Abstract: Theta oscillations have been shown to clock memory processing in hippocampus. Recent studies using spatial memory tasks have shown that when the task contains opposing alternatives, e.g. left versus right, the hippocampus represents these alternatives at different theta cycles (Kay et al., Cell, 2020) or theta phases (Kunz et al., Sci. Adv., 2019). It is unclear whether this theta-locked separation extends to non-spatial tasks.
Here, we explore the signatures of encoding and retrieval of associations and how these are impacted by the presence of opposing answer alternatives. We recorded intracranial EEG from the hippocampi of 9 epilepsy patients using Behnke-Fried electrodes, while the patients learned and later recalled cue-object associations. The patients were asked to remember two features about each object, namely whether they were photographs or drawings, and animate or inanimate objects. We analysed the representational similarity (RSA) between objects and features using local field potentials (LFPs) and single unit activity from hippocampus.
We report an increased separation during encoding of cue-object association patterns for both LFPs and spikes. The cue-object binding patterns were reinstated after the cue was shown in the retrieval phase of the task. Intriguingly, pattern similarity oscillated with frequencies in the low theta range (1-5 Hz). Opposing object features, e.g. photo versus drawing, were more prominent at opposite phases of this theta rhythm, suggesting task demand influences the representation of

objects in hippocampus. Our data suggest that representations in hippocampus not only reflect perceptual information, but also capture the mnemonic decision.

Abstract: While a hallmark of hippocampal function is the integration of different types of information, anatomical and functional research in rodents and monkeys indicate segregated functional pathways in the transversal axis of the entorhinal-hippocampal (EC-HC) circuitry. Accordingly, distinct functional subregions within the EC and the subiculum were identified in humans (Maass, Berron, et al., 2015; Navarro Schröder et al., 2015). Here, we replicate and advance these findings in an independent ultra-high resolution 7 Tesla fMRI dataset (N = 32) and provide striking insights into the organizational principles of the human EC-HC circuitry. The results show a preferred functional connectivity of the anterior-lateral EC seed with proximal subiculum and distal CA1 in the HC body. In addition, our explorative investigation of the HC head indicate a highly specific connectivity profile, notably expressing features that resemble ex vivo atlases of the human HC head. The identified functional connectivity profile along the transversal axis of the EC-HC circuitry bridges findings from animal and ex vivo human research towards in vivo fMRI. Clinically, the connectivity preference between distal CA1 and proximal subiculum and anterior-lateral EC is highly relevant as tau pathology can be observed early on in those subregions in Alzheimer's disease. Our findings replicate recent studies and fundamentally advance insight into the architecture of the human EC-HC circuitry that help to understand its central role in memory function and decline.

Title: Interval-scale sequence memories in the hippocampus generalize temporal structure across sequences

Authors: *J. L. S. BELLMUND[1], L. DEUKER[2], N. D. MONTIJN[3], C. F. DOELLER[1]; [1]Max Planck Inst. for Human Cognitive and Brain Sci., Leipzig, Germany; [2]Inst. for Cognitive Neurosci., Ruhr-University Bochum, Bochum, Germany; [3]Dept. of Clin. Psychology, Utrecht Univ., Utrecht, Netherlands

Abstract: Time is a fundamental dimension along which our experience unfolds. Sequences of events shape episodic memory. The hippocampal-entorhinal region forms cognitive maps of learned relations such as the temporal relationships of events in a sequence. However, it is unclear whether representations of sequence structure reflect the order of events, elapsing time, or whether they are flexibly scaled to experimentally-defined temporal reference frames. Furthermore, how the formation of specific sequence memories relates to the extraction of regularities from sequences with shared temporal structure remains elusive. Here, we combined a sequence learning task with fMRI. Participants encountered four event sequences and inferred the times of individual events based on infrequent umaskings of a hidden clock. Importantly, we manipulated the clock's speed between sequences to partially dissociate event times from sequence order and objectively elapsing time. Memory tests revealed that participants successfully learned which events belonged to which sequence. They accurately inferred the times of individual events relative to the hidden clock. After learning, multi-voxel pattern similarity in the anterior hippocampus correlated with temporal distances between event pairs. These sequence representations reflected temporal relations relative to the hidden clock beyond event order and elapsed time. Our findings further revealed that temporal relations shape representational similarity in the hippocampus differently for event pairs from the same or from

two different sequences. In contrast, the anterior-lateral entorhinal cortex employed a common representational format within and across sequences. Our findings suggest that hippocampal sequence representations can be scaled to incorporate interval-level knowledge of temporal relations that does not exclusively depend on order and passively elapsing time. Consistent with the cognitive mapping of structural knowledge, our findings demonstrate that temporal structure organizes memories across multiple sequences.

Title: Unifying STDP and theta-phase-dependent synaptic plasticity in a computational model to explain theta-dependent memory effects in humans and animals

Authors: *D. WANG[1,2], G. PARISH[2], K. L. SHAPIRO[2], S. HANSLMAYR[1,2];
[1]Ctr. for Cognitive Neuroimaging (CCNi), Inst. of Neurosci. and Psychology, Univ. of Glasgow, Glasgow, United Kingdom; [2]Sch. of Psychology, Ctr. for Human Brain Hlth. (CHBH), Univ. of Birmingham, Birmingham, United Kingdom

Abstract: Long-lasting synaptic modifications found in the hippocampus make the region ideal to support binding rich multisensory information into unitary episodes. Rodent studies suggest that the timing of spikes relative to ongoing hippocampal theta activity determines whether potentiation or depression of synapses arise. Such changes also depend on the timing between spikes of pre- and post-synaptic neurons. This form of synaptic plasticity, known as spike-timing-dependent plasticity (STDP), together with theta-phase-dependent learning, has inspired several computational models of learning and memory. However, evidence to elucidate how these mechanisms directly link to human episodic memory is lacking. We build on a previous model, the Sync/deSync model, to explore the interaction between these mechanisms and their impact on episodic memory. As such, we modulate the two components of STDP, long-term potentiation (LTP) and long-term depression (LTD), by opposing phases of a simulated theta rhythm. With the addition of hetero-synaptic plasticity on non-stimulated pathways, alongside thresholds for potentiation and depression, we are able to reproduce findings from a popular hippocampal cell culture study. In this study, synaptic potentiation and depression were observed to occur during burst-like activity in opposing phases of a theta rhythm. Further, we successfully simulate several results obtained in humans, which used a novel multisensory entrainment

paradigm to provide causal evidence that relative timing between stimulus inputs and theta activity are critical determinants of human episodic memory. Two stimulus inputs were modulated by cosine waves with synchronous and asynchronous phase offset conditions. Our model successfully replicates the key empirical findings in that learning for the synchronous condition was more efficient than for the asynchronous conditions. This learning advantage was specific to theta modulated stimulus inputs and was not observed for alpha or delta modulated stimulus inputs. Interestingly, this learning advantage is particularly reliant on the presence of theta-modulated LTD, indicating the importance of phase-dependent synaptic depression in increasing the specificity of encoded episodic memories. Moreover, simulations with and without each mechanism suggest that both STDP and theta-phase-dependent LTP and LTD are necessary to replicate the findings from these human episodic memory experiments. Together, the results indicate a functional role of the circuit-level mechanisms in human memory, which bridges the gap between slice preparation studies to human memory dependent behaviour.

London, London, United Kingdom

Abstract: BACKGROUND: Early-life episodes of hypoxia-ischemia can damage the hippocampus and lead to developmental amnesia (DA). Patients with DA exhibit severe episodic memory impairment while their semantic memory is largely preserved. It is not clear however whether the residual hippocampus plays a role in encoding and/or retrieval of new information, or the surrounding neocortical areas compensate to rescue hippocampal function after early injury.

AIMS: We aimed to investigate anatomo-functional correlations between cognitive performance and the volumes of residual hippocampal subregions in patients with DA. We also aimed to evaluate the structural integrity of the parahippocampal gyrus in these patients.
METHODS: We used manual segmentation on MRI acquisitions to estimate the volume of three hippocampal subregions: uncus, CA-DG (including CA fields and dentate gyrus) and subicular complex; and the volume of three surrounding cortical areas: entorhinal, perirhinal and parahippocampal cortices, in an exceptionally large cohort of 21 patients with DA and 26 controls of comparable age. The groups were assessed on: i) the Four Mountains Test, which provides measures of spatial perception and immediate spatial memory, and ii) the Doors and People Test, which provides equated measures of recognition and recall.
RESULTS: In patients with DA, the level of atrophy was greater in the CA-DG than in the Subicular complex and greater in the Subicular complex than in the Uncus which showed only mild atrophy in most of the patients. Patients' spatial perception and spatial memory performance correlated negatively with the volume of the Subicular complex. Also, patients' recall, but not recognition memory performance, correlated negatively with the volume of the Uncus. The entorhinal, perirhinal and parahippocampal cortices did not show evidence of volume reduction in patients with DA. Also, we did not observe correlations between the volume of the rhinal cortices and patients' performance.
CONCLUSIONS: In patients with DA, cognitive processing is compromised as a function of extent of atrophy in hippocampal subregions, such that the greater the damage, the more likely that preserved surrounding cortical areas will be recruited to rescue the putative functions of the damaged subregions. This causes the paradoxical finding that greater atrophy in specific hippocampal subregions leads to improved task-dependent mnemonic or spatial function.

Abstract: Episodic memory relies on the efficient encoding of memory associations, which are often complex in nature. Animal research suggests that brain oscillations in the theta and gamma frequency range in the hippocampus regulate memory encoding via synaptic plasticity mechanisms, which reflect fine-grained timing differences in firing between neurons. One such mechanism is spike timing dependent plasticity (STDP), which states that the time delay between the firing of pairs of cells dictates the change in synaptic connection (i.e. shorter latencies resulting in stronger weight changes). We explored this question by recording single and multi-unit activity alongside local field potentials in the human medial temporal lobe during an associative episodic memory task. Results show that the complete encoding of memory associations correlates with increased spike-field coherence in a fast gamma (65-70 Hz) and a fast theta (8-10 Hz) frequency band. Conversely, synchronization to slower gamma and theta oscillations resulted in an incomplete or no memory. Importantly, memory formation correlated with a short latency (~20 ms) of co-incident spikes between pairs of theta/gamma coupled neurons. A computational model exploring the consequences of spike-field coupling in theta/gamma oscillations demonstrates that synchronization to fast gamma/theta oscillations efficiently encodes memory associations via STDP. These results demonstrate that theta and gamma oscillations play a crucial role in memory via establishing efficient neuron-to-neuron communication. The difference in gamma and theta frequencies, and the time windows of co-firing are consistent with a well-known synaptic plasticity mechanism (STDP) and implicate this mechanism for the first time in humans during an episodic memory task.

Abstract: The hippocampus (HIPP) is tightly connected to other areas within the brain. It's connectivity to neocortical structures (NC) has been deemed important for a wide variety of cognitive functions, such as the formation and retrieval of episodic memories. While there is an abundance of studies investigating both areas individually, the connectivity between the HIPP and the NC is still underexplored. Most research into the HIPP and its connectivity to NC is observational/correlational, drawing only indirect links between the areas. Furthermore, the majority of the research is based on animal models, due to the relative inaccessibility of the HIPP. How the properties determined in these animal models carry over to humans is therefore still an open question. In this exploratory study, epileptic patients (N=6) under clinical observation, were implanted with stereotactic 'Behnke-Fried' depth electrodes in the hippocampus, which can record iEEG signal at eight channels along their shafts and are even sensitive enough to detect single and multi-unit spiking activity at the tips. These electrodes allowed us to directly record electrophysiological data from the human HIPP and the NC, while repeatedly and systematically administering single pulse electrical stimulation (SPES) throughout several sites within the HIPP and the NC. By recording data while administering electrical pulses, we were able to causally investigate properties of cortico-hippocampal connectivity. The results show that SPES leads to increased neural activity following a pulse, both locally in the HIPP and in connected NC regions. These pulses allowed us to gauge the cortico-hippocampal conduction delay and compare it to existing animal models as well as correlational findings in humans. Furthermore, we investigated oscillatory patterns elicited by SPES and the role of phase as possible functional signatures in cortico-hippocampal communication. We relate these findings to a computational model describing cortico-hippocampal interactions [1], which ascribes special importance to the relationship for specific frequency bands in the HIPP (Theta power, 4-8 Hz) and NC (alpha/beta power, 8-20 Hz) for episodic memory processes. This study is one of few studies causally investigating the electrophysiological mechanisms underlying cortico-hippocampal communication in humans by directly altering the states of the investigated areas.

Abstract: The hippocampus is a central brain structure that plays a role in many cognitive functions as well in various neurological diseases. Neuro-imaging studies have revealed that when a person is at rest, different sets of brain regions become activated at different moments in time. The relationship between the hippocampus and these so-called resting-state networks remains poorly understood. Previous studies in resting-state functional magnetic resonance imaging (rs-fMRI) have revealed that the hippocampus participates in a resting state network called the default mode network (DMN). However, it is still not known: 1) What section of the hippocampus connects to the DMN, 2) whether the hippocampus also connects to other types of resting-state networks, and 3) how the different subfields of the hippocampus participate in the resting state networks. Here we examined these issues using the high spatial-resolution rs-fMRI 7T dataset from the Human Connectome Project (HCP). Specifically, we analyzed the functional connectivity of the hippocampus and its subfields with the rest of the brain by means of data-driven techniques that relied on spatially restricted Independent Component Analysis (srICA). The srICA technique was used to observe hippocampal activation areas and to determine clusters of voxels within the hippocampus that become activated during the resting-state. In addition, connectivity between these hotspots and the rest of the brain was derived using the Dual Regression technique. Group-based analyses relied on linear mixed-effect group-analyses that took into account participant-specific brain morphology. Consistent with other studies, our results revealed two main activity hotspots inside the hippocampus. The first hotspot was placed in the anterior part of the hippocampus, and it was correlated with the somatomotor network. The second hotspot of activity was located from middle to posterior sections along the hippocampal long-axis, and was correlated with the DMN. In addition, we found that whereas the anterior/somatomotor network relied on activity in the CA4, DG, CA1 and CA3 subfields (and less on the subiculum), the middle-posterior/DMN network relied on activity in the CA4, DG and subiculum subfields (and less on CA1 and CA3). These results therefore clarify the precise section of the hippocampus that participates in the DMN, that the hippocampus participates in at

least two different resting-state networks, and that there are dissociations in connectivity between the CA1 and CA3 subfields on the one hand, and the subiculum on the other. Overall these results further our understanding of hippocampal functional connectivity.

Title: Frontotemporal theta multiplexing underlies memory formation in the developing brain

Authors: *E. L. JOHNSON[1], Q. YIN[2], L. TANG[2], E. ASANO[2], N. OFEN[2];
[1]Univ. of California, Berkeley, Berkeley, CA; [2]Wayne State Univ., Detroit, MI

Abstract: Neuronal oscillations are ubiquitous and associated with processes ranging from physiological to cognitive to pathological. These periodic rhythms change considerably during development. However, typical scalp EEG does not access medial brain areas directly and offers low spatial resolution of lateral areas it does access. Noninvasive EEG therefore offers a limited window into the development of cognitive processes such as declarative memory which rely on the medial temporal lobe (MTL) and its connections to specific lateral prefrontal (PFC) areas. To circumvent this issue, we capitalized on a unique opportunity to record EEG directly from the brains of pediatric neurosurgical patients (i.e., ECoG). Twenty-one children and adolescents (5.9-20.5 years) attended to visual scenes in preparation for a memory recognition test. We analyzed theta rhythms, which are consistently linked to memory processes in the MTL of adults as well as animal models, in 80 MTL channels and 357 PFC channels. After disentangling oscillatory components from aperiodic 1/f activity, we detected a faster rhythm ~7 Hz which sped up with age and a slower rhythm ~3 Hz which slowed down with age. These results reveal that: (1) recent findings of fast and slow theta rhythms in the adult MTL extend to children; (2) both rhythms are also evident in PFC; and (3) development is associated with the functional differentiation of theta oscillations. Further analyses showed that both theta oscillations support MTL-PFC functional connectivity patterns predictive of subsequent memory formation. Specifically, fast theta supported inter-regional phase coupling and slow theta supported inter-regional amplitude coupling, demonstrating that MTL and PFC interact via distinct oscillatory mechanisms during successful memory formation. These results link the functional differentiation of theta oscillations to the development of declarative memory and suggest that

multiplexed interactions between MTL and PFC underlie memory formation in the developing brain.

Title: Spiking sequences as a general organizational principle for neural activity in the human cortex

Authors: ***A. P. VAZ**[1,2,3], J. H. WITTIG, Jr.[2], S. I. INATI[2], K. A. ZAGHLOUL[2];
[1]Duke Univ. Sch. of Med., Durham, NC; [2]Natl. Inst. of Neurolog. Disorders and Stroke (NINDS), Bethesda, MD; [3]Duke Univ. Med. Scientist Training Program, Durham, NC

Abstract: The temporal dynamics of spiking activity in cortical networks are of great importance in understanding behavior, cognition, and disease states. An organizational motif, the spiking sequence, has recently been shown to be associated with memory formation and retrieval in the human cortex. However, it remains unknown how sequences may manifest in other behavioral scenarios and if spiking sequences are a general organizational principle for network level activity in the human brain. We recorded intracranial micro-LFP and single unit data in 6 participants with medically refractory epilepsy during monitoring for potential resective surgery. To accomplish this, we implanted Utah micro-electrode arrays under the subdural macro-iEEG contacts in the anterior temporal lobe of each patient. In order to examine the presence of spiking sequences across many behavioral states, we examined spiking activity from the participants during rest, memory formation and retrieval, and during distractor periods. We found that spiking sequences are present across all epochs of our data. In fact, we were able to extract an average 'backbone' sequence that was loosely adhered to across all behavioral states, and individual time periods exhibited variation around this sequence. To explicitly demonstrate the temporal and behavioral invariance of this pattern of activity, we show that the average sequence from the 5 minute resting period persists through memory tasks, distractor periods, and subsequent rest periods for up to an hour later. Our findings demonstrate that spiking sequences are a general motif for the organization of spiking activity in the human cortex. In broader terms, the existence of an average 'backbone' spiking sequence likely indicates a constrained set of neural dynamics that arise inherently from the network level synaptic structure of a given cortical column.

Title: Localized gamma EEG activity differences during cognitive testing in young adults

Authors: *M. R. FOY, J. G. FOY;
Dept. of Psychology, Loyola Marymount Univ., Los Angeles, CA

Abstract: Electroencephalograph (EEG) shows distinct patterns of activity in engaged neural networks, and may be a useful clinical biomarker. For example, the power spectral density (PSD) of the gamma frequency band is elevated during learning and working memory, and lower in patients with Alzheimer's disease. While differences in EEG activity at different scalp locations may be clinically important, an understanding of EEG activity in normal populations can also be useful. The purpose of this study was to describe spatial patterns of EEG PSD while normal young adults (n = 29) completed cognitive tests of clinical relevance (National Institutes of Health-Toolbox: NIHTB). Wireless EEG recordings from 9 scalp sensor locations (3 frontal, 3 central, 3 posterior) were collected during an eyes open resting state (RS), and three NIHTB cognitive tests. PSD for delta, theta, alpha, beta and gamma was computed following artifact decontamination and data smoothing. Here, only the statistically significant (p<.05 or less) EEG findings for PSD gamma activity (30-40 Hz) during the NIHTB picture sequence memory (PSM) test, a standardized episodic working memory task, are reported. During RS, gamma PSD was greater at the central right location (C4) compared to the parietal right site (P4) and to Cz. In both the RS and PSM test, gamma PSD at Fz was smaller compared to F3 and F4. During the PSM test, gamma PSD was greater at the three most posterior sites (P3, POz, P4) compared to RS gamma PSD at these sites (see Figure). In summary, in normal young adults, we found a discrete localization of higher gamma PSD during a cognitive test to the more posterior (parietal) scalp locations. Figure Legend: Illustrations of eyes open gamma (RS) and memory gamma (PSM) identify relative gamma PSD standardized for each event across 9 sensory sites, with proportional differences in activity highlighted in the color spectrum (1 refers to highest gamma PSD activity level; 0 to lowest gamma PSD activity level).

Abstract: The association between physiological/physical activity levels and cognitive performance was examined in 23healthy young adults (12 women/11men) with age range between 21-35 years (SD=2,7). Participants carried the Samsung Gear S3 smartwatch with multiple sensors of biometric data for a long period of 3 consecutive months. Cardiovascular activity was measured with photoplethysmogram, physical activity levels were measured with

pedometer, accelerometer and gyroscope and sleep/ wake activity with sleep tracker. Physical activity levels during waking as well as during sleep were assessed using short term energy extracted from the accelerometer and gyroscope and number of steps and distance covered using the pedometer (during waking hours only). Physiological activity was measured with indexes of long-and short term diurnal changes of heart rate variability. Finally an extensive neuropsychological battery was administered covering domains of cognition (speed of processing, working memory, sustained attention, executive function, verbal learning, verbal fluency, vocabulary). Our results showed a specific relation between physical activity measured using the accelerometer short energy during waking hours and performance in Verbal Fluency tests (Category Fluency Test and Controlled Oral Word Association Test COWAT) (General Linear Model GLM, $F_{1,15}$ =9.96, p = 0.006, η^2 = 0.39) . The same correlation was observed by using short term energy extracted from the gyroscope (GLM, $F_{1,15}$ = 8.83, p = 0.009, η^2 = 0.37), total steps using the pedometer (GLM, $F_{1,15}$ = 12.3, p = 0.003, η^2 = 0.44) and distance covered using the pedometer (GLM, $F_{1,15}$ = 12.07, p = 0.003 , η^2 = 0.44). There was a significant correlation of physiological activity measured during waking hours but not during sleep using the low and high frequency power of heart rate variability and working memory (GLM low freq, $F_{1,15}$ = 8 p = 0.012, η^2 = 0.35; high freq. $F_{1,15}$ = 8, p = 0.01, η^2 = 0.35), executive function (GLM low freq. $F_{1,15}$ = 8, p = 0.01 , η^2 =0.36, high freq. , $F_{1,15}$ = 8 p = 0.01, η^2 = 0.36) and verbal fluency (GLM, low freq. $F_{1,15}$ = 5, p = 0.038, η^2 = 0.26; high freq. $F_{1,15}$ = 5, p = 0.038, η^2 = 0.26) cognitive function. These results suggest a common underlying neurophysiological mechanism connecting physical activity and physiological reactivity and cognitive ability, especially the motor component of verbal fluency, namely the oral-motor features of word production.

Abstract: Retrieval of episodic memory hinges on the reinstatement of neural activity at initial encoding in the hippocampus. According to the indexing theory the hippocampus does not store episodic content itself but instead acts as a pointer to the information that is stored in the neocortex [1]. This pointer is thought to be represented by a sparse, distributed assembly of single units.
In search of the index, we leveraged intracranial EEG recordings to investigate the firing pattern of single neurons in the human hippocampus during encoding and retrieval of episodic memories. In total, we recorded 631 putative single neurons during a self-paced free association paradigm.
We computed the firing frequency for every single neuron during each individual trial and then determined the firing reinstatement by multiplying the firing rate for each trial during encoding and retrieval. Using a shuffling procedure, we then calculated the reinstatement expected under the null. In a second level shuffling procedure we showed that a significant number (N = 173) of single units exhibited a memory specific reinstatement of neural firing for individual episodes.
How single neurons are initially allocated as index neurons remains an open question. Here we find that indexed episodes were characterized by a decreased delta power preceding the encoding period. This is in line with literature on engram allocation in animals that suggest higher excitability being the key factor responsible for single neuron recruitment. Another potential mechanism for index formation is ripple activity. Ripples are transient high-frequency oscillations that have been linked to memory formation in humans. Here we showed an increase in both the number and length of hippocampal ripples during the encoding period.
Although proposed over three decades ago, this is the first empirical evidence of index cells in humans. We propose two candidate mechanisms through which single neurons might be allocated as index units: (1) a decrease in pre-stimulus delta activity and (2) an increased ripple activity in the hippocampal local field potential.

Title: Neurons in the human medial temporal lobe dynamically represent multiple implicit associations between objects in a map-like manner

Authors: *P. TACIKOWSKI[1,3], G. KALENDER[1], D. CILIBERTI[1], I. FRIED[1,2,4];

Abstract: Events and objects that we encounter often follow certain rules, for example, they occur cyclically, or they are organized into hierarchies. Humans have a remarkable ability to extract these sometimes complex patterns rapidly and implicitly. This type of learning plays an important adaptive role in our everyday life but the underlying brain mechanisms remain largely unknown. Here, we recorded the activity of 1009 neurons from twelve pre-surgical epilepsy patients (8 females; age: 38 ± 15 y. o.) to test the hypothesis that neurons in the human medial temporal lobe (MTL) represent an associative structure among multiple objects in a dynamic and map-like manner. For each participant, we selected six images of people that elicited selective neuronal responses in the preceding screening task and, unbeknownst to the patients, we assigned these images to different locations on an arbitrary associative pyramid graph. During learning (~ 40 min), the order of stimuli presentation was determined by the graph's structure, so that only images that shared a direct link were shown immediately one after another. Before learning (baseline) and after learning (read-out) the sequence of images was fully randomized thus in those sessions no implicit temporal structure was present. In all parts of the study, the participants performed behavioral tasks unrelated to the main research question. We found that over the course of learning, MTL neurons that initially responded to only one preferred image started responding more strongly to images that were directly linked to the preferred image on the pyramid graph. Control analyses showed that this pattern of responses was not present for neurons located outside of the MTL. Furthermore, we were able to reconstruct the structure of the associative pyramid graph from the population activity of MTL neurons. This reconstruction became more accurate with learning and the effect persisted after learning, when no implicit structure was present. Together, these findings demonstrate that the human MTL neurons dynamically change their spiking activity to represent implicit associations between multiple objects in a map-like manner.

Abstract: Critical to the survival of all animals is the detection of appetitive, neutral and aversive stimuli in the environment. Pathological valence processing, particularly altered threat evaluation and response, represents the core etiology of anxiety disorders and post-traumatic stress disorder (PTSD)]. Thus, characterizing the intracranial neural mechanisms of valence attribution is clinically relevant to the development of strategies directly targeting core anxiety-related symptoms. Here, we provide the first characterization of medial temporal lobe iEEG oscillatory dynamics across a range of emotional stimuli (negative/neutral/positive) in humans (8) with and without anxiety-related disorders (PTSD/Generalized Anxiety Disorder (GAD)). Based on prior reports in rodents and humans, we hypothesized that (i) amygdala theta and gamma power will be increased during viewing of aversive stimuli compared to positive and neutral stimuli and (ii) patients with anxiety-related disorders will have reduced oscillatory discrimination between valence categories. Results confirm these hypotheses and highlight a key role of amygdala theta power in tagging negatively charged stimuli.

Title: Hippocampal theta and gamma oscillations differentially signal surprise and uncertainty

Authors: ***D. FRANK**[1], J. SARNTHEIN[2], R. TOLEDANO[3], A. GIL-NAGEL[3], B. STRANGE[1];
[1]Univ. Politecnica de Madrid, Madrid, Spain; [2]Klinik fur Neurochirurgie, Universitatsspital Zurich, Zurich, Switzerland; [3]Hosp. Ruber Internacional, Madrid, Spain

Abstract: To adaptively encode information into memory, the hippocampus should be able to extract statistical regularities in the environment in order to form predictions about upcoming sensory inputs. Indeed, previous fMRI findings show that the anterior hippocampus tracks the expected uncertainty of an event in a given context, such that it is maximally engaged in highly uncertain conditions (Strange et al., 2005). Here we used intracranial EEG to examine the pre-

and post-stimulus temporal dynamics underlying hippocampal sensitivity to contextual uncertainty (Shannon's entropy) and surprise (a given event's improbability). Ten medication-resistant epilepsy patients, with depth electrodes implanted in the anterior hippocampus, participated in the experiment. On each trial, patients were presented with a coloured shape, and performed a match-to-sample task. Two colours and two shapes were combined to form four possible stimuli per block. In each block, there are likely and unlikely stimuli, varying surprise within-block; the entropy of stimuli varied across blocks (different probability distribution of the four stimuli in each block). Time-frequency analysis of the electrophysiological data utilized a trial-wise GLM approach, with two predictors of interest: entropy and surprise. Mean entropy over blocks was included as a covariate to model non-specific time effects. Cluster-based permutation t-tests were used for statistical inference at the group level. Consistent with previous findings, we found a positive association between surprise and hippocampal theta power (2.5-7.5 Hz) from stimulus onset until 300 ms post-stimulus. We also found a negative association between entropy and gamma power (47.5-82.5 Hz) in the pre-stimulus time window (-980 to -520 ms). Overall, these results suggest hippocampal theta oscillations signal the improbability of a given event, whereas gamma oscillations track anticipation of upcoming stimuli, with decreased synchronization in uncertain contexts.

Title: Elucidation of functional connectivity patterns of the lateral/medial mammillary body using resting-state fMRI in the human brain

Authors: *M. TANAKA[1], T. OSADA[1], A. OGAWA[1], S. HAN[1], K. KAMAGATA[2], S. AOKI[2], S. KONISHI[1];
[1]Dept. of Neurophysiol., [2]Dept. of Radiology, Juntendo university Sch. of Med., Tokyo, Japan

Abstract: The mammillary body (MB) has been thought to implement mnemonic functions. Although recent animal studies have revealed dissociable roles of the lateral and medial parts of the MB, the dissociable roles of the lateral/medial MB in the human brain is still unclear. Functional connectivity using resting-state functional magnetic resonance imaging (fMRI) provides a unique opportunity to noninvasively inspect the intricate functional organization of the human MB with a high degree of spatial resolution. The present study aimed to reveal the

dissociation between the two systems consisting of the lateral/medial MB and target regions of interest (ROIs) connected with the MB, such as the hippocampus, tegmental nuclei (TN), and anterior thalamus (AT).
Ten right-handed healthy young subjects (six men and four women;mean age, 27.0 ± 7.7 years (mean ± SD), age range, 20–39 years) participated in the experiments. Resting-state fMRI (RSfMRI) data were acquired using multiband gradient-echo echo-planar sequences with a 3-T MRI scanner (Siemens Skyra).To attain a sufficient signal-to-noise ratio in functional images with a higher spatial resolution ($1.25 \times 1.25 \times 1.25$ mm^3), each subject was highly sampled: 1,000 volumes in each of the 10 daily sessions. RSfMRI data were preprocessed using SPM8, and the temporal correlation between time-series signals of MB and those of target ROIs was calculated. After the whole MB was manually delineated using normalized functional images, the whole MB was divided into lateral and medial parts according to the anatomical structure of the past studies. The target ROIs were manually delineated using normalized functional and structural images.
RSfMRI analysis revealed a significant difference of connectivity between medial/lateral MB. The medial MB was functionally connected with the subiculum, ventral TN, and AT. On the other hand, the lateral MB was functionally connected with the pre/parasubiculum and dorsal TN. A three-way analysis of variance (ANOVA) was conducted with the region, lateral/medial MB, and left/right sides as factors; a significant interaction (subiculum or pre/parasubiculum × lateral/medial MB) was observed ($F_{(1,9)} = 27.9$, $P = 0.0005$), and a significant interaction (ventral or dorsal TN× lateral/medial MB) was observed ($F_{(1,9)} = 35.9$, $P = 0.0002$). A two-way ANOVA of AT revealed a significant main effect of the lateral/medial MB ($F_{(1,9)} = 16.3$, $P = 0.003$). The present study provides the human analog of the two extended systems that implement different functions whose underlying biological mechanism is centered in the lateral/medial MBs.

Title: Does pattern separation/ magnitude estimation operate on information recovered from remote long-term memory? Modulation of activation along the long axis of the hippocampus, parahippocampal and retrosplenial cortex during spatial distance and object size judgements.

Authors: *M. MOSCOVITCH[1], **M. ZIEGLER**[1], Z. LIU[2], J. ARSENAULT[3], C. DANG[4], C. GRADY[3], S. ROSENBAUM[5];
[1]Psychology, Univ. of Toronto, Toronto, ON, Canada; [2]Behavioral Sci., Univ. of Michigan,

Dearborn, MI; [3]Rotman Res. Inst. at Baycrest, Toronto, ON, Canada; [4]Royal Melbourne Hosp., Natl. Ageing Res. Inst., Parkville, Australia; [5]Fac. of Hlth., York Univ., Toronto, ON, Canada

Abstract: It has been proposed that pattern separation processes, mediated by the hippocampus (HC), operate on information encoded into memory to produce orthogonal memory representations for stimuli that are similar to one another (overlapping features). *Does pattern separation in HC, especially along its longitudinal axis, operate similarly on both object and spatial information retrieved from remote long-term memory?* To address this question, 24 participants were asked to make both spatial distance judgements among well-known Toronto landmarks and size judgements among well-known animals in the MRI scanner. For the spatial distance task, participants need to decide whether a cue landmark (A) was closer to 1 of 2 target landmarks (B or C). In the animal size task, participants needed to judge whether a cue animal (a) was larger in size than 1 of 2 target animals (b or c). All stimuli were displayed in words. The differential distance or size (i.e., ΔAB-ΔAC or Δab - Δac; Δ: distance/size difference between cue A/a and targets B/b or C/c) was varied from small to large across trials. This allowed us to examine not only the brain activation triggered by spatial distance and object size processing, but also how the activation can be modulated by processing different magnitudes (refineness) of the distance and size difference. We found spatial distance processing engaged HC more strongly than animal size processing. In the spatial task, the posterior HC (pHC) showed stronger activation than the anterior HC (aHC). Importantly, in the animal size processing task, the aHC and pHC activation were independent of the magnitude of the differential size differences (i.e., whether Δab and Δac are similar). However, both aHC and pHC, as well as other spatial processing network regions such as the parahippocampal and retrosplenial cortex, were activated more strongly when more refined differential distances were processed (i.e., when ΔAB is closer to ΔAC). Interestingly, aHC activation showed stronger distance dependence than pHC. We conclude (1) that pattern separation processes operate on information retrieved from remote long -term memory, more so on space than on objects ;(2) that regions of the long-axis of the hippocampus, and spatial network, are modulated differently by judgements of object size and spatial distance.

Title: Sub-acute differences in right inferior frontal gyrus activation following a mild traumatic brain injury and correlations with sleep quality

Authors: *O. Y. RAEVSKAYA[1], A. S. COTTON[1], J. MATHEW[1], R. BODDAPATI[1], A. GRAU[1], E. GIBSON[1], S. GRIDER[2], C.-H. SHIH[2], T. LEWIS[3], H. XIE[4], X. WANG[1]; [1]Psychiatry, [2]Emergency Med., [3]Radiology, [4]Neurosci., Univ. of Toledo, Toledo, OH

Abstract: Sub-acute differences in right inferior frontal gyrus activation following a mild traumatic brain injury and correlations with sleep quality Sleep deficits after mild Traumatic Brain Injury (mTBI) are common, but the underlying neurobiological mechanisms are still unclear. Increasingly, functional Magnetic Resonance Imaging (fMRI) studies suggest that mTBImayalterthe activation of brain regions associated withattention and emotionregulation. However,the relationship betweensuch changesand sleep impairments after mTBI has not been studied.To explorethat relationship, subjects (n=90, female=50)were recruited from Emergency Departments (EDs) after experiencing traumas such as motor vehicle accidents, physical assaults, or sexual assaults. Theywere assigned to either the mTBI group (n=22) or non-mTBIgroup (n=68) based on the American Congress of Rehabilitation mTBI diagnostic criteria.Not all subjects experienced a head injury.Approximately two weeks after their traumas, subjectswere administered the Pittsburg Sleep Quality Index (PSQI) questionnaire and completed the Shifted-attention Emotion Appraisal Task (SEAT) during fMRI scanning. For SEAT, subjects viewed fearful or neutral faces superimposed on indoor or outdoor scenesin three sub-tasks designed to assessimplicit emotion processing (identifying male/female faces), attentionshifting (identifying indoor/outdoor scenes), and appraisal (like/dislike the faces).The non-mTBI group had significantly greater activation associated with the appraisal of fearful and neutral faces in the right inferior frontal gyrus (rIFG;peak voxel: x=50, y=34, z=0, Z-max=4.33;cluster size=553 voxels; FWE corrected in FSL). The mean cortical activation of the rIFGcluster negatively correlated with the PSQI (r(19)=0.338, p=0.134)in the non-mTBI group, suggesting that greater activation of that region was associated with lower PSQI scores, or better sleep quality. In contrast, for the mTBI group, the correlation between rIFG activation and the PSQI was not statistically significant (r(61)=-0.265, p=0.036).The PSQI scores also did not differ significantly between the two groups (t(82)=-0.771, p=0.443). These findings suggest that mTBI may alter rIFG activation associated with implicit emotion modulation during the appraisal of fearful and neutral faces. Moreover, the fact that rIFG activation only correlated with better sleep quality in trauma survivors without mTBI suggests that mTBI may disrupt the association between the two.

Title: Frequency-specific driving of frontal cortical feedback differentially engages V1 microcircuits.

