with NWB Best Practices. Most recently, we have developed the NWB Graphical User Interface for Data Entry (GUIDE), an application that walks users through the process of converting raw data to NWB, without writing any code.
The NWB software ecosystem has grown to include support for NWB in tools for pose estimation and tracking (DeepLabCut, SLEAP), intracellular electrophysiology (PatchView), optical physiology (EXTRACT), data analysis (Pynapple, Spyglass), and data acquisition (OpenEphys). In addition, the DANDI Archive for neurophysiology now contains over 100 open datasets from a diversity of data modalities, model animals, and labs in the NWB format. We will describe several projects that make use of published NWB data on DANDI and our efforts to train and support neuroscientists from around the world to reuse NWB data.

Title: Cortical gamma-beta rhythms perform predictive routing via stochastic reinforcement learning

Authors: *H. NEJAT[1], J. SHERFEY[2], A. BASTOS[1];
[1]Psychology, Vanderbilt Univ., Nashville, TN; [2]Psychological and Brain Sci., Boston Univ., Boston, MA

Abstract: Predictive coding is a key theoretical framework in neuroscience. Deficits in prediction are associated with mental disorders such as schizophrenia and major depressive disorder. Recent studies have revealed a dynamic shift between beta and gamma bands in cortical circuits during predictable and unpredictable tasks. This suggests a gamma [40-90Hz]/beta[10-30Hz] push-pull mechanism for suppressing unpredictable stimuli. We call this mechanism predictive routing. Current neuronal models of predictive coding/routing are incomplete. One class of models can be trained to perform computations but are not biophysically realistic. Another class of models focus on dynamics but do not perform computations. One solution to this limitation is to implement biophysically detailed neuronal models capable of learning. However, current models lack detailed neurobiological constraints and rely on manual tuning. To address these limitations, we introduce DynaLearn, an extension of DynaSim, which utilizes reinforcement learning to discover neurobiologically constrained solutions for optimization problems. In this study, we employed the semi-supervised learning algorithm known as the "Generalized Stochastic Delta Rule" to train DynaLearn on resting membrane potential, Pyramidal Interneuron Network Gamma/Beta (PING/PINB) network frequency tuning, and gamma-beta push-pull. Our findings demonstrate that learned top-down connection weights effectively reduce gamma strength while enhancing beta strength, enabling predictive routing. Therefore, computational modeling using DynaLearn/DynaSim can be used to understand both neuronal circuit mechanisms as well as the computations they perform.

Title: Tools for large-scale modeling, simulation and visualization of realistic biological networks: The SONATA Data format and integrated software

Authors: *K. DAI[1], B. ISRALEWITZ[2], X.-P. LIU[1], M. SPIVAK[2], S. ITO[1], N. REN[1], D. HAUFLER[1], E. TAJKHORSHID[2], A. ARKHIPOV[1];
[1]Allen Inst., Seattle, WA; [2]Beckman Inst. for Advanced Sci. and Technol., Univ. of Illinois at Urbana-Champaign, Urbana, IL

Abstract: With the emergence of large-scale experimental multi-area connectomic and extracellular electrophysiology recordings, there is an increasing need for detailed in-silico modeling and simulation on a matching scale. Yet much of the current research into neural dynamics of computation and behavior is still limited to the scale of individual cells or very small circuits. Biologically realistic simulatable network models ranging from thousands to billions of cells can elucidate the fundamental working of large-scale networks and drive future research. But for most neuroscientists working in network and systems neuroscience, trying to create, run, analyze, and share such large scale models can be an intractable technological hurdle. Here we present a set of tools and formats that can help scientists with the efforts in building and simulating large-scale biologically realistic network models. At the core of this effort is the SONATA data format, a multi-organization, open-source set of standards for describing and sharing large heterogeneous network models. With SONATA a scientist can describe their model, simulation parameters and results in a way that can be readily shared and reproduced. It is highly modular, easy to read and write, and can be used across a variety of model types ranging from multi-compartment, to point-neurons, and even rate models. SONATA has already been implemented across a range of software simulation and analysis software tools, including the Brain Modeling Toolkit (BMTK) and Visual Neuronal Dynamics (VND).
BMTK is an open-source python API for building and simulating large network models across different levels-of-resolutions. It provides an intuitive workflow including automated parallelization and an array of built-in features. VND is a C++ network visualization tool, with advanced data querying and rendering techniques to visualize and analyze large network models and simulations ranging from synaptic activity to whole-network spiking dynamics. By utilizing SONATA, both pieces of software can be used seamlessly for building, simulating, and analyzing large network models in an intuitive workflow.