Authors: *G. BASTOS, C. G. GALLIMORE, J. P. HAMM;
Georgia State Univ., Atlanta, GA

Abstract: Temporal synchronization among distributed regions and cell types in the cortex tends to be rhythmic or oscillatory in nature. Given the diverse intrinsic properties of individual neurons and synapses, distinct neuro-oscillatory frequency bands may serve to selectively route information processing in cortical networks. That is, in cortical circuits, it may matter not only which brain regions innervate each other, but in what frequency this innervation occurs at a given time. Feedback inputs from higher level brain regions are known to modulate sensory processing in lower sensory regions in accord with context and behavioral goals. Observational work during a visual attention task suggests that this feedback may typically occupy the beta frequency range (20Hz), but it is unclear whether activity of these circuits in other frequencies (alpha or gamma) may have functional relevance. Further, given the distinct intrinsic firing rates and synaptic properties of local interneuron populations, top-down feedback may serve to differentially engage these cells depending on the frequency of activation. We aimed to test whether frequency-specific activation of prefrontal cortical (PFC) feedback inputs leads to neuron-type specific activation in primary visual cortex (V1). Here, we used simultaneous wide-field optogenetics (AAV1-viral expression of ChR2 in PFC) and fast two-photon microscopy (GCaMP6s; 28-Hz) to activate PFC axonal segments in V1 (i.e. feedback inputs) at specific frequencies (0-40Hz) while recording activation of V1 cells of awake mice (n=8) at rest. We focused on genetically targeted cell types, such as somatostatin (SST+) interneurons and pyramidal (VGlut+; PYR) cells, in layers 2-4 of cortex. Interestingly, SSTs were strongly activated when PFC inputs were driven at gamma range (40Hz), while decreasing its activation when PFC inputs were probed at theta (6Hz) through beta (20Hz). Notably, there were a subset of SST cells that did not follow these trends, suggesting variability within the SST class of interneurons. Alternatively, we found that PYRs increased their activation when PFC inputs were driven at frequencies from delta (2Hz) to beta (20Hz). This study demonstrates that the microcircuit dynamics of V1 is determined by the oscillatory profile of its feedback connections, and the cells it innervate. Given that SST interneurons and PYR cells showed a unique preferred activation bandwidth, our results indicate a frequency-dependence in the ability of PFC to route information across regions. Future work is needed to understand the effects of frequency-specific feedback input during task-relevant processing and behavior.

Title: Synchronous oscillatory neural ensembles flexibly encode inference of abstract rules in prefrontal and posterior parietal cortices

Authors: *S. TAFAZOLI, C. I. JAHN, N. T. MARKOV, C. J. MACDOWELL, T. J. BUSCHMAN;
Princeton Neurosci. Inst., Princeton Univ., Princeton, NJ

Abstract: To act intelligently in a situation, we must learn what rules to follow for that context. Then, as the situation changes, we must learn new rules. To understand the neural mechanisms of learning rules, we trained monkeys on a task that required them to learn a new attentional 'rule' on each block of trials. On each trial, monkeys chose between three random colors. They were rewarded as a function of how close their chosen color was to the current 'template color'. Importantly, the animals were not instructed as to the template color. Instead, they had to learn it through trial and error. Once the animals learned the template color, it changed abruptly (and without cuing), requiring the animal to repeatedly learn new attentional templates throughout the day. Recordings in prefrontal and parietal cortex found oscillatory synchronization of local field potentials (LFPs) between frontal and parietal areas change with learning. Immediately after a switch, there was a sharp decrease in beta-band synchrony between prefrontal and parietal cortex. This was followed by an increase in beta-band activity, as the animal discovered the new rule. These results are consistent with beta-band oscillations carrying top-down attentional signals. In contrast, synchrony in the gamma band had a sharp increase immediately after the switch, suggesting an increase in bottom-up drive. Our results build on previous work showing oscillations support rule representations and argue that these representations can develop during learning.

Title: A neural circuit mediating rat category learning

Authors: *M. B. BROSCHARD[1], J. KIM[1], B. C. LOVE[2], J. H. FREEMAN[1];
[1]Univ. of Iowa, Iowa City, IA; [2]Univ. Col. London, London, United Kingdom

Abstract: Category learning is a critical cognitive process that organizes our memories and environments into a meaningful structure that can be generalized to novel situations. Despite its

importance, the neural mechanisms mediating category learning are largely unknown. We recently adapted classic human learning paradigms to investigate categorization in rats, a model organism well-suited for leveraging key neural mechanisms. Using a touchscreen apparatus, rats are trained to categorize distributions of circular stimuli containing black and white gratings that across exemplars change in their spatial frequency and orientation. For some rats, the stimuli must be categorized according to a single stimulus dimension (1D tasks; either spatial frequency or orientation). For other rats, the stimuli must be categorized according to both dimensions (2D tasks; spatial frequency and orientation). In the current experiments, we used NMDA lesions and inhibitory DREADDs to test the necessity of the prelimbic prefrontal cortex (PL), dorsal hippocampus (HPC), dorsomedial striatum (DMS), and dorsolateral striatum (DLS) as rats learned to categorize 1D and 2D tasks. The PL was critical for learning the 1D tasks, but not the 2D tasks. The HPC and DMS were critical to learn both task types. The DLS was not necessary to learn either task type. Then, we used the neural network model SUSTAIN to simulate the inactivation data and examine the function of each target region. Simulations suggest that the PL directs attention to relevant stimulus information, the HPC stores previous training experiences, and the DMS maps exemplars to appropriate behavioral responses.

Title: Neural dynamics among the prefrontal cortex, dorsal striatum, and hippocampus during rule-based rat visual categorization

Authors: *J. KIM, M. B. BROSCHARD, S. J. FARLEY, N. S. CREMERS, J. H. FREEMAN; Univ. of Iowa, Iowa City, IA

Abstract: Visual categorization is a critical cognitive function. Quick but reliable categorization either reduces danger or increases the benefits of new stimuli and experiences. The prefrontal cortex (PFC), dorsal striatum (DS), and hippocampus (HPC) are thought to be involved in successful categorization, but how those sites interact during category learning has not been determined. Here, we conducted simultaneous multi-tetrode recordings from the PFC, DS, and HPC while rats learned a rule-based categorization task in which Gabor patches differ in spatial frequency and orientation. Both single unit activity and local field potentials (LFP) were recorded throughout training. Single cell spiking activity from all three sites showed stronger category-specific modulation after rats learned the task. The category-specific firing, however, differed in time when the rat processed the category stimuli: PFC cells showed the earliest category-specificity while the other two regions tended to lag behind. Spectral power analyses

showed a similar category-specificity in specific power frequencies of LFPs. Category selectivity in theta power (4 - 10 Hz) in the three regions became differentiated once the rat learned the task. In the HPC, beta (15 - 20 Hz) power also showed learning-driven category-specificity. More direct comparisons of firing patterns of single units or oscillatory patterns of the LFPs were conducted to build similarity matrices by categories. After category learning, similarity matrices became more similar within-categories, while they become more dissimilar between-categories, indicating that all three sites show category-specific neural modulations. Functional connectivity analyses showed that coherence patterns elongated in both time and frequency became very well localized after the learning. Complimentary computational modeling and machine learning also supported learning-driven category-specific neural modulations of three sites. The findings indicate that interactions among the PFC, DS, and HPC strengthen as rats learn categories.

Title: Disynaptic, VTA-mediated, cerebellar modulation of the prefrontal cortex

Authors: *J. A. VERA[1], M. OÑATE[1], C. CHEN[2], N. CAYLA[1], V. LOVALLO[1], K. KHODAKHAH[3];

Abstract: The cerebellum (Cb) has been associated with cognitive disorders that potentially affect the medial prefrontal cortex (mPFC), such as schizophrenia and autism. However, how the cerebellum affects the mPFC remains to be established. The mPFC is thought to be involved in decision-making processes that guide behavior based on predicted outcomes. The ventral tegmental area (VTA) is a key region of the brain reward system that provides reward-related signals to the mPFC via dopaminergic projections. We have recently shown that the Cb sends direct excitatory projections to the VTA, raising the possibility that there might be a disynaptic pathway from the Cb to the mPFC via the VTA. Here we describe experiments aimed at delineate the anatomical and functional properties of the Cb->VTA->mPFC circuit in the mouse brain. Using intersectional tracing, we found that ~50% of VTA neurons that receive inputs from the Cb also send direct synaptic projections to the mPFC, confirming the presence of this disynaptic circuit. Using in vivo recordings in head-fixed awake mice, we found that optogenetic stimulation of Cb axons in the VTA excites mPFC cells within a fast time scale (average latency of 31.9 ± 13 ms). Moreover, by using fiber photometry we show that optogenetic activation of

Cb axons in the VTA releases dopamine in the mPFC, supporting the functional connectivity of the proposed circuit. These results show that the cerebellum might have a direct contribution to cortical dopamine levels, pointing to dopamine deregulation as a possible link between cerebellar dysfunction and mental disorders.

Title: Molecular and circuit level modulation of flexibility: Understanding the effects of PAE on reversal learning

Authors: *J. CHANDRASEKARAN[1], J. KENTON[2], *C. VALENZUELA[1], J. L. BRIGMAN[1]; [1]Dept. of Neurosci., Univ. of New Mexico, Albuquerque, NM; [2]Univ. of San Diego, San Diego, CA

Abstract: Across species moderate prenatal alcohol exposure (PAE) is known to impair executive functioning specifically behavioral flexibility. Thus, understanding the mechanisms responsible for mediating cognitive flexibility is of critical importance in developing successful treatments for individuals with cognitive impairment. Studies in rodent models show that the dorsal striatum (dS) is heavily engaged during choice learning while the lateral orbitofrontal (OFC) cortex is important for tracking and updating changing reward values. In addition, NMDAR subunits 2A, 2B have been suggested to act as a gate for synaptic plasticity during learning experiences. While we have shown that loss of cortical 2B is sufficient to impair flexibility, it is still unknown is if the 2A/2B ratio varies during stages of learning and reversal. We therefore investigated if dynamic regulation of the GluN2A/2B ratio in the synapse is critical for efficient learning, flexibility during reversal. C57BL/6J were trained on a touchscreen based discrimination-reversal task. Using immunoblotting we quantified the levels of 2A, 2B, N1 after the criterion for various stages of learning and reversal was reached. In an attempt to rescue the inflexibility following PAE, a separate cohort was trained, micro infused with channelrhodopsin-expressing adeno-associated virus (AAV-CAMKαII-ChR2 (H134R)-mCherry), fitted with fiber stub for optogenetic stimulation. After 4 weeks, during reversal sessions 1-4 PAE/SAC mice received light pulses (10 Hz, 5mW, 5ms pulse for 1s) or no stimulation, 1 second following a correct choice. We then used retrograde expression of ChR2 in the dS to tag OFC-dS projection neurons and test if stimulation of these neurons was sufficient to restore flexibility. NMDAR subunit quantification revealed a striking trend in increase in the 2B subunit in the OFC during early reversal stage, increase in the dS when the mice have learned to discriminate, during which

plasticity changes are important in these two regions. Direct stimulation of OFC reduced average perseverative responding in PAE mice compared to controls. Stimulation of just the projection neurons not only improved the flexibility in PAE mice but also in SAC controls which received stimulation. These data provide evidence that NMDAR subunit expression is dynamically regulated, stimulation of specific populations of cortical neurons may reduce the impaired flexibility seen after PAE. Current studies, by combining in vivo electrophysiology and optogenetics, are examining if this direct stimulation of OFC-dS projection neurons was sufficient to restore behavioral flexibility and coherence within the OFC.

Title: Muscarinic acetylcholine receptor localization on distinct excitatory and inhibitory neurons within the ACC and LPFC of the rhesus monkey

Authors: *A. TSOLIAS[1], W. CHANG[1], T. GUILLAMON-VIVANCOS[2], C. KOPP[1], S. BUSCH[3], J. I. LUEBKE[1], M. MEDALLA[1];

Abstract: The lateral prefrontal (LPFC) and the anterior cingulate cortex (ACC) are two functionally-distinct prefrontal areas that are differentially innervated by ascending cholinergic pathways that modulate arousal and motivational signaling in higher-order functions. The nature and organization of prefrontal-cholinergic circuits in primates are not well understood although it is clear that muscarinic acetylcholine receptors (mAChRs) play a predominant role. Using multi-labeling immunohistochemistry and high-resolution microscopy, we assessed the co-localization of m1 and m2 mAChRs with distinct excitatory and inhibitory neuronal populations and pre-synaptic markers in the brains of rhesus monkeys. Our findings showed that 50-57% of either m1+ or m2+ neurons in supragranular layers 2-3 (L2-L3) of ACC and LPFC are excitatory pyramidal neurons, and the rest are non-pyramidal interneurons. However, within pyramidal neuron subpopulations expressing specific cytoskeletal proteins, MAP2+ and SMI32+, LPFC had significantly ($p<.05$) greater densities of m1+/MAP2+ and m2+/SMI32+ neurons compared to ACC. Distinct inhibitory neuron classes also showed regional diversity in mAChR expression; the density of m2+ calretinin-interneurons was significantly greater in ACC and m1+ and m2+ parvalbumin interneurons were significantly greater in LPFC, specifically in L3. The functional

effect of mAChRs strongly depend on synaptic localization. Compared to LPFC, ACC exhibited a greater proportion of excitatory (VGLUT1+) axon terminals with presynaptic m2+. The distribution of m2+ on inhibitory (VGAT+) axon terminals targeting specific pyramidal neuron compartments varied between the two areas. Compared to ACC, LPFC exhibited significantly greater m2+ colocalization on axo-axonal VGAT+ cartridges, and VGAT+ terminals targeting MAP2+ dendrites. However, the density of perisomatic m2+/VGAT+ inputs specifically on SMI32+ pyramidal neurons was greater in ACC than LPFC. To test the functional effects of muscarinic activation on excitatory and inhibitory postsynaptic currents (EPSCs and IPSCs), we used in vitro whole-cell patch-clamp recording from L3 pyramidal neurons. The cholinergic agonist, carbachol (CCh), significantly decreased the frequency of EPSCs in ACC and LPFC pyramidal cells, but decreased the frequency and prolonged decay times of IPSCs to a greater degree in LPFC, suggesting stronger muscarinic suppression of inhibitory inputs in LPFC than in ACC. Together, these findings contribute to our understanding of cholinergic neuromodulation of specific cell types in functionally-distinct prefrontal areas that underlie executive function.

Title: Relationship between alcohol misuse, gaba:glutamate/glutamine ratios in dorsolateral prefrontal cortex, and habitual behavior in adulthood

Authors: *E. VIDRASCU, S. DOVE, X. ZONG, R. CORR, K. MEYER, M. ROBERTSON, M. SHERIDAN, D. ROBINSON, C. BOETTIGER;
Univ. of Chapel Hill, Chapel Hill, NC

Abstract: Purpose: Excessive alcohol intake blunts gamma-aminobutyric acid (GABA) signaling and upregulates excitatory glutamate signaling, disrupting excitatory/inhibitory (E/I) balance. This misuse of alcohol by excessive consumption puts individuals at increased risk of adverse health consequences. Both acute and chronic alcohol use in humans has been shown to cause deficits in executive functioning that requires the prefrontal cortex. Moreover, data from rodent models show that binge ethanol exposure results in persistent loss of GABAergic neurons in prefrontal cortex. However, it is unknown how adult alcohol misuse impacts E/I balance in the human prefrontal cortex and what effect this has on habitual behavior. We addressed this question using a behavioral flexibility task and single-voxel proton magnetic resonance spectroscopy (^{1}H-MRS) to detect GABA and glutamate/glutamine (Glx) within the left

dorsolateral prefrontal cortex (DLPFC) of adults. Methods: We recruited healthy adult participants (22-38 years; mean=27) who reported either a history of adolescent binge drinking (ABD; n=10, 6 females) or no adolescent binge drinking (CON; n=15, 9 females). We used perseverative errors as a proxy of habitual behavior, which was measured using the Hidden Association Between Images Task (HABIT; described in McKim 2016). Adult alcohol misuse was calculated based on pattern of drinking, adapted from Townshend & Duka's binge score (2005). We conducted ^{1}H-MRS on a Siemens 3T MRI system using water-suppression with J-difference spectral editing to detect GABA and glutamate/glutamine (Glx). A T1-weighted structural image was used to correct for gray matter fraction within the voxel. We used hierarchical regression analysis to assess whether current adult alcohol use predicts levels of GABA, Glx, or GABA/Glx ratio, and whether any of these levels predict habitual behavior. Results: Controlling for a history of adolescent binge drinking, adult alcohol misuse predicted significantly lower GABA/Glx in the DLPFC (β=-.482, p=.048). Alcohol misuse did not predict individual variance in GABA or Glx levels. Additionally, DLPFC GABA/Glx ratio predicted habitual behavior (β=-.440, p=.038). Conclusions: Our results indicate that alcohol misuse in adulthood is associated with reduced GABA/Glx ratios in human DLPFC. Furthermore, reduced DLPFC GABA/Glx ratio is associated with habitual behavior. These results suggest that alcohol misuse disrupts E/I in the DLPFC, which further impairs executive function.

Abstract: Running influences the genus Homo (Bramble and Lieberman, Nature 2004), and is one of the most popular exercises worldwide. Much evidence supports that running has a beneficial effect not only on the body, but also on the brain. In recent studies including our own, physical exercise that enhances positive mood has been reported to stimulate the left dorsolateral

prefrontal cortex (l-DLPFC), which improves executive function (Byun et al., NeuroImage 2014, Suwabe et al., Neuroscience 2020). Many of these studies have used cycling as a popular and easy exercise, but no study has investigated the neuronal substrate with which running enhances executive function, even though running may be a beneficial mode of exercise for the brain. The present study aimed to determine the acute effect of a single bout of moderate-intensity running on mood and executive function. We hypothesized that running would have a beneficial effect on executive function by enhancing mood-related prefrontal activation. Twenty-six healthy participants (8 females; age 23.12 $\pm$ 2.12 years) completed both a 10-minute running session on a treadmill at 50%VO_{2peak} and a resting control session in random order. Stroop interference time from the Color-word matching Stroop task (CWST) and mood based on the Two-Dimensional Mood Scale were measured before and after both sessions; additionally, functional near-infrared spectroscopy (fNIRS) was used to investigate prefrontal hemodynamic changes while performing the CWST. The results corresponded to our hypothesis in that running significantly enhances positive mood compared to control, and in particular revealed pleasure levels not observed in our previous cycling studies ($p < 0.001$, paired *t*-test; Byun et al., NeuroImage 2014, Suwabe et al., Neuroscience 2020). Running also led to a significantly greater reduction of Stroop interference time ($p = 0.002$, paired *t*-test) coinciding with a significant increase of Oxy-Hb signal in the l-DLPFC ($p = 0.001$, paired *t*-test, FDR correction). A new finding revealed activation in the right ventrolateral prefrontal cortex (r-VLPFC), an important brain locus for emotional regulation (Wager et al., Neuron 2008), which was significantly greater than that of control ($p = 0.007$, paired *t*-test, FDR correction). The coincidence frequency between r-VLPFC activation and positive mood was subsequently checked and the results showed significant coincidence ($p = 0.001$, McNemar test). This is the first study to report that 10 minutes of moderate-intensity running has a strong beneficial effect on inducing positive mood and enhancing executive function coincidentally with specific sub-regional prefrontal activation.

Title: Effect of clinical sensory organization test on prefrontal cortical activation among older women with and without osteoarthritis

Authors: *A. BISHNOI, Y. HU, M. HERNANDEZ;
Univ. of Illinois at Urbana-Champaign, Urbana, IL

Abstract: Osteoarthritis (OA) is a musculoskeletal condition that has been associated with a higher risk of fall. However, the underlying mechanisms that result in balance and gait changes and potential contributions from cognitive processes remain unclear. An individual's posture relies on visual, vestibular, and proprioceptive senses to maintain a stable upright posture, but if this is altered as per aging or due to disease, it increases the fall risk of an individual. This is in part due to a decline in neuromuscular functioning and reduced cognitive and visuospatial processing abilities. Although osteoarthritis is known to lead to functional changes in daily activities, however, little is known about the effect of OA on brain activation. This is the first study examining the effect of sensory organization test (SOT) on prefrontal cortical (PFC) activation patterns evaluated by functional near infrared spectroscopy (fNIRS) among older women with and without osteoarthritis (OA, HOA, respectively). We hypothesize that there will be increase in activation going from the easiest to most difficult SOT condition among HOA and OA. In a cross-sectional study design, we examined 7 OA (66.33±3.64yrs; WS:3.74; BMI:27.84) and 12 HOA (67.25±6.51yrs; WS:0.35; BMI:21.83). There were significant differences between OA and HOA in BMI and Womac pain score (WS) ($p<0.001$). Participants completed baseline cognitive and motor testing before starting the SOT on Neurocom Clinical Research System. In SOT, participants completed 3 trials each of 6 conditions: Eyes open (EO), Eyes closed (EYC), Eyes open sway reference moving (EYO_SR), Eyes open plate reference moving (EYO_PR), Eyes closed plate reference moving (EYC_PR), Eyes open sway and plate reference moving (EYO_SPR). They were instructed to stand upright on the force plate while experiencing different perturbations throughout the test. The results of the linear mixed model analysis revealed condition (CND) ($p<0.001$) and trial (TR) ($p<0.0001$) effects, and 2-way interactions among CND*TR ($p<0.01$) and Cohort*CND ($p<0.01$) and a 3-way interaction between Cohort, CND & TR ($p<0.0001$). In addition, post hoc analysis confirmed these interactions between CND*TR, Cohort*CND and Cohort*CND*TR. We found significantly higher PFC activation i.e. higher mean oxyhemoglobin & lower mean deoxyhemoglobin levels among both cohorts while going from easier to difficult task. This study confirms the use of increased attentional resources in the PFC as sensory disturbances increase and suggests an inability of older women with OA to recruit additional attentional resources, which merits further exploration. Keywords: fNIRS, PFC, OA, SOT.

Title: Fluoxetine administration during adolescence impacts rodent cognition and behavior

Authors: *J. S. RODEFER[1], A. GRIGGS[2], D. AGUDELO[2];
[1]Neurosci. & Psychology, [2]Neurosci., Mercer Univ., Macon, GA

Abstract: Recent epidemiological data suggest that approximately 5-10% of adolescent children are diagnosed with major depressive disorder. In addition, problems related to adolescent depression are well documented to continue into adulthood. Existing treatment regimens for adolescent major depressive disorder include both talk therapy and drug therapy using fluoxetine (Prozac), with fluoxetine being the only drug currently approved by the US Food and Drug Administration for the treatment of depression in adolescents. Yet long term effects of adolescent fluoxetine treatment have only recently begun to be studied. Given that central nervous system growth and maturation continues throughout adolescence and into early adulthood, the effects of fluoxetine treatment on developing neurocircuitry and behaviors is unclear. The goals of these experiments were to examine the long term effects of adolescent fluoxetine treatment and compare those data to adult animals treated with fluoxetine in a rodent model of behavior and cognition. Male and female rats that were obtained from commercial sources (Envigio) were used as subjects in these experiments. These experiments used a 2 (age) x 2 (drug treatment) factorial design, with about 10-12 animals in each of the 4 experimental groups (adolescent+fluoxetine; adolescent+vehicle; adult+fluoxetine; adult+vehicle). Animals were administered 10 mg/kg of fluoxetine hydrochloride (Toronto Research Chemicals), or vehicle, for 14 days either during adolescence or adulthood. Afterwards during adulthood, all animals experienced a series of behavioral and cognitive tasks that assessed locomotor behavior in an open field, memory for novel objects after a short delay period, and behavior in an elevated zero-maze, which is a well validated task to assess anxiety-like behavior. Our hypotheses were that fluoxetine treatment during adolescence, but not adulthood, would be more likely to impact those behaviors more closely related to symptoms observed during major depressive disorder (anxiety, cognition). Data from these experiments suggested that adolescent fluoxetine dosing produced sex-selective effects on measures of cognition, exploratory, and anxiety-like behaviors. Taken together, these results may suggest that drugs like fluoxetine that alter serotonergic activity may produce functional changes in aspects of behavior and cognition during adolescence.

Abstract: According to the World Health Organization obesity worldwide has tripled since 1975. Not only adults have been affected with this obesity epidemic; in 2019, 38 million children and adolescents were overweight or obese. In addition to its association with chronic diseases like hypertension and diabetes, obesity affects neurocognitive features including learning and memory. To assess the effects of juvenile obesity on hippocampal function, we used a model of diet induced obesity in male Wistar rats. Rats were exposed after weaning to a regular diet (control group, 2.9Kcal/g) or a high-fat diet (HFD group, 4.7Kcal/g) for 3 months thus covering adolescence. HFD induced increased basal glucose blood levels, diminished glucose tolerance and insulin insensitivity. Once completed the diet exposure time, rats were implanted with microdialysis guide cannulae in the ventral hippocampus. While rats from both groups were submitted to an exploration task, we collected 4 minutes samples to assess catecholamines, glutamate and GABA. We found that in control rats norephinephrine release increased during exploration, and this increment was absent on the HFD group despite having similar exploration times. No significant differences between groups were observed regarding the other neurotransmitters. To further evaluate the effect of the HFD on the hippocampus, rats were trained in the Morris water maze (WM) and during the long-term test we found that HFD group showed an impaired performance taking significantly more time to reach the platform area. This impairment in hippocampal dependent long-term memory could be due to the dysregulation of norepinephrine transmission.

Title: Establishment of conditioned place avoidance induced by gastric malaise requires the functional integrity of dorsal and ventral hipocampus

Authors: *A. HERNANDEZ-MATIAS[1], L. A. CRUZ-GARCÍA[2], F. BERMUDEZ-RATTONI[2], D. OSORIO-GÓMEZ[1];
[1]Neurociencia Cognitiva, Inst. De Fisiologia Celular - UNAM, Mexico City, Mexico;
[2]Neurociencia Cognitiva, Inst. de Fisiología Celular - UNAM, Mexico City, Mexico

Abstract: Literature concerning learning and memory is based on several studies of the hippocampus, a brain structure necessary for the formation and expression of episodic memories. The hippocampus has well delimited areas and its level of organization has promoted specific regional analyses. Thus, in the hippocampus, a dorsal and a ventral portion can be distinguished. Traditionally, the dorsal area has been thought to mainly contribute to spatial or contextual information processing, while the ventral hippocampus is considered a critical region related to the codification of the emotional content, specifically stressful or anxiety-related situations. However, there are scarce results about the functional role of the hippocampal regions on conditioned place avoidance induced by gastric malaise. Therefore, we aimed to determine the role of dorsal and ventral subregions of the hippocampus in the association of a context with aversive stimulation provided by gastric malaise, first by means of general inactivation and subsequently through blockade of specific receptors. For this purpose, male Wistar rats were trained in a protocol of Conditioned Place Avoidance (CPA) in which the animals received intraperitoneal injections of lithium chloride and then were confined in a compartment. In another set of experiments, dorsal or ventral portions of the hippocampus were inactivated by the administration of a mixture of muscimol and baclofen applied before the conditioning. Finally, we assessed the dependence of CPA on the NMDA receptors infusing APV within the ventral or dorsal regions before and after the conditioning. Our results indicate that LiCl promotes conditioned place avoidance to the compartment associated with the injection. Furthermore and interestingly, the inactivation of either dorsal or ventral hippocampus led to a memory impairment for the task. Moreover, we provide evidence that NMDA receptors are necessary for consolidation, but not acquisition, of CPA. Considering these results, it is proposed that contextual memories associated to gastric malaise are driven by both portions of the hippocampus, suggesting a joint activity of dorsal and ventral subregions through NMDA receptors activity.

Title: A novel non-toxic histone deacetylase inhibitor enhances spatial memory consolidation in male mice

Authors: *S. B. BEAMISH[1], J. B. BELAYET[2], T. RAHMAN[2], M. RAHAMAN[2], S. ALANANI[3], M. M. HOSSAIN[2], D. A. STEEBER[3], K. M. FRICK[1];
[1]Psychology, [2]Chem. & Biochem., [3]Biol. Sci., Univ. of Wisconsin-Milwaukee, Milwaukee, WI

Abstract: Memory dysfunction is a hallmark of Alzheimer's disease (AD) and other dementias, yet truly effective treatments for memory loss do not exist. Memory dysfunction stems in part from reduced gene expression that leads to decreased levels of proteins essential for neural plasticity. Gene expression is facilitated by histone acetylation, an epigenetic mechanism that regulates chromatin accessibility. Compounds that maintain histone acetylation, called histone deacetylase inhibitors (HDACi), enhance memory by preventing deacetylation of core histone proteins, which allows for transcriptional machinery to bind open chromatin and increase gene expression. Although HDACi are promising therapeutics that could be used to prevent or delay memory loss associated with AD and other dementias, existing HDACi have poor solubility and undesirable toxicity. To address these shortcomings, our group has developed a novel HDACi compound, MJM-1, that is brain-penetrant and shows no evidence of toxicity. Here, we determine the extent to which MJM-1 can enhance spatial and object recognition memory consolidation. Male C57BL/6 mice were tested in object placement (OP) and object recognition (OR) tasks, which were used to assess spatial and object recognition memory consolidation, respectively. Mice received a post-training intraperitoneal (i.p.) injection of either negative control (100% DMSO), positive HDACi control (sodium butyrate; 0.6 g/kg NaBu), or one of three doses of MJM-1 (20, 30, or 40 μg/g). During testing, one training object was moved to a new location in the open field (OP task) or was replaced with a novel object (OR task). Mice who remember the training objects should spend more time with the moved and/or novel objects. Mice receiving NaBu, 20 μg/g MJM-1, or 40 μg/g MJM-1 spent significantly more time with the moved object, whereas DMSO-treated controls mice did not, suggesting that the established HDACi NaBu and two doses of the novel HDACi MJM-1 enhanced spatial memory consolidation. Mice receiving the 30 μg/g dose of MJM-1 also tended to prefer the moved object. Conversely, none of the doses of MJM-1 affected object recognition memory. The novel non-toxic brain penetrant HDACi MJM-1 can enhance spatial memory consolidation, suggesting encouraging proof of principle for future testing in models of aging and AD.

Abstract: Treatments for stress-related psychiatric disorders are inadequate. Behavioral therapies such as exposure therapy can be effective in ameliorating cognitive dysfunction associated with post-traumatic stress disorder and depression. We have recently established extinction learning in rats as a behavioral intervention that models the beneficial effects of exposure on cognition. In our recent studies, we have shown that extinction used as an intervention in rats, reverses chronic stress-induced deficits in cognitive flexibility on the attentional set-shifting test (AST), a medial prefrontal cortically-mediated executive process. Extinction requires the activity of pyramidal neurons in the infralimbic cortex, and Brain Derived Neurotrophic Factor (BDNF) signaling mediates these effects. The combined use of psychotherapy and pharmacotherapy may be more effective than either alone. Since extinction shares BDNF-mediated molecular mechanisms exerted by ketamine, we reasoned that extinction and ketamine used in combination will have enhanced efficacy. Methods: In these studies, we developed a model of sub-effective extinction therapy in rats that showed impairment in two readouts of prefrontal cortex function, AST and evoked local field potentials in the infralimbic cortex, following chronic unpredictable stress. Results: We found that reducing the duration of extinction attenuated its therapeutic effects on set shifting performance and activity of the infralimbic cortex in Sprague-Dawley rats after stress ($n=6$-9/group, $p<0.01$, $d=1.87$). We then established sub-effective doses of ketamine on the same measures of cognition and electrophysiology. Combining sub-effective extinction with a sub-effective dose of ketamine (1mg/kg) reversed the effects of stress on set shifting ($n=5$-11/group, $p<0.01$, $d=2.27$). Conclusions: We have developed a model to study adjunct treatment combining extinction and candidate drug therapies such as ketamine. Ongoing experiments will be conducted to determine the effects of the combined extinction plus ketamine treatment in female rats. Title: Role of serotonin in the memory impairment caused by food deprivation in Aplysia

Authors: *X. DENG[1], I.-S. HUANG[3,2], K. WILLIAMS[1], M. WAINWRIGHT[1], P. V. ZIMBA[2], R. MOZZACHIODI[1];

Abstract: Brain dysfunctions including memory deficits are caused by malnutrition. The mollusk *Aplysia* can be a suitable model for study of memory deficits raised from starvation because of its quantifiable behaviors, simple neural circuits and its ability to sustain long-term food deprivation without health deterioration (e.g., Kandel, 2001; Mac Leod et al., 2018). The mechanisms of an elementary form of learned fear known as sensitization have been extensively studied in *Aplysia* (e.g., Kandel, 2001). In normally-fed *Aplysia* (i.e., animals fed every two days, 2DFD), four strong electrical shocks to the body wall, mimicking attacks of a predator, induce long-term sensitization (LTS), which is exhibited as increased duration of defensive responses, including the tail-induced siphon withdrawal reflex (TSWR), 24 h after delivery of the shocks (Kandel, 2001). Serotonin (5-HT) is known to contribute to LTS in *Aplysia* (e.g., Kandel, 2001). Following shocks, 5-HT is released both in the neuropil and in the hemolymph (Glanzman et al., 1989; Levenson et al., 1999). LTS can be induced by 5-HT bath application without electrical shocks (Levenson et al., 2000). Fourteen days of food deprivation (14DFD) prevent LTS (Mac Leod et al., 2018). This study aimed to investigate the role of 5-HT in the absence of LTS in food deprived *Aplysia*. We hypothesize that 1) 5-HT levels may be reduced by 14DFD and 2) 5-HT bath application may rescue the prevented LTS in food deprived *Aplysia*. To investigate the first hypothesis, high-performance liquid chromatography with triple quadrupole mass spectrometer (HPLC-MS/MS) was used to detect 5-HT level in *Aplysia*. 5-HT concentrations in ganglia and hemolymph were measured and compared between the 2DFD and 14DFD *Aplysia*. 5-HT was significantly reduced in the hemolymph of 14DFD animals compared to 2DFD animals, whereas there was no significant difference in 5-HT levels in the ganglia between the two groups. To test the second hypothesis, four groups of animals were investigated: 2DFD *Aplysia* treated with 5-HT, 2DFD *Aplysia* treated with artificial seawater (ASW, vehicle solution to dissolve 5-HT), 14DFD *Aplysia* bathed with 5-HT and 14DFD *Aplysia* bathed with ASW. TSWR duration was measured prior to and 24 h after the treatment with either ASW or 500 µM 5-HT for 1.5 h. 5-HT induced LTS in both 14DFD and 2DFD animals. However, the amount of LTS was significantly smaller in 14DFD *Aplysia* compared to the 2DFD *Aplysia*, indicating that 5-HT alone was not sufficient to fully recover the memory deficits caused by 14DFD. Altogether, the above data suggest that shortage of 5-HT may be one of the causes that lead to the memory impairment caused by prolonged food deprivation in *Aplysia*.

Title: Involvement of protein phosphatase 1 in conditioned inhibition-related reductions in excitability of Hermissenda type B photoreceptors

Authors: ***J. B. ANDERSON**[1,2], J. CAVALLO[2], J. FARLEY[1,2];
[1]Psychological and Brain Sci., [2]Neurosci., Indiana Univ., Bloomington, IN

Abstract: Explicitly unpaired (EU) presentations of light and rotation produce behavioral changes (e.g., increased phototaxis) in the sea snail Hermissenda crassicornis that satisfy the behavioral criteria for conditioned inhibition (CI) learning. This is accompanied by decreased excitability of type B photoreceptors (B cells) due to corresponding increases in potassium (K^+) currents. We've previously shown that protein phosphatase 1 (PP1) inhibitors (e.g., Calyculin A): 1) depolarize Untrained B cells and reduce somatic K^+ currents, partially mimicking the effects of associative conditioning (light - rotation pairings), 2) contribute to the excitability (spike frequency) decreases produced by extinction training (a form of learning that overlaps mechanistically with EU conditioning). Conversely, injection of catalytically-active PP1 (caPP1) into Untrained B cells partially mimicked the spike frequency declines produced by extinction training, and occluded further reductions in spiking by additional extinction training. Thus, we hypothesized that PP1 activity may also contribute to EU-training effects on B cells. To test this, we measured B cell photoresponses from Untrained and EU-trained animals following treatment with caPP1. B cells showed marked reductions in steady state generator potentials (SSGPs) and spike frequencies over the course of five 30-sec test lights, mimicking EU training. Prior EU training occludes the effects of caPP1 injection. Additional measurements showed that caPP1 increased both the transient (I_A) and delayed ($I_{K\text{-}Ca}$) components of K^+ current, previously shown to mediate the EU-related decrease in B cell excitability. We next injected B cells from Untrained and EU-trained animals with the core peptide fragment of the PP1 regulatory G subunit (G_M), which acts as a competitive inhibitor of PP1. Iontophoresis of 25uM G_M increased B cell SSGPs from untrained (19.5%; n.s.) and EU-trained (52.7%; p=0.0167) animals. Whereas EU training resulted in a 40.0% reduction in B cell SSGP ($P<0.001$), SSGPs of G_M treated B cells from EU-trained animals were indistinguishable from untreated B cells from Untrained animals. Thus, G_M treatment abolished the EU-related decrease in B cell excitability. Our results suggest that: 1) upregulation of PP1 activity is an important component of the EU-mediated decrease in B cell SSGP, 2) PP1 is constitutively active in B cells of Untrained animals. These data indicate that EU training increases PP1 activity in B cells, decreasing excitability through effects on downstream K^+ currents.

Title: Quantitative description of the dynamic interactions among kinase cascades underlying long-term neuronal plasticity of Aplysia sensory neurons

Authors: *Y. ZHANG, P. SMOLEN, L. CLEARY, J. BYRNE;
Neurobio. & Anat., McGovern Med. Sch. of UTHSC At Houston, Houston, TX

Abstract: Protein kinase A (PKA) and mitogen-activated protein kinase (MAPK) pathways are critical components of a molecular network underlying serotonin (5-HT) - induced long-term synaptic facilitation (LTF) of the *Aplysia* sensorimotor synapse and long-term enhancement of sensory neuron intrinsic excitability (LTEE). Nevertheless, the details of how these pathways interact and contribute to the temporal patterns of activity of these and other kinase pathways remain unclear. In this study, we used immunofluorescence analysis to measure the activities of PKA and three key components of MAPK cascades after a single brief treatment with 5-HT in the presence and absence of kinase inhibitors. The MAPK cascade components were extracellular signal-regulated kinase (ERK), p38 mitogen-activated protein kinase (p38 MAPK), and p90 ribosomal S6 kinase (RSK). Dishes of SNs cultured from the same animals were paired for all the 5-HT treatments. One dish received a solution consisting of 50% isotonic L15 and 50% artificial seawater (L15-ASW) as vehicle control (Veh). The other received the same solution with the addition of 5 HT. At least five animals were used in each experiment. All experiments were performed in a blind manner so that the investigator analyzing the images was unaware of the treatment the SNs received. The results suggest that one pulse of 5-HT induced substantially different dynamics of PKA, ERK, p38 MAPK and RSK activation. The PKA inhibitors KT5720 and Rp-cAMP blocked activation of ERK and RSK. The blocks occurred at distinct time points after 5-HT, indicating temporally restricted roles for PKA in regulating the dynamics of activation of ERK and RSK. BI-D1870, a specific
inhibitor of RSK, blocked the delayed (~45 min) activation of p38 MAPK, suggesting a novel activation of p38 MAPK by the ERK/RSK pathway in *Aplysia*. Empirical data from this and previous studies, including engagement of MAPK by the growth factors *Aplysia* neurotrophin (NT) and transforming growth factor-β (TGF-β) that are critical for LTF, were incorporated into a computational model. The model simulated the temporal patterns of ERK activity produced by training procedures that induce long-term memory and made predictions. The model represents the most detailed quantitative description of the complex interactions in *Aplysia* sensory neurons among PKA pathways, MAPK pathways and the neurotrophin and TGF-β extracellular loops

necessary for LTF and LTEE.

Title: The multiple look effect enhances the cutaneous rabbit illusion

Authors: *D. YOSHIOKA[1], M. MIYAZAKI[2,1];
[1]Grad. Sch. of Sci. and Technol., [2]Dept. of Computer Science, Fac. of Informatics, Shizuoka Univ., Hamamatsu, Japan

Abstract: The cutaneous rabbit illusion is a phenomenon that reveals "postdiction." For example, when two successive tactile stimuli, S1 and S2, are delivered to two locations on the forearm (e.g., the sides of the wrist and elbow) with a short inter-stimulus interval (ISI) such as < 100 ms, S1 and S2 are perceived at the locations as attracted to each other. Here, it should be noted that the relatively future event S2 affects the perception of the past event, S1. Goldreich (2007) proposed a Bayesian model of cutaneous rabbit illusion. According to this model, if decreasing uncertainty of the ISI between S1 and S2, the amplitude of the cutaneous rabbit illusion should increase. To verify the theoretical predictions, we focused on the following psychophysical phenomenon. After exposure to repeated stimuli with a constant ISI, participants can more accurately detect the deviation of stimulus timing from the constant ISI (multiple-look effect, Schulze 1989). Thus, the multiple look effect is a phenomenon that increases accuracy (i.e., decreases uncertainty) in the discrimination of stimulus intervals. The multiple-look effect increases as the number of repetitions of prior stimuli increases. Based on the Bayesian model and the multiple look effect, we hypothesized that a repetition of S1 prior to S2 with a coherent ISI would increase the amplitude of the cutaneous rabbit illusion. Eight volunteers participated in our experiments. We set four conditions of repetitions of S1 prior to S2: (1) S1 only, (2) S1-S2, (3) S1-S1-S2, and (4) S1-S1-S1-S1-S2. We used 60 ms for the ISI between S1 and S2 as well as among S1s. Results show that, as the number of repetitions of S1 increased, the perceived location of the last S1 was closer to the S2 location, which is consistent with our hypothesis. That is, the multiple look effect enhanced the cutaneous rabbit illusion. The multiple look effect is considered to occur due to the "prediction" generated by a prior stimulus sequence with constant rhythm (Jones et al. 2002). A recent psychophysical study on individuals with autism spectrum disorder proposed that postdiction involves different neural processes than does prediction (Wada et al. 2020). However, our results suggest that there is an interaction between

prediction and postdiction, which may mean that prediction and postdiction partially share neural processes.

Title: Encoding Stimulus Duration in Sensory Guided Behavior

Authors: *S. POST[1], S. ALI[2], A. GOEL[2];
[1]UC Riverside, Riverside, CA; [2]Univ. of California Riverside, Riverside, CA

Abstract: Timing and making predictions are integral to most behaviors. Predicting a change in the traffic light, foraging, or speech perception all necessitate accurate timing of an event. Thus, understanding the circuit mechanisms of how temporal features of sensory input are represented and stored in cortical circuits is crucial to understanding complex behavior. One hypothesis of timing is that stimulus intervals are encoded in the population responses of locally connected neurons ("Intrinsic model'). This is supported by several psychophysical studies and stands in contrast to a "dedicated" clock model (Ivry and Schlerf, 2008; Goel and Buonomano, 2014). In support of the intrinsic model, we demonstrated that isolated cortical circuits can "learn" temporal intervals, a process mediated by local changes in network dynamics via temporally defined changes in excitation-inhibition (E-I) balance (Goel and Buonomano, 2016). To test this behaviorally, we used a novel **temporal interval sensory discrimination (TISD) paradigm**, in which water-deprived adult wild-type mice were presented with two identical visual sinusoidal gratings separated by gray screens of two different durations (0.2s vs 0.9s). One duration was associated with a water reward (preferred interval) and the other was not (non-preferred interval). Our preliminary results show that mice learned to discriminate between the two intervals, indicated by a discriminability index (d') of greater than 1.75 and a decrease in bias(c) (naïve session: c=1.714; learned session, c=-0.2356) and the normalized entropy of lick times across sessions. **These results suggest that stimulus duration features contribute to learning a goal directed task**. We hypothesize that TISD learning is accompanied by alterations in E-I balance mediated by parvalbumin (PV) and vasoactive intestinal peptide (VIP) interneurons. Specifically, ***enhancement of VIP function reduces PV output, via the disinhibitory circuit during the duration of gray screen (0.2s vs 0.9), which allows interval specific pyramidal cell activity patterns to emerge.*** To test this, we are performing two-photon calcium imaging in V1 during the TISD task. Similar to our *in vitro* studies (Goel and Buonomano, 2016), we expect that trained mice will exhibit a difference in the slope of the pyramidal cell population activity such that distinct patterns of activity emerge that encode information of about a 0.2s or 0.9s duration. Simultaneous imaging of pyramidal and PV or VIP cells will be performed using PVCreAi9 and

VIPCreAi9 transgenic mice. This study will ***provide novel insights into how shifts in E-I balance via stimulus durations influence sensory guided behavior.***

Title: Effect of hippocampus lesions on temporal discrimination learning and maintenance

Authors: *W. E. DECOTEAU[1], J. LADISON[1], L. DONOHUE[1], E. GOLDEN[2], L. GULBICKI[3], A. E. FOX[1];
[1]Psychology, [2]Biol., [3]Neurosci., St. Lawrence Univ., Canton, NY

Abstract: This study assessed the ability of rats with hippocampus lesions to acquire an operant chamber temporal discrimination task. Lesions were made by infusing 0.5 µl (0.1 µl/min) of NMDA (20mg/ml) dissolved in sterile saline at stereotaxic coordinates targeting the dorsal hippocampus (AP - 2.8; ML ±1.6; DV - 3.6 and AP - 3.6; ML ±2.6; DV - 3.6 mm from bregma). Control animals were injected in the same manner but with sterile saline. Following recovery, animals were trained to discriminate two light cues of different duration by pressing one of two levers. Cue-lever pairings were counterbalanced across subjects. In the first phase of training, the house light in the chamber was illuminated for either a short (2 s) or long (8 s) duration, followed by the insertion of one of the corresponding, paired levers. A lever press was rewarded with food delivery. In the next phase, each house light cue was followed by the insertion of both levers. Incorrect trials were repeated until a correct response occurred. In the third phase, the correction procedure was removed and rats were trained until 80% of trials per session were correct for at least five consecutive sessions with no visual trends. For the fourth and final phase, intermediate house light cue durations (2.6, 3.2, 4, 5, and 6.4 s) were intermixed with the previously trained "anchor cues" (2 and 8 s). Only correct responses to the anchor cues were reinforced. Data from this final testing phase provided measures of timing accuracy and precision at the individual and group level. We found no differences between treatment groups in the number of trials to acquire the discrimination (phase 3). Multi-level, non-linear (sigmoid) regression analyses during phase 4 of training revealed that treatment group was not a significant predictor of the center/bisection point or slope parameters, but was a significant predictor of the asymptote parameter, $t = 2.27$, $p = 0.023$ (see figure). These results suggest the hippocampus is involved in maintaining the acuity of temporal reference memories, particularly for events of longer duration.

Title: Acquisition of multiple prior distributions in human coincidence timing: testing effects of motor-effector specificity

Authors: *Y. MATSUMURA[1], R. SATO[1], J. HERON[3], N. ROACH[4], M. MIYAZAKI[2,1]; [1]Grad. Sch. of Integrated Sci. and Technol., [2]Dept. of Computer Science, Fac. of Informatics, Shizuoka Univ., Hamamatsu, Japan; [3]Sch. of Optometry and Vision Sci., Univ. of Bradford, Bradford, United Kingdom; [4]Sch. of Psychology, Univ. of Nottingham, Nottingham, United Kingdom

Abstract: The brain can acquire prior distributions of sensory input and use them to optimize performance on sensorimotor tasks. Roach et al (2017) demonstrated that when exposed to two different prior distributions during a duration-reproduction task, participants first acquired a mixed distribution of the two priors ("generalization"). Moreover, they showed that if the two priors were assigned to two different motor outputs (keypress/vocalization), participants could acquire the two priors respectively ("motor specificity"). Here we hypothesized that if two prior distributions are assigned to two different motor effectors (right/left hand), participants can learn two prior distributions respectively even though the motor outputs are identical (keypress). To test the hypothesis, we conducted psychophysical experiments using a coincidence-timing task. Target timings were sampled from short (424-988ms) or long (1129-1694ms) time distributions. Participants in the effector-specific group responded to targets sampled from the two distributions with a specific index finger (right/left hand), whereas participants in the effector-fixed group used their dominant index finger throughout. In line with our hypothesis, we found that only participants in the effector-specific group were able to acquire both short-time and long-time distributions. Interestingly however, initial results for both groups were consistent with selective learning of the long-time distribution, rather than generalization across both distributions. This asymmetry was not a consequence of the short-time prior being inherently difficult to acquire; we found that an additional group of participants were able to quickly acquire the short-time distribution when it was presented in isolation. Instead, our results suggest that the brain initially prioritizes acquisition of the long-time prior over the short-time prior for coincidence timing. This difference in prior acquisition strategy compared to previous findings obtained with duration-reproduction tasks may reflect the ready availability of feedback in this paradigm and a desire to mitigate against large magnitude errors caused by duration-dependent internal noise (i.e. scalar variability).

Title: Temporal Expectation in Marmosets: Global influences of task structure and local modulation by trial history

Authors: *T. DRAGOI[1], H. SUGIHARA[1], N. LE MINH[1], E. ADAM[1], J. SHARMA[1], G. FENG[2], R. DESIMONE[2], M. SUR[1];
[1]Picower Inst. for Learning and Memory, [2]McGovern Inst. for Brain Res., MIT, Cambridge, MA

Abstract: It is generally believed that in absence of overt cues, humans and macaques implicitly use prior information to predict upcoming events and reduce uncertainty. Temporal expectation has been modeled using the hazard rate, which posits the likelihood of an event to occur in the future provided it has not occurred already. However, previous studies have not addressed how internal models of temporal expectation are acquired as a consequence of learning. To answer this question, we implemented a simple timing task in which freely behaving marmosets were required to make a timed response prompted by a visual stimulus change with a uniform distribution of stimulus durations. Our results demonstrate that, similar to previous findings in humans and macaques, marmoset reaction times follow the hazard rate model of expectation, consistent with the global task structure. Further, we examined how this model emerges from learning and found that with repeated task exposure, trial history and hence local task structure begins to influence reaction time. The combined effects of global and local task structure are well described by a multiple regression model, and computationally by Bayesian updating of the hazard function. Parallel experiments in human subjects similarly demonstrate global and local influences on reaction times and temporal expectation, which are also well captured by multiple regression and Bayesian models. These results demonstrate the evolution of dynamic internal models of temporal expectation based on multiple cues, along with the richness of temporal cognition in marmosets comparable to that in humans. An open question is whether the effects of local and global influences are distinct parallel processes or rather if they synergistically interact to influence temporal expectation. To reveal the neural underpinnings of temporal expectation, future studies in marmosets will measure large scale population activity across visual, parietal and dorsomedial prefrontal cortex.

Title: Flexible spatial memory encoding and hours-long retention reduce the stability of the hippocampal place code but promote goal selective representations

Authors: *S. AHMADI[1], A. RAMEZANI[1], C. K. LUONG[1], S. LEUTGEB[1,2], J. K. LEUTGEB[1];
[1]Neurobio. Section, Div. of Biol. Sci., [2]Kavli Inst. for Brain and Mind, UCSD, La Jolla, CA

Abstract: The hippocampus is important for flexible memory-guided navigation, a process thought to be supported by the stability of hippocampal spatial representations. However, over the timescale of hours to days, hippocampal place fields gradually reorganize in familiar environments. This raises the question how spatial memory can be supported after many hours when hippocampal representations no longer correspond to the spatial locations they initially encoded. One possibility is that hippocampal representations remain stable even across hours-long periods when animals perform a memory task that requires them to retain recently encoded spatial information over extended intervals. To test this, we trained two groups of rats to perform either a spatial memory or a non-memory task on an 8-arm radial maze. In the memory task, rats learned a new goal arm location daily (SAMPLE) and were tested 6 hours later for memory retention (TEST). The goal arm was selected randomly each day and remained consistent for five SAMPLE trials and at TEST. In the behaviorally matched non-memory task a randomly chosen arm was rewarded in each of the five SAMPLE trials as well as at TEST. Memory task performance led to lower single-cell place map stability in comparison to the non-memory task (29.3% vs. 20.9%, $P = 0.011$, prop. SAMPLE-TEST map correlations < 0.1), and a greater decrease in the correlation between pairs of highly overlapping place representations across SAMPLE and TEST (Cohen's $d = -0.535$). These changes were deleterious for Bayesian position decoding accuracy, suggesting that a purely spatial hippocampal code cannot support memory performance. However, memory task performance also gave rise to a distinct goal-arm-selective population. SAMPLE correlations between goal-selective cells and the rest of the population were better preserved over the retention period until TEST in the memory task (54.6% vs. 48.4%, $P < 10^{-5}$). During the retention period between SAMPLE and TEST, hippocampal spikes were also preferentially biased toward long-duration sharp-wave ripples in the memory task (SWRs, $P < 10^{-57}$). Moreover, pairwise co-activations measured in SAMPLE were more strongly re-expressed in SWRs during the entire six hour long retention period between SAMPLE and TEST compared to the non-memory task. Taken together, our results describe neural dynamics that support memory of a new goal location after hours-long retention intervals despite the rapid reorganization of place selective representations. Furthermore, these findings segregate task-related network changes in service of memory from those related to environmental features, such as space and context.

Title: Stability of memory representations in the Hippocampus

Authors: *E. R. J. LEVY, E. PARK, A. A. FENTON;
Ctr. for Neural Sci., New York Univ., New York, NY

Abstract: The Hippocampus is crucial for the formation and persistence of memories. Two hypotheses describe how to decode information from neuronal discharge and how these signals store memory. One hypothesis states that information is encoded in the discharge rate of single neurons. A second hypothesis asserts that information is encoded in the co-firing relationships between the neurons' discharge.

To test these two hypotheses, we evaluated the activity of CA1 neurons across the entire multi-week experience of two pairs of environments: the first were physically distinct (cylinder and box), and the second were behaviorally distinct (conditioned and neutral). Each time, we recorded neuronal activity from mouse CA1 principal neurons expressing virally-induced GCaMP6f with a bright-field miniature microscope placed above a surgically implanted GRIN lens.

In the two environments, firing field stability measured by correlated firing rate maps is unstable across days, yet within-environment stability and across-environment discriminability increase with experience. Temporal reliability measured by correlating population activity vectors was similarly stable and discriminable but did not develop across experience. The activity vectors contain information that is both conserved and distinct between the cylinder and box, changing with environments and across experience.

We also evaluated how environment-specific information is organized across the CA1 population activity by projecting it onto two different sets of dimensions: we measured environment-specific discriminability using an SVM decoder and evaluated the natural non-linear temporal structure using an unsupervised Isomap algorithm. Both methods confirmed the preceding results. The SVM analysis indicates that both place and non-place cells are important for discriminating the environments and that the discriminative information distributes across more of the population with experience. Indeed, Isomap analysis reveals that the population activity readily collapses onto a low dimensional subspace that discriminates the two environments.

We conclude that the results from the first pair of geometrically-distinct environments are insufficient to decide between the two hypotheses. Results from the comparisons between distinct memories in the second pair of environments may be more appropriate for evaluating the differential validity of the two coding hypotheses.

Title: The role of visual inputs in theta rhythmicity and coding of location and running speed in the medial entorhinal cortex

Authors: *H. DANNENBERG, H. LAZARO, P. NAMBIAR, A. HOYLAND, M. E. HASSELMO;
Ctr. for Systems Neuroscience, Dept. of Psychological and Brain Sci., Boston Univ., Boston, MA

Abstract: Neuronal representations of spatial location and movement speed in the medial entorhinal cortex (MEC) during the "active" theta state of the brain are important for memory-guided navigation. A key question is how external sensory cues such as visual inputs are integrated with internal self-motion cues in path integration to update self-location on a cognitive map. In this study, we use the spatially periodic firing pattern of grid cells in the MEC as a neuronal readout of such an integration mechanism and test the role of visual inputs on the spatial stability of grid cell firing and two proposed speed signals in the MEC, a speed signal represented directly by firing rate and an oscillatory speed signal represented by the slope of the local field potential (LFP) theta frequency to running speed relationship. By manipulating visual inputs in mice, we demonstrate that spatial stability of grid cell firing increases and decreases fast (< 10 s) and slowly (10-180s) during dark-to-light and light-to-dark transitions, respectively. The fast changes in grid cell stability were matched by fast changes in the mean firing rates of many MEC neurons, including speed cells, as well as fast changes in theta rhythmic firing and spike-to-theta phase coupling. Intriguingly, both fast and slow changes in grid cell stability over the course of three minutes were strongly correlated to changes in the slope of the LFP theta frequency to running speed relationship. In contrast, we did not observe slow changes in the potential speed signal represented by firing rate indicating that the slow change in grid cell stability is not driven by changes in speed cell firing. We further demonstrate that changes in the slope of speed cells' speed tuning curves during darkness can be fully explained by changes in mean firing rates as opposed to changes in the slope of the speed cells' running speed-dependent

gains in firing rates. Finally, we characterize changes in theta rhythmic firing in MEC neurons as a function of visual inputs and running speed.
In summary, data in this study demonstrate that spatial accuracy of grid cell firing is intrinsically linked to the slope but not y-intercept of the LFP theta frequency to running speed relationship. Moreover, changes on a slow time scale of tens of seconds suggest that grid cell firing is a function of velocity signals integrated over past time and thus malleable by internal memory processes.

Title: A dynamical systems approach to understanding spatial localization in recurrent neural networks

Authors: *J. GORNET, G. RAGHAVAN, C. LIN, M. THOMSON;
Caltech, Pasadena, CA

Abstract: Grid and place cells produce a spatial map of the environment suggesting the hippocampal system also maps abstract concepts using a similar map. A recurrent neural network trained to path-integrate, or calculate its position from past velocities, can show a similar grid-like firing pattern as grid cells. This suggests that there may be a universal computation for spatial mapping. Here we study the recurrent neural network as a dynamical system to understand this computation. Attractor states are stable fixed points, or a basin of attraction, in a dynamical system. A working model for grid cell computation is that localized grid-like bump activity corresponds to attractor states. The network's inputs move the network to different attractor states, which updates the network's internal prediction of position. We investigate whether the network uses attractor states for computing a spatial map. To understand how the network's spatial map may generalize to a cognitive map, we explore how the network's dynamics depend on different geometric properties. Training the network on different curved manifolds, we show how the environment's curvature, dimensionality, and symmetry affects the network's computation.

Title: Circuit motifs for vector navigation and goal-directed action selection: insights from the Drosophila central complex connectome

Authors: *B. K. HULSE, D. B. TURNER-EVANS, H. HABERKERN, R. FRANCONVILLE, S.-Y. TAKEMURA, T. WOLFF, M. NOORMAN, M. DREHER, C. DAN, R. PAREKH, A. M. HERMUNDSTAD, G. M. RUBIN, V. JAYARAMAN;
Howard Hughes Med. Institute, Janelia Res. Campus, Ashburn, VA

Abstract: The neural basis of goal-directed navigation has been the subject of decades of study, with a growing catalog of neuron types that form internal representations of an animal's spatial relationship to the external world. Yet, it has proven challenging to understand how these neurons acquire these representations and how navigation circuits ultimately guide an animal's behavior. The navigation center of insects resides in a highly recurrent, evolutionarily conserved region known as the central complex. The region houses a ring attractor network that computes the fly's head direction (HD) using both self-motion and allothetic sensory cues (Seelig & Jayaraman, 2015; Kim et al., 2017). Within this network, whose topography matches its function (Green et al., 2017; Turner-Evans et al., 2017, 2020), HD cells are arranged into columns according to their preferred firing direction, and population activity is organized as a traveling activity 'bump' whose columnar position encodes the fly's HD. Yet, how this 'compass network' is used to guide the fly's behavior remains largely unknown. Here we analyze a recently-released, complete connectome of the *Drosophila* central complex and identify circuit motifs downstream of the fly's compass network whose structure strongly suggests the implementation of vector-based computations for navigation. We used these motifs to build a conceptual model that describes how cosine-formatted activity bumps could form a four-vector basis set for navigational computations. The motifs suggest that the amplitudes of the basis vectors could be independently gain-modulated by self-motion signals to perform coordinate transformations, such as converting head direction into body direction. We highlight the utility of this motif in the context of path integration, a canonical vector-based navigation strategy used by a diverse array of both flying and walking insects. Specifically, we describe how the four-vector basis set could be used to compute an insect's translational velocity vector, which need not be the same as its head direction. We end by describing central complex output neurons that appear anatomically-configured to compare the fly's current HD to that of an allocentric goal direction to generate egocentric motor commands, ensuring a return to the goal. These results establish general circuit motifs for vector computation in the central complex, with specific implementations that likely depend on cell type, species, and behavioral need. More broadly, they highlight how the fly

connectome can be used to generate functional hypotheses about broadly relevant navigational circuit computations.

Title: Broad and sharp tuning to head-direction in the brainstem

Authors: *L. Y. WANG, A. J. DUSZKIEWICZ, G. VIEJO, H. BEAUDOIN, A. PEYRACHE; Montreal Neurolog. Inst. and Hosp., McGill Univ., Montréal, QC, Canada

Abstract: Head direction (HD) cells serve as the brain's internal 'compass' and each of them is tuned to the specific direction the animal is facing, independently of its location and ongoing behaviour. Brain state-invariant dynamics and computational models suggest that HD network is endowed with particular connectivity constraining the neuronal population to represent a single HD, made possible by mutual interaction between excitatory and inhibitory circuits and forming a so-called 'ring attractor'. While anatomical and lesion studies indicate that attractor dynamics in the HD system are likely supported by the reciprocal interactions between the dorsal tegmental nucleus (DTN) and the lateral mammillary nucleus (LMN), the underlying neuronal circuits and dynamics transforming vestibular angular head velocity (AHV) inputs into a coherent HD signal remain largely unknown.In order to elucidate the neural basis of the mammalian HD signal generator, we conducted bilateral population recordings in mouse DTN using high-density multi-shank silicon probes. We first confirmed previous observations of lateralized AHV coding in DTN: many recorded cells showed either unidirectional (tuned to clockwise or clockwise head turns) or bidirectional AHV tuning, and clockwise and anticlockwise AHV cells were enriched in right and left DTN, respectively.We then focused our analysis on the HD tuning present in the DTN and characterized two discrete populations of DTN-HD cells based on their millisecond-timescale spike train autocorrelograms: 'broad' and 'sharp' HD cells with average refractory period half-widths of 9 ms and 2 ms, respectively. These two DTN-HD cell types differ in their HD and AHV tuning: HD tuning curves of broad HD cells and sharp HD cells have average half-

widths of 180 degrees and 120 degrees, respectively, and broad HD cells are more likely to be asymmetrically tuned to AHV than sharp HD cells. Importantly, these two cell populations differ in their anticipatory firing: broad HD cells anticipate animal's HD 60 ms and sharp HD cells do so 30 ms into the future. A direct comparison of the two cell types with LMN-HD cells highlighted similarities in HD tuning and anticipatory firing between LMN-HD cells and sharp but not broad DTN-HD cells.Together, these observations indicate that these two DTN-HD cell types may be parts of different sub-circuits of the HD signal generator, with sharp HD cells positioned downstream of broad DTN-HD cells and possibly influenced by HD signal fed back from LMN. Further experiments will elucidate whether the directional tuning of these two newly characterized HD cell types depends on intact DTN-LMN feedforward and feedback connectivity.

Title: Non-uniform tuning in the cortical head-direction system

Authors: *A. J. DUSZKIEWICZ[1], E. R. WOOD[2], A. PEYRACHE[1];
[1]McGill Univ., Montréal, QC, Canada; [2]Ctr. for Discovery Brain Sci., The Univ. of Edinburgh, Edinburgh, United Kingdom

Abstract: Head-direction (HD) cells are each tuned to a specific direction the animal is facing, independently of its location. The HD signal is generated subcortically and is relayed via the anterior thalamus, the postsubiculum (PoSub) and the medial entorhinal cortex (MEC), where it serves as a critical component of the grid cell code. While MEC grid cells are anatomically organized into modules with different grid spacing, it is unclear whether the HD system also exhibits a kind of anatomical organization. To address this, we used 64-channel linear electrode arrays to conduct population recordings across the cortical layers in mouse PoSub. A major obstacle in investigating the anatomical distribution of HD tuning is that it requires high-density local sampling of HD cells. To overcome this, we instead focused on the broad HD tuning of locally connected fast-spiking (FS) cells (putative interneurons) as a proxy for local HD tuning distribution. First, we confirmed that PoSub-FS cells are postsynaptic to local HD cells within

200 μm radius and their tuning is positively correlated with the population tuning of locally recorded HD cells. Further analysis revealed unexpected symmetries in PoSub-FS cell HD tuning: approximately half of recorded FS cells showed either two-fold or three-fold radial symmetry in their HD tuning, indicating PoSub FS cells pay be part of local modules of HD cells with preferred directions biased towards specific equally spaced angular values. We then looked for patterns in anatomical distribution of FS cells with radially symmetrical tuning. While FS cells with two-fold symmetries were enriched in middle cortical layers, FS cells with three-fold symmetries were instead present in the deep as well as the most superficial layers. These differences in anatomical distribution were further corroborated by subsequent PoSub recordings conducted parallel to the cortical layers. Overall, these results constitute the first evidence of local anisotropy in the HD system. Future experiments will aim to increase the number of locally sampled HD cells in order to directly investigate the fine details of functional organization in PoSub.

Title: Fast-spiking interneurons shape symmetrical tuning to head-direction

Authors: *P. ORHAN[1], A. PEYRACHE[2], A. J. DUSZKIEWICZ[3];
[1]McGill Univ., Montréal, QC, Canada; [2]Montreal Neurolog. Inst., [3]Montreal Neurolog. Inst. and Hosp., McGill Univ., Montreal, QC, Canada

Abstract: Neuronal representations of external variables are organized into strikingly symmetrical maps. These geometrical organizations form the backbone of neuronal computations, how can they emerge robustly? In this work we show that as soon as fast-spiking interneurons are randomly connected into a network, they promote the emergence of symmetrical maps. We focus on the postsubiculum (PoSub), the cortical relay of the head-direction (HD) signal. It projects to the superficial layers of the medial entorhinal cortex, transferring HD inputs from the thalamus. Recent evidence from our laboratory suggests a topographical arrangement of the HD signal within the PoSub, as evidenced by symmetrical tuning of fast-spiking (FS) inhibitory neurons. Specifically, FS cells show a 1-, 2- or 3-fold symmetries in their tuning to HD, the 2- and 3-fold symmetries corresponding to peaks in the

tuning curves separated by exactly 180 or 120 degrees, respectively. The origin of this arrangement could reflect a topographical arrangement of local (<200 um) excitatory HD cells or could result from a transformation of thalamic inputs directly by the inhibitory networks.
To address this question, we have investigated the problem from a computational perspective. Surprisingly, models built with random thalamocortical (AD-to-PoSub) connections capture the emergence of the FS interneuron tuning curves. This is valid under the assumptions of linear integration by PoSub FS cells and the existence of inter-FS cell connectivity. The fold distribution of FS cell tuning curves is well reproduced over a wide range of AD-to-Posub connectivity parameters. In addition, the pyramidal cells in the PoSub are more selectively tuned to head-direction than in AD, yet some PoSub pyramidal cells also present symmetrical tuning to HD. This selectivity also emerged in a model based on random thalamocortical connections. These findings suggest that FS-FS connections and linear integration of thalamic inputs by FS cells in a randomly connected thalamocortical network are sufficient prerequisites for the emergence of symmetric and selective sensory tuning.

Title: Landmark-based representations of spatial context in postrhinal cortex

Authors: *P. A. LACHANCE, J. GRAHAM, B. L. SHAPIRO, J. S. TAUBE;
Dartmouth Col., Hanover, NH

Abstract: Animals use visual landmarks to establish a sense of orientation and spatial context. This process requires the brain to integrate visual inputs with information about the animal's head direction (HD). The rat postrhinal cortex (POR), which receives inputs from visual brain areas as well as areas carrying a vestibular-driven HD signal, may play a role in this integration. We recorded from single HD cells in POR and found that, while they had a single preferred firing direction (PFD) in the presence of a single visual landmark (a large white cue card placed along one wall of the square enclosure), they adopted a second PFD when a second identical landmark was placed into the environment, with the orientation of the second PFD depending on the placement of the second landmark. These cells showed higher firing rates for a more familiar landmark, and they generally did not respond to a novel landmark (a black cue card) that was visually distinct from the familiar landmark. When the familiar landmark was removed from the environment, the cells still fired relative to the previous location of the landmark but with reduced firing rates, suggesting that they retained a memory for the familiar landmark. In

contrast, HD cells recorded from the anterior thalamic nuclei (ATN) maintained a single PFD under all circumstances. In addition, we could use the firing of a few co-recorded POR HD cells to discriminate among different spatial contexts (landmark configurations). In contrast again, ATN HD cells did not provide adequate information for the same contextual decoding. This study provides insight into how visual landmarks are integrated into a spatial framework that enables the neural encoding of landmark-based orientation and spatial context.

Title: A matter of complexity? The role of the rodent posterior parietal cortex in processing spatial layouts

Authors: *T. B. WISE[1], V. L. TEMPLER[2], R. D. BURWELL[1];
[1]Brown Univ., Providence, RI; [2]Psychology, Providence Col., Providence, RI

Abstract: The posterior parietal cortex (PPC) has long been associated with spatial cognition in rodent models. This region is thought to integrate multiple streams of information; however, most rodent studies have focused on simple tasks, for example, recognition of spatial relocation of one or two objects. Whereas these methods provide a necessary foundation for understanding PPC contributions to spatial cognition, new approaches are needed to expand on these results. In this study, we used experimental lesion methods to examine PPC function across a series of object exploration tasks which varied in spatial complexity. In Experiment 1, both PPC-lesioned and sham-lesioned rats were run on separate, single-feature change tasks including object recognition (OR), object location (OL), and object in place (OiP). Two object were presented in the study phase. In the test phase, one object was replaced (OR), moved to a novel location (OL), or moved to a familiar location (OiP). In Experiment 2, subjects were run on a complex spatial change (CSC) task in which object manipulations were similar to those in Experiment 1 but were presented in a more complex environment including four objects and four or five locations (Save, Poucet, Foreman, & Buhot, 1992). Our results show that in Experiment 1, all subjects preferred the novel spatial feature in the OR and OL tasks; however, control rats, but not lesioned rats, preferred novelty in OiP. In Experiment 2, all subjects preferred novelty for the combined OL/OiP change; however, control rats, but not lesioned rats, preferred novelty during the OR change. Interestingly, lack of response to specific changes (OR. OL, OiP) did not align

across experiments for lesioned rats. This suggests that exploration of spatial novelty may be dependent on the complexity of an environment when the PPC is intact. Further discussion is presented regarding PPC function and the ability to shift attention between environmental stimuli.

Title: Spatial representations in macaque hippocampal formation

Authors: *D. MAO[1], E. AVILA[1], B. CAZIOT[1], J. LAURENS[2], D. DICKMAN[3], D. ANGELAKI[1];
[1]New York Univ., New York, NY; [2]Ernst Strüngmann Inst., Frankfurt, Germany; [3]Baylor Col. of Med., Houston, TX

Abstract: The hippocampal formation is linked to spatial navigation but there is little direct evidence in primates during active, unconstrained behavior. We recorded neurons across hippocampal regions in rhesus macaques during free foraging in an open arena while tracking their head and eye. We found that neurons encode a broad spectrum of spatial variables beyond place fields, and generally show mixed selectivity. Spatial representations were dominated by the allocentric location the head is facing and head tilt relative to vertical, whereas only a small fraction of neurons showed place or grid fields. Spatial facing selectivity was better explained by head-, rather than gaze-related properties. These findings reveal that the macaque hippocampal formation represents space using a multiplexed code, with heading properties dominating over simple place coding during free behavior.

Abstract: The hippocampus and surrounding regions of the hippocampal formation are critical for spatial memory in multiple mammalian species, with single-neuron representations of allocentric place, direction or boundary well-established in rodents. Conjunctive, or mixed-selective, representations of two or more spatial variables are also abundant, even after isolating the independent contributions of each spatial variable. In contrast, clear examples in non-human primates of neurons exclusively selective for place are scarce. Instead, neurons selective for allocentric view of the environment, as well as a mix of spatial variables, have been found. However, many primate studies of spatial memory to date have used environments where place was heavily confounded with view, making it difficult to assess accurately the prevalence of different types of representations. The present study addressed that by recording hippocampal activity from a male non-human primate (macaca fascicularis) during a goal-directed virtual navigation task, where the direction of motion and view direction were not constrained by location. Neural activity was recorded from the right hippocampus with a 124-channel chronically-implanted microelectrode array, while eye gaze was tracked concurrently with location in the maze. Spatial information content was used to determine place and view selectivity, and the independence of the contribution of either variable to cell activity was assessed. 364 putative hippocampal cells were recorded, 38 of which were jointly selective for place and view, 20 selective for place only, and 10 selective for view only. Our results suggest that cells exhibiting mixed selectivity may be more prevalent than cells exhibiting exclusive selectivity for place or view in the primate hippocampus.

Title: Navigation using spatial view cells

Authors: *E. T. ROLLS;
Oxford Ctr. For Computat. Neurosci..

Abstract: A new theory is proposed of the mechanisms of navigation in primates including humans in which spatial view cells found in the primate hippocampus (Rolls and Wirth 2018) are used to guide the individual from landmark to landmark. The sequence of landmarks for the route could be stored in a time-cell sequence memory in the hippocampus (Rolls and Mills 2019), or in a continuous attractor network for a well-learned route, or in humans in a working memory in the prefrontal cortex (Rolls 2021). The individual moves along each leg of the route towards the next landmark, and then looks for the next landmark, and moves towards that. This type of navigation does not require a Euclidean topological map. Two other cells types found in primates, whole body motion cells, and head direction cells, can be utilized in the spatial view cell navigational mechanism, but are not essential. It is shown how if the landmarks are temporarily obscured, the spatial view cells can be idiothetically updated using mechanisms in the dorsal visual system areas in the parietal cortex (Rolls 2020), which reach the hippocampus via the retrosplenial and posterior cingulate cortex. The theory has been implemented in a model, and simulations will be presented showing the operation of the navigational mechanism. It is proposed that this navigational mechanism using spatial view cells is frequently used by humans. The mechanism is relatively simple because primates have visual neurons that respond allocentrically to locations in spatial scenes (Rolls and Wirth 2018). An advantage of this approach to navigation is that spatial view neurons are also useful for episodic memory, and for imagery (Rolls 2021).

Abstract: Everyday tasks in social settings require humans to encode not only their own spatial location, but also the location of other individuals within an environment. Currently, the vast majority of what is known about neural representations of space for self and others stems from research in rodents and other non-human animals. However, it is largely unknown how the human brain represents the location of others, and how aspects of human cognition may impact these location-encoding mechanisms. To address these questions, we examined participants with chronically implanted electrodes while they performed real-world spatial navigation and observation tasks. We report boundary-anchored neural representations in the medial temporal lobe that are modulated by one's own as well as another individual's spatial location. Moreover, these representations were modulated by one's momentary cognitive state and strengthened when encoding of location was of higher behavioral relevance. Altogether, these results provide the first evidence for a common encoding mechanism in the human brain to represent the location of oneself and others in shared environments, and shed new light on the neural mechanisms that underlie spatial navigation and awareness of others in real-world scenarios.

Title: The Emergence of Head Direction Signals in Human Navigation

Authors: *Y. CHENG[1], E. R. CHRASTIL[2];
[1]Cognitive Sci., [2]Neurobio. & Behavior, Univ. of California, Irvine, Irvine, CA

Abstract: Head direction is crucial in human wayfinding, but whether head direction signals can be classified in the brain in a complex environment, and how this signal relates to navigation performance remain open questions. In an fMRI study, we tested over 90 participants in a cardinal-direction-aligned virtual maze. The navigation task consisted of an exploration and a test phase. During the 16-minute exploration, participants freely explored to find 9 objects

located in the environment and were instructed to remember their locations. For each of the 48 test trials, participants started at one object and were directed to go to another object, without feedback and with a limited time. We conducted an intra-subject multivariate pattern classification for the four head directions in four a priori regions of interest (ROIs). Our preliminary results suggest that we can successfully discriminate between head directions in retrosplenial cortex, extrastriate cortex, precuneus, and thalamus, as well as the whole brain. For some regions, head direction signals could only be classified successfully during the exploration phase, whereas others could discriminate during both exploration and test phases. Furthermore, we observed a relationship between an individual's classification strength and their subsequent navigation performance. Although in some regions we observed that better performance in discriminating directions was related to better navigation performance, in other regions classifier strength was related to worse navigation performance. This study indicates that the basic navigational signal of head direction is important for successful navigation in a complex environment and could form the basis of individual abilities.