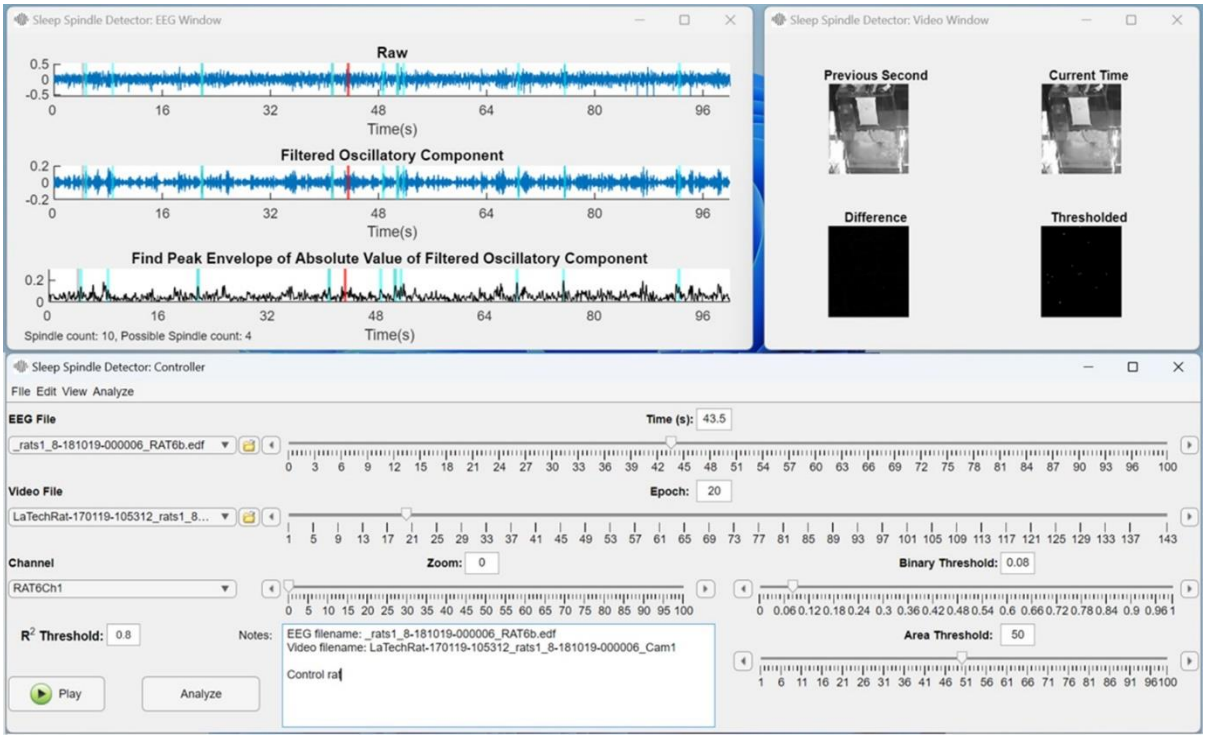
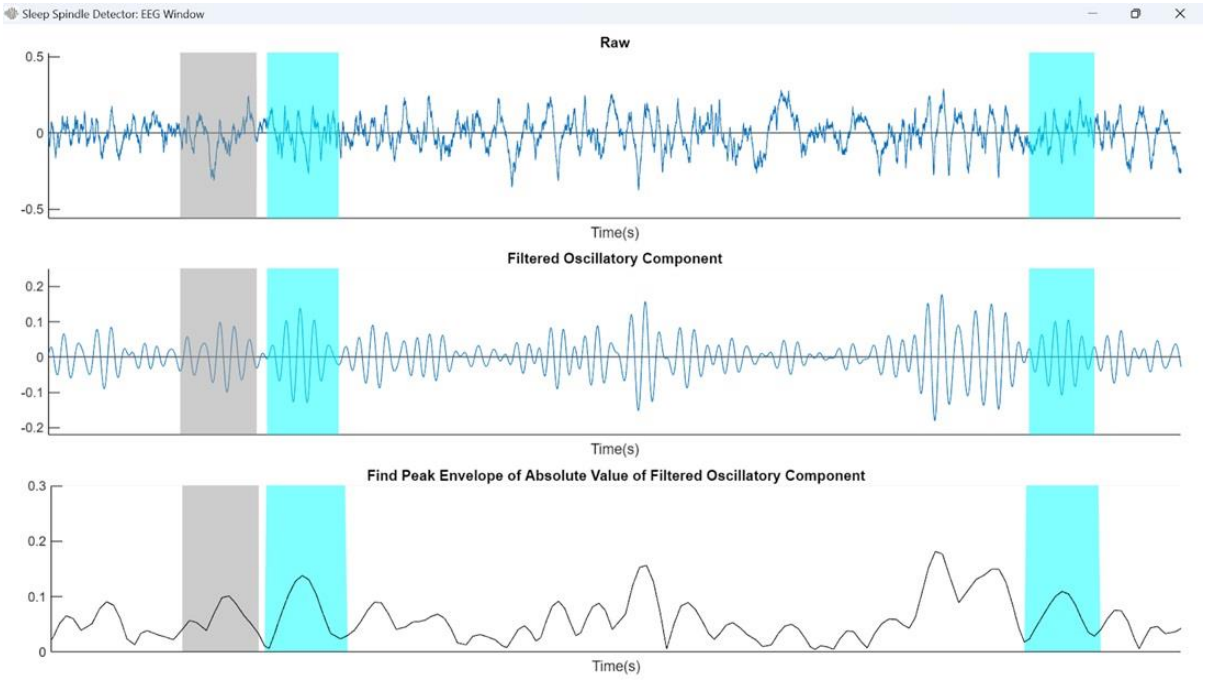
Abstract:





A Rodent Sleep Spindle Detector application was developed to assist researchers working with high volume studies examining the impact of sleep on neurological function. Our Rodent Sleep Spindle Detector app is a MATLAB-based program with a user interface that automatically identifies sleep spindles within intracranial EEG (iEEG) recordings of rodents using two novel yet complementary algorithmic approaches. To validate the program, 6,000 real spindles of 5 different variations ranging from 11-17 Hz with a duration of at least 0.3 seconds were randomly placed within a noisy simulated prefrontal cortex iEEG signal with a duration of 50,000 seconds. When compared to the ground truth on a datapoint-by-datapoint basis, the program had an accuracy of 98.40±5.62% (mean±SD) with 95% C.I.[91.93,104.89] and 96.90±4.34% (mean±SD) with 95% C.I.[91.91, 101.90] for the primary and secondary algorithmic approach, respectively. On a holistic evaluation, the program had an accuracy of 93.68±13.66% (mean±SD) with 95% C.I.[81.71, 105.66] and 99.85±0.12% (mean±SD) with 95% C.I.[99.71, 99.96], for the primary and secondary algorithmic approach, respectively. The robustness of the sleep spindle detection was evaluated in additional validation tests by embedding artificial spindles at various durations, amplitudes, and frequencies in lieu of real spindles. Optionally, the app can process video recordings to identify periods of quiescence to improve sleep spindle detection.