Title: Medial temporal lobe subfields balance representational dimensionality during prospective planning

Authors: *S. S. P. LIAPIS[1,2,3], T. T. I. BROWN[5], J. T. MCGUIRE[1,2,3,4], C. E. STERN[1,2,3,4]; [2]Grad. Program for Neurosci., [3]Cognitive Neuroimaging Ctr., [4]Psychological & Brain Sci., [1]Boston Univ., Boston, MA; [5]Georgia Tech., Atlanta, GA

Abstract: Prior research has identified a prominent role for medial temporal lobe (MTL) subfields in the disambiguation of overlapping episodes during navigational "look-ahead" periods. However, it remains unclear how these areas mediate disambiguation. One solution is to orthogonalize overlapping representations by expanding their dimensionality. We hypothesized that hippocampal and related MTL subregions perform a balancing act - compressing representational space by identifying and extracting the relevant dimensions of neural representations over the course of learning, while simultaneously leveraging a higher-dimensional space for initially overlapping representations. To test this hypothesis, we reanalyzed a high-resolution functional magnetic resonance imaging study of the MTL in healthy adults performing a navigational disambiguation task (Brown, Hasselmo, & Stern, 2013). During scanning, participants (N=15) navigated virtual mazes that were well-learned from prior training

while also learning new mazes. Each maze began with a unique contextual cue period where subjects prospectively planned their routes. Critically, some of the routes overlapped (OL) while others did not (NOL). We employed a data-driven approach as used in Mack, Preston, & Love, 2020 to examine the dimensionality of neural representations during prospective planning. Neural representations for each OL and NOL cue were extracted using a Least Squares - Separate GLM approach. We then derived a dimensionality score for these representations using principal components analysis. In accordance with our hypothesis, we predicted greater dimensionality for OL relative to NOL representations as well as a decrease in dimensionality over the course of learning. We discovered evidence in MTL subfields of a higher-dimensional space for OL relative to NOL route representations. Furthermore, we found evidence for dimensionality compression over the course of learning within entorhinal and parahippocampal cortices and hippocampal subfields CA1 and subiculum when we compared early and late trials, consistent with a changing role for these regions over the course of learning. Finally, we demonstrated that previously well-learned routes were represented in a low-dimensional space in entorhinal cortex. Taken together, these results suggest that MTL subfields play a critical role in disambiguating overlapping sequences during prospective planning by balancing between the orthogonalization and compression of neural representational space.

Title: Spatial learning through interaction: A hybrid route to a cognitive map?

Authors: *M. J. STARRETT[1], D. J. HUFFMAN[3], A. D. EKSTROM[1,2];
[1]Psychology, [2]Evelyn F. McKnight Brain Inst., Univ. of Arizona, Tucson, AZ; [3]Psychology, Colby Col., Waterville, ME

Abstract: A growing body of research has characterized how we learn information from maps vs. routes although how we differentially learn and interact with route and map information remains poorly understood. While the networks that underlie human spatial cognition are believed to be similar or homologous to other mammalian species, humans may be the only species that uses figural representations of spaces (i.e., maps) to learn how to navigate actual spaces. To better understand learning of "figural" spaces like cartographic maps compared to "environmental" spaces like routes, we developed a novel hybrid learning task in which a similar underlying mental process (e.g., navigation) can be observed through interaction with a 3D scale model of an environment. In the novel hybrid task, participants moved an avatar while viewing

the environment from above on a virtual table top. Participants learned the configuration of 8 buildings within a virtual city (102x142 meters) by either navigation, a map, or our hybrid task. After learning, participants then completed 56 memory trials of either the judgements of relative direction (JRD) pointing task or the scene- and orientation-dependent pointing (SOP) task. The pattern of results for navigation and map learning were qualitatively similar to previous findings from our lab, with overall lower error on the SOP task compared to the JRD task and a benefit from map learning on JRD performance relative to navigation learning. For hybrid learning, however, performance across both JRD and SOP tasks was worse than map or route learning. There are several possibilities for why hybrid learning may have shown the worst performance, despite its seemingly intuitive combination of figural and environmental spaces. One possibility is that the hybrid learning task involved additional cognitive load imposed by maintaining multiple frames of reference (observer and remote avatar), impairing tracking spatial location and orientation. Another possibility is that prior experience was relevant: because participants had experienced routes and cartographic maps, but not hybrid spaces, they were better able to learn based on strategies they had developed previously with these modalities. A final possibility relates to the difficulty of combining scales of space, suggesting a degree of inflexibility in combining information from figural and "vista" scales.

Title: The relationship between navigation abilities and mental disorders

Authors: ***N. HATAMIAN**, R. F. WOODRY, B. TRANQUADA-TORRES, A. YEE, E. R. CHRASTIL;
Neurobio. & Behavior, Univ. of California, Irvine, CA

Abstract: The link between navigational abilities and Alzheimer's disease has provided an exciting early marker for detection of dementia in at-risk individuals. However, it is unclear whether navigational abilities can be used to detect other neurological and mental disorders. The present study examines the relationship between two aspects of navigational ability and behavioral traits associated with various mental disorders. We propose that navigational ability may utilize the same brain circuitry as certain mental disorders, and may be a beneficial early marker for these disorders. This study is inspired by the Research Domain Criteria (RDoC), a framework outlined by NIMH to study the basic dimensions of functioning that span the range of behavior from normal to abnormal. For example, we hypothesize that spatial perspective taking that is important for navigation could be associated with social perspective taking in disorders

such as autism spectrum disorder or eating disorders. To test this question, participants recruited online through Amazon Mechanical Turk completed two web-based spatial cognition tasks and a battery of standardized questionnaires to capture non-pathological ranges of mental disorders. The Open Field Task (OFT) is similar to a virtual Morris water maze. It tests an individual's ability to recall, locate, and navigate to four hidden objects scattered in an open field environment from a first-person perspective. The OFT tests allocentric spatial learning and path integration. In the Spatial Orientation Task (SOT), participants see a top-down view of a layout of objects, then are asked to imaging standing at one object, facing a second object, and then to point to a third object. The SOT tests spatial perspective taking ability. The behavioral questionnaires assess pathological and non-pathological levels of mental disorders such as depression, anxiety, autism, and schizotypy to examine individual variability within the healthy population. Preliminary correlations indicate relationships between navigational ability and several mental disorders, particularly between spatial task performance error and autistic traits.

Title: Strategy development and feedback processing during complex category learning in young adults

Authors: *V. TILTON-BOLOWSKY, S. VALLILA-ROHTER, Y. ARBEL;
MGH Inst. of Hlth. Professions, Boston, MA

Abstract: For individuals who have sustained a neurologic injury, the rehabilitation process involves learning and relearning everyday processes. Therefore, rehabilitation researchers are interested in characterizing individuals' learning ability. Category learning tasks are often used to examine learning ability. In the current study, we analyzed performance on a probabilistic A/B prototype category learning task under observational and feedback training conditions. We counterbalanced two stimulus sets across participants and training conditions. We examined differences in learning success (percent accuracy) and strategy use (optimal versus suboptimal) between training conditions. We also evaluated the feedback-related negativity (FRN) event related potential as a measure of feedback processing during feedback training. We used the Geodesic EEG System with a 32-channel HydroCel Sensor Net following the international 10-20 system to collect and analyze EEG data. Thirty-eight healthy young adults (M = 25 years, SD = 3.33; 25 females) participated. A dependent samples t-test revealed that the difference in testing accuracy between training conditions was not significant, $p = 0.13$. A chi-square test indicated that strategy proportions under the two training conditions were significantly different, $p = 0.03$. One-way ANOVAs revealed that optimal strategy users achieved significantly greater testing

accuracy than suboptimal strategy users across training conditions, $p = 0.001$. A mixed-design ANOVA revealed a significant three-way interaction between feedback valence, training phase, and strategy trajectory on FRN amplitude, $p = 0.02$. Specifically, participants who switched from a suboptimal to optimal strategy during training exhibited a significantly larger FRN to negative feedback in late training than in early training. We found significant relationships between testing accuracy and FRN amplitudes to negative feedback in late training, $p = 0.02$, as well as between testing accuracy and FRN difference scores in late training, $p = 0.02$. In conclusion, those who developed an optimal strategy outperformed suboptimal strategy users, and more participants developed an optimal strategy under feedback training than observational training. Few studies have combined strategy analyses with measures of feedback processing. Our findings are consistent with prior research that suggests that method of instruction influences learning, and also suggests that measures of feedback processing in late-stage training of probabilistic category learning may reflect strategy optimization and may further illuminate differences among individual learners.

Title: Emergence of distributed value representations and learning in naturalistic reward environments

Authors: *S. FARASHAHI[1,2], J. XU[2], A. SOLTANI[2];
[1]Flatiron institute, New York, NY; [2]Dartmouth Col., Hanover, NH

Abstract: Learning an appropriate representation of the reward environment is extremely challenging in the real world where there are many options to learn about and these options have many attributes or features. Although recent studies have provided important insights into behavioral adjustments during such representation learning, neural mechanisms underlying these processes are still unknown. To address this, we measured learning and choice during a novel multi-dimensional probabilistic learning task in humans and trained recurrent neural networks (RNNs) to capture our experimental observations. Experimentally, we found that participants learned about a single informative feature before learning about the conjunctions of the uninformative features that carried partial information about stimulus-reward associations. The trained RNN exhibited a similar transition in learning strategy. Further analysis of neural response in RNNs revealed that the representations of reward value emerge over time as a distributed code that differentially relied on distinct types of excitatory and inhibitory units. Specifically, we found a higher degree of similarity between representation in inhibitory pools

and the informative feature value, a higher degree of similarity between representation in excitatory pools and object value, and a higher degree of similarity between representation in pools with reward-dependent learning in their sensory inputs and conjunction value. In addition to these results, our model predicts that recurrent connections from inhibitory pools that are endowed with reward-dependent learning in their sensory inputs to homologous excitatory pools play a crucial role in emergence of the observed distributed representations.

Title: Optimal dopaminergic tone for reward learning and executive control in humans

Authors: ***I. C. BALLARD**[1], D. FURMAN[1], A. S. BERRY[2], R. WHITE[3], W. JAGUST[1], A. KAYSER[4], M. D'ESPOSITO[1];
[1]Univ. of California, Berkeley, Berkeley, CA; [2]Brandeis Univ., Waltham, MA; [3]Washington Univ., Saint Louis, MO; [4]Univ. of California San Francisco, San Francisco, CA

Abstract: The dopaminergic neurotransmitter system is known to play important roles in both learning and executive control. It has been proposed that these two roles are subserved by interacting, but dissociable systems, with executive control processes such as working memory dependent on prefrontal dopamine and learning processes dependent on ventral striatal dopamine. To test this hypothesis, healthy subjects performed a probabilistic learning task that involves both trial-by-trial learning and executive control. Subjects (n = 77) performed the same task on placebo, bromocriptine, an agonist of the dopamine D2/3 receptors that predominate in the striatum, and tolcapone, a COMT inhibitor that predominantly affects prefrontal dopamine. Moreover, our subjects were stratified according to their DRD2 Taq1A and COMT genotypes, which influence dopaminergic function predominantly in the striatum and prefrontal cortex, respectively. In addition, PET measurements of striatal dopamine synthesis capacity and D2 receptor density were collected in the same subjects. This dataset provides a unique opportunity to query the genetic, regional, and cellular aspects of dopamine function in a large cohort of subjects.
We found that both higher dopamine synthesis capacity in the ventral striatum and DRD2 Taq1A- status correlate with reinforcement learning performance, suggesting that baseline dopamine tone (perhaps in tandem with D2 receptors) influences the degree to which reward associations are learned. However, these higher-performing subjects are most impaired by

dopamine drugs, consistent with a model in which a moderate level of dopamine tone is most beneficial for performance. In contrast to the ventral striatum, D2 receptor density in the dorsal striatum was related to the ability to form explicit knowledge of probabilistic associations, consistent with this region's association with executive function. Finally, we found that tolcapone, which increases prefrontal dopamine, impairs executive control in our task (i.e., response variability), especially for COMT Met homozygotes who have higher prefrontal dopamine at baseline. Our results show that dopamine influences behavior differentially depending on the neural system, and that optimal behavior arises at a level of moderate dopamine tone.

Title: Sculpting new visual concepts into the human brain

Authors: *M. IORDAN[1], V. J. RITVO[2], K. NORMAN[2], N. B. TURK-BROWNE[3], J. D. COHEN[1];
[1]Princeton Neurosci. Inst., [2]Psychology, Princeton Univ., Princeton, NJ; [3]Psychology, Yale Univ., New Haven, CT

Abstract: Humans continuously learn through experience, both implicitly (e.g., statistical learning) and explicitly (e.g., instruction). As humans learn to group distinct items into a novel category, neural patterns of activity for those items become more similar to one another and, simultaneously, more distinct from patterns of other categories. We hypothesized that we could leverage this process using neurofeedback to devise a fundamentally new way for humans to acquire conceptual knowledge. Specifically, sculpting patterns of activity in the human brain that mirror those expected to arise through learning of new visual categories may lead to enhanced perception of the sculpted categories, relative to similar, control categories that were not sculpted. To test this hypothesis, we implemented a closed-loop system for neurofeedback manipulation using fMRI measurements recorded from the human brain in real time (every 2s) and used this method to sculpt/create new neural categories for complex visual objects. After training, participants exhibited behavioral and neural biases for the sculpted, but not for the control categories, and we observed a significant positive correlation between the increase in behavioral discrimination and the increase in neural separation of the categories. Neural

sculpting provides causal evidence (through direct experimental intervention) that distributed patterns of activity evoked by complex visual stimuli can be formed de novo in high-level cortex to create categories that didn't previously exist in the brain or behavior. The ability to sculpt new conceptual distinctions in the human brain has broad relevance to many domains of cognition such as perception, decision-making, memory, and motor control. It also broadens the possibility for non-invasive clinical intervention in humans with fMRI (e.g., brain-machine interfaces, neuroprosthetics, neurorehabilitation). Finally, this hints at the distant possibility of sculpting more extensive knowledge or complex concepts directly into the human brain, bypassing experience and instruction.

Title: Neurobehavioral value mediators of abstraction in human learning

Authors: *A. CORTESE[1,2], M. KAWATO[1], B. DE MARTINO[2];
[1]ATR BICR, Soraku-gun, Japan; [2]Univ. Col. London, London, United Kingdom

Abstract: Humans excel at creating concepts, organizing information in schemas and hierarchies, which in turn enable efficient learning and behavior. Here, we hypothesized that value assigned to sensory features is key in driving abstraction that subserves learning. While their brain activity was recorded with functional magnetic resonance imaging (fMRI), human participants repeatedly learned new associations between imaginary characters (made of a combination of visual features), and symbols (fruits). Leveraging reinforcement learning algorithms, we designed models differing in their state-space dimensionality to characterize participants' behavioral strategies in solving the task. We show that abstraction was associated with higher expected value, revealing superior performance. In turn, participants with higher abstraction ability solved the task problems faster, and were more confident in their performance. Participants' learning speed was predicted by the functional connectivity between visual cortex and the area encoding value signals (the ventromedial prefrontal cortex - vmPFC). Moreover, we found that feature-level information was represented in the hippocampus and vmPFC when behavior was 'abstract', suggesting that these areas may actively transform incoming sensory information, under a specific goal. In a second experiment, we used multivoxel neurofeedback to test for the causality of feature valuation as a mechanism of abstraction. Pairing the neural sensory representation of a task's feature with rewards subsequently led to a shift towards abstraction in behavioral learning strategies. Thus, these findings help carve a new understanding of valuation as a goal-dependent process, key to constructing the abstract representations at the basis of reasoning and intelligent behavior.

Title: Episodic memory impairments in Parkinson's disease: a meta-analysis

Authors: *A. Y. YOUM[1,2], E. WILLIAMS[1], J. KOH[1], M. VAZIRI[1], H. LEE[1], R. SIMPSON[2], K. DUNCAN[1], M. COHN[1,2];

Abstract: While there is growing consensus that episodic memory is impaired in Parkinson's disease (PD), variability across studies has obscured our understanding of the severity and nature of these impairments. To address this, we are conducting a meta-analytic review of episodic memory performance on clinical tools in nondemented PD patients compared to controls. In addition to quantifying the severity of episodic memory deficits in PD, we are coding for moderators to inform a current debate — whether these impairments stem solely from fronto-striatal dysfunction or whether hippocampal degeneration also contributes. If memory decline is a secondary effect of frontal-striatal deficits in PD, tasks that provide less support at retrieval (e.g. free recall versus cued recall or recognition) would show larger group differences. On the other hand, if memory impairments in PD are also hippocampal-mediated, PD groups would show greater forgetting after delays and worse performance in associative compared to item memory. From a sample of 25 studies, we found preliminary evidence for a large effect in which patients perform worse than controls across all memory measures, $p<0.0001$, $g= -0.7$, 95% CI [-0.85, -0.50]. These impairments seem to diminish when patients are tested over delays ($p=0.08$), and there is no significant difference between item and associative memory ($p=0.18$), inconsistent with a strong hippocampal contribution. However, we also found that greater degree of retrieval support did not minimize memory deficits ($p=0.82$), inconsistent with fronto-striatal predictions. Although preliminary, our findings do not provide unequivocal support for either proposal; analyses of other features of memory performance is warranted. Ultimately, such analyses will help elucidate the neural underpinnings of memory dysfunction in PD and inform the development of compensatory learning strategies.

Title: Effects of aging on women's brain health: a multivariate analysis of task fMRI data

Authors: *A. CRESTOL[1], S. RAJAGOPAL[4], A. ELSHIEKH[1], L. KHAYYAT[4], R. YOUNG[4], J. SNYTTE[2], S. LOPARCO[1], A. DUVAL[2], S. SUBRAMANIAPILLAI[2], S. RABIPOUR[3], S. PASVANIS[4], M. N. RAJAH[3];
[1]Integrated Program in Neurosci., [2]Psychology, [3]Psychiatry, McGill Univ., Montreal, QC, Canada; [4]Brain Imaging Centre, Douglas Inst. Res. Ctr., Montreal, QC, Canada

Abstract: Hormonal fluctuations resulting from menopause in middle-aged (MA) women have a robust impact on episodic memory - our ability to encode, store and retrieve past experiences in rich contextual detail. In a previous study, we demonstrated that sex differences were present in the effect of aging on brain function associated with episodic memory. The objective of the current task fMRI study was to contribute to this field of knowledge by assessing the impact of aging on brain function when targeting women at midlife. We compared fMRI task-related brain activity patterns in 20 young (18-39) and 26 MA (40-65) women as they encoded and retrieved face-location associations while being scanned. Multivariate partial least squares (PLS) analyses were performed to assess age differences in brain activity associated with different memory phases (encoding vs. retrieval), response types (source hits [SH] vs. source failures [SF] vs. correct rejections [CR]), as well as performance in the behaviour PLS (proportion of SH vs. SF). A mean-centered PLS identified three significant latent variables (LV; $p<.02$). The first two LVs demonstrated main effects of encoding vs. retrieval and encoding vs. CR in both groups. LV3 identified age-related differences in encoding and retrieval activations such that young women activated negative salience regions, including regions of the recollection network during SH retrieval to a greater degree than MA women, while MA women activated these regions to a greater degree during SH encoding (see figure). Both groups activated positive salience regions during SF retrieval, which comprised of the ventrolateral prefrontal cortex. Parallel sets of regions were identified in the behaviour PLS, which predicted encoding success in young women and retrieval success in MA women. These results reveal that an aging effect in both encoding and retrieval activations arise at midlife in women. A post hoc analysis was performed to compare pre/peri and post-menopausal MA women. While no significant results were found ($p>.05$), these preliminary results are currently underpowered.

Title: Bilingual language experience and education moderate the relationship between menopause and cognition.

Authors: *A. DUVAL[1], A. BEATTY-MARTINEZ[1], A. CRESTOL[1], A. ELSHEIKH[1], S. PASVANIS[2], L. KHAYYATT[2], R. YOUNG[2], J. SNYTTE[1], S. SUBRAMANIAPILLAI[1], D. TITONE[1], M. N. RAJAH[1,2];
[1]McGill Univ., Montreal, QC, Canada; [2]Douglas Mental Hlth. Univ. Inst., Montreal, QC, Canada

Abstract: Cognitive reserve (CR) refers to how individual differences in lifestyle impact one's ability to maintain normal cognitive processes in the presence of brain pathology. CR has been shown to mitigate age-related cognitive decline, such that people with higher levels of CR can withstand greater levels of neuropathology associated with neurodegenerative diseases i.e., Alzheimer's Disease. Education and bilingual language experience are common proxy measures of one's level of CR. Recently, our group found that women at midlife were more likely to show cognitive improvements with increased bilingual experience, yet midlife is also the time when women transition into menopause (Subramaniapillai et al., 2019). Menopause causes a decrease in 17b-estradiol levels, which have been linked to cognitive decline, however, little is known about how CR impacts the relationship between menopausal status and cognition. Thus, in this study, we investigated this issue. Specifically, we hypothesized that postmenopausal women would exhibit worse task performance compared to other groups, however, this effect would be smaller for women with high CR. We recruited 138 healthy adult women (pre and postmenopausal) with an age range of 19-66 (mean 38.75, SD 13.12). A Language and Social Background Questionnaire assessed proxy measures of CR (number of languages known, percentage of non-native language use and age of second language acquisition), as well as years of education. Cognitive performance was measured using the California Verbal Learning Task (CVLT; episodic memory) and the Wisconsin Card Sorting Task (WCST; cognitive control). Preliminary robust regression analyses revealed an interaction of age of second language acquisition and menopause status on CVLT long-free recall ($p < .01$, $B = -.33$) and WCST non-perseverative error ($p < .001$, $B = .22$) scores, such that postmenopausal women performed worse than premenopausal women with a later onset of second language. Additionally, a significant interaction effect of menopause status and the number of languages known on WCST non-preservative error scores was observed, such that postmenopausal women performed worse than premenopausal women ($p < .05$ $B = .14$), and premenopausal women with a higher number of languages known showed improved scores. These data provide preliminary evidence that CR,

operationalized as bilingual language experience and education, impacts the relationship between menopause and cognition. We continue to evaluate whether more social aspects of bilingual language experience play an especially critical role.

Title: Extrapolating the unobserved past and future in other people's autobiographical timelines

Authors: ***X. XU**[1], Z. ZHU[2], J. R. MANNING[1];
[1]Dept. of Psychological and Brain Sci., Dartmouth Col., Hanover, NH; [2]Sch. of Psychological and Cognitive Sci., Peking Univ., Beijing, China

Abstract: In our social interactions, we readily make inferences about what happened to other people in their past, and what will happen in their future. This can happen on short timescales, e.g. when we use contextual cues to join an in-progress conversation, or on longer timescales, e.g. when we make inferences about someone's past or future when we first meet them. To study these phenomena, we had participants view sequences of segments excerpted from the TV series *Why Women Kill*. Participants used free-form text responses to either predict what would happen next, or retrodict what had happened just prior, to the just-watched segment. We systematically varied whether participants watched the segments in forward or reverse temporal order, and how many segments preceding or proceeding the target segment they had seen prior to making a response. We also varied whether participants were told the main characters in the target segment. Participants were better at retrodicting past events than predicting future events. One reason is that, when characters referenced specific events from their past or future, participants better retrodicted and predicted those events. These references also indirectly affected predictions and retrodictions about their temporally proximal (non-referenced) events. When controlling for these references, participants were equally good at retrodicting and predicting. This suggests that asymmetries in how often characters referenced their past versus their future might account for the asymmetry in how well participants retrodict and predict past versus future events. Our work elucidates how we retrodict others' pasts and predict others' futures by showing how we draw on our observations in the present (including specific references to past or future events), and from our own relevant prior experiences and knowledge. This also explains the apparent contradiction between temporal symmetry in the information that the present gives people about the past versus the future, and the empirical observation that people tend to be better at retrodicting what happened in other people's pasts than predicting their futures.

Title: High resolution imaging of a parieto-occipital cortical network involved in monitoring peri-personal space

Authors: ***Z. NASIRIAVANAKI**[1], R. TOOTELL[1], B. BABADI[1], S. NASR[1], D. GREVE[2], J. POLEMINI[2], D. HOLT[1];
[1]Massachusetts Gen. Hosp., Boston, MA; [2]Martinos Ctr. for Biomed. Imaging, Boston, MA

Abstract: **Background**: The regulation of preferred physical distance from another individual ('personal space') is altered in several neuropsychiatric conditions, including autism and schizophrenia. Many prior studies have described regions in inferior parietal cortex that responds selectively to visual stimuli (including faces) that intrude into near (personal) space. To better understand that functional organization, we conducted high-resolution functional imaging (7T, 1.1 mm isotropic), extensively signal-averaged in within-subject analyses. **Methods:** Seven healthy subjects were scanned using three different tasks. In the main task, subjects viewed human face images that appeared to approach or withdraw from the subjects. In the second (control) task, we presented random dot stereograms, which formed a stereoscopic (3D) percept of a cuboid at different distances from a subject. In a third (control) task, we tested responses to stationary (rather than moving) face stimuli. **Results:** The first task (approaching vs. withdrawing faces) activated discrete patches in inferior parietal cortex. Approach-biased patches dominated the withdrawal-biased patches, in size and number. All patches were radially elongated, similar to cortical columns in lower visual areas. The near-vs. far columns based on personal space were systematically interdigitated with the columns based on visually-defined (stereoscopic) distance. The third task showed that the approach-biased patches showed a BOLD amplitude x distance response that was similar to that found earlier in behavioral tests: i.e. highest to the nearest faces, decreasing to increasingly further faces as a power function, reaching baseline near and well beyond the behaviorally-defined personal space boundary in each subject. **Conclusions:** Specific radially-elongated patches ('columns') located in inferior parietal cortex are activated by faces that intrude into personal space. The topography suggests that 'near-vs. far' columns in eye-based coordinates (based on stereopsis) are systematically paired with another set of columns that are selective for 'near vs. far' distances in visually-defined space.

Title: Midline Thalamus Modulating Mnemonic Discrimination

Authors: *M. V. RIVERA NUNEZ, D. MCMAKIN, A. T. MATTFELD;
Psychology, Florida Intl. Univ., Miami, FL

Abstract: Anxiety is a common pediatric psychopathology that affects 1 in 3 youth and increases the risk of comorbid pathologies, such as depression. This pernicious disorder begins during peripuberty – a transitioning period between childhood and adolescence. One of its common features is negative overgeneralization, or responding similarly to innocuous situations that share features with past aversive events. Prior research has investigated bottom-up mechanisms, such as amygdala-salience detection. Yet, evidence in rodents shows the nucleus reuniens (RE), a medial thalamic nucleus, exercises control over fear memory specificity by modulating medial prefrontal cortex inputs to the hippocampus. To our knowledge, no studies have examined the role of the RE in negative overgeneralization. We analyzed data from 34 children, between 9-14 years of age with varying degrees of anxiety. Clinic and community samples were recruited to maximize our effect of interest: negative overgeneralization. To approximate the location of the RE, we used probabilistic tractography and a k-means clustering approach based on ipsilateral connectivity to cortical and subcortical targets. We collected brain activation to positive, neutral, and negative valenced pictures during Study and Test sessions separated by 12 hours. During Test, participants performed a memory recognition test with target, foil, and lure (i.e., similar but not identical) pictures. False alarming (FA) to negative, relative to neutral images was our operational definition of negative overgeneralization. We predicted decreased RE activation at encoding for negative stimuli that were subsequently replaced by a lure and FA. Analyses were made with either a paired samples t-test or a Wilcoxon signed rank test, if assumptions of normality were violated. We found a significant increased RE activation for negative compared to neutral images that were replaced by lures and FA ($t(33) = 1.99$, $p = 0.05$). To examine an extension of our original definition of negative overgeneralization, we assessed activation differences for negative images subsequently replaced by a lure and FA, relative to those correctly rejected (CR). We expected RE activity at encoding would decrease for negative lures FA, compared to those CR. Our results showed no differences in RE activation ($t(33) = 0.08$, $p = 0.93$). The present findings shed light onto a novel limbic thalamus mechanism of negative overgeneralization that could further our understanding of anxiety.

Title: The neural signatures of extensive training

Authors: P. HUYCKE, P. VERBEKE, C. BOEHLER, T. VERGUTS;
Ghent Univ., Ghent, Belgium

Abstract: Objectives: Frontal theta-frequency rhythms are important for dealing with cognitive tasks, but their exact role remains obscure. Theta oscillations might resolve conflict or error arising during task execution. Alternatively, they may support task processing at a slower time scale. For example, theta may support learning task-relevant stimulus-response (S-R) mappings. Furthermore, alpha-frequency rhythms have been implicated in optimizing task performance via inhibition of task-irrelevant processing pathways. The differential roles of theta and alpha have not been empirically clarified, however. For example, it is unknown whether they operate at similar (fast or slow) time scales, and whether they support different learning processes.
Research question: We present an EEG study to address this issue. Within each task block (fast time scale), 8 S-R mappings of a procedural learning task were presented repeatedly. Across blocks, the same S-R mappings were repeated (slow time scale; interleaved with novel S-R mappings). At behavioral level, we expect that reaction times (RT) decrease, and accuracy increases with training. Neurally, we expect that theta power decreases and alpha power increases with training. Moreover, we investigate whether theta and alpha evolved (resp., decrease and increase) according to fast or slow time scales.
Materials and methods: We recorded EEG in 28 participants while they performed a procedural learning task. Participants learned which stimulus is associated to which response. Some S-R pairs were repeated throughout the task. The experiment consisted of 16 blocks, where eight blocks showed new stimuli, and eight blocks (interleaved) showed recurring stimuli. This allowed us to disambiguate the fast time scale (i.e. number of times one saw a stimulus in a block) from the slow time scale (i.e. the number of blocks completed so far).
Results: Behaviorally, both RT and accuracy improve (resp. decrease and increase) over both fast and slow timescales. Neurally, theta significantly decreases following the slow timescale, whereas alpha instead significantly increases along the fast timescale.
Conclusion: We demonstrate that theta and alpha both play a role during procedural learning, but operate at different time scales. Specifically, our results suggest that theta and alpha may operate on slow and fast time scales, respectively.

Title: Prediction in Autism Spectrum Disorder: What Does the Empirical Evidence Say?

Authors: J. CANNON[1], ***A. M. O'BRIEN**[2,1], L. BUNGERT[1], P. SINHA[1];
[1]MIT, Cambridge, MA; [2]Harvard Univ., Boston, MA

Abstract: According to a recent influential proposal, several phenotypic features of autism spectrum disorder (ASD) may be accounted for by differences in predictive skills between autistic and neurotypical individuals. In the past five years, over 700 studies have explored this possibility. In this presentation, we will describe the results from a systematic review of the subset (n=47) that have used empirical methods to directly test this hypothesis. We followed the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines to identify these articles, and assessed the results based on two observable aspects of prediction: learning a pairing between an antecedent and a consequence and responding to an antecedent in a predictive manner. The aggregated results highlight distinct differences in both predictive learning and predictive response. Studies showing differences in habituation and perceptual adaptation suggest low-level predictive processing differences in ASD. Studies documenting differences in learning predictive pairings indicate challenges in detecting such relationships, especially when predictive features of an antecedent have low salience or consistency. These challenges may account for the observed differences in the influence of predictive priors, in spontaneous predictive movement or gaze, and in social prediction. These results point to several promising avenues for future research. These include studying prediction within naturalistic contexts, assessing the effect of prediction-based interventions, and testing multiple types of prediction within the same individuals, which may help establish a link between low-level processing differences and predictive learning impairment.

Title: Investigating hippocampus sensitivity to learning sequence in a categorization task using a neural network model

Authors: *E. M. HEFFERNAN, M. L. MACK;
Psychology, Univ. of Toronto, Toronto, ON, Canada

Abstract: Introduction. Category learning is key to navigating an information-rich world. However, many categories contain exceptions that violate a general rule. Previous research has implicated hippocampus (HC) in rule-plus-exception (RPE) category learning, but limited work has explored hippocampal sensitivity to changes in learning sequence. Specifically, does delaying the introduction of exception stimuli (ES) in an RPE category learning task impact learning outcomes? We predicted that participants who were able to learn the rule before learning ES would be better able to detect and properly categorize ES. The delayed introduction of ES would elicit surprise, prompting the formation of distinct, pattern-separated memories for ES that would improve subsequent ES categorization. We explored HC's role in this manipulation using an anatomically inspired neural network model. **Methods**. Ninety-three participants completed the experiment. Participants sorted eight flower stimuli that varied across three binary-valued dimensions. Two stimuli were defined as category prototypes and were maximally dissimilar. Rule-followers differed from their category's prototype along one dimension, and ES differed from their category's prototype across two dimensions (i.e., they were more similar to the prototype of the opposite category). Participants completed three learning blocks with 48 trials. Full feedback was provided after each trial. Participants were randomly assigned into one of two conditions. In the "early exceptions" (EE) condition, participants viewed ES in all three learning blocks. In the "late exceptions" (LE) condition, participants were not exposed to ES until the second learning block. Following the learning blocks, participants completed a "no-feedback" (NF) block with 48 trials. This task was then simulated with a previously developed neural network model of HC to assess HC's sensitivity to trial order. **Results**. In the behavioural experiment, ES categorization improved significantly more with repetition in the late condition than in the early condition throughout the learning blocks ($P<.001$). ES categorization accuracy was also higher in the NF block for the LE condition ($P=.001$). These results were replicated by the model: ES categorization accuracy in the LE condition was significantly higher than in the EE condition ($P=.005$). **Conclusion**. This work offers an empirical demonstration of how learning sequence effects performance in a category learning task. Moreover, we provide novel computational evidence of HC's sensitivity to learning sequence in an RPE task that lends further support to HC's broad role in cognition.

Title: Flexible frameworks of thought advance creativity and innovation

Authors: *N. C. CATANZARITE[1], K. N. DUNBAR[2];
[1]Program in Neurosci. and Cognitive Sci., [2]Dept. of Human Develop. and Quantitative Methodology, Univ. of Maryland, College Park, MD

Abstract: From children building a pillow fort to technology giants in Silicon Valley, creativity is overwhelmingly apparent in learning and innovation. To uncover factors that modulate the generation of new ideas, we investigated creativity as a flexible ability rather than a fixed trait. To do this, 133 human subjects were randomly assigned to hypothetically adopt an eccentric mindset, a simple mindset, or to the control condition in which no instructions regarding mindset were given. An Alternate Uses Task (AUT), in which subjects generated as many uses as possible for a series of ten everyday objects, was used to measure divergent thinking ability under the assigned mindsets. Hypothetically adopting an eccentric mindset enhanced subjects' divergent thinking ability, while no difference was found between adopting a simple mindset or receiving no instructions regarding mindset. These findings shed light on the bounds of divergent thinking. We conclude that the framework in which humans generate new ideas is flexible and can be modulated by mindset. Moreover, these findings lay a foundation for the development of interventions that may hold power in advancing humans' ability to generate new ideas. Further, we are using functional near-infrared spectroscopy (fNIRS) to investigate the neural networks and time course of activation of the brain regions underlying creative thought. By contrasting activation patterns observed during completion of the AUT to those evoked by a control task in which subjects name the characteristics of a set of objects, we are able to determine the neural correlates of divergent thinking. However, our collection of neural data is currently paused due to the COVID-19 environment. This study is innovative in its use of stimuli that reflect the way humans encounter information in the real world, as well as its ability to collect detailed behavioral responses.

Title: Test-retest, internal consistency, and split-half reliabilities of the Gibson Assessment of Cognitive Skills, a brief tool for screening cognitive function across the lifespan

Authors: *C. LEDBETTER[1], A. L. MOORE[2];
[1]Neurosurg., LSU Hlth. Sci. Ctr. - Shreveport, Shreveport, LA; [2]Gibson Inst. of Cognitive Res., Colorado Springs, CO

Abstract: Human cognition researchers need a rapid tool for assessing cognitive skills. Robust tools to quickly screen performance across the lifespan on primary cognitive skills or that can be administered and scored by non-clinical research personnel are in high demand. The aim of the current study was to examine reliability of the Gibson Assessment of Cognitive Skills (GACS), a paper-based, brief cognitive screening tool for children and adults measuring working memory, processing speed, visual processing, fluid reasoning, and three auditory processing constructs: sound blending, sound segmenting, sound deletion along with work attack skills. The sample (n = 103) for the current study consisted of children (n = 73) and adults (n = 30) between the ages of 6 and 80 (M = 20.2, SD = 17.7), 47.6% female, and 52.4% male. Analyses of test data included calculation of internal consistency reliability, split-half reliability, and test-retest reliability. Internal consistency reliability was conducted using JMetrik's Item Analysis procedure which produced a coefficient alpha for each subtest. Split-half reliability was determined by dividing the test items into odd and even halves and running Pearson's correlations in JMetrik for each subtest and applying a Spearman-Brown formula to each one. To determine test-retest reliability, we used SPSS to run Pearson's correlations between the two test administrations spaced one week apart. A regression analysis in SPSS examined differences in subtest scores based on sex. Overall coefficient alphas range from .80 to .94, producing a strong source of internal consistency reliability evidence. The split-half reliability coefficients ranged from .83 to .96 overall, producing a strong second source of reliability evidence. Across all ages, the test-retest reliability coefficients ranged from .83 to .98. For adults ages 18 to 80, test-retest reliability coefficients ranged from .73 to .99. For children ages 6 through 17, test-retest reliability coefficients ranged from .89 to .97. All correlations were statistically significant at $p < .001$, indicating strong test-retest reliability and stability across administrations. Post hoc analysis of sex differences found no statistically significant differences in mean scores on any subtest. The evidence collected for the current study suggests that the GACS is an accessible and reliable brief screening tool for assessing cognitive skill performance across the lifespan. Each subtest was stable over time, indicating it is reliable method for assessing performance in pre-post intervention studies as well as longitudinal studies with cognition outcomes.

Title: Sub-second dopamine fluctuations in human striatum and their role in trial-to-trial variations in interval timing.

Authors: *R. SADIBOLOVA[1], E. DIMARCO[2], A. JIANG[2], D. TERHUNE[1], K. T. KISHIDA[2,3];
[1]Goldsmiths, Univ. of London, London, United Kingdom; [2]Physiol. and Pharmacol., Wake Forest Univ. Sch. of Med., Winston Salem, NC; [3]Dept. of Neurosurg., Wake Forest Sch. of Med., Winston Salem, NC

Abstract: As a factor critical to most forms of learning, behaviour, and sensory-motor processing, time is a fundamental dimension of human experience. However, even though the ability to perceive time belongs to the most important and basic functions and the timing of intervals is a ubiquitous daily task, our timing estimates are notoriously variable and prone to biases. Multiple strands of evidence implicate dopamine systems in interval timing, including the pharmacologically induced altered temporal performance or poorer temporal precision in clinical populations with aberrant striatal dopamine profiles such as the Parkinson's disease or schizophrenia. Here, we investigated how striatal dopamine tracks trial-by-trial variations in interval timing in a sample of patients with Essential tremor undergoing deep brain stimulation treatment. Using fast scan cyclic voltammetry (FSCV), we recorded the in vivo electrochemical signal (at 10 Hz) during completion of a visual temporal bisection task (stimulus range: 500 - 1100 ms). On each trial, patients classified the duration of a stimulus based on its similarity to short or long reference intervals which they learnt prior to the testing phase. The behavioural responses yielded standard psychophysical measures of temporal bias and precision. The FSCV approach additionally involved in vitro experiments which generated recordings with known concentrations of dopamine and other analytes for the purpose of cross-validated training of an elastic net regression model for optimal dopamine signal prediction. This model was subsequently applied to infer human dopamine concentrations. Our primary analyses and predictions are based on a similar study reporting on midbrain dopamine tracking of temporal performance in rodents. Accordingly, we predicted that the human data would show analogous trends with high and low dopamine concentration levels associated with a tendency to under- and over-estimate temporal intervals, respectively. To evaluate this prediction, we will divide behavioural responses into high, medium, and low terciles of the distribution of dopamine response following the end of the stimulus interval. We expect that the psychometric function

fitted to low-tercile trials will show a leftward shift reflecting temporal overestimation whereas that fitted to the high-tercile trials will show a rightward shift reflecting temporal underestimation. If these predictions hold, these results will help to advance current understanding of the neurochemical bases of fluctuations in time perception.

Abstract: Spoken language development requires support of the structures along the auditory neural pathway from the auditory brainstem to the cortex. Children's early language development is highly variable despite growing up in the same language environment. We hypothesize that one source of this behavioral variability is physiological variability in the auditory neural system across individuals. To test this hypothesis, EEG responses were collected from 118 Cantonese-learning infants (1-12 months of age) while they listened to three speech stimuli, that differed principally in pitch, during natural sleep. Between 3 to 16 months after the initial EEG recording, their language and communication skills were assessed using the Words and Gestures form of the Chinese Communicative Development Inventories – Cantonese version (CCDI-C). Predictive models were constructed via support vector machine classification with cross-validation to classify infants into either two or three groups. In the two-way classification, children were classified into those with future CCDI-C scores below 25th percentile and those above 25th percentile for their age and sex group, while the three-way classification classified them into <25th, 25th – 75th, and >75th percentile groups. Age-corrected EEG data that included both early- and late-latency neural responses to speech such as FFR pitch strength and P1 latency as well as gestational age and birth weight were used as model inputs. The statistical significance of the predictive model was calculated as the proportion of the randomly permuted data above the mean of the model performances across 10,000 bootstrapping iterations. Across the CCDI-C

measures, the mean area under the receiver operating characteristic curve of the predictive models of early gestures, later gestures, vocabulary comprehension and vocabulary production were respectively at 0.92 ± 0.030, 0.91 ± 0.028, 0.90 ± 0.034, and 0.89 ± 0.04 for the two-way classification, and 0.88 ± 0.041, 0.88 ± 0.33, 0.85 ± 0.046 and 0.85 ± 0.049 for the three-way classification (ps<0.001). These results demonstrate a strong association between functions of the auditory neural pathway and children's future language outcome, to the extent that individual-level outcome prediction is possible and within the range of clinical utility. Early prediction enables caregivers and clinicians to plan for early intervention should it be needed. Measuring neural responses to speech coupled with language outcome prediction models is a potential avenue for early prediction and personalization of preventive early intervention for those infants who are susceptible to communication disorders.

Title: Revealing factors of subjective impressions affecting learnability of novel concepts using the semantic differential method

Authors: *H. KURASHIGE, J. KANEKO;
Res. & Information Ctr., Tokai Univ., Tokyo, Japan

Abstract: In knowledge acquisition or learning of the human, we actively select an item to be acquired. However, especially for the learning of abstract items such as semantic concepts, so far, attributes characterizing the items that are selectively learned better has not been studied in depth. To reveal such attributes, we conducted an experiment in which human subjects were asked to learn novel compositional words that should mean new semantic concepts. The novel compositional words used in the present study were constructed by randomly combining two two-character Japanese kanji nouns. We investigated relationships between the learnability and the features of each compositional word that were quantified based on the semantic differential (SD) ratings of it. The experiment was composed of the following five tasks: 1) flash presentation task, 2) N-back working memory task, 3) recognition memory test, 4) SD rating task, and 5) questionnaire survey of the Schwartz's core values. In the flash presentation task, 20 target and 20 dummy novel compositional words were presented to the subjects. This was

followed by the N-back task to wash the short-term memory of the compositional words. Next, we tested the recognition memory of the target compositional words. Then, we conducted the SD rating task in which the subjects were required to rate each target compositional word with 40 bipolar adjective scales. Finally, we investigated the individual attributes of values using the Schwartz's core value survey. We applied the factor analysis into the data of the SD ratings and found the following SD factors: "badness", "farcicality", "activity", "simplicity", "innovativeness", "importance", "beauty", and "bigness". One factor was empty. We also applied the same analysis to the data of the Schwartz's core value survey and identified three factors that roughly correspond to the "Social Focus", "Openness to change", and "Self-Enhancement", respectively. Using the linear model analysis, we investigated relationships between memory confidence of each compositional word and the SD and value factors. The values of coefficients corresponding to "badness", "farcicality", and "importance" factors are significantly positive. Importantly, the coefficient of the interaction between the "badness" SD factor and the "Openness to change" value factor is significantly negative. Those results suggest that human selectively learn important, bad, and/or farcical information to construct knowledge.

Title: Exploring Structural Brain Changes Induced by Vocabulary Learning of a Second Language: A Short Longitudinal MRI Study.

Authors: *A. E. CARRILLO[1], Z. YANG[2], L. GHAZI-SAIDI[3];
[1]Inst. Politécnico Nacional, Ciudad de Mexico, Mexico; [2]Cleveland Clin., Cleveland, OH;
[3]Communication Disorders, Univ. of Nebraska at Kearney, Kearney, NE

Abstract: A number of neuroimaging studies have reported structural neuroplasticity as a result of life-long and short period language use and exposure. To this date, results have been inconsistent across studies, with variability in terms of the location and directionality of changes. We examined the structural brain changes regarding volume of the structures and cortical thickness, as a result of learning 132 selected words in a second language (L2) during four weeks. In this study, 24 healthy monolingual participants, matched for gender, age, motivation and previous language learning experience participated in a four week computerized audiovisual L2 vocabulary training for 15 minutes a day. Participants were scanned after the first week (Phase I; Accuracy rate: 35%; low proficiency level) and four week (Phase II; Accuracy rate 98%; high proficiency level). Behavioral assessment at phase I and II included confrontation naming of the vocabulary learnt during the training. Accuracy rates and response times were compared after the first week and the fourth week. Freesurfer was used to measure cortical thickness and volumetrics of the cortical and subcortical areas, using the default setting. The

output of cortical thickness and volumes of cortical and subcortical structures recorded at phase I and II were compared using SPSS. Behavioral measurements including accuracy rates and response times (RT) confirmed consolidated learning (RT_{T1}= (M = 2.1, S = 0.32); RT_{T2}=(*M* = 1.7, SD = 0.23), $t(12) = 4.52$, $p = .001$. Cortical thickness and volumetric measures reflected non-significant changes across phases. Our findings suggest that three weeks of vocabulary learning is not enough to make any significant structural brain changes. Compared with the functional changes reported previously, these findings reflect functional changes come before structural changes, which require longer or more intensive practice. Better understanding of how structural changes occur can have implications in teaching a second language, as well as in developing successful intervention plans for patients with aphasia in which the duration, frequency and intensity of language therapy is optimal.

Title: Modeling pronoun resolution in the brain

Authors: *J. LI[1], W.-M. LUH[2], L. PYLKKÄNEN[3], Y. YANG[4], J. HALE[5];
[1]New York Univ. Abu Dhabi, Abu Dhabi, United Arab Emirates; [2]Natl. Inst. on Aging, Baltimore, MD; [3]New York Univ., New York, NY; [4]Jiangsu Normal Univ., Jiangsu, China; [5]Univ. of Georgia, Athens, GA

Abstract: One unique machinery of human language is reference, that is, using a linguistic symbol such as pronouns to pick out certain entities in the discourse context. We typically have no difficulty linking a pronoun to its antecedent during language comprehension, yet the neural computations underlying this linking process remain elusive. To achieve a detailed, process-based understanding of pronoun resolution, we utilize computational models that lay out specified and carefully thought-out steps to achieve pronoun resolution. By evaluating the cognitive validity of these models against human brain activity, we provide insights on the constituting elements and their interactions during the cognitive process of pronoun resolution. We selected three symbolic models that formalize three influential theories on pronoun

resolution. The syntax-based Hobbs model implements the classic Binding Theory in formal linguistics, which states that pronouns cannot be coindexed with antecedents in the same clause. The discourse-based Centering model implements the Centering Theory that views pronominalization as a means to achieve discourse coherence. The memory-based ACT-R model conforms to the salience account for pronoun resolution, and selects the most highly-activated entity in the working memory as the antecedent of the pronoun. In addition to the knowledge-based models, we also included one data-oriented deep neural network model that learns a statistical pattern to cluster coreferential mentions from a labeled dataset. We correlated the four model predictions with brain activities during pronoun resolution. We recorded the BOLD signals while participants listened to a 100-minute audiobook of "The Little Prince" in the fMRI scanner. We collected data from English and Chinese speakers using the same paradigm to test whether linguistic typology would influence the strategies for pronoun resolution. To further explore the temporal dynamics of the model fit, we also collected an MEG dataset while English speakers listened to a 12-minute audio excerpt from the YouTube channel "SciShow Kids". We applied both multivariate RSA and univariate GLM analyses to compare the four models' relatedness to the BOLD responses and the source-localized MEG data time-locked at each third person pronoun in the narratives. Our combined results suggest that the memory-based ACT-R model best explains the neural signatures for third person pronoun processing, primarily localized at the left middle temporal gyrus (LMTG) at around 300-400 ms after the onset of the pronouns. We propose a domain-general mechanism for pronoun resolution that resembles memory retrieval.

Title: Convergence of Heteromodal Lexical Retrieval in the Lateral Prefrontal Cortex: A Brain Tumor Model

Authors: *A. A. AABEDI[1], S. KAKAIZADA[1], J. S. YOUNG[1], O. WIESE[2], C. VALDIVIA[1], S. KRISHNA[1], M. BERGER[1], D. H. WEISSMAN[2], D. BRANG[2], S. L. HERVEY-JUMPER[1]; [1]Neurolog. Surgery, Univ. of California San Francisco, San Francisco, CA; [2]Psychology, Univ. of Michigan, Ann Arbor, MI

Abstract: Lexical retrieval requires selecting and retrieving the most appropriate word from the lexicon to express a desired concept. Prior studies investigating the neuroanatomic underpinnings of lexical retrieval used lesion models that rely on stereotyped vascular distributions, functional neuroimaging methods that lack causal certainty, or direct electrical stimulation which is confounded by anesthesia and narrow cortical exposures. Furthermore, only a few studies have

probed lexical retrieval with tasks other than picture naming and have yielded conflicting results regarding the role of the temporal lobe as a convergence zone for both visual and auditory inputs. In the present study, we set out to identify areas of the brain required for heteromodal lexical retrieval by implementing a lesion-symptom model in patients with cytoarchitecturally disruptive brain tumors in perisylvian language areas. We asked fifty-three patients with lesions encompassing dominant frontal, temporal, and anterior parietal areas to perform four language tasks: picture naming, text reading, auditory naming, and describing line drawings with correct syntax. A subset of participants also underwent the Quick Aphasia Battery, which provides a validated measure of lexical retrieval via the word finding subtest. Generalized linear modeling and principal components analysis revealed multicollinearity between picture naming, auditory naming, and word finding, implying redundancies among these linguistic measures. Support vector regression lesion-symptom mapping across participants tested whether and where lesioned voxels were associated with lower accuracies on each of the four language tasks. We found that both picture naming and auditory naming survived cluster-level corrections. Specifically, lesions within overlapping clusters of 8,333 voxels and 21,512 voxels in the left lateral PFC were predictive of impaired picture naming and auditory naming, respectively. Notably, in contrast to prior studies that used correlational functional imaging techniques, we did not find a significant association between lesions in the temporal lobe and lexical retrieval task performance. Overall, these findings provide novel support for models that posit convergence of heteromodal lexical retrieval processes within the PFC. They also illustrate the feasibility of lesion-symptom mapping in patients with cytoarchitecturally disruptive brain tumors.

Title: Neural mechanism underlying speech production during delayed auditory feedback

Authors: *M. OZKER SERTEL, W. DOYLE, O. DEVINSKY, A. FLINKER;
NYU Sch. of Med., New York, NY

Abstract: Monitoring the vocal output during speech production allows the detection and correction of vocalization errors in real-time, however the neural mechanism underlying this auditory feedback control of speech is poorly understood. We obtained electrocorticography

recordings from human subjects while they read aloud words and sentences during delayed auditory feedback. Subjects slowed down their speech rate to compensate for the delay and this behavioral effect was stronger for sentences. Neural responses in superior temporal, supramarginal, inferior frontal and dorsal prefrontal regions were both enhanced in amplitude and extended in duration for large delays reflecting the error signal caused by altered feedback and the subsequent longer articulation. Response enhancement was stronger across the speech network for sentences when delayed feedback had a stronger disruptive effect on speech. Our results highlighted dorsal precentral gyrus as a critical region for auditory feedback control of speech, which showed selective response enhancement during slowed down speech and was recruited much earlier compared to other vocal motor sites. Furthermore, our subjects performed an auditory repetition task, which we used to identify auditory sites that show suppressed responses during speaking compared to listening. Our results revealed that sites that show stronger auditory suppression also show stronger response enhancement to delayed feedback, providing evidence for a shared mechanism between speech-induced auditory suppression and sensitivity to altered feedback in humans.

Title: Neural basis of sound-symbolic pseudoword-shape correspondences

Authors: D. A. BARANY[1], *S. A. LACEY[2], L. C. NYGAARD[3], K. SATHIAN[2];
[1]Dept. of Kinesiology, Univ. of Georgia, Athens, GA; [2]Penn State Col. of Med., Hershey, PA; [3]Emory Uinversity, Atlanta, GA

Abstract: Sound symbolism is a form of crossmodal correspondence that refers to a non-arbitrary mapping between the sound of a word and its meaning. Research has mostly concentrated on the mapping of sound to shape, in which people assign auditory pseudowords, like “moh-loh” and “keh-teh”, to rounded and pointed visual shapes, respectively. However, the neural basis of this sound-symbolic correspondence is not well understood. Here, we used functional magnetic resonance imaging (fMRI) to investigate neural representations of the sound-to-shape correspondence. Participants (n = 24) were presented with audiovisual stimuli consisting of a visual shape (rounded or pointed) and an auditory pseudoword (“moh-loh” or “keh-teh”) that were either congruent (e.g., rounded/moh-loh) or incongruent (e.g., pointed/moh-loh) with respect to the sound-symbolic correspondence. Blood oxygen level-dependent (BOLD) responses were estimated using the general linear model with each trial modeled as a boxcar of

variable duration to control for differences in response time across conditions. All reported analyses were corrected for multiple comparisons at the group level. A univariate contrast showed greater activation in the left precentral gyrus for incongruent relative to congruent stimuli and greater activation in the right caudate nucleus for congruent relative to incongruent stimuli. Searchlight multivariate pattern analyses (MVPA) were then conducted after factoring out univariate effects. Higher above-chance classification of the audiovisual stimuli was found in the pars opercularis of the left inferior frontal gyrus (Broca's area) and the right middle occipital gyrus when the stimuli were congruent across modalities, relative to when the stimuli were incongruent. Cross-classification analyses showed that while visual and auditory cortices robustly differentiated visual or auditory stimuli, respectively, regardless of audiovisual congruency, the left precentral gyrus, the right thalamus, and the right caudate distinguished congruent from incongruent stimulus pairs, independent of the visual or auditory features. Taken together, these findings indicate distinct roles for different brain regions during the processing of sound-symbolic correspondences. For instance, visual and auditory cortices encode visual and auditory stimuli, respectively; the left precentral gyrus and right caudate nucleus are associated with audiovisual congruency; and Broca's area distinguishes audiovisual stimuli better when they are congruent than incongruent. Thus, sound symbolism engages neural processes in sensory, motor and language domains.

Title: Referential semantics implicates medial parietal cortex and hippocampus in electrocorticography

Authors: *E. MURPHY, K. FORSETH, *P. ROLLO, Z. ROCCAFORTE, N. TANDON; Univ. of Texas Hlth. Sci. Ctr., Houston, TX

Abstract: The ability to establish referential relations is a hallmark of language. While the formal processes of semantic computation have received detailed theoretical treatment, a compositional neural architecture for language remains at a distance. Here, we isolate the mapping of sentential representations onto successful versus unsuccessful referents. Currently, there is no consensus in the field about the neural localization of referential composition. We used intracranial electrocorticography with penetrating depth and surface grid electrodes with high spatiotemporal resolution to address this issue. Patients (n=71) were implanted with depth and surface grid electrodes (n=13298) for the evaluation of medically refractory epilepsy, with full coverage over language-dominant cortex. They were asked to quickly and accurately

articulate the name of common objects in response to descriptions (range: 3-12 words; average: 6.5; average response time: 1200ms), presented in rapid serial visual presentation (500ms per word). The final word in each sentence was either congruent or incongruent ("*A person at the circus who makes you* [*laugh/commute*]") (80 trials per condition). We analyzed broadband gamma (70-150Hz) activity to index cognitive engagement of cortical substrates. We identified greater gamma activity at the onset of the final word in congruent trials across left inferior frontal regions (~150ms post-onset), medial parietal cortex (~250ms) and hippocampus (-400ms post-onset). Medial parietal regions mediate action encoding, which possibly explains these effects since incongruent items often involved impossible/failed actions (e.g. "*Something that grows on your* [*face/name*]"). These regions are also part of the default network, which shows activity increases during endogenous attentional tasks, with representational search likely being greater for referential relations. Research into this fronto-parietal referential network will contribute to rehabilitative solutions and neuro-prosthetic designs for individuals with reading deficits, and in particular patients with anomic aphasia and alexia. In addition, we provide the first intracranial analysis in a large patient cohort of the central component of natural language semantics - reference.

Title: Dynamics of superior temporal sulcus in self-generated speech in large-scale electrocorticography

Authors: *L. BULLOCK, K. J. FORSETH, N. TANDON;
Dept. of Neurosurg., Texas Inst. for Restorative Neurotechnologies, Houston, TX

Abstract: To communicate effectively, humans readily recognize different voices in their environment. The means by which we perceive our own speech and that generated by another person are distinct in nearly all models of speech perception, but the mechanisms subserving this process remain unclear. While fMRI studies have implicated the right superior temporal sulcus (STS) in speaker recognition, we compile high-SNR intracranial EEG (iEEG) to paint a more detailed picture of the cortical dynamics of this region during the processing of self-generated speech. Epileptic patients (n=81) were implanted with electrodes (n=13218) for resective surgery evaluation. This included both stereotactic depth electrodes (n=8096) and cortical-surface grid electrodes (n=5122). Patients engaged in a picture-naming task in which they responded with the name of the object if the picture was intact, and "scrambled" if the image was incoherent. The latter condition served as the self-generated speech condition. In another cued-naming task, patients listened to pre-recorded definitions, many of which begin with the word "something".

The passive perception of this somewhat similar (fricative-initial, disyllabic) word served as the control condition of externally-generated speech. We first used surface-based mixed-effects multilevel analysis (SB-MEMA), with high-gamma activity (60-120 Hz) as a measure of cortical activity, to identify regions implicated in self-generated speech. We then narrowed our focus to the right STS, inspecting time-series high-gamma at individual electrodes and at the population level within the ROI.In addition to the expected increased activity in speech motor regions and suppressed activity in primary auditory cortex, we find right anterior STS (raSTS) is more active at articulation onset in the self-generated speech condition. Further, raSTS is re-engaged just after the offset of the first syllable (~300ms) through the end of the second syllable, remaining at least 30-40% higher for self-generated speech. See accompanying figure for tentative results.

Title: Exploring the limitations of field potential recordings in electrocortocography; how referencing scheme, electrode size and inter-electrode distance confound level interpretability

Authors: *M. J. MCCARTY[1], O. WOOLNOUGH[2], N. TANDON[3];
[1]MD Anderson UT Hlth. Grad. Sch., Houston, TX; [2]Vivian L Smith Dept. of Neurosurg., UT Hlth., Houston, TX; [3]Neurolog. Surgery, Univ. of Texas Med. Sch. at Houston, Houston, TX

Abstract: Intrinsic to the analyses of electrocorticography (ECoG) are assumptions regarding the source and extent of neural activity a given electrode can detect. This problem of source localization is not new, and there are a diversity of methods in both human and animal models by which best estimations are implemented. Difficulties emerge when incorporating data across various electrode types and recording scales. These assumptions ultimately limit our understanding of what the informative resolution is when we record task-related human neural activity.
We explored these ambiguities across three scales of recording electrodes implanted in patients

monitored for intractable epilepsy (n=21). The largest are subdural electrodes (SDE; 3mm diameter and 3-4mm pitch (inter-electrode distance)), macro stereo-EEG electrodes (sEEG; 2mm length and 2mm pitch), and micro sEEG electrodes (0.5mm length and 1mm pitch). We compared activity bandpass filtered into theta (4-8Hz), alpha (8-15Hz), beta (15-30 Hz), narrowband gamma (30-60 Hz), and broadband high gamma (70-150 Hz) in the second following auditory stimulus onset. By fitting an exponential decay curve we estimate the full-width half maximum (FWHM) of the decay of signal cross-correlations over distance between electrodes.
The mean FWHM between SDE pairs (n=5152) was 18.7 ± 1.6 (Mean ± SE) and between macro-sEEG pairs (n=76646) was 23.2 ± 0.8 and between micro-sEEG pairs (n=471) was 24.1 ± 1.9. There was a significant effect of frequency band on the FWHM with gamma band activity showing significantly smaller spread across SDE and micro-sEEG electrode pairs. A pivotal confound of ECoG recordings is referencing scheme, and we compare correlation across multiple referencing conditions including common average, selective power, white matter, and bipolar references. We found FWHM of lower frequencies of macro-sEEGs to be most influenced by the referencing scheme, which suggests the referencing condition is pivotal to analyses which incorporate lower frequency ECoG recordings.
Invasive neural recordings provide a unique, high spatiotemporal window into human cognition, but the limitations intrinsic to this method must be considered. With continued progress in neuroengineering pushing advances in neural recording interfaces, the key question remains how best to integrate findings across varying recording scales. Our analyses not only explore caveats of field potential recordings across scale, but can also inform probe design, to eliminate redundancy and over-sampling of neural space while maximizing for signal to noise ratio.

Title: The crucial role of the mid fusiform cortex in lexical access

Authors: *K. SNYDER[1,3], C. DONOS[4], P. ROLLO[1], J. BREIER[1], S. FISCHER-BAUM[5], N. TANDON[2];
[2]Neurolog. Surgery, [1]The Univ. of Texas Hlth. Sci. Ctr. at Houston, Houston, TX; [3]McGovern Med. Sch., Houston, TX; [4]Univ. of Bucharest, Bucharest, Romania; [5]Rice Univ., Houston, TX

Abstract: Resections of the temporal lobe for epilepsy or neoplasms often result in a decline in naming, especially for low frequency words. The resulting deficit can be socially disabling and impair the return of these patients to independent functioning. The exact substrates responsible for this cognitive loss are not known, and such knowledge might influence the surgical strategies to minimize language declines. We used voxel-based lesion symptom mapping (VLSM), which

allows for precise relation of cognitive function, measured as performance on a specific test, to anatomical substrate. In this study, we implement a multivariate VLSM with multimodal integration of lesion data with imaging to assess language function in in the dominant anterior temporal lobe. Data were obtained from 77 patients in whom a surgical procedure was performed for medication-resistant epilepsy originating in the dominant left-sided temporal lobe. This included either an anterior temporal lobe resection (n=51) or a mesial temporal ablation (n=26) for focal epilepsy. All patients underwent neuropsychological testing and MRI prior to and 6 months following surgery. Lesion masks were traced on postoperative MRI and aligned to a normative imaging space. The effects of preoperative scores and seizure outcomes (ILAE scores) were removed from the postoperative behavior scores via a linear regression prior to analysis. VLSM was then performed using a multivariate SVR model to assess postoperative neuropsychological test scores. Resulting Beta maps were converted to p values and corrected using a permutation-based cluster level correction. Lastly, we integrated an ecologically relevant language-based task fMRI (picture naming) with the VLSM results.
Beta maps from multivariate VLSM analysis revealed that the loss of basal temporal regions (mid and anterior fusiform gyrus and temporal pole) was associated with a prominent decline in Boston Naming Test (BNT) scores ($p<0.005$). Many of these voxels were spatially correlated with the susceptibility artifact on echo-planar imaging, perhaps explaining why this region has been under-appreciated as the locus responsible for postoperative deficits. This crucial contribution of the ventral temporal cortex in lexical access as shown using this multivariate VLSM approach should inform surgical approaches to this region.

Title: The neural correlates of modality-independent and modality-dependent semantic integration

Authors: *A. MEDVEDEVA[1,2], O. WOOLNOUGH[1,2], P. ROLLO[1,2], P. F. DOMINEY[3], N. TANDON[1,2,4];
[1]Vivian L. Smith Dept. of Neurosurg., Univ. of Texas Hlth. Sci. Ctr. At Houst, Houston, TX; [2]Texas Inst. for Restorative Neurotechnologies, Houston, TX; [3]INSERM U846, Dijon, France; [4]Mem. Hermann Hosp., Houston, TX

Abstract: Introduction: Current advances in the understanding of language and applications to patients with language disorders are limited by a lack of understanding of higher-order semantic

processes such as semantic integration. Semantic integration is the process of forming sequential relationships between concepts, such as perceiving the continuation of events by integrating information from event 2 with event 1. The regions involved in semantic integration remain unclear. Aims: The current research aims to address this limitation by analyzing intracranial neural recordings with high spatiotemporal resolution while 20 patients with intracranial electrodes for seizure monitoring in drug-resistant focal epilepsy performed a semantic integration task. Specifically, the aim was to identify the neural correlates of semantic integration by presenting pairs of events that followed a sequence (coherent) or disrupted a sequence (incoherent). Methods: The events were presented for three seconds on screen as sentences or images, with 95 unique pairs for each modality. Initially, regions that were more active (over 10% above a baseline of -400 to -100 ms before trial onset in 70-150 Hz) for the second stimulus compared to the first stimulus were identified at an FDR-corrected alpha level of .0099, particularly in the second time window (1500-2500 ms) which was selected to ensure completion of initial visual processing and reading. Results: For sentences and images, a wide network of frontal, parietal, temporal, regions was active during stimulus 2 for the first time window (500-1500 ms), with overlapping activation predominantly in visual areas for the second time window (1500-2500 ms). From 500-1500 ms, there was significant activation in parietal regions for images but not sentences and in frontal areas for sentences but not images. However, frontal electrodes in both sentences and images showed greater activation for stimulus 2 compared to stimulus 1. Parietal electrodes showed greater activation for stimulus 2 compared to stimulus 1, from 500-1500 ms for images and from 1500 to 2500 ms for sentences. Conclusions: The findings suggest potential roles for parietal and frontal regions in processes related to semantic integration. The time windows of activation may differ depending on the amount of time taken to process the stimulus, which may differ for images compared to sentences due to longer time for reading than visual processing.

Title: Functional magnetic resonance imaging and magnetoencephalography reveal different aspects of meaning composition

Authors: *M. TONEVA, T. MITCHELL, L. WEHBE;
Machine Learning, Carnegie Mellon Univ., Pittsburgh, PA

Abstract: Understanding language in the real-world requires us to compose the meaning of individual words in a way that makes the final composed product more meaningful than the string of isolated words. For example, we understand the statement that ``Mary finished the apple'' to mean that Mary finished eating the apple, even though ``eating'' is not explicitly specified. This supra-word meaning is at the core of language comprehension, and its neurobiological bases and processing mechanisms must be specified in the pursuit of a complete theory of language processing in the brain.
The current work provides an operational definition of supra-word meaning by defining it as the multi-word meaning that is beyond the meaning of individual words. We further provide a computational representation of supra-word meaning using powerful neural network algorithms and a new approach to disentangle individual- from supra-word meaning.
We found that the supra-word meaning representation significantly predicts fMRI recordings in the bilateral anterior and posterior temporal lobes (ATL and PTL, FWE-corrected pvalue<0.05). Our finding poses questions for the theory that posits left PTL as primarily a site of lexical (i.e. word-level) semantics [1] and suggests a common substrate for lexical and combinatorial semantics. Strikingly, we found that the supra-word meaning representation did not significantly predict any MEG sensor-timepoints. Instead, the MEG recordings were significantly predicted by information unique to the two most recently-read words (FWE-corrected pvalue<0.01).
Our results suggest that fMRI recordings are sensitive to supra-word meaning, while MEG recordings reflect instantaneous processes related to both the current and the previously-read word. A likely candidate for this instantaneous process is the integration of a word with the previous context. MEG may be sensitive to the previously-read word because a word might take longer to process than the duration it is on the screen, or a word may constrain the processing of the following word, highlighting its relevant properties and aiding with composition.
The surprising finding that supra-word meaning is difficult to capture using MEG has implications for future neuroimaging research and applications where natural language is decoded from the brain. While high temporal imaging resolution is key to reaching a mechanistic level of understanding of language processing, our findings suggest that a modality other than MEG may be necessary to detect long-range contextual information.

Title: Task-specific Network Dynamics in ECoG during Language Perception and Production

Authors: *J. JESCHKE[1], W. DOYLE[2], O. DEVINSKY[3], A. FLINKER[4];
[1]NYU Langone Med. Ctr., New York, NY; [2]Neurol., [3]NYU Langone, New York, NY; [4]Neurol., NYU Sch. of Med., New York, NY

Abstract: It is well established that resting state network dynamics emerge during cognitive tasks as well as rest. However, it is unclear how these connectivity patterns emerge and change over time during language related tasks and speech production. Here we use Electocorticography (ECoG), with a combined high signal to noise ratio, temporal and spatial resolution to investigate the functional connectivity (FC) during rest compared to language tasks. Seven adult epilepsy patients undergoing intracranial, pre-surgical evaluation completed a prompted rest task and 5 speech production tasks involving auditory (repetition, sentence completion, naming to definition) and visual (picture naming, reading aloud) modalities with matched stimuli across tasks. We used Pearson's r of the high-gamma (70-150 Hz) signal to generate FC correlations between all electrode pairs within subjects, for each task (epoched into stimulus perception and item production) as well as rest. Permutation testing (1000 iteration, $p<0.01$ threshold) was used to test for significant electrode pair FC (r values) change from rest. We find a distinct temporal pattern of network states from perception to production characterized by a significant network change from baseline during perception (across language tasks) followed by a reduction (L2 distance from baseline) during pre-articulation and finally a return to a network state closely matching perception (non-significant difference in L2 network distance). Surprisingly the perception and production network states were similar regardless of task modality. This was most striking during visual perception vs. auditory feedback during production, likely representing a task-specific network dynamic which is distinct from local high gamma changes.

Title: Distributed frontal cortex activity encodes prearticulatory single word retrieval

Authors: *L. YU[1,3], D. WERNER[3,2], O. DEVINSKY[1,3], A. FLINKER[1,3];
[1]Neurol., [2]Neurosurg., NYU Sch. of Med., New York City, NY; [3]Comprehensive Epilepsy Ctr., New York City, NY

Abstract: Speech production critically depends on frontal cortex activity to retrieve, plan, and execute speech utterances, but the timing and extent of cortical activation across different task demands, modalities, and the nature of the neural representations remain unknown. To investigate this, we employed a battery of five functional language tasks which prompt the subject to produce the same word through varying word retrieval routes: word reading, picture naming, auditory naming, auditory word repetition, and auditory sentence completion. We obtained direct cortical ECoG recordings in a cohort of 27 neurosurgical patients undergoing treatment for refractory epilepsy. We focused on high gamma (70 ~ 150 Hz) spectral responses shown to correlate with the spiking rate of underlying neuronal populations. We employed analyses based on specific regions of interest, unsupervised clustering of the data as well as Representational Similarity Analysis in order to investigate which areas are recruited and when in time stimulus identity is encoded. Based on anatomy, robust activity was evident in STG locked to perception for the three auditory tasks as well as pre- and post-central gyri activation locked to production. We found a pre-articulatory response profile in the posterior IFG (pars opercularis) and dorsal MFG, with significant activity prior to speech onset for all five production tasks.
While IFG and MFG activity was significant prior to speech, it varied greatly across tasks. In order to test if a more distributed representation, rather than specific anatomical regions, encode retrieval we applied non-negative matrix factorization, an unsupervised clustering technique. This technique revealed a pre-articulatory cluster distributed across frontal cortex. Unlike IFG and MFG alone, the distributed activity of the frontal cluster showed significant activity prior to speech similarly across all five tasks. We employed an RSA analysis in order to probe the nature of this distributed neural activity over time. The dissimilarity matrix of the frontal cluster was most correlated with word identity models prior to speech onset and with semantic models (word embedding vectors) locked to and during speech. Our results suggest that frontal cortex represents stimulus identity during retrieval in a distributed manner across frontal regions prior to and throughout speech production.

Title: BOLD activations in the cerebellum as an additional diagnostic feature for determination of language lateralization

Authors: ***I. R. THAKKAR**[1], L. ARRAÑO-CARRASCO[1], B. CORTÉS RIVERA[2], R. ZUNINO-PESCE[1], F. MERY-MUÑOZ[1], M. SMITS[3], C. MENDEZ-ORELLANA[1];

[1]Pontificia Univ. Catolica De Chile, Santiago, Chile; [2]Univ. Santo Tomás, Santiago, Chile; [3]Erasmus MC–University Med. Ctr., Rotterdam, Netherlands

Abstract: Postsurgical preservation of language is a focus in life-saving tumor removal surgeries. Thus, presurgical language localization is important in surgical resection planning. fMRI studies assessing language lateralization in patients mainly focus on the cerebrum. But recently, crossed cerebro-cerebellar BOLD activations during language paradigms have come to light as additional diagnostic features (Hubrich-Ungureanu et al, 2002; Mendez-Orellana et al, 2015). A major advantage of considering these contralateral cerebellar activations is that they remain undisturbed by cortical tumor presence. Currently, in the clinic, language lateralization determination based on BOLD is done through visual inspection by neuroradiologists. Recently, automatized calculation of lateralization index (LI) using the number of active voxels is gradually being adapted to the clinic. Yet, these techniques rely on the statistical threshold chosen during preprocessing. Here, we use a threshold-independent LI calculation technique (Branco, et al., 2016). Healthy subjects (n = 23) performed three language paradigms: a verbal fluency task, and button-press semantic and phonological association tasks. BOLD images were preprocessed using SPM and LI values were obtained separately for cortical and cerebellar activations. To test contralaterality between cerebral and cerebellar activations, Pearson's correlation was performed between their LI. Pearson's *r* for the three tasks was -0.63, -0.53, -0.63 respectively. Language activations were then assigned left-, right-, or bi-laterality depending on their LI. A McNemar test for all three tasks also showed significant contrast between cerebral and cerebellar laterality (p = .007, .019, .018 respectively). A Cohen's Kappa between laterality based on LI versus by neuroradiologists also showed fair agreement. Thus, substantial contralateral activations between the cortex and cerebellum were observed pointing to the possibility of cerebellar activations being used as additional language lateralization determination tools in the clinic.

Abstract: The neurobiology of language has been studied for a century but remains highly debated. A dual-stream model has been proposed to represent the cortical networks involved in speech processes. However, it is not yet known if the dual-stream model represents an intrinsic brain network that exhibits functionally connectivity at rest, and the right hemisphere's ventral stream is still debated. It also is unclear how stroke affects the functional connectivity of the dual-stream model beyond the area of focal damage. To investigate these questions, 30

neurotypical participants (20-79 years, native English-speaking, right-handed) and 14 chronic left hemisphere stroke survivors (28-80 years, native English-speaking, right-handed) underwent resting-state functional MRI and T1-weighted structural MRI. SPM12 and in-house Matlab and R scripts were used to calculate: 1) the average functional connectivity within and between the bilateral streams within the dual-stream model in the control group, 2) compare this connectivity to other well-defined brain networks (i.e. default-mode and visual networks) and 3) group-level comparisons of functional connectivity between the control and stroke groups in each stream and hemisphere of the dual-stream network. Pearson correlations and pairwise t-tests indicate: The dual-stream model regions are significantly functionally correlated, including a bilateral ventral stream and left-lateralized dorsal stream. The functional connectivity within the dual-stream model is significantly higher than the functional connectivity within the default mode network, and the functional connectivity within the dorsal and ventral streams is significantly higher than between the dual-stream network and the comparison networks (default mode and visual). Two-sample t-tests indicate functional connectivity within the ventral stream and between ventral and dorsal streams is significantly lower in the stroke than the control group, including within the right ventral stream and the
right hemisphere homologue of the left dorsal stream. These preliminary results suggest regions depicted in the dual-stream model of speech processing represent an intrinsic, bilateral, cortical network. The left hemisphere stroke survivors exhibiting significantly lower resting-state functional connectivity not only in the left dorsal and ventral streams, but also in the right hemisphere's ventral stream and the right homologue of the left-lateralized dorsal stream, suggests that the neural disruptions affecting language abilities extend well-beyond the stroke's area of infarct, including contralateral (right hemisphere) disruptions.