Title: The Open Ephys GUI: A collaboratively developed platform for high-channel-count electrophysiology data acquisition

Authors: *A. DOSHI[1], P. KULIK[1], A. MUNK[2], A. LÓPEZ[3], J. VOIGTS[4], J. H. SIEGLE[1]; [1]Allen Inst. for Neural Dynamics, Seattle, WA; [2]Integrated Electronics and Biointerfaces Laboratory, UCSD, La Jolla, CA; [3]Open Ephys Production Site, Lisbon, Portugal; [4]HHMI Janelia Res. Campus, Ashburn, VA

Abstract: The Open Ephys GUI (https://open-ephys.org/gui) is an open-source, cross-platform application for acquiring data from multichannel implanted electrodes, a technique that has fostered countless discoveries in systems neuroscience. Unlike most other software in this domain, the GUI was designed from the ground up with collaborative development in mind.

Modules for real-time analysis and visualization are encapsulated within plugins that adhere to a standardized interface, providing a straightforward way for users to write their own extensions without needing to understand the entire code base. A growing number of scientists have developed their own plugins for the GUI, which had previously been stored in a variety of locations, typically in source-code form. With funding from a BRAIN Initiative U24 award, we have created a centralized repository for plugins, which can be downloaded and installed via a single click. Over the course of this award, we have curated, polished, and documented additional community-developed plugins in order to expand the capabilities of the software. Some examples of these plugins include Falcon Output, which streams high-channel-count data with low latency, Phase Calculator, which can be used to deliver closed-loop feedback at specific phases of an ongoing oscillation, and Ripple Detector, which emits events at the onset of hippocampal sharp-wave ripples. Priority has been given to plugins that can be used with Neuropixels, a new type of silicon probe capable of recording single units across dozens of cortical and subcortical structures simultaneously. Providing free, flexible, user-friendly, and performant software for recording spiking activity makes extracellular electrophysiology experiments more accessible to labs around the globe.

Title: Neuroscience Gateway enabling software dissemination and large scale modeling and data processing

Authors: *A. MAJUMDAR[1], S. SIVAGNANAM[1], K. YOSHIMOTO[2], N. CARNEVALE[3], M. KANDES[2], S. YEU[2], D. CHOI[2];

Abstract: For about a decade the Neuroscience Gateway (NSG) has been enabling the broader neuroscience community of computational neuroscientists, experimental neuroscientists, cognitive neuroscientists, psychologists, biomedical researchers, and clinical researchers to easily utilize high performance computing (HPC), high throughput computing (HTC) and cloud computing resources for large scale modeling, data processing, and Artificial Intelligence/Machine Learning (AI/ML) work. NSG provides close to 20 neuroscience modeling, data processing and AI/ML software and tools optimally made available on supercomputer resources at national supercomputer centers in the US. It currently has over 1,550 users and has acquired 27 million supercomputer-time allocation for 2023 for its users. Via NSG's easy to use web-based and programmatic interface neuroscientists can upload input file or data to the NSG, choose the appropriate tool, specify the tool and computing related parameters and submit the computing workload to a supercomputer. Upon completion of the processing, users can download the output results. NSG eliminates administrative and technical barriers to utilize supercomputing resources for modeling, data processing and data analytics work in neuroscience. NSG also provides a software developer platform which neuroscience software developers can use to test, benchmark and scale their software and then release the software on supercomputers where NSG acquires yearly allocation for the neuroscience community. NSG provides a platform for dissemination of neuroscience software. NSG is free and open to any neuroscientist researchers and students from US and other countries. Yearly training and workshops are hosted by the NSG team where NSG users and software developers discuss their research results and software. NSG is utilized by other neuroscience projects, such as the NeuroElectroMagnetic data Archive and tools Resource (NEMAR), the Open Source Brain, as the computational engine for processing of data and simulations. NSG is used in classroom teaching for undergraduate and graduate students. NSG has special training and classroom teaching sessions for Minority Serving Institutions. The presentation at SfN will describe the tools that NSG provides, how they are utilized on supercomputers, statistics of NSG's growth, research enabled by NSG and external projects that are utilizing NSG as the compute engine.