Title: The gradient of population receptive field stimulus-dependence in ventral visual cortex

Authors: *G. LERMA-USABIAGA[1], R. LE[2], C. GAFNI[3], M. BEN-SHACHAR[4], B. WANDELL[2];
[1]BCBL. Basque Ctr. On Cognition, Brain and Langua, Donostia - San Sebastian, Spain; [2]Stanford Univ., Stanford, CA; [3]Univ. of Haifa, Haifa, Israel; [4]Bar-Ilan Univ., Ramat Gan, Israel

Abstract: Regions of ventral occipito-temporal (VOT; Figure 1A) visual cortex are more responsive to written words than other categories of visual stimuli. We refer to these regions as

the VOT reading circuitry (VOTRC; Figure 1B, red clusters). The population receptive field (pRF) of a voxel is the portion of the visual field in which stimuli evoke a response. The pRFs of voxels in the VOTRC are stimulus-dependent (Le et al., 2017). Measured with word stimuli, the pRF centers are mainly confined to the central visual field; measured with checkerboard stimuli, the pRF centers span a wider range of locations, extending to the periphery. To understand this stimulus dependence, we analyzed pRFs in visual field-maps (V1-3, hV4, VO1) whose signals are the likely inputs to the VOTRC. We measured pRFs in 34 subjects (20 readers of English only; 14 readers of Hebrew and English) using the moving bar paradigm with several types of contrast patterns within the bar (checkerboards, English or Hebrew words of different sizes, false fonts). We found that stimulus dependence emerges gradually along the visual field map hierarchy. The stimulus dependence is small in visual areas V1 and V2, becoming more pronounced in V3, hV4, and VO-1 (see Figure 1C). The pRF center can be expressed in Cartesian [x,y] or Polar [eccentricity,angle] coordinates. The largest variation in stimulus dependence is seen in the eccentricity of the pRF center; the angle remains relatively constant. Given that the pRF position is stimulus dependent, it is important to use the relevant stimulus when using pRFs to model the visual components of different tasks. With an interest in reading development, it seems best to use word stimuli in a legible orthography. Establishing pRF properties using such stimuli in good readers may help understand the visual reading circuitry and provide a baseline for comparing responses in poor readers.

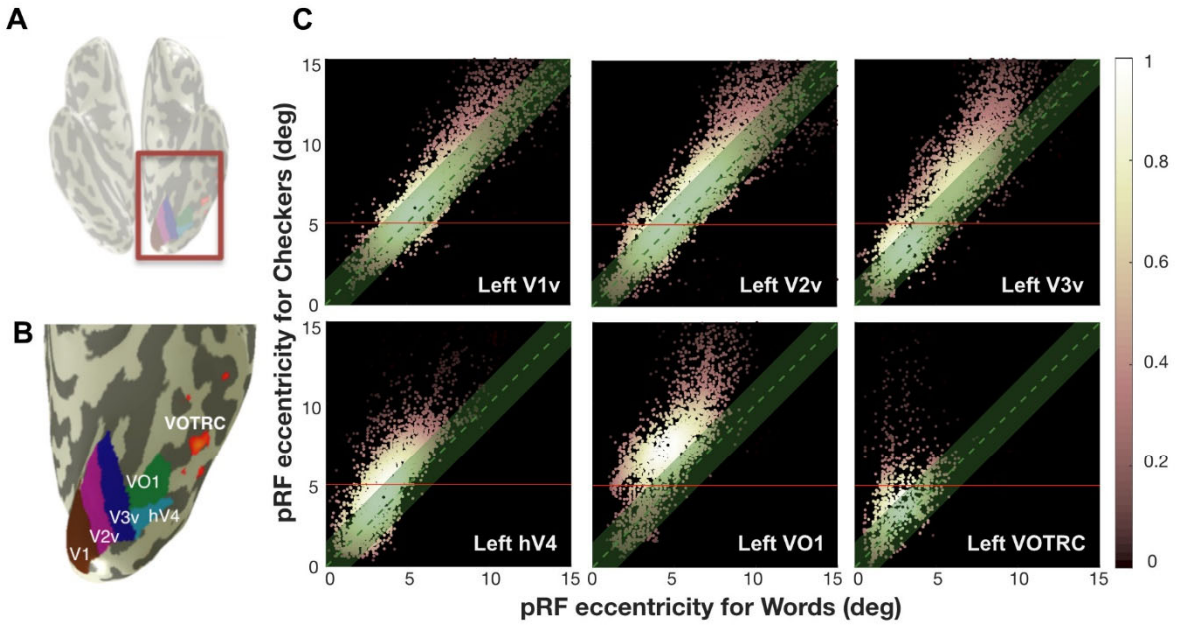

FIGURE 1. In the VOTRC, pRFs measured with word stimuli are more foveal with word stimuli compared to checkerboard stimuli.

A. Ventral view of an inflated brain surface, VOT inside red square. B. Detail of the left VOT, with the ventral maps V1v, V2v, V3v, hV4, VO1 and the VOTRC. C. The eccentricity of pRF centers for words versus the eccentricity for checkerboards for the left ventral V1, V2, V3, hV4, VO1 and VOTRC. The color bar indicates relative density of points; the green band express 5 deg around the identity line. The pRFs shown have > 20% variance explained.

Title: Catch me if you can: Least myelinated white matter bundles develop fastest during early infancy

Authors: ***M. GROTHEER**, M. ROSENKE, H. WU, H. KULAR, F. R. QUERDASI, V. NATU, J. D. YEATMAN, K. GRILL-SPECTOR;
Stanford Univ., Stanford, CA

Abstract: White matter myelination is one of the key hallmarks of infant brain development and abnormalities in myelination have been linked to a plethora of neurological and cognitive disorders. Early histological work has suggested heterogeneous myelin content of white matter bundles at birth and heterogenous myelination rates after birth. However, it is unclear if white matter that is less myelinated at birth continues to develop slower during infancy (starts-first/finishes-first hypothesis), or if it develops faster to catch up with the rest of the brain (catch-up hypothesis). To distinguish between these hypotheses, we collected diffusion (dMRI) and quantitative MRI (qMRI) longitudinally at birth (N=9), as well as, 3 month (N=10) and 6 months (N=10) after birth. Using the dMRI data, we developed a novel method for automated fiber quantification in individual infant brains (babyAFQ), which we validated by comparing to manually identified "gold-standard" bundles. From qMRI, we derived T_1, which is directly related to white matter myelination. In all bundles, we find a linear decrease of T_1, which suggests increasing myelination, from birth to 6 months of age (Fig 1a). Consistent with histology, we find differential T_1 at birth and differential rates of T_1 development during infancy across the white matter. Critically, we discovered a significant negative correlation between T_1 at birth and the rate of T_1 development both across bundles (Fig 1b) and within bundles along their length. These data suggest that less mature white matter at birth develops faster to catch up with the rest of the brain. This, in turn, leads to the equation of differences in myelination during early infancy, which may promote efficient communication across the entire brain.

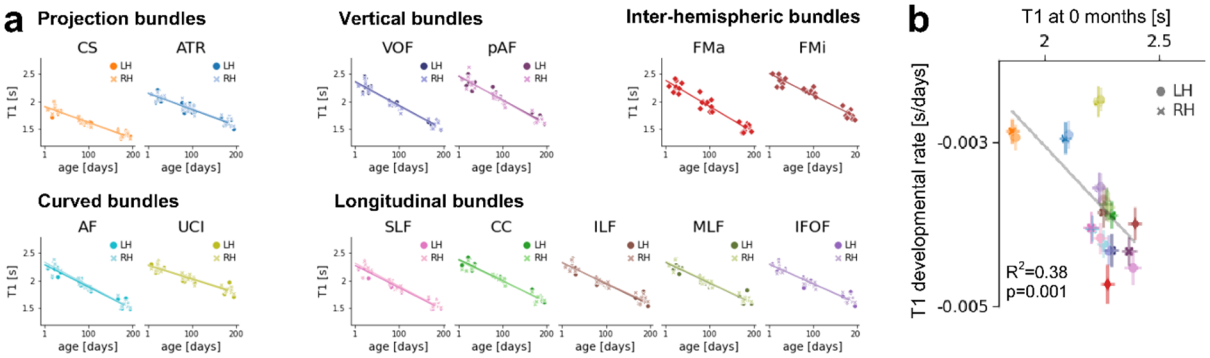

Figure 1. T_1 at birth and T_1 developmental rate are negatively correlated, supporting the catch-up hypothesis. a. Mean T_1 of each bundle decreases linearly from 0 to 6 months of age. Dots correspond to individual's left and right hemispheres. b. Across bundles, mean T_1 at birth and rate of T_1 development are negatively correlated.

Title: Identifying Prepubertal Children with Risk for Suicides Using Deep Neural Network Trained on Multimodal Brain Imaging

Authors: G. AHN[1], **B. KIM**[2], *J. CHA[2];
[1]seoul national university, Seoul, Korea, Republic of; [2]seoul national university, seoul, Korea, Republic of

Abstract: Suicide is among the leading cause of death in youth worldwide. Early identification of children with high risk for suicides is key to effective screening and intervention strategies. Yet, little is known about the neural pathways to the clinical outcomes of suicide, such as suicidal ideation and attempts, and methods to screen youth with high risk for suicide. In this study, we tested what brain functional signals are associated with the risk for suicidality in young children. Based on the large, multi-site, multi-ethnic, representative, prospective developmental population study in the US, we trained the state-of-the-art interpretable deep neural network for tabular data, TabNet (https://github.com/dreamquark-ai/tabnet), on functional brain imaging. Our model shows the best model predicting suicidality contains several functional estimates of the

brain circuitry, such as intrinsic functional couplings among middle and inferior temporal gyrus, paracentral gyrus, and activation patterns during the emotional memory task among cingulate gyrus, inferior frontal gyrus. Of note, our interpretable neural network shows that these brain functional features appeared to interact with the known risk factors of childhood suicidality, such as depression and impulsivity. This study demonstrates the novel application of the interpretable deep neural network to childhood suicidal research, uncovering the complex interactions between psychological and neural factors underlying childhood suicidality.

Title: Differential Influences of Alcohol by Type and Frequency on Body Composition in Older Adults: A UK Biobank Study

Authors: *B. A. LARSEN[1], B. S. KLINEDINST[2], T. WOLF[3], C. PAPPAS[2], S. T. LE[2], N. F. MEIER[4], Y.-L. LIMF[5], B. E. FRIZELL[6], L. LANNINGHAM-FOSTER[2], A. A. WILLETTE[2]; [1]Dept. of Biomed. Sci., [2]Dept. of Food Sci. and Human Nutr., Iowa State Univ., Ames, IA; [3]Dept. of Hlth. Sci., Western Carolina Univ., Cullowhee, NC; [4]Dept. of Kinesiology, Concordia Univ., Irvine, CA; [5]Dept. of Psychology,, Virginia Polytechnic Inst., Blacksburg, VA; [6]Sch. of Med. and Publ. Hlth., Univ. of Wisconsin, Madison, WI

Abstract: INTRODUCTION: Aging is characterized by physiological alterations in body composition, such as increased visceral adiposity accumulation and bone loss. Alcohol consumption is thought to partially drive these associations, but findings have been mixed. To clarify inconsistent findings, different types of alcohol--beer, liquor, and wine--may show different association patterns with body composition. **METHODS**: Our longitudinal U.K. Biobank study leveraged 1,874 White British participants (aged 40-79 years; 58.9% male). Participants self-reported demographic, alcohol and dietary consumption patterns, and lifestyle factors using a touchscreen questionnaire. Anthropometrics and serum for proteomics were collected and body composition was obtained via dual-energy X-ray absorptiometry (DEXA). Structural equation modeling was used to probe direct and indirect associations between adiposity and bone, alcohol types, and cardiometabolic biomarkers. **RESULTS**: Over a mean duration of four years, greater consumption of beer and liquor were significantly associated with more visceral adiposity (β=.069, $p<.001$ and β=.014, $p<.001$, respectively); these associations were driven by dyslipidemia and insulin resistance. In contrast, greater red wine consumption predicted less adipose mass (β=-.023, $p<.001$), and this association was mediated by reduced

inflammation and higher high-density lipoproteins (HDL) cholesterol. White wine consumption did not influence visceral adiposity but did predict greater bone mineral density (β=.051, p=.003). **DISCUSSION**: Taken together, these data suggest that beer and liquor may drive the "empty calorie" hypothesis related to adipogenesis, while red wine may be protective due to anti-inflammatory and eulipidemic effects. Furthermore, white wine may benefit bone mineral density in older adults.

Title: Persisting effects of multitasking on car drivers' braking responses

Authors: *O. BOCK[1], R. STOJAN[2], K. WECHSLER[1], M. MACK[2], C. VOELCKER-REHAGE[2];
[1]German Sport Univ., Köln, Germany; [2]Univ. of Münster, Münster, Germany

Abstract: It is well established that participants' driving performance on one task suffers when they concurrently engage in another task. Here we investigate whether driving performance also suffers when participants had engaged in another task a few seconds ago. For potential practical implications, this work is carried out in a driving simulator. A total of 59 young (age: 23.2 ± 2.9 years) and 42 older adults (age: 70.0 ± 2.9 years) followed a lead car in a driving simulator, and had to brake when the lead car braked. Trials of the braking task were interspersed with trials form a battery of different loading tasks (typing, reasoning, and memorizing, each presented visually and auditorily). Stimulus onset asynchrony between a braking trial and the last preceding loading trial was 11.49 ± 1.99 s. In a control condition, the braking task was administered in absence of any loading task. Participants also completed eight executive-function tests. A multivariate general linear model with the factors Group and Condition, was followed up by Bonferroni corrected post-hoc tests. We found that (1) older participants kept a larger distance to the lead car, steered their car occasionally closer to the curb, and kept their car less steady in the lane; (2) participants in the multitasking condition kept a larger distance to the lead car before but not during the braking maneuver and steered their car occasionally closer to the median or to

the curb; (3) the effects of loading tasks on driving parameters were not substantially different between age groups. Adding an overall executive function score as a predictor reduced the effects of Age by about 41%, and the effects of Condition and of Group * Condition by about 25%. We conclude that our loading tasks had persistent effects on braking responses, which lasted for at least about 10 s. Those effects were associated with executive functions. We interpret our findings as evidence that each loading task establishes a persistent "task set", which needs to be reconfigured when a subsequent task - e.g., a braking task - is presented.

Title: The impact of long-term social housing on biconditional association task performance and neuron ensembles in the anterior cingulate cortex and CA3

Authors: *A. M. DANKERT[1], K. I. DAYAW[1], J. N. DAYAW[1], L. TRUCKENBROD[2], T. WISE[3,1], A. HERNANDEZ[4,2], S. N. BURKE[2], V. L. TEMPLER[1];
[1]Psychology, Providence Col., Providence, RI; [2]Neurosci., Univ. of Florida, Gainesville, FL; [3]Cognitive, Linguistic, and Psychological Sci., Brown Univ., Providence, RI; [4]UAB, Fultondale, AL

Abstract: Cognitive decline and changes in neuronal activity are hallmarks of advancing age across species. Among the first brain regions to show age-associated dysfunction are the prefrontal cortex (PFC) and medial temporal lobe (MTL). Likewise, behaviors that rely on these structures are vulnerable to decline with advancing age. For example, aged rats are consistently impaired on biconditional association tasks (BATs), which require rats to learn that the target object in a pairwise discrimination problem changes trial-by-trial based on its location within the maze. Previous work using Compartmental Analysis of Temporal activation with Fluorescent *in situ* Hybridization (catFISH) has revealed that poorer BAT performance in aged rats is associated with altered activity patterns in the PFC and MTL. It has been observed that successful human agers with positive social relationships present larger anterior cingulate cortices (ACC) in the PFC and a higher density of von Economo neurons, which are thought to be important for social cognition, as compared to their less-social counterparts who experience

more cognitive difficulties. However, the mechanisms by which sociality might protect against cognitive aging and if this can be modeled in a rodent model have not been determined. Here we investigate the differences in performance on a BAT and the corresponding neuronal activity between socially housed (SH) and nonsocially housed (NSH) aged rats in comparison to individually housed young controls. All male Long-Evans were trained to criterion on BAT and were then tested on both BAT and an alternation control task on the day of sacrifice. On the final day of testing, aged NSH rats were significantly less accurate on BAT than the young control rats; however, there was no significant difference between aged SH rats and young control rats. These data suggest that social housing may have protected against cognitive decline with advancing age. Immediately following behavior, animals were sacrificed and brain tissue was processed to label the immediate-early gene mRNA for *Arc* and *Homer1A* mRNA. CatFISH was used to identify the neuronal populations in the CA3 subregion of the hippocampus and the ACC that were active during the BAT and the control task. SH rats had less overall neuronal activity in distal CA3 than the NSH rats and young controls. Furthermore, the SH and NSH aged rats had less overall neuronal activity in proximal CA3 than the young controls. These findings indicate that sociality may protect against the cognitive decline that occurs with advancing age and that physical, social, and cognitive enrichment are essential for preserving neuronal activity.

Title: Microglial and Lipid Droplets Accumulation Age-Related Changes in Sleep Brain Regions in Cx3cr1 Mouse Model.

Authors: *M. BADAWY[1], S. GE[2], Q. XIONG[3];
[1]Neurobio. and Behavior, [3]Neurobio. & Behavior, [2]Stony brook university, Stony Brook, NY

Abstract: Natural aging affects brain homeostasis. Sleep pattern is reported to be dramatically disturbed with age. Older adults tend to have higher sleep latency, sleep stage transition, sleep-wake fragmentation, and less sleep duration when compared to younger adults. This is thought to be because of the global effect of aging on brain cells. One of these cell types is Microglia that is reported to behave differently as animals age. Microglia inflammation profile is reported to increase with age. Additionally, lipid droplets accumulation is another factor that is considered to increase with age. Pro- inflammatory microglia is reported to be more prominent with age. Furthermore, lipid droplets accumulation in the brain is reported to be associated with age and contributes, in part, to microglia activation. We used well-established morphological approaches

to investigate the changes that happen to microglia, and lipid droplets accumulation with age across sleep related brain regions. We had 8 Cx3cr1 mice, with ages ranging from 3 to 21 months, males and females. The animals were perfused, and their brains were sliced. Microglia and neuronal cell bodies were immunofluorescence-labelled for microglia, neuronal cell bodies, and lipid droplets and imaged in the cortical, preoptic, thalamic, midbrain, and medulla brain regions. We analyzed microglia total process length, sholl analysis, and lipid droplets accumulation within microglia and neurons to determine the pattern of change across ages. Our results indicate a global pattern of significant microglia cell processes retraction starting from mice with 6 months of age. Furthermore, we observed a prominent increase lipid droplets accumulation within microglia and neuronal cell bodies as mice aged. However, our sholl analysis' AUC indicates a gradual decrease of microglia coverage area and cell complexity as the mice age. Our work presents evidence of age effect on brain sleep regions. Nonetheless, based on our analysis parafacial zone, and ventrolateral preoptic area were affected the least. This work, when complete, will give a perspective to answer the question about the contribution of microglia, and lipid droplets accumulation in age-related sleep disturbance.***Keywords—*** Aging, Lipid droplets accumulation, Microglia, sleep brain regions.

Title: Effects of age and non-combat military service on memory and cognitive flexibility in a virtual Morris water maze task

Authors: A. MOLLUSKY[1], N. REYNOLDS[1], D. LEE[1], J. ZHONG[2], *K. R. MAGNUSSON[1]; [1]Oregon State Univ., Corvallis, OR; [2]Air Traffic Mgmt. Res. Inst., Nanyang Technological Univ., Singapore, Singapore

Abstract: This study applied a virtual version of the Morris water maze (vMWM) task, which is commonly used for assessing spatial memory performance in rodents, to an examination of age-related differences between younger (18-30 years; N=5 male, 11 female) and older (60-86 years; N=8 female, 21 male) participants, and the impact of non-combat military service in the Vietnam and Korean war eras in older men (60-86 years; N=10 military, 11 non-military) on spatial memory and cognitive flexibility. Participants performed the Logical Memory task (WMS IV) that included immediate and delayed recalls, the NIH Toolbox Cognitive test battery that included the Fluid Cognition Composite (FCC) and the Crystallized Cognition Composite (CCC), and cognitive tasks in vMWM that included long-term memory, cognitive flexibility, and

working memory trials followed by visible control trials, while seated at a computer desk. Older individuals performed significantly worse than young (immediate recall; p<.0001; delayed recall, p=.0012) in the Logical Memory task. All NIH Toolbox Cognitive measures showed significant effects of age (p range: <.0001 to .035). For the FCC, older individuals performed worse than younger adults (uncorrected; p< .0001). In the CCC, older individuals performed better than young (p< .0001), but older male veterans performed worse than older male civilians (p=.026). In the vMWM tasks, older individuals showed significantly worse proximities than young in probe trials (p=.0004) and hidden trials (p=.0003) for spatial memory, and in delayed (15 seconds) match-to-place trials (p <.0001) for working memory. Older individuals had worse proximity scores than young (p=.016), and older male veterans showed significantly poorer performance than older male civilians (p=.0035) in reversal trials for cognitive flexibility. Although there was a significant effect of age in visible platform trials (p=.0003), the differences between scores were 8.7 fold higher in the hidden platform trials. There were no significant effects of gender (p = .13-.54) on vMWM performances. This study provided novel findings showing that military service in the Vietnam and Korean war eras may have reduced cognitive flexibility later in life.

Title: Characterizing the therapeutic application of amphetamine in age-associated cognitive decline

Authors: *S. SCOGNAMIGLIO, G. DEZFULI, K. J. KELLAR;
Pharmacol. and Physiol., Georgetown Univ., Washington, DC

Abstract: Memory impairment often accompanies normal aging and is thought toinvolve hypofunctional glutamatergic systems in the cerebral cortex andhippocampus. Glutamate, the major excitatory neurotransmitter in the brain,plays a fundamental role in functions such as cognition, motor behavior andemotion (Meldrum, 2000). Along with glutamate, norepinephrine (NE) is animportant modulator of memory, especially emotional memory (Tully *et al.*,2010). Our previous study demonstrated a marked deficit in glutamate-stimulated NE release in slices from the cortex and hippocampus of aged (22-24 months old) male Fischer 344 rats, which is rescued by addition ofamphetamine (Dezfuli *et al.,* 2019). Thus, amphetamine potentiatesglutamate-stimulated NE release (and possibly release of othermonoamines). The purpose of our current study was to test the cognitiveeffects of amphetamine treatment in aged rats. To do this, we investigatedwhether memory performance as measured in the novel object recognitiontask (NOR) is enhanced by acute treatment with amphetamine in agedFischer 344 rats. An additional

goal of this study, is to test the effects ofchronic amphetamine treatment on the NOR task. Our initial results indicatethat in aged Fischer 344 rats, acute treatment with amphetamine (0.5 mg/kg)increases object recognition memory in the NOR task. These results set thestage for our chronic studies, which will be reported.

Title: The association of cognitive, motor, and cardiovascular fitness with street crossing performance under multitasking conditions

Authors: M. MACK[1], R. STOJAN[1,2], O. BOCK[3,2], *C. VOELCKER-REHAGE[1,2];
[1]Univ. of Muenster, Muenster, Germany; [2]Chemnitz Univ. of Technol., Chemnitz, Germany; [3]German Sport Univ. Cologne, Cologne, Germany

Abstract: Human gait often changes under multitasking conditions, probably because walking and the additional loading task compete for processing resources. This interference is particularly prominent in older age. We investigate whether multitask interference is influenced by participants' individual levels of cognitive, motor, and/or cardiovascular fitness. For ecological validity, we use a virtual street crossing scenario. Younger adults (n = 63, 20-30 years) and older adults (n = 61, 65-75 years) participated in the study. A non-motorized treadmill translated their forward movement into forward shifts towards and across a virtual street, where cars were passing with a constant speed and increasing gaps. The participants' task was to cross the street without getting hit by a car, both under single-task (ST) and under multitask (MT) conditions. Performance was assessed as stay time at the curb, crossing speed, and crossing failures. Loading tasks were presented visually or auditorily, and required participants to remember a shopping list or to type three-digit numbers. Participants also performed seven cognitive tests (executive functions), five motor tests (balance, movement speed, and bimanual coordination), and one cardiovascular test (graded maximal exercise testing on a cycle ergometer). A linear mixed effect approach yielded significant performance decrements from ST to MT, which were age-independent for crossing failures, increased with age for stay time and existed only in older age for crossing speed. Effects of cognitive, motor and cardiovascular fitness on MT performance decrements in young and older adults will be analyzed. An association between MT decrements and fitness would suggest that MT represents an overarching ability rather than a task-specific ability.

Title: Acute effects of cannabis on cognition in aging

Authors: *S. ZEQUEIRA[1], A. A. GÜVENLI[1], M. M. BRUNER[2], C. HERNANDEZ[3], J. F. DESLAURIERS[1], M. FEBO[1,2,3], J. L. BIZON[1,2,3], B. SETLOW[2,3,4,5];
[2]Dept. of Neurosci., [3]Dept. of Psychiatry, [4]Dept. of Psychology, [5]Ctr. for Addiction Res. and Educ., [1]Univ. of Florida, Gainesville, FL

Abstract: Adults over age 65 are the fastest growing demographic of cannabis users. These individuals use cannabis for a variety of reasons, including pain management, appetite stimulation, and sleep, but cannabis can exert effects on cognition as well. Compared to young adults, aged individuals exhibit deficits in cognitive functions supported by the prefrontal cortex (PFC) and the hippocampus. These same cognitive functions are impaired by acute administration of cannabis or delta-9-tetrahydrocannabinol (THC) in young subjects; however, effects in aged subjects are less well understood. The current study used a rat model to determine whether the effects on cognition of acute exposure to cannabis smoke differ between young and aged subjects. Male, fully mature young adult (6 months) and aged (24 months) Fischer 344 x Brown Norway F1 hybrid rats were tested on both a PFC-dependent delayed response working memory task and a hippocampal-dependent trial-unique non-match to location (TUNL) task in touchscreen operant chambers. The delayed response task required rats to remember the location of a visual stimulus over variable delay periods ranging from 0-12 s. The TUNL task required rats to remember the location of a visual stimulus with varying degrees of discriminability from other, distractor stimuli. A semi-randomized, within-subjects experimental design was used such that each rat was exposed to smoke from burning 0, 3, 5, and 10 cannabis cigarettes immediately prior to test sessions in each task. In the delayed response task, acute exposure to cannabis smoke impaired accuracy in young rats but enhanced accuracy in aged rats. In contrast, in the TUNL task, cannabis smoke had no effects on performance in either age group. Considered together, this pattern of results shows that in aged rats, which exhibit impaired cognitive performance, cannabis smoke can enhance PFC-dependent cognition, but has no effect on hippocampus-dependent cognition. A follow-up study evaluated plasma THC levels over time in young and aged rats following exposure to smoke from burning 5 cannabis cigarettes. Compared to young adults, aged rats exhibited greater variability in their THC concentration-time profiles and showed a trend toward higher THC levels overall. Future studies will evaluate the mechanisms underlying these age differences in cognitive and pharmacokinetic properties of cannabis.

Title: Influence of Dim Light at Night and Sex on Cognitive Aging and Vascular Contributions to Cognitive Dementia

Authors: *J. A. LIU, J. C. WALTON, J. R. BUMGARNER, W. H. WALKER, II, O. H. MELENDEZ-FERNANDEZ, A. C. DEVRIES, R. J. NELSON;
Dept. of Neurosci., West Virginia Univ., Morgantown, WV

Abstract: Several components of brain vasculature are altered in response to acute dim light at night (dLAN) and cardiac arrest, including reduced vascular density in the hippocampus, decreased VEGF, reduced BDNF in males, and increased neuroinflammation (IL-1β) in females. We previously reported that dLAN impairs performance on the Barnes maze task in Nile grass rats; thus, we investigated the interacting effects of disrupted circadian rhythms by dLAN in conjunction with aging on cognitive function. We hypothesized that chronic exposure to white dLAN impairs cognition in aged mice, and proposed that in addition to being a risk for poor ischemic outcome, dLAN may be a risk factor for vascular contributions to cognitive dementia-like impairments. Eighteen month old (+/- 2 months) male and female C57BL/6 mice were individually housed and exposed to 10 weeks of standard light/dark conditions (LD; 14:10 light/dark) or dim light at night (5 lux), then cognitive function was assessed using the Barnes maze, spontaneous alternation, novel object recognition, and an auditory fear associative learning task. We observed an interaction effect between lighting condition and sex on body weight as a percent change from baseline; females display a significant decrease in body weight after 10 weeks of dLAN exposure compared to females in dark nights, whereas males inversely displayed a reduced percentage of body weight loss in LD. In addition, chronic exposure to dLAN increased mortality in female mice. We also observed a sex difference in the acquisition aspect of the Barnes maze task, where aged males were significantly impaired in their ability to locate escape location compared to females, although no effect of lighting condition was observed. Aged male mice froze significantly more during contextual fear retention tasks compared to females, but there was no effect of sex or lighting condition on acquisition or CS/US pairings. No differences were observed in spontaneous alternation or novel object recognition. Together, light at night alters body mass and survival in aged females, and the data suggest that there may be a sex difference in cognitive aging irrespective of lighting conditions.

Title: Quantitative and volumetric and diffusion weighted MRI analysis of rodent brains as a function of age and cognition

Authors: *L. DO[1], M. A. ZEMPARE[2,3], A. S. BERNSTEIN[1], P. BHARADWAJ[3], C. UGONNA[1], N.-K. CHEN[1], G. E. ALEXANDER[2,3], C. A. BARNES[2,3,4], T. P. TROUARD[1,2]; [1]Dept. of Biomed. Engin., [2]Evelyn F. McKnight Brain Inst., [3]Dept. of Psychology, [4]Departments of Neurol. and Neurosci., Univ. of Arizona, Tucson, AZ

Abstract: Animal models play an important role in preclinical and translational studies of the human brain. MRI, being both non-invasive and inherently translational, can play an important role in comparing brain anatomy in animal models and humans. Furthermore, diffusion weighted MRI is an established tool for the examination of white matter connectivity and microstructural changes as a function of age. Volumetric and diffusion weighted MR imaging have the potential to detect differences in rat brains as a function of age and cognition. The volumes and structural integrity of important brain regions as a function of age and cognition are continuing to be explored and these results will give important information as to the connectivity of different brain regions during both healthy cognitive aging as well as characterizing structural differences in rat brains with various levels of cognitive aptitude. Young (6mo), middle-aged (15mo) and old (23mo) male F344 rats were used in this study. A T2-weighted template image was registered to each animal's anatomical image using rigid body, affine and non-linear techniques and the deformation fields produced were applied to an 85 region labeled atlas to calculate the volume of individual regions of interest (ROIs) in the brain. This allowed for volumetric measurements across age and cognitive groups regionally. Image processing for the diffusion weighted images involved eddy current corrected and motion corrected, denoising, brain extraction and diffusion tensor generation. Scalar parameters such as fractional anisotropy (FA) can then be used to microstructurally characterize the white matter tracts. Volumetric MR imaging detected differences in rodent total intracranial volume and the data suggests that the rat brains are continuing to grow past 6 months of age. Body weight measurements confirm the imaging findings to middle aged however there is a deviation at old age where total intracranial volume (TIV) plateaus and body weight decreases significantly. These results will inform future analysis comparing regional brain volumes with age and cognitive performance. Diffusion MRI analysis is in progress and will show the microstructural integrity of white matter tracts both globally and regionally and those results will be compared across age and cognitive groups by comparing scalar indices such as fractional anisotropy, mean diffusivity and radial diffusivity.

Abstract: Aging is accompanied by irregularities in circulating glucose, altered secretion of glucocorticoids, and synaptic changes within corticolimbic structures that support normal cognition and regulate homeostasis. These disturbances are especially pronounced in Alzheimer's disease (AD), supporting a theory wherein age-related deficits in neural glucose metabolism underlie bioenergetic disturbances that contribute to memory loss and dyshomeostasis in AD. Our study evaluated metabolic, neuroendocrine and neurobiological differences between young adult (6 months) and aged (24 months) male F344 × Brown Norway F1 rats. First, we observed that blood glucose levels were significantly elevated in aged rats, compared to young adults, at the start of the active phase of the day. When challenged with 60 minutes of physical restraint, a potent stressor, aged rats effected no change in blood glucose while young adults showed increases in blood glucose. Age-related changes in blood glucose profile could not be attributed to differences in hypothalamic-pituitary-adrenal (HPA) axis function, as both age groups exhibited significant and similar modulation of corticosterone secretion in response to circadian cues and stressful experience. Next, synaptosomal fractions were prepared from the hippocampus and prefrontal cortex from all animals to evaluate changes to expression/localization and function of enzymes responsible for producing ATP that fuels synaptic activity. Using an antibody cocktail that probes representative subunits from each of the five complexes that comprise the electron transport chain, we determined there was no difference in the abundance of these subunits between age groups in hippocampal or prefrontal synapses.

Our initial findings suggest that normally aging rats are a translationally useful model to examine the antecedents and consequences of glucose dysregulation. Blood glucose levels in aging become uncoupled from the typical modulation by the HPA axis, which suggests defective glucocorticoid signaling is not the basis for these changes. The abundance of synaptic mitochondria does not appear to change in response to differences in blood glucose, but ongoing experimentation will determine if intervening processes such as glucose transport or glycolysis influence metabolic efficiency of aging synapses.

Title: Age-associated memory impairments correlate with decline of excitatory and inhibitory synapses in hippocampal area CA3

Authors: *D. J. HOROVITZ, L. A. ASKINS, G. M. REGNIER, J. A. MCQUAIL; Pharmacology, Physiology, and Neurosci., Univ. of South Carolina Sch. of Med., Columbia, SC

Abstract: Aging is characterized by declining memory and escalating risk for Alzheimer's disease (AD). Anomalous patterns of hippocampal activity manifest in prodromal AD, wherein a shift in the excitatory-inhibitory (E/I) dynamic signals the transition from normal brain aging to neurological disease. E/I imbalance is most evident within the dentate gyrus (DG)-CA3 network and is proposed to underlie age-related deficits in spatial learning that are ascribed to the dorsal, but not the ventral, hippocampus. Collectively, these observations indicate that a neuroanatomically precise characterization of changes to excitatory and inhibitory hippocampal synapses could elucidate the circuit-basis of memory changes that confer age-associated risk for AD. Consequently, we quantified changes to VGluT1, a marker of glutamatergic synapses, and VGAT, a marker of GABAergic synapses, in hippocampal sections from young 6-months old F344×Brown-Norway F1 rats (6M; n=9) relative to strain-matched 24-months old rats that were rated as spatial-learning unimpaired (24M-U; n=12) or impaired (24M-I; n=12) based on performance in the Morris water maze. We identified significantly lower VGluT1 in both dorsal and ventral divisions of area CA3 between 6M and 24M-I rats. Subsequent analysis of synaptic layers localized these changes to the stratum lacunosum moleculare of the dorsal CA3 and the stratum radiatum of the ventral CA3. Using a complementary approach that leverages the full range of individual differences in spatial learning, correlational analyses applied across the entire spectrum of aged performance revealed significant relationships between spatial learning decrements and lower level of VGAT in all synaptic layers of the dorsal CA3. These new

findings are consistent with our hypothesis that E/I disruption centered on dorsal CA3 is of special relevance to age-related memory loss. More specifically, impaired memory is related to diminished input from glutamatergic terminals synapsing upon apical dendrites of pyramidal neurons (putative perforant path terminals) in dorsal CA3 as well as more distributed decline of GABAergic terminals innervating proximal dendrites, neuronal soma and initial axon segments.

Title: Age-related changes in hippocampal lfp dynamics during behavior

Authors: *N. M. DICOLA[1], A. L. LACY[1], J. L. WHITNEY[1], A. SHEREMET[2], S. N. BURKE[3], A. P. MAURER[3];
[2]Engin. Sch. of Sustainable Infrastructure and Envrn., [3]Neurosci., [1]Univ. of Florida, Gainesville, FL

Abstract: The number of aged individuals is increasing, bringing with it medical challenges which includes increased rates of age-related cognitive impairment. Many of these impairments have been linked to neurobiological dysfunctions within the medial temporal lobe, though the specific mechanisms are not fully understood. Local field potential dynamics are one means of assessing network integrity, as this signal primarily reflects the accretion of synaptic activity over a population of neurons. Several well described changes within the hippocampus are likely to disrupt LFP activity in aged animals. For example, degradation in the perforant path, which connects the entorhinal cortex and hippocampus, has been reported in rats (Barnes and McNaughton, 1980) and humans (Yassa et al., 2010a). Additionally, the CA3 subregion of the hippocampus in aged rats (Wilson et al., 2005), monkeys (Thomé et al., 2016) and humans (Yassa et al., 2010b) have been found to be hyper-excitable. During waking behaviors, the theta (6-12 Hz) and gamma (50-100 Hz) rhythms are prominent. While theta frequency and theta-gamma coupling have been reported to change in old rats within the CA1 subregion (Shen et al., 1997; Jacobson et al., 2013), these LFP dynamics have not been examined in the dentate gyrus or CA3 in the context of aging. To investigate this phenomenon, 5 young (6 months) and 5 aged (24 months) were implanted with a silicon probe spanning the CA1, CA3, and the Dentate Gyrus (DG) of the hippocampus. Rats were then run on an inter-region dependent Object-Place Paired Association task, on which aged rats perform worse than their young counterparts (Hernandez et

al., 2015). Because this task requires the use of multiple regions working simultaneously it is possible to use it, in tandem with the silicon probes, to examine how age-related changes in one region may translate to changes in another region. Synaptic changes are likely to manifest as changes in network measures such as oscillatory activity. We hypothesize that age-related degradation of the perforant path and age-related hyperexcitability of the CA3 will result in not only changing peak frequencies in CA3, but also to less coherence of theta and gamma both within CA3 as well as between CA3 and CA1.

Title: Pair bonding slows epigenetic aging and alters methylation in brains of prairie voles

Authors: *L. L. SAILER[1], A. HAGHANI[2], J. A. ZOLLER[3], C. Z. LI[3], A. G. OPHIR[1], S. HORVATH[2,3];

Abstract: The quality of romantic relationships can be predictive of health consequences related to aging. DNA methylation-based biomarkers of aging have been developed for humans and many other mammals and could be used to assess how pair bonding impacts aging. Prairie voles (*Microtus ochrogaster*) have emerged as a model to study social attachment among adult pairs. Here we describe DNA methylation-based estimators of age for prairie voles based on novel DNA methylation data generated on highly conserved mammalian CpGs measured with a custom array. The multi-tissue epigenetic clock for voles was trained on 3 tissue sources (ear, liver, and samples of brain tissue from within the pair bonding circuit). A novel dual species human-vole clock accurately measured relative age defined as the ratio of chronological age to maximum age. According to the human-vole clock of relative age, sexually inexperienced voles exhibit accelerated epigenetic aging in brain tissue ($p = 0.02$) when compared to pair bonded animals of the same chronological age. Epigenome wide association studies identified CpGs in four genes that were strongly associated with pair bonding across the three tissue types (brain, ear, and liver): *Hnrnph1*, *Fancl*, *Fam13b*, and *Fzd1*. Further, four CpGs (near the *Bmp4* exon, *Eif4g2* 3 prime UTR, *Robo1* exon, and *Nfat5* intron) exhibited a convergent methylation change between pair bonding and aging. This study describes highly accurate DNA methylation-based estimators of age in prairie voles and provides evidence that pair bonding status modulates the methylome.

Title: Age-related hearing loss is associated with lower functional connectivity

Authors: *M. C. FITZHUGH[1], J. PA[1,2];
[1]Stevens Neuroimaging and Informatics Inst., USC, Los Angeles, CA; [2]2Department of Neurology, Alzheimer's Dis. Res. Ctr., Keck Sch. of Medicine, Univ. of Southern California, Los Angeles, CA

Abstract: Age-related hearing loss was recently identified as a modifiable risk factor for dementia (Livingston et al., 2017) and is highly prevalent (>50%) among the older adult population (Lin et al., 2011). Previous studies examining how the brain may be impacted by hearing loss have largely used measures from the better ear without reporting which ear this represents. However, speech perception is typically poorer in the left ear. Thus, it is unclear if the effects of hearing loss on the brain may be driven by one ear. In the current study, we investigated how age-related hearing loss within each ear separately impacts brain functional connectivity between regions critical for auditory and higher-order cognitive processing.
We assessed resting-state fMRI functional connectivity in 1,000 participants (61.98±7.41 years, 50% women) from the UK Biobank. Functional connectivity was computed between left and right planum temporale as seed regions and the 1) default mode (DMN), 2) frontoparietal (FPN), and 3) cingulo-opercular (CON) network ROIs as target regions. Hearing was measured with a speech in noise reception threshold task (SRT), which was used to group participants into better performing ear groups (better left ear (56%): -5.97±1.50 dB; better right ear (n=44%): -6.07±.1.55 dB), in which a higher score indicates poorer hearing. ANCOVA models were used to predict functional connectivity from left and right ear hearing measures, controlling for age and sex, and separated into groups by their better ear ($p<.05$ FDR).
Poorer SRT scores in the left ear were associated with lower functional connectivity between left planum temporale and target regions: bilateral posterior parietal ROIs of the FPN and right posterior parietal ROI of the DMN, only in the group who had a better left ear. Right ear SRT scores were not significantly associated with functional connectivity. Secondary, voxel-wise analyses supported these findings, revealing that poorer SRT scores in the left ear were associated with lower functional connectivity in posterior and medial parietal regions, in the better left ear group only.
Our results show that age-related hearing loss in the left ear (but not the right) is associated with

reduced brain functional connectivity, specifically in individuals whose left ear is their better ear. We observed lower connectivity to the DMN, a network associated with memory and known to be impaired in Alzheimer's disease, and the FPN, a network associated with attentional resources. Thus, these findings suggest that age-related hearing loss may be a risk factor for cognitive decline due to reduced connectivity with higher-order cognitive networks.

Title: Prefrontal and parietal brain activation during dual-task walking in older adults - an fNIRS study

Authors: *R. STOJAN[1,2], M. MACK[1], O. BOCK[3,2], C. VOELCKER-REHAGE[1,2];
[1]Univ. of Muenster, Muenster, Germany; [2]Chemnitz Univ. of Technol., Chemnitz, Germany;
[3]German Sport Univ. Cologne, Cologne, Germany

Abstract: Walking while being engaged in an additional cognitive task is a common yet cognitively highly demanding behavior in daily life. Many neuroimaging studies investigated brain activity during dual-task (DT) walking by use of fNIRS or EEG. Most of them were limited to the prefrontal cortex (PFC), and found that PFC activity was increased during DT walking, and compared to single-task (ST) walking and ST cognition. This upregulation was typically more pronounced in older than younger adults, and was often explained by neural inefficiency or capacity limitation models. We used high-density multi-channel fNIRS to monitor an additional brain region, i.e., the parietal cortex (PC), aiming to better understand a potential interaction between frontal and parietal brain regions during DT walking. Data of 46 older adults (age: 68.57 ± 3.92; 26 females) were analyzed. Participants completed a virtual DT walking scenario that comprised two different DTs (walking + Serial's Threes; walking + Stroop), three STs (walking; Serial's Threes; Stroop), and a baseline task (standing). All tasks were carried out in a pseudorandomized order (5 trials per task, 30 s per trial) that was identic for all subjects. Brain activity was assessed using multi-channel continuous-wave fNIRS over the PFC and PC. HbDiff (the difference between oxygenated and deoxygenated hemoglobin concentrations) was computed as a marker of brain activation, and averaged within an interval of 10 to 30 s after trial onset. A 5 x 2 ANOVA (Task x Region) with follow-up pairwise estimated marginal means contrasts revealed higher brain activation in PFC and PC for both DTs compared to ST walking and ST cognition. Further, brain activity during DT was higher than the summed

activity of ST walking and ST cognition in PFC (overadditive), but slightly lower than that sum in PC (underadditive). Higher overadditivity in PFC was associated with smaller underadditivity in PC. Consistent with previous studies, PFC and PC upregulation in older adults under DT conditions suggests increased neurocognitive task demands during DT walking. Further, larger overadditive PFC activity during DT may indicate higher cognitive effort or ineffective task coordination processing in PFC (neural inefficiency). That higher PFC overadditivity was associated with smaller underadditivity in PC might be a further hint for ineffective task coordination and/or might highlight the allostatic interaction of both regions. Our findings provide new insights into the interplay of PFC and PC and highlight the importance of the application of multichannel fNIRS measures in multiple regions during DT walking.

Title: Mapping structure to function and behavior with individual-level connectome embedding

Authors: *G. LEVAKOV[1], J. FASKOWITZ[2], G. AVIDAN[3], O. SPORNS[2];
[1]Ben Gurion Univ. of the Negev, Beer Sheva, Israel; [2]Psychological and Brain Sci., Indiana Univ., Bloomington, IN; [3]Dept. of Psychology, Ben-Gurion Univ. of the Negev, Beer Sheva, Israel

Abstract: Embedding of a graph or connectome embedding (CE), involves finding a compact vectorized representation of nodes that captures their topological attributes. Such embeddings would ideally represent not only the pairwise connections of a given node, but also its higher-order relations within the graph. Obtaining CE can be done using the word2vec algorithm adapted from linguistics. This algorithm finds a low-dimensional latent representation of words such that words that appear in the same context within a sentence would be closer in the embedded latent space. The approach can be adapted to study connectivity in the human brain, such that nodes that appear in a similar context in a random walk on a brain graph would be closer in the embedding space. Previous work was focused on characterizing the embedding of group averaged structural connectivity. This framework allowed inference of edges missing in the reconstructed structural connectivity matrix and improved structural to functional connectivity mapping. In the current work, we further develop and advance this framework by presenting a novel approach to align separately learned embeddings to the same latent space using a close form solution that utilizes parameters learned in the embedding fitting process. This enables us to apply the CE framework at the individual level, rather than the group level, to investigate the relation between individual differences and CE. To test this approach, we used

large lifespan datasets (NKI: n=542; Cam-CAN: n=601) that included diffusion-weighted imaging, resting-state fMRI, as well as physiological and behavioral measures. We empirically evaluated our approach for aligning CE within and between individuals. We demonstrate that CE substantially improves the mapping of structural connectivity to functional connectivity at the individual subject level as found previously in mapping of group-averaged connectivity. Furthermore, we found that important age-related individual differences in this structure to function mapping are preserved and even more pronounced when quantified using our new approach. Finally, as a proof of concept, we showed that CE captures individual differences in physiology and behavior by predicting age, intelligence, and gender. For age and intelligence, the predictive accuracy was substantially higher when using CE compared to the raw structural connectivity. Our novel alignment approach provides a substantial advancement in our ability to examine individual differences in structure-function correspondence as well as relating network topology to physiology and behavior.

Title: Adults with autism spectrum disorder show steeper age relationships with decreasing amygdala size: sex differences and associations with autism symptoms

Authors: ***B. A. PAGNI**, N. GUERITHAULT, M. J. M. WALSH, J. R. COOK, B. B. BRADEN;
Arizona State Univ., Tempe, AZ

Abstract: While abnormal amygdala volumes have been observed in various age groups of individuals with autism spectrum disorder (ASD), little research has explored how volumes change across the adulthood lifespan, whether men and women have different aging trajectories, and what changes in symptomatology coincide. Children with ASD have enlarged amygdala which reach neurotypical size around adolescence and becomes smaller in adulthood, suggesting the developmental arc in ASD is altered compared to neurotypicals (NTs). Amygdala sizes strongly correlate with anxiety and social symptoms in ASD, however it is still unclear if age-related changes in volume have consequences on these symptoms. In this cross-sectional study of adults ages 18-71 years, amygdala volumes in men and women with ASD (n=143) were examined and compared to aging trajectories in NT men and women (n=86). Participants completed self-report measures for anxiety (State-Trait Anxiety Inventory, STAI) and ASD symptoms (Social Responsiveness Scale-2, SRS-2) and T1 MRI images were processed in

FreeSurfer and amygdala volume estimations were corrected by total intracranial volume. A MANOVA for left and right amygdala volume revealed a significant three-way diagnosis-by-sex-by-age interaction ($F(7,106)=2.147$, $p=0.045$). Post-hoc correlations showed a significant negative relationship between age and amygdala volume bilaterally for men with ASD (right: $r(98)=-0.517$, $p<0.001$; left: $r(98)=-0.481$, $p<0.001$) and in the right hemisphere for women with ASD ($r(34)=-0.343$, $p=0.021$). Age correlations in this age range did not reach significance for NT men or women. Behavioral correlations showed relationships between amygdala volumes and SRS-2 subscales 'Awareness' (right hemisphere: $r(128)=-0.187$, $p=0.034$), 'Cognition' (right hemisphere: $r(128)=-0.291$, $p=0.001$; left hemisphere: $r(128)=-0.261$, $p=0.003$), and 'Communication' (right hemisphere: $r(128)=-0.207$, $p=0.019$) for adults with ASD. Surprisingly, there were no significant correlations with anxiety symptoms in adults with ASD. These findings support a larger body of work which suggests an altered developmental arc in neuroanatomical structures in ASD and extends our knowledge by showing age-related volumetric changes in the amygdala are associated with ASD symptoms across the adult lifespan. Future work should seek to confirm these findings using longitudinal designs. Understanding age and sex effects may provide insights into the contribution of the amygdala in symptom presentation in ASD.

Title: Medial temporal lobe volumetric trajectories across midlife and associations with episodic memory

Authors: *J. SNYTTE[1], C. BEAUDOIN[1], K. HOOPER[1], R. K. OLSEN[2], N. RAJAH[1];
[1]McGill Univ., Montreal, QC, Canada; [2]Univ. of Toronto, Toronto, ON, Canada

Abstract: Age-associated declines in episodic memory for contextual details (context memory) arise in early midlife and are associated with altered brain activity in prefrontal and medial temporal cortices (Ankudowich et al., 2017; Kwon et al., 2015). Yet, it remains unclear how memory circuitry in the medial temporal lobes (MTL) changes at midlife, and how this relates to declines in context memory. Importantly, women report increased memory deficits as they transition through menopause (Greendale et al., 2011), which may contribute to the greater prevalence of memory disorders in women in late life (Gao et al., 1998). To better understand these sex-specific changes in memory circuitry at midlife, we investigated sex-specific differences in the association between age and volume of MTL regions in young adults (YA: 19-

35 years old) and middle age adults (MA: 40-58). Additionally, we examined associations between MTL structure and episodic memory performance. We tested 81 participants (18 YA females, 15 YA males, 38 MA females and 10 MA Males) on context memory tasks. We employed a semi-automated segmentation protocol, by segmenting the perirhinal (PRC), entorhinal (ERC) and parahippocampal (PHC) cortices, and the anterior and posterior segments of the hippocampus (antHC and postHC). We modeled age-related changes in volume with quadratic regressions within each sub-group. Further, we predicted memory performance on the context memory tasks based on MTL volumes using multiple linear regression. Results from structure-age regressions demonstrate a positive quadratic relationship between PRC volume and age in YA females ($R2_{adj} = 43.93$, $p < 0.01$), and negative quadratic relationships between ERC ($R2_{adj} = 21.57$, $p < 0.01$) and PRC volumes ($R2_{adj} = 11.11$, $p < 0.05$) with age in MA females. We did not observe significant age-structure relationships in either of the male subgroups. Additionally, within the MA female subgroup, we found that volume of the anterior hippocampus significantly predicted performance on the hard component of the temporal context memory task ($R2_{adj} = 25.09$, $p < 0.01$). While midlife is understudied from a brain-imaging perspective, cognitive changes during this time may be especially important in women transitioning through menopause. Taken together, our results suggest differences in MTL structure across midlife, which decrease around 50 years old. By focusing on adults early in the aging process, and throughout the menopausal transition, we reveal sex-dependent characteristics underlying how regions involved in episodic memory processes change with age.

Title: The Functional Roles of L-Type Calcium Channels in Odour Learning and Spatial Discrimination

Authors: *T. CRITCH, A. GHOSH, C. REINHARDT, C. FLYNN, L. MACGOWAN, Q. YUAN;
Mem. Univ. of Newfoundland, St. John's, NL, Canada

Abstract: L-Type calcium channels (LTCCs) have been shown to be intricately involved in the process of learning and memory. Calcium influx through LTCCs has been shown to be critical for learning and memory in several animal models. However, as we age, our ability to recall and form new memories deteriorates, leading to cognitive impairment. Interestingly, LTCC mediated

calcium current in neurons is also found to increase with ageing. We hypothesize that during the process of ageing, there is a paradoxical shift in the role of LTCCs in learning and memory. An increased amount of calcium entry through LTCCs results in a deviation from normal calcium homeostasis and contributes to cognitive decline that we see in an ageing population.We have set out to systematically investigate the potential effects of blocking LTCCs in respective brain areas associated with two types of learning in rats: an olfactory discrimination learning task in a food deprived model, in which the animals learn to associate one odour with an appetitive reward; as well as a spatial learning task in which the animals learn to discriminate between identical objects based on their location within an open field. We will use nimodipine at various age points (Young 6-10 months and Ageing animals >18 months), by first exploring the effects of systemic injection (5.5mg/kg), then, direct infusion to the olfactory cortex (Piriform Cortex (PC) and hippocampus (CA1) (10uM – 100uM), before undergoing either task.Preliminary results from the food retrieval paradigm suggests that when given an i.p. injection of nimodipine to young rats, it prevented their ability to learn the odor reward association. Moreover, direct infusion of nimodipine to the PC of the young animals showed the same trend as seen in the i.p injection group in the food retrieval task. In contrast, in the ageing animals, nimodipine permitted the animal's ability to learn the task, while control ageing animals showed little to no learning. When exploring the effects of nimodipine in the spatial discrimination, young animals given i.p injections of nimodipine, showed a drastic impairment in
their discrimination ability, strikingly, when examining ageing animals under the same condition, nimodipine showed a complete enhancement in the animal's ability to discriminate between the objects.This project will shed light on the differential roles that LTCCs play during development and support the potential for the investigation and development of therapeutics that target LTCCs and for age-related learning deficits as well.

Title: The role of slow-wave-sleep in hippocampus-dependent memory

Authors: *O. E. IGIESUOROBO, L. FERRARI, H. GOMPF, C. ANACLET;
UNIVERSITY OF MASSACHUSETTS MEDICAL SCHOOL, Worcester, MA

Abstract: Our modern society allows us to live longer, however the increase in lifespan is associated with deficits such as decreased quality of sleep and cognitive function. Sleep deprivation/restriction studies indicate that excellent quality of sleep is necessary for optimal cognitive function, yet the evidence remains correlative and the mechanisms remain poorly understood. For example, deep non-rapid eye movement (NREM) sleep, also called slow-wave-sleep (SWS), a stage of sleep that is impaired with aging, has been implicated in hippocampus-dependent memory.
We are studying the role of SWS in hippocampus dependent memory function using, for the first time, gain-of-sleep experiments. We hypothesize that sleep deficits associated with aging are, at least in part, responsible for memory impairments and increasing the quantity and quality of SWS will reverse these memory deficits by enhancing synaptic plasticity and increasing protein synthesis necessary for memory.
Using chemogenetic activation of the sleep-promoting GABAergic neurons located in the parafacial zone (PZGABA), SWS is enhanced in adult (3-6months) and aged (18-24 months) mice. Mice are subjected to hippocampus dependent memory tests; spatial object recognition (SOR) and contextual fear conditioning (CFC). The same mice are also used for measuring protein synthesis in the cortex and hippocampus as a molecular mechanism by which SWS promotes memory. Finally, synaptic plasticity is measured in the hippocampus. Control groups include littermate non-SWS enhanced mice.
Our aged mice recapitulate the sleep and cognitive deficits associated with aging, phenotypes that are reversed by SWS enhancement. This is associated with an increase in protein synthesis and enhanced long term potentiation (LTP) in the hippocampus.
This study has the potential to not only definitively link SWS with hippocampus-dependent memory but also provide new molecular targets to promote cognition in aging and in neurological patients combining sleep disruption and memory consolidation, such as Alzheimer's disease.

Title: Carnosine counteracts age-related hypoactivity and cognitive dysfunction by reducing dysregulation of plasma corticosterone and secondary structure of amyloid-beta in the brains of aged rats.

Authors: *S. BANERJEE[1,2], B. MUKHERJEE[2], M. K. PODDAR[2], S. RAHA[3], A. K. SINGHA[3], G. L. DUNBAR[1];
[1]Psychology, Neurosci. Program, Field Neurosciences Inst. Lab. for Restorative Neurol., Central Michigan Univ., Mount Pleasant, MI; [2]Pharmaceut. Technol., Jadavpur Univ., Kolkata, India; [3]Physics, Bose Inst., Kolkata, India

Abstract: Age-related stress leads to dysregulation of different biochemical pathways, leading to proteinopathies. Carnosine is an endogenous antioxidant that attenuates age-related stress and neurochemical pathologies. The goal of the present study was to assess the role of carnosine in modulating age-related: (a) plasma corticosterone status; (b) Aβ deposition in different brain regions (prefrontal cortex, hippocampus, hypothalamus, pons-medulla and cerebellum) and potential conformational changes as measured by Raman spectroscopy; (c) alterations in locomotor activity (rearing and locomotion) and (d) cognitive deficits. Young (4-month-old) and aged (18 and 24-month-old) male Wistar rats were given carnosine (2.0 μg/kg/day, i.t.) for 21 consecutive days and tested for spontaneous motor activity (rearing and locomotion) and cognitive (radial-arm-maze) abilities before being euthanized for plasma and histological analyses. Results indicated that in the aged rats: (a) the plasma corticosterone level was increased; (b) a graded deposition of Aβ in the examined brain regions (except for the cerebellum) was observed, with a maximum deposition in prefrontal cortex with the increase in abundance of β-sheet in the secondary structure of Aβ plaque; and (c) locomotor activity and cognitive abilities were reduced. Treatments of carnosine attenuated the age-related increase in plasma corticosterone levels, as well as the reduction in locomotor activity and cognitive abilities. Carnosine also reduced regional graded Aβ deposition with elevated β-sheet levels and improved the cognitive abilities in the aged rats. It can be concluded from the present study that: (a) age-related decreases in rearing and locomotor activities are associated with the increase of plasma corticosterone and a graded Aβ accumulation in the brain regions (except for the cerebellum) by increasing the abundance of β-sheets; (b) carnosine can attenuate these age-induced deficits by reducing (i) the abundance of β-sheet in the Aβ secondary structure and (ii) allostatic load.

Title: Whole-body senescent cell clearance alleviates age-related brain inflammation and cognitive impairment in mice

Authors: *D. JURK[1], M. OGRODNIK[1], S. EVANS[2], S. VICTORELLI[1], T. TCHKONIA[1], J. F. PASSOS[1], N. NERETTI[2], J. L. KIRKLAND[1];

Abstract: Background and aims: Cellular senescence is characterized by an irreversible cell cycle arrest and a senescence-associated secretory phenotype. Recent studies have shown that clearance of senescent cells has beneficial effects in several neurodegenerative diseases and alleviates anxiety in obese mice. However, it is still not known if senescent cells influence brain aging and age-associated cognitive impairment. This study aimed to investigate the impact of senescent cell clearance in age-associated cognitive decline. **Methods:** INK-ATTAC mice were aged until ~27m of age and treated with vehicle, AP20187 (AP) or senolytic drug cocktail Dasatinib/Quercetin (DQ). Drugs were administered for 3 days per week, every two weeks (total 8 wks). Stone T-maze was used to measure cognition. For single-cell RNA-sequencing, the hippocampus was dissected from 4 and 24m old mice. Senescent cells and efficacy of senolytic interventions was assessed by IHC, IF and RNA-ISH. **Results:** We first conducted single-cell RNA-sequencing in the hippocampus from young and aged mice. We observed an age-dependent increase in p16+ cells, which was more pronounced in microglia and oligodendrocyte progenitor cells (**Fig A**). We then aged INK-ATTAC mice, in which p16+ cells can be eliminated with the drug AP and treated them with AP or DQ. We observed that both strategies resulted in a decrease in p16 exclusively in the microglial population, reducing microglial activation. Next, we used a modified Stone T-maze and confirmed that aged animals make more errors (**Fig B**) and need a longer time to complete the maze. We found that both AP and DQ resulted in a significant reduction in the frequency of errors made by aged mice (**Fig C**). **Conclusion**: Here, we show by scRNA-seq that p16 expression increases with age predominantly in microglia and oligodendrocytes. Importantly, we found that interventions targeting senescent cells are effective at removing p16+ microglia and improve cognitive function. Our data provide proof-of-concept for senolytic interventions' being a therapy to alleviate age-associated cognitive impairment.

Title: Sex differences in Memory Subtype Deficits in Parkinson Disease

Authors: *T. H. REEKES[1], C. I. HIGGINSON[3], K. A. SIGVARDT[4], D. S. KING[5], D. LEVINE[5], V. L. WHEELOCK[5], E. A. DISBROW[2];

Abstract: Parkinson Disease (PD) disproportionately affects patients by sex; the incidence in males is 1.5 times higher than females. The Movement Disorder Society Task Force identified five domains for the diagnosis of mild cognitive impairment in PD: attention and working memory, executive function, language, episodic memory and visuospatial function. However, while most studies agree that in PD females have superior cognitive performance, sex differences in visuospatial performance have yet to be evaluated. Interestingly, in healthy populations, females perform better in verbal based tasks of memory while males show superior performance in visuospatial tasks; however, we tested the hypothesis that females with PD would have superior performance compared to males on measures of verbal memory and visuospatial processing. A total of 146 participants (52 female) diagnosed with PD ages of 50 and 82 years were recruited. Sex was determined by self-report and only those entered as male or female were included. Demographic/disease information and a large battery of neuropsychological tests including measures verbal and auditory memory and visuospatial function using the Wechsler Memory Scale-third edition (WMS-III), were collected from each patient. All patients were tested in his or her best ON state. One-way ANOVA revealed no significant differences between sexes in age ($F(1,145) = 0.073$, $p = 0.788$), global cognitive status as indicated by MMSE performance ($F(1,139) = 0.057$, $p = 0.811$), nor disease descriptive variables such as illness duration ($F(1,56) = 0.103$, $p = 0.750$), disease stage ($F(1,88) = 0.589$, $p = 0.445$), or motor evaluation $F(1,95) = 0.021$, $p = 0.886$). There was a significant difference in years of education favoring males ($F(1,145) = 12.240$, $p = 0.001$), thus years of education was used as a covariate in all analyses of cognitive measures. Results from the MANCOVA using years of education as a covariate revealed significant differences across sex in immediate auditory memory index ($F(3,135) = 4.313$, $p = 0.040$, Cohen's $d = 0.13$), and immediate ($F(3,135) = 8.739$, $p = 0.004$, Cohen's $d = 0.51$) and delayed visual memory index ($F(3,135) = 5.183$, $p = 0.024$, Cohen's $d = 0.40$). We see significant and consistent sex differences in measures of cognitive function with superior performance in females compared to males. While our results are consistent with superior verbal performance in females, we found that females also outperformed males on visuospatial tasks inconsistent with results in healthy populations. Therefore, PD may have sex specific mechanisms that disproportionately affect memory in males.

Title: Mindful awareness attenuates the negative effect of worry on processing speed

Authors: *N. HARPER[1], M. DELGADILLO[1], A. ERICKSON[1], J. K. FAIRCHILD[2]; [1]Palo Alto Univ., Palo Alto, CA; [2]VISN 21 Mental Illness Research, Education, and Clin. Ctr., VA Palo Alto Hlth. Care Syst., Palo Alto, CA

Abstract: Introduction: Worry has been shown to have a negative impact on many aspects of neurocognitive performance. Interestingly, research indicates that mindfulness both improves aspects of cognitive ability and also reduces worry symptoms. Yet, the impact of mindfulness on the relationship between worry and cognition has yet to be explored. The present study investigates the potential moderating influence of mindfulness on the relationship between worry and cognitive performance. **Method:** The sample included 113 older Veterans who were screened at the VA Palo Alto Health Care System (94.7% male, mean age = 71.20±9.05). Domains of interest included episodic memory (Rey Auditory Verbal Learning Test; RAVLT), processing speed (Trail Making Test Trial A; TMT A), and executive function (Trail Making Test Trial B; TMT B). Mindful awareness was assessed with the Five Facet Mindfulness Questionnaire (FFMQ). Worry symptoms were assessed using the Penn State Worry Questionnaire (PSWQ). Multiple linear regression was used to evaluate the relationship between mindful awareness, worry, and cognitive function. Due to its relationship with cognitive performance, age was included as a covariate in all regression models. Post-hoc simple slopes analysis was conducted to further evaluate the moderating effects of mindful awareness. **Results:** Mindful awareness significantly moderated the relationship between worry and processing speed. Older Veterans with low mindful awareness and high worry performed worse compared to those with low mindful awareness and low worry. In those older Veterans with high mindful awareness, level of worry did not impact processing speed performance. Mindful awareness did not significantly impact the relationship between worry and executive functioning or episodic memory. **Conclusions:** Mindful awareness attenuates the negative impact of worry on processing speed in older Veterans. Importantly, mindful awareness is only one aspect of mindfulness. Future research should explore the impact of other facets of mindfulness on the relationship between worry and cognition.

Title: Effects of chronic, high-dose minocycline treatment on cognitive performance in aging rats

Authors: *K. YOUNG[1,2], M. A. ZEMPARE[1,2], A. L. DALMENDRAY[1,2], A. GREGOLYNSKYJ[1,3], M. K. CHAWLA[1,2], J. F. GUZOWSKI[5], C. A. BARNES[1,2,4];
[1]Evelyn F. McKnight Brain Inst., [2]Dept. of Psychology, [3]Undergraduate Biol. Res. Program, [4]Departments of Neurol. and Neurosci., Univ. of Arizona, Tucson, AZ; [5]Dept Neurobiol/Behavior, Univ. of California Irvine Dept. of Neurobio. and Behavior, Irvine, CA

Abstract: The antibiotic minocycline is a promising therapeutic intervention in multiple age-associated diseases that share inflammation as a symptom. Its neuroprotective effects have been attributed to anti-inflammatory properties exerted through interaction with T-cells and microglia. Minocycline crosses the blood-brain-barrier and can ameliorate cognitive deficits in experimental models of ischemic stroke, traumatic brain injury, and neurodegenerative conditions like Alzheimer's, Parkinson's, and Huntington's diseases. To address the lack of research into the effects of minocycline on normative aging in the absence of brain trauma or disease, we investigated whether minocycline might affect age-related cognitive decline in rats. Middle-aged (16mo) male Fischer rats were divided into control and treatment groups, with treated rats receiving 70mg/kg/day of minocycline via drinking water (a high dose chosen for its minimal effect on water consumption). After 8 weeks of treatment, rats (18 mo) were administered a behavior test battery, with a retest 10 weeks later (20mo) to assess the impact of continued minocycline treatment on cognitive performance. The battery includes spatial and cued versions of the Morris watermaze, a spontaneous object recognition (SOR) task, and a delayed matching-to-place working memory task. Analysis of the 1st battery shows that while treated rats trend towards learning the spatial watermaze slower than controls (2WAY RM ANOVA: treatment: $F(1, 21) = 4.049$, $p = 0.057$), both groups perform similarly at the end of the task, and did equally well on the perirhinal cortex-dependent SOR task and prefrontal cortex-dependent working memory task. When retested 10 weeks later, treated rats learn the spatial watermaze at the same rate as controls, and both groups display age-related decline in performance on the SOR task. On the working memory retest, both treated and control rats achieve a shorter pathlength on the retention trial. The present data suggest minocycline is not effective for modifying cognition in normative aging. While minocycline has been successful

treating cases of severe brain injury or neurodegenerative disease, the degree of neuroinflammation in the aging brain may be below threshold for such beneficial effects.

Title: Cortical and hippocampal activity altered with loss of perforant path fibers

Authors: *T. L. COOPER[1], S. M. TURNER[1], K. N. LUBKE[1], J. J. THOMPSON[1], S. A. JOHNSON[3], A. P. MAURER[1], S. N. BURKE[2];
[2]Neurosci., [1]Univ. of Florida, Gainesville, FL; [3]Dept. of Neurosci., Rosalind Franklin Univ. of Med. and Scien, North Chicago, IL

Abstract: Discrimination between objects that share similar features is a cognitive function often impaired with normal aging and exacerbated with progressive neurodegenerative conditions such as Alzheimer's Disease (AD). The perforant path, a connection that plays a crucial role in mnemonic discrimination, is also highly vulnerable to aging, with extensive fiber loss associated with Mild Cognitive Impairment and episodic memory deficits. In a prior publication from our lab, animals with a unilateral perforant path transection were tested on a mnemonic discrimination task using LEGO object pairs with 90%, 70%, or 50% feature overlap and additional lure trials using a LEGO and standard object for 0% similarity. Animals with loss of perforant path fibers showed impaired performance on a mnemonic discrimination task, and this difference from sham animals exacerbated as similarity between objects increased. The results of that study mimic findings from aged rats on the same task in comparison to young animals, though there was a greater magnitude of age-related deficits, supporting the idea that loss of perforant path fibers may be one factor of many involved in the progression of AD and age-related cognitive decline. This study elaborates upon those behavioral deficits by analyzing neuronal activity in cortical and hippocampal sub-regions involved in mnemonic discrimination following unilateral perforant path transection. As dentate gyrus disruption did not produce a behavioral deficit, we hypothesize that the dysfunction may arise from reduced connectivity between CA1/CA3 subregions of the hippocampus and the perirhinal (PER) and lateral entorhinal (LEC) cortices. Sections of CA1, CA3, PER, and LEC were stained for immediate-early gene (IEG) *Arc* to visualize neuronal activity associated with behavioral testing. Cells were counted as being positive for cytoplasmic *Arc*, nuclear *Arc*, both cytoplasmic and nuclear *Arc*, or

negative for *Arc* expression. Only pyramidal cells, not glial cells, were included in the analysis. Cells positive for nuclear *Arc* indicate principal neuron activity 5 minutes prior to brain collection, and *Arc* in the cytoplasm indicates activity approximately 30 minutes prior. Analysis of *Arc*-positive neurons in each of the four regions reveals the pattern of activity associated with a mnemonic discrimination task as well as how cognitive impairment due to perforant path transection manifests in neuronal activity. Preliminary analysis indicates increased cells in the LEC positive for both cytoplasmic and nuclear *Arc* and decreased cytoplasmic-*Arc* positive cells in the CA3 for animals with loss of the perforant path.

Title: White matter tract integrity mediates relationships between learning-related activity in younger and older adults

Authors: *J. L. MERENSTEIN[1], I. J. BENNETT[2];
[1]Psychology, Univ. of California Riverside, Riverside, CA; [2]Psychology, Univ. of California, Riverside, Riverside, CA

Abstract: Healthy aging is accompanied by declines in our ability to learn associations between events without awareness, termed implicit associative learning (IAL). Functional magnetic resonance imaging (fMRI) studies have attributed these age-related IAL deficits to over-recruitment of the hippocampus and under-recruitment of the basal ganglia and prefrontal cortex. Our recent fMRI work further showed age-related decreases in relationships between IAL-related activity from these regions, which may be due to the negative effect of aging on their white matter connections disrupting the propagation of neural signals. Here, we tested this hypothesis in healthy younger (n = 28; 20.8 ± 2.3 years) and older (n = 22; 73.6 ± 6.8 years) adults who completed the Triplet Learning Task (TLT) during fMRI and diffusion tensor imaging (DTI). The TLT measures IAL as the difference in reaction time to cue-cue-target "triplets" that occurred more versus less frequently. IAL-related activity was modeled as the difference between high and low frequency triplets within four functionally defined regions of interest from our prior voxel-wise fMRI work: the prefrontal cortex, hippocampus, and basal ganglia (putamen, globus pallidum). Tract integrity (fractional anisotropy; FA) was extracted from four skeletonized standard white matter tracts connecting the hippocampus (fornix, hippocampal cingulum) or basal ganglia (external capsule, and internal capsule) to prefrontal

cortex. As expected, results revealed age group differences in IAL performance, hippocampus and prefrontal IAL-related activity, and fornix and external capsule white matter integrity. Independent of age group, IAL-related prefrontal activity was significantly related to activity in the hippocampus and basal ganglia. Moreover, these prefrontal-hippocampus relationships were mediated by integrity of the fornix and hippocampal cingulum in both younger and older adults. However, the prefrontal-basal ganglia relationships were mediated by internal capsule integrity in younger, but not older, adults. Together, these results provide minimal support for the hypothesis that age-related differences in white matter integrity affect the coordination of neural activity between interconnected brain regions and instead suggest that individual differences in brain structure constrain inter-region relationships between brain function in both younger and older adults.

Title: Improvement in Cognitive and Psychological Functioning after Surgical Decompression in Chiari Malformation Type I - A Prospective Study

Authors: *S. C. SEAMAN[1], C. DEIFELT STREESE[3], K. MANZEL[2], J. KAMM[6], D. TRANEL[4], B. J. DLOUHY[5];
[1]Neurosurg., [2]Neurol., Univ. of Iowa Hosp. and Clinics, Iowa City, IA; [3]Neurosci., [4]Neurol., [5]Neurosurg., Univ. of Iowa, Iowa City, IA; [6]The Cicaco Sch. of Professional Psychology, Chicago, IL

Abstract: Introduction: Chiari Malformation Type I (CM-I) is a congenital and developmental abnormality in which the cerebellar tonsils are displaced more than five millimeters below the foramen magnum. This can result in cerebrospinal fluid obstruction, brainstem compression, and syringomyelia. Symptoms attributed to CM-I include Valsalva-induced headaches and bulbar symptoms, and these typically improve after surgery. However, little is known about the cognitive profile in CM-I and whether surgery has any impact. We therefore sought to perform a comprehensive analysis. **Patients/Methods**: Patients age ≥7 with classic symptoms and imaging of CM-I were included; patients with any cognitive confounders were excluded. Assessments were made preoperatively and at 6-18 months postoperatively. Evaluators blinded to the clinical severity assessed subjects using 26 neuropsychological and psychological tasks with data converted to Z scores based on normative data. Analysis was conducted using mixed fixed effect

modeling for preoperative assessment and change in performance after a standard suboccipital craniectomy and decompression. Overall performance change between time points was assessed with the Wilcoxon match-pair sign testing. **Results**: Thirty-six patients met criteria, with 25 tested at both time points. The mean age was 28, mean education 12 years, and a majority were female (75%) and right-handed (78%). Mean tonsillar descent was 14 mm. Adjusted for preoperative motor performance, baseline performance in tasks of visual perception/visuospatial construction and memory were significantly different from the normative mean (complex figure copy $z = -0.86$, $p = 0.002$; complex figure recall [CFT-Recall] $z = -1.09$, $p < 0.0001$). No mean z scores showed above-normal performance. Adjusted for mood and motor performance, postoperative improvement was noted in tasks of construction and memory (CFT-Recall, $p = .004$). The cumulative postoperative performance across all measures demonstrated improvement ($p = 0.002$). **Conclusion**: CM-I patients had mildly impaired baseline (preoperative) performance compared to normalized data in visuospatial and visuoconstructional abilities. Importantly, CM-I patients had general improvement in cognitive and psychological performance after surgery, with specific improvements in visuospatial memory. We cautiously interpret these findings to suggest the cerebellum's involvement in cognitive function.

Title: Differential impacts of VPA (Valproic acid) exposure on male and female cerebellar volumes in Long-Evans rats.

Authors: *B. PLAKKE[1], Z. E. MCKINNELL[4], M. PAYNE[2], I. MALI[2], S. H. BOSSMANN[5], T. B. SHRESTHA[3];
[2]Chem., [3]Anat. and Physiol., [1]Kansas State Univ., Manhattan, KS; [4]Kansas State, Manhattan, KS; [5]Cancer Biol., Univ. of Kansas Med. Ctr., Kansas City, KS

Abstract: Autism spectrum disorder (ASD) is a developmental disorder effecting communication, social interactions, and repetitive behaviors. In order to develop better treatment strategies, it is important to understand the underlying neurobiology of the disorder. The VPA model is a well- known animal model of autism-like behavior with both construct and face validity (Mabunga et al., 2015; Roullet et al., 2013). Women who were prescribed medications containing VPA to treat seizures and bi-polar disorder had increases in the number of children

that developed ASD compared to the regular population (Chomiak et al., 2013; Dean et al., 2002). The VPA model mimics this by introducing VPA into the system of a pregnant dam and then the offspring are raised and tested. This study used the VPA model to examine behavioral deficits and related brain changes between treated and untreated offspring. Pregnant dams were injected with VPA or saline and the offspring were reared to adulthood. Our prior work examined performance on social interactions, marble burying behavior and attentional set-shifting performance. This study used those same animals (males and females) and measured brain volumes of the cerebellum via MRI (magnetic resonance imaging). After 3D scans were obtained, volumes of lobules and crus regions were taken using a region of interest (ROI) approach. ROIs were hand segmented by blind to condition researchers. Preliminary results indicate that female VPA offspring had significant differences in brain volume in several lobules of the cerebellum compared to control females. Female VPA rats had decreased volumes of lobules I, IV and X, whereas male VPA rats had increased volumes of lobule VI. Female humans with ASD frequently have hypoplasia of the cerebellum whereas, males with ASD can have hypoplasia or hyperplasia of the cerebellum (Chen et al., 2017). Thus, this study highlights sex differences found in ASD are also occurring in a rodent model of ASD, and provides future hypotheses for testing cerebellar function in relation to behavioral deficits.

Title: Longitudinal cognitive decline and neuropathology in aging marmosets (Callithrix jacchus).

Authors: *E. ROTHWELL[1], K. P. WORKMAN[1], C. FREIRE COBO[2], M. VARGHESE[2], M. EDWARDS[1], W. JANSSEN[2], P. R. HOF[2], A. LACREUSE[1];

Abstract: Nonhuman primate (NHP) models of human cognitive aging are critical to understand vulnerabilities to neurodegenerative diseases such as Alzheimer's disease (AD). However, longitudinal designs which evaluate cognitive change within the same individual are difficult to implement in long-lived NHPs. Common marmosets (*Callithrix jacchus*) are ideally suited for longitudinal studies of cognitive aging, as they have a naturally short lifespan of about 10 years

and develop AD-relevant neuropathology during aging. We studied 27 marmosets (14 F, 13 M) from middle ($\bar{X}$ age=5) to old age across 4 years. Each year, marmosets completed a reversal learning task on a touchscreen interface. Cognitive performance improved during the first three years due to practice effects but declined in the fourth year with the onset of old age. Importantly, this decline was more prominent for females than males. Female cognitive impairment was not explained by sex differences in motivational factors, motor competence, stress reactivity or differences in overall behavioral profiles. Trajectories of cognitive decline were highly variable among both male and female marmosets, suggesting pathological aging and neurodegenerative processes in some individuals. Indeed, we observed different degrees of β-amyloid burden in these aged marmoset brains along with microglial activation and atrophy in the prefrontal cortex and hippocampus. Analyses of neuronal dendritic spine density and morphology in these areas will also be characterized. Future studies in this valuable model of preclinical AD will help identify risk factors, clarify the mechanisms leading to neuropathology and design interventions to prevent or delay disease progression.

Title: Inflammation and innate inflammatory cGAS/STING mechanisms may play a role in obesity- and prediabetes-mediated cognitive decline in aged mice

Authors: S. E. ELZINGA, R. E. HENN, E. GLASS, F. E. MENDELSON, J. M. HAYES, G. G. MURPHY, *E. L. FELDMAN;
The Univ. of Michigan, Ann Arbor, MI

Abstract: Obesity, prediabetes, the metabolic syndrome, and diabetes are growing in prevalence around the world. These conditions also predispose patients to the development of neurological complications, including cognitive decline. This is especially true for patients with midlife obesity and diabetes. A potential shared mechanism that may be responsible for this increased risk is chronic inflammation. One innate inflammatory pathway that has received recent attention is the intracellular double stranded DNA sensing cGAS/STING pathway. Therefore, we performed a pilot study using our non-transgenic murine model, which develops insulin resistance and nervous system complications in response to high fat feeding, to investigate the potential role of cGAS/STING in midlife obesity and prediabetes-mediated cognitive decline. At 1 yr of age, male C57/BL6 mice were started on either standard diet (SD; n=10) or a 60% high

fat diet (HFD; n=10) composed primarily of lard. Animals were fed their respective diets for 12 weeks, at which time they were assessed for cognitive changes using social recognition testing. After 13 weeks on diet, metabolic phenotyping was performed with glucose tolerance testing and general inflammatory phenotyping was carried out via ELISA. Hippocampi were isolated and assessed by Western blotting for cGAS/STING pathway protein expression. As expected, animals fed HFD had impaired glucose tolerance compared to SD controls. Additionally, they had increased circulating levels of the cytokine tumor necrosis factor alpha and the chemokine monocyte chemoattractant protein-1, indicating a pro-inflammatory phenotype. When looking at central nervous system specific hippocampal changes, STING protein expression was lower in HFD animals compared their SD counterparts. Interestingly, HFD mice also had deficits in short and long term memory. Taken together, these data indicate that HFD-induced obesity and prediabetes in mice promote cognitive decline and that this may be, at least in part, due to changes in inflammatory profiles and specifically regulation of the cGAS/STING pathway. However, more studies are warranted to fully understand these potential links and to understand underlying mechanisms of cGAS/STING involvement in obesity, prediabetes, and cognitive decline.

Title: Late-life social isolation in female mice leads to increased exploratory behaviors

Authors: *G. SULLENS[1], K. GILLEY[1], K. JENSEN[1], H. RODGERS[1], M. SEKERES[2]; [1]Baylor Univ., WACO, TX; [2]Univ. of Ottawa, Ottawa, ON, Canada

Abstract: This study aims to investigate the effects of late-life social isolation in a female mouse model. All mice (n = 40) were female and 18-months of age at the beginning of the study and had been group housed during that rearing period. At 18-months of age mice were randomly assigned to either continue group housing for one month (n = 20) or undergo social isolation (n = 20) for one month. After the experimental rearing period mice underwent a battery of tests to assess depressive-like symptomology, social behaviors, exploratory behaviors, and contextual fear conditioning. The testing battery lasted one week. Tests were conducted only one per day in least-to-most aversive order, and isolated mice remained isolated throughout the testing. Hippocampal tissue was collected for examination of inflammatory cytokines (*IL-6*, *IL1β*, *Tnf-α*) and microglia activation (*Itgam*). We found increases in hyperactivity and exploratory behaviors after isolation, but no alterations in depressive-like symptomology, social interaction, fear memory, or inflammatory cytokines and microglia activation. Previous research has shown that humans, and young rodents, may engage in enhanced exploratory and social behavior following

a period of social isolation. This is the first model of female late-life social isolation which can be used to inform future research and interventions for this population.

Abstract: Schizophrenia (SZ) is a neurodevelopmental psychiatric disorder affecting 1% of the population. While the diagnosis is currently based on signs and symptoms, by understanding the molecular determinant of SZ, we may be able to identify biomarkers and better direct treatment to the underlying causal factors. MicroRNAs (miRNAs) are a class of small non-coding RNAs which are already known to be associated with the disease. The aim of the current pilot study was to investigate the plausible association of miRNA expression with the severity of SCZ cognitive symptoms. We conducted small RNA-Seq on peripheral blood mononuclear cells (PBMCs) of five male patients with severe cognitive deficits and compared it to ten male patients with moderate impairments (CS group), collected by the Australian Schizophrenia Research Bank (ASRB). Of the 15 differentially expressed miRNAs with PValue<0.05, only hsa-miR-3175, which was 12-fold down-regulated in CD cases, survived multiple testing correction (FDR<0.05). TargetScan database and ToppFun online tool revealed that miR-3175 predicted targets are involved in neurogenesis, synaptic signalling, and regulation of synaptic plasticity, and associated with several neurodevelopmental disorders, including SZ. Transfecting SH-SY5Y-derived neuron-like cells with the miRNA mimic and inhibitor oligonucleotides led to the expression dysregulation of 68 and 895 genes, respectively, with 56 genes common between the two conditions. Among these 56 genes, 16 are miR-3175 predicted targets, of which 14 are related to the immune system, and 12 are known to be associated with psychiatric disorders. In addition, Gene Set Enrichment Analysis (GSEA) by ToppFun tool showed that they are involved in many processes and pathways related to the immune system, and are linked to autoimmune disorders, which is an important observation considering the well-established link between immune dysfunction and psychiatric disorders, including SZ. Collectively, our results suggest

that miR-3175 might be an interesting candidate biomarker for cognitive deficit subtype of SZ worthy of further investigation.

Title: Effects of anxiety on p50 sensory gating and cognition in schizophrenia and bipolar disorder

Authors: *D. CAO[1], W. E. BUNNEY[2], J. V. PATTERSON[1];
[1]Dept. of Psychiatry and Human Behavior, Univ. of California Irvine, Irvine, CA; [2]Distinguished Professor, Dept. of Psychiatry, Univ. of California Irvine Dept. of Psychiatry and Human Behavior, Irvine, CA

Abstract: Schizophrenia and bipolar I disorder (BPI) are characterized by severe symptoms like psychosis and debilitating mood swings between depression and mania, respectively. Anxiety is another symptom frequently experienced but oftentimes is not properly acknowledged and diagnosed during treatments for these psychiatric disorders. The goal of this exploratory research was to bring more notability to the impact of anxiety on schizoaffective (SczA), BPI and schizophrenia chronic paranoid type (SczP) patients in their daily lives by focusing on its effect on sensory gating and neurocognition. Subjects diagnosed with SczA (n=40), SczP (n=30), and BPI (n=55) were recruited along with controls (n=41) from the UCI Medical Center and the community. Selected item scores from the Positive and Negative Syndrome Scale (PANSS) and the Hamilton Depression Rating Scale (HAM-D) were taken to measure levels of anxiety. Using a paired click (S1 and S2) task, sensory gating was measured focusing on the positive evoked potential occurring around 50 msec (P50). Peak amplitudes were measured and used to calculate the S1-S2 difference and S2/S1 ratio. A neurocognitive test battery was also conducted, and the relationships among the anxiety, cognitive, and evoked potential measures for each group were studied, as well as differences between groups on these measures. Results from this study showed that anxiety scores clearly separated the patient groups from controls. Neurocognitive performance consistently distinguished the patient groups, with SczA performing worse than the others in the domains of attention, delayed memory, and short memory. Specifically, high anxiety in SczA correlated with deficiencies in sensory gating and in performances on various domains of neurocognition. BPI performed better in most domains than the other patient groups, but SczA was affected by anxiety more than both the BPI and SczP groups. High PANSS Gen Anxiety significantly correlated with decreased S1-S2 differences, while high HAM-D Anxiety significantly correlated with increased S2/S1 ratios. Both of these are characteristics of deficiency in sensory gating.

Title: Effective connectivity analyses of the plasticity of brain networks in schizophrenia during learning

Authors: *K. G. NANAAWARE[1], A. CHOWDURY[2], S. BAAJOUR[2], J. A. STANLEY[2], V. A. DIWADKAR[2];
[1]Wayne State Univ., Detroit, MI; [2]Psychiatry and Behavioral Neurosciences, Wayne State Univ. Sch. of Med., Detroit, MI

Abstract: Schizophrenia is suggested to be a disorder of brain network plasticity, and the process of learning is characterized by the plasticity of neural circuits. Ostensibly, patients with schizophrenia demonstrate poor learning performance in comparison to healthy individuals. Understanding the network plasticity of schizophrenia patients has rarely been attempted at the macroscopic network scale. Thus, we used a learning paradigm that induced negatively accelerated associative learning, and then utilized Dynamic Causal Modeling (DCM) to investigate the plasticity of ascending and descending pathways in the brain networks in schizophrenia. The early and late stages of encoding and retrieval externally modulate pathways in the brain during associative learning tasks. The associative learning task required engagement from ventral and dorsal visual pathways, the hippocampus (HPC), and frontal regions. We hypothesized two possible models to test for whether descending pathways from frontal regions were being modulated by the conditions and found that in the most probable model this was not the case. We implemented DCM to estimate effective connectivity of pathways and how their degree of modulation changed in response to the conditions. This allowed us to investigate altered plasticity in schizophrenia. The object-location association paradigm required subjects to associate the name of a unique object with a location in space and recall it later. The paradigm consisted of eight cycles of encoding, rest, and retrieval to induce asymptotic performance. All subjects (n=90) were provided informed consent and were compensated for their participation. Subjects in the control (n=38; nine females; mean age: 28.20; range: 18-45) group (HC) are those who are free from any neurological or psychological evaluation. Subjects in the patient (SCZ) group (n=52; ten females; mean age: 31.96; range: 18-50) were stabilized on anti-psychotics. The fMRI data was acquired using a 3T Siemens Verio scanner (32-channel volume head coil).

Images were pre-processed for spatial irregularities and analyzed using SPM 12. Our findings demonstrate that both SCZ and HC network pathways had a similar increase in the degree of modulation from early to late encoding, displaying plasticity of their networks. The results during the condition of retrieval differ, displaying evidence for altered plasticity in schizophrenia patients. The ascending pathway from the inferior temporal gyrus to the HPC had a time by group difference of significance 0.009, signifying contrasting effects of retrieval on this pathway. Overall impairment of frontal regions was also observed in patients.

Title: Gender Differences in Neurocognition and Symptom Severity in Schizophrenia and Bipolar I Disorder

Authors: *T. A. CHU, S. L. FERRETTI, S. T. SIDDIQI, W. E. BUNNEY, J. V. PATTERSON; Dept. of Psychiatry and Human Behavior, Univ. of California, Irvine, Irvine, CA

Abstract: Schizophrenia (Scz) and bipolar I disorder (BPI) can have symptom overlap, making diagnosis difficult, and profound cognitive impairments that greatly affect clinical outcomes and quality of life. Previous studies have shown a gender difference in symptom severity (SS) for Scz; it remains poorly studied in BPI. Little research has been done on gender differences in neurocognition for Scz or BPI, and none have explored the role of SS on these differences. This study investigated whether there are gender differences in neurocognition and/or symptom severity in BPI and two Scz subtypes: schizoaffective disorder (SczA) & schizophrenia paranoid type (SczP). The BPI group was sub-categorized into “with psychosis” (BPI Psy) and “without psychosis” (BPI woPsy). Groups were: SczA (F=26; M=24); SczP (F=9; M=23); BPI Psy (F=11; M=13); BPI woPsy (F=21; M=17). Subjects (14-78 years old) were interviewed to establish diagnosis, completed a series of clinical rating scales (PANSS, Hamilton Depression Scale, Beck Depression Inventory, MADRS, etc.) to evaluate SS, and then completed a neurocognitive assessment that included tests for memory, attention, executive function, fine motor control, language, and emotional perception domains. Domain z-scores were calculated using control score means & standard deviations. SS was assessed using each clinical scale’s scoring rubric. ANOVA (Diagnostic Group by Gender) and Newman-Keuls method were used to investigate Group and Gender differences. ANOVA demonstrated multiple significant results ($p<0.05$) due to diagnosis or gender; there was no significant interaction between diagnosis and gender. Females had significantly worse scores for depression scales (Beck, Hamilton, MADRS) and the Mee-Bunney psychological pain scale than males. Males scored significantly higher in the attention and fine motor control domains, but lower for immediate memory. Significant Pearson

correlations existed between many SS measures and neurocognitive domain scores for all gendered subgroups except SczA Males. BPI Psy males had a correlation between CGI and executive function (r= -0.537, p=0.058); SczP females had a correlation between the Hamilton score and attention domain (r= -0.794, p=0.011). BPI Psy females had a correlation between the Hamilton score and visual memory (r= -0.739, p=0.009); SczA females had one between CGI and emotion perception (r= -0.429, p=0.037). These results and others suggest that females with Scz or BPI have more neurocognitive impairments and more severe symptoms (especially for depression) than males, and that worse neurocognitive performance may be associated with increased symptom severity.

Title: Correlation Between Sensory Gating Deficits and Smoking in Patients with Schizophrenia and Bipolar Disorder

Authors: *R. VERMANI, J. V. PATTERSON, W. E. BUNNEY, Jr.;
Psychiatry and Human Behavior, Univ. of California, Irvine, Irvine, CA

Abstract: The prevalence of smoking is 22.5% in the U.S. general population. For those with mental illness such as schizophrenia (Scz) and bipolar disorder (BPI), the prevalence values are almost 3 times the norm. The prevalence of smoking in these groups highlights the need to understand the role of smoking in Scz and BPI, as it can lead to high morbidity and mortality. The purpose of this research was to investigate the effects of chronic smoking on sensory gating, a measure of brain inhibitory function. Sensory gating is the ability to attend to selective stimuli and ignore redundant or irrelevant information, preventing the brain from being exposed to an overflow of information. When paired auditory clicks are presented to normal controls, the P50 evoked potential (EP) response to the second click (S2) is attenuated in amplitude compared to the first (S1), measured as the S2/S1 ratio or S1-S2. In Scz, and often BPI, sensory gating is usually impaired. A previous study assessing the immediate effect of smoking on sensory gating in Scz found impaired gating before, but temporarily improved gating after smoking. In contrast, another study showed that chronic smoking impaired gating in Scz smokers compared to Scz nonsmokers. However, little research has been done on the effects of smoking on sensory gating in BPI or SczA specifically. This project studied the smoking effects on sensory gating in 3 patient groups: Scz paranoid type (SczP, n=32), schizoaffective disorder (SczA, n=35), and bipolar I disorder (BPI, n=60). Subjects participated in a 64-channel EEG during an auditory

paired click test. Ninety paired clicks (S1 and S2) were separated by 10 seconds with 500 ms between pairs. Neuroscan software was used to record EEG data, with channels referenced to linked mastoids. Electro Magnetic Source Estimation Suite (EMSE) was used to process the raw data and measure the P50 peaks. Results indicated a significant difference in pack-yrs between the three groups, with BPI having a lower mean pack-years than SczA and SczP. Analysis of variance showed a significant difference in P50 peak amplitude between smokers and nonsmokers at S1 in all three groups, with reduced peak amplitude in smokers, but not at S2. For the SczA and BPI groups, but not for SczP, there was a larger S2/S1 ratio and smaller S1-S2 difference, both indicating worse gating, in smokers compared to nonsmokers. The conclusion to be drawn from these results is that chronic smoking impairs sensory gating. While previous studies have shown that smoking can temporarily improve function in these groups, there is a long-term negative effect. This underscores the need for the development of effective cessation therapies for these patients.

Program #/Poster #: P366.05

Topic: H.13. Schizophrenia

Title: Effect of age of onset of schizophrenia and duration of illness on sensory gating mechanisms and neurocognitive performance

Authors: *A. YASEEN[1], W. E. BUNNEY[2], J. V. PATTERSON[1];
[1]Univ. of California, Irvine, Irvine, CA; [2]Distinguished Professor, Dept. of Psychiatry, Univ. of California Irvine Dept. of Psychiatry and Human Behavior, Irvine, CA

Abstract: Earlier onset of schizophrenia has been associated with poor neuropsychological functioning and typically more symptom severity, but there are few studies regarding the effect of illness duration. There also is a paucity of evidence about the relationship of age of onset and duration of illness with sensory gating or with neurocognitive function in subgroups of schizophrenia(Scz). This study investigated whether illness duration and age of onset of Scz can predict deficits in sensory gating and neurocognitive performance. Subjects diagnosed with schizoaffective disorder (SczA; N=44; F=23; M=21) and paranoid schizophrenia (SczP; N=30;F=8; M=22) ranging in age from 15-60 years were recruited. Patients completed clinical surveys and interviews to quantify severity of their symptoms. CMINDS ® software was used to evaluate neurocognitive function using performance in 6 domains (attention, executive, immediate, short-term, delayed, and visual memory) calculated in standard deviation units from average performance for controls (N=35). Sensory gating was assessed using P50 evoked potentials, elicited using the paired click paradigm, and measured with an automated software. SczA and SczP groups were also studied by gender. Correlation and multiple regression analyses were performed with significance levels at $p \leq 0.05$. Pearson correlations for age of onset and

illness duration were significant in SczA and SczP males but not in females. Duration of illness and S1amplitude correlated in the SczA males and age of onset and S2/S1 ratio were correlated in SczP females. In SczA females, onset age was correlated with attention and short-term memory, and illness duration was correlated with delayed memory. In SczP males, illness duration was correlated with both executive and short-term memory. Regression analysis using age of onset and illness duration as independent variables showed that duration of illness predicted S1 peak amplitude and the S1-S2 difference in SczA males. As duration of illness increased, S1amplitude and the S1-S2 difference decreased, showing a comparatively less effective sensory gating mechanism. In SczA females, duration of illness predicted performances in executive and delayed memory domains, and age of onset predicted performances in attention and short-term memory domains. In SczP males, duration of illness predicted performance on short-term memory. These relationships show that as duration of illness increased or age of onset decreased, neurocognitive performance decreased. These results supported a conclusion that age of onset and duration of illness can influence both sensory gating and neurocognitive performance in Scz.

Title: Effects of distinct excitatory cortical and inhibitory reticular and local thalamic inputs on spindle dynamics

Authors: A. YAZDANBAKHSH[1], ***B. ZIKOPOULOS**[2];
[1]Psychological & Brain Sci., [2]Hlth. Sci., Boston Univ., Boston, MA

Abstract: Based on two distinct thalamocortical (TC) circuits with reciprocal components in primates, we developed models of core, matrix, and mixed TC loops. The core TC circuit, prevalent in sensory thalamus, drives activity focally in the middle cortical layers and gets feedback through small modulatory cortical axon terminals from pyramidal neurons in layer 6 (L6). The matrix TC circuit, can drive activity in high-order thalamus, through large axon terminals from cortical layer 5 (L5) pyramidal neurons and includes broad thalamic feedback to the superficial cortical layers. The inhibitory thalamic reticular nucleus (TRN) intercepts all TC communication and is situated strategically between the thalamus and cortex. We used distinct core and matrix TRN components to engage cortico-TRN and thalamo-TRN loops in pure core, pure matrix or mix TC loops to investigate the functional consequences of different ratios of core and matrix node connectivity contribution to spindle dynamics. Our models comprised more numerous projections from cortical L6 pyramidal neurons to TRN and thalamus, but we also

included direct L5 projections to matrix TRN (L5-TRN) and thalamus with a range of density of L5-TRN, starting from zero. Based on our rate-based model circuit we found: a) increased local inhibition in the thalamus or b) increased TRN inhibition of core and matrix thalamic neurons enhances spindle generation and sustains spindle activity for longer periods; c) a more diffuse nature of spindles in matrix compared to core, with the mix type showing intermediate properties in agreement with hypotheses that spindles can be classified in core-generated, matrix-generated or mixed types, depending on the neuroanatomy of pathways involved in their generation; d) the involvement of L5-TRN projection enhances the spindle generation and propagation; and e) spindle power can be modulated based on the level of cortical feedback and involvement in model core vs. matrix. Our rate-based model tested the impact of different ratios and specializations of neuroanatomical connectivity at multiple nodes of the TC circuit in spindle dynamics. Our simulations provide detailed metrics for shifts in the engagement of distinct TRN, core, and matrix circuits underlying typical sleep spindle generation and states of vigilance. This work can help establish a framework to study disruption of TC-TRN circuit balance in seizures, atypical sensory reactivity, and deficits in sleep and attentional gating seen in autism and schizophrenia.

Abstract: The spatiotemporal organization of neuronal firing is crucial for information processing, but how thousands of inputs to the dendritic spines drive the firing remains a central question in neuroscience. Despite the fact that the distribution of spine sizes, an index of synaptic weight, is strongly skewed with a heavy tail, the (patho)physiological significance of large spines

remains entirely unknown. Here, we found that extra-large (XL) spines (more than three standard deviations from the average) supralinearly boosted the firing triggered by NMDA spikes within these spines. The resulting synaptic amplification in a few XL spines was sufficient to drive neuronal firing in the absence of the normally required Ca^{2+} spike. Interestingly, mice with knockdown of DISC1, a molecule implicated in psychiatric conditions, exhibited ten-fold more XL spines and markedly increased firing. We experimentally and theoretically observed that XL spines negatively correlated with working memory, which can contribute to psychiatric pathophysiology.

Title: Phencyclidine (PCP) causes cognitive control failures by rapidly dysregulating translation, and discoordinating gamma-timescale neural discharge

Authors: *E. PARK[1], D. DVORAK[1], H.-Y. KAO[1,2], H. JOURDI[1,3], K. W. TUNNELL[1], J. GUTIERREZ[1], E. WALLACE[4], A. A. FENTON[1,4];
[1]Ctr. for Neural Sci., New York Univ., New York, NY; [2]Univ. of Michigan, Ann Arbor, MI; [3]Univ. of Balamand, Balamand, Lebanon; [4]SUNY Downstate Med. Ctr., Brooklyn, NY

Abstract: We previously reported that the psychotomimetic phencyclidine (PCP) causes hyperlocomotion and theta (8-Hz)-modulated 70-Hz mid-frequency gamma oscillations to dominate 30-Hz slow gamma in hippocampus CA1 local field potentials, which consequently discoordinates the timing of discharge amongst CA1 place cells, which make ensemble discharge representations of a familiar space unrecognizable, without disturbing individual place fields (Kao et al., J. Neurosci., 2017). Here we investigate in mice, the mechanisms of the PCP effects. Although PCP is a noncompetitive NMDA receptor antagonist, we observed that, not only does 8mg/kg PCP cause hyperlocomotion, but the systemic administration of PCP also impairs a familiar active place avoidance task on a rotating arena that requires cognitive control to avoid the stable location of shock while ignoring irrelevant locations on the rotating arena. Pretreatment with either of the negative regulators of translation anisomycin (60 mg/kg) or MPEP (70 mg/kg), prevents both the sensorimotor and the cognitive impairments. Next, using acute hippocampus slices, we directly determined that PCP unbalances translation that engages the AKT, mTOR and 4EBP1 translation machinery and increases ARC protein. These effects are mimicked by NR2A blockade, confirming that NMDAR-antagonism can dysregulate translation.

Based on these findings, we suggest a translation dysregulation hypothesis that PCP causes cognitive impairments by dysregulating translation. This hypothesis predicts that pretreatment with translation inhibitors will also prevent the PCP-induced discoordination of sub-second neural ensemble discharge. We are testing this prediction by recording the temporally coordinated discharge within large ensembles of hippocampus cells in head-fixed mice before and after MPEP, PCP, and their control administrations, blinded to the treatment. These findings identify a molecular mechanism for the cognitive effects of PCP: NR2A-mediated antagonism of a subset of NMDA receptors that dysregulate translation and discoordinate the sub-second temporal organization of hippocampal discharge, ultimately impairing cognitive control.

Title: Phenome-wide association study of complement component 4 variants with neuropsychiatric disease and beyond

Authors: ***S. VENKATESH**[1], M. KIM[2], M. GANDAL[2], G. VOLOUDAKIS[1], P. ROUSSOS[1]; [1]Icahn Sch. of Med. at Mount Sinai, New York City, NY; [2]Univ. of Califoria, Los Angeles, Los Angeles, CA

Abstract: The Major Histocompatibility Complex (MHC) locus is critical to immune response, and also contains the strongest genetic association with Schizophrenia. Of particular interest is Complement Component 4 (C4), which is involved in synapse elimination, and thus contributes to the “excessive pruning” hypothesis of Schizophrenia. By utilizing novel catalogues of C4 variants, we impute C4 isoforms and perform a Phenome-Wide Association Study (PheWAS) to identify their phenotypic effects in the Million Veteran Program (MVP). We are particularly interested in neuropsychiatric disorders, but given the broad range of effects of the Complement System, we also hope to contribute to a greater understanding of C4 dynamics. Moreover, the large sample size of the MVP will help elucidate effects associated with rare C4 isoforms. Finding biologically relevant phenotypes associated with C4 variants will open greater avenues for understanding MHC locus dynamics with neuropsychiatric diseases. We use Beagle and the Sekar lab’s C4 reference panel to impute C4 isoforms in the MVP. Then, we perform PheWAS to query the association of C4 variants with phenotypes and examine interesting relationships further. Across the phenome, we see significant hits for a variety of diseases. Interestingly, the directions of these effects seem to be common among broad categories of phenotypes but often opposite across different phenotypic categories, indicating a possible mechanism driving differential effects across the phenome with possible evolutionary trade-offs. There are also numerous significant phenotypes for other C4 isoforms outside the realm of neuropsychiatric

diseases. Initial results indicate C4 haplotype BS is neuroprotective for several neuropsychiatric disorders including Schizophrenia, mood disorders, and anxiety disorders. Particularly interesting is the fact that upon controlling for Schizophrenia PRS score, haplotype BS now increases risk for Schizophrenia. This suggests strong population effects that correlate with the presence of haplotype BS. Given the arcane dynamics of the MHC locus, C4 imputation is a useful tool to understand a complicated region involved in many different traits. Our results here show that understanding an individual's C4 isoform can aid in explaining the risk for a variety of diseases.

Abstract: Hyperactivity of the mesolimbic pathway (dopaminergic axons from the ventral tegmental area to the ventral striatum or nucleus accumbens: NAcc) underlies the neurobiology of psychotic symptoms in schizophrenia. The increase of the dopaminergic tone in the NAcc compromises the structure and function of the spiny projection neurons (SNPs), which consequently disrupts the connectivity among limbic system areas, and also could produce inflammation and oxidative/nitrosative stress (O/NS). It has been suggested that atypical antipsychotic drugs attenuate psychosis beyond their modulatory activity on the mesolimbic pathway, since these drugs have anti-inflammatory and antioxidant effects. Therefore, the effects

of the atypical antipsychotic risperidone (RISP) on the structural neuroplasticity and the biochemistry of the NAcc of adult male rats with neonatal ventral hippocampus lesion (NVHL) were evaluated, which is a neurodevelopmental schizophrenia-related model. For this purpose, using the Golgi-Cox technique, the following morphological parameters of SPNs of the NAcc were evaluated: arborization, length by dendritic order, total dendritic length, number of dendritic spines and morphological classification of dendritic spines; neuronal counting by stereology, and inflammatory mediators and O/NS markers were evaluated by colorimetric reactions and Western-blot.The 21-day treatment with RISP (0.25 mg/kg, ip) ameliorates neuronal atrophy and improves dendritic spine dynamics by increasing the number of functional spines of the SPN in the NAcc of rats with NVHL. Furthermore, RISP normalizes alterations in inflammatory pathways regulated by nitric oxide, nuclear factor-κB (NF-κB), and mitogen-activated protein kinases (MAPK); and consequently, reduces O/NS. Also, RISP stimulated the antioxidant pathway regulated by the nuclear factor (erythroid-derived 2)-like 2 (Nrf2) by increasing the concentration of the antioxidant enzyme metallothionein I-II (MT I-II). These RISP effects in the NAcc together with its neurotrophic, anti-inflammatory, and antioxidant effects on the prefrontal cortex in rats with NVHL can be related to the behavioral improvement of these animals in motor activity and social interaction tests.These results highlight the importance of studying the alternative mechanisms of atypical antipsychotics such as RISP and establish the usefulness of this animal model to explore links between neurodevelopment and the immune response relevant to the pathophysiology of schizophrenia.

Title: Long-term behavioral and neuroanatomical effects induced by the schizophrenia animal model of neonatal administration of MK-801 in male Wistar rats

Authors: M. LOPEZ-PACHECO[1], *H. MANCHA GUTIÉRREZ[2], C. LOPEZ-RUBALCAVA[3];

Abstract: Schizophrenia is a psychiatric disorder that affects around 1% of the adult population worldwide; it is characterized by a wide range of symptoms known as positive (hallucinations and delusions), negative (social isolation), and cognitive. Due to its complexity, schizophrenia neurobiology remains unknown. A theory about the origin of schizophrenia is the hypofunction of the NMDA receptors in early neurodevelopmental stages. Neonatal administration of the non-competitive NMDA receptor antagonist (MK-801) is an animal model that mimics negative and cognitive symptoms of schizophrenia. On the other hand, the hippocampus, a brain region crucial for memory and cognitive processing, has been implicated in the neurobiology of schizophrenia. However, the neuroanatomical effects induced by neonatal administration of MK-801 in this brain region are unknown. Therefore, we aimed to evaluate the long-term (up to postnatal day 90) behavioral effects (locomotion, social interaction, and cognitive performance) and the neuroanatomical effects induced by neonatal administration of MK-801. To achieve this aim, male Wistar rats were injected during five days with MK-801 (0.2 mg/kg) or vehicle (saline solution 0.9%), starting at the postnatal day (PND) 7. Thereafter, rats were housed in groups until the beginning of adulthood (PND 90). At the PND 90, independent groups (n=12) were evaluated in five behavioral tests: open field, social interaction, novel object recognition, Barnes maze, and pre-pulse inhibition, or were euthanized by decapitation to obtain their brains, which were stained with Golgi-cox solution. Our results show that the neonatal administration of MK-801 has long-term behavioral effects such as hyperlocomotion, reduced social interaction, learning and memory impairments, and alterations in sensory gating and motor response. Moreover, neonatal administration of MK-801 also induced alterations in the dendritic morphology of the pyramidal neurons of the dorsal hippocampus CA3 area. Specifically, pyramidal neurons in the MK-801 group presented a significant increase in the total dendritic length compared to the control group, but only apical dendrites contributed to this effect. However, despite its major length, the pyramidal neurons' arborization in the MK-801 group was less complex than the control group. Altogether, we found that the hypofunction of NMDA receptor in early stages of neurodevelopment induced by neonatal administration of MK-801 produces behavioral and neuroanatomical alterations that resemble those observed in schizophrenic patients, which adds more construct and appearance validities to the model.

Title: Multiplexed Expansion Revealing of 3D multi-protein synaptic nanostructures

Authors: J. KANG[1], ***M. SCHROEDER**[2], A. WASSIE[3], M. ZENG[1], G. FENG[4], D. SARKAR[3], E. S. BOYDEN[5];

Abstract: The ability to study the crowded and complex three-dimensional molecular architecture of the synapse remains a challenge, as electron microscopy lacks molecular specificity, and the resolution of optical microscopy is diffraction-limited. Existing optical super-resolution methods are limited by the crowdedness of the biomolecules themselves, which constrains access to epitopes by tags such as antibodies. We recently developed Expansion Revealing (ExR; Sarkar et al., *bioRxiv* 2020), a novel expansion-based technology that enables super-resolution imaging (~20 nm resolution) of brain tissue using conventional antibodies and that reveals previously hidden brain nanostructures. Here, we report multiplexed Expansion Revealing (mExR), a complementary tool to ExR, which enables immunostaining of tens of synaptic proteins in the same tissue sample using conventional antibodies without signal deterioration or bleed-through between rounds. Multiplexing has the potential to facilitate discovery of previously uncaptured high-dimensional protein organizations and even complex multi-protein interactions. Using this technology, we revealed the three-dimensional nanoscale architecture of ten synaptic proteins in the mouse primary somatosensory cortex, including Bassoon, $Ca_V2.1$, CamKII , Gephryn, GluR1, Homer1, PSD-95, RIM1/2, SynGAP, and Shank3 (**Fig. 1**). We deployed custom-written MATLAB software to register serial imaging rounds with high precision and extracted 700+ features of synaptic puncta in each channel, including measures of colocalization and inter-puncta distance. We further demonstrate mExR in Thy1-YFP and Dlx5/6-GFP mice, enabling cell-type specific labeling of neuronal spines and boutons alongside multiplexed synaptic proteins. mExR is the first technology to facilitate high-throughput, low-cost super-resolution imaging of tens of synaptic proteins in a single sample. mExR enables unprecedented access to “molecular connectomes” and will facilitate the discovery of previously undiscovered synapse types.

Title: Estrogen Profiling in Microdissected Brain Tissue using a Novel Ultra-Sensitive LC-MS/MS Assay

Authors: *C. JALABERT[1,2], M. A. SHOCK[3], C. MA[2,3], K. K. SOMA[1,2,3,4];
[1]Zoology, [2]Djavad Mowafaghian Ctr. for Brain Hlth., [3]Psychology, [4]Grad. Program in Neurosci., Univ. of British Columbia, Vancouver, BC, Canada

Abstract: Estrogens are steroid hormones that affect many aspects of brain function, including cognition, social behavior, and neuroprotection. It is well-known that estrogens are synthesized in the ovaries. Estrogens are also synthesized in the brain, where aromatase is expressed in specific regions. Steroids synthesized within the brain are called neurosteroids. Importantly, estrogens play crucial roles in the brain, even at extremely low levels. Current assays lack the necessary sensitivity and/or specificity to measure brain-synthesized estrogens. Furthermore, current methods focus on only 17β-estradiol and generally disregard other estrogens that are synthesized in the brain. Here, we developed a method to measure several estrogens simultaneously, with high sensitivity and specificity. To improve sensitivity, we derivatized estrogens with 1,2-dimethylimidazole-5-sulfonyl-chloride (DMIS). We used liquid chromatography tandem mass spectrometry (LC-MS/MS) to examine a panel of eight estrogens: 17β-estradiol, 17α-estradiol, estrone, estriol, 2-hydroxyestradiol, 4-hydroxyestradiol, 2-methoxyestradiol, and 4-methoxyestradiol. After derivatization, we have improved sensitivity 20-fold, detecting as little as 0.01 pg per sample, demonstrating that our method is extremely sensitive. For each analyte, we have identified a distinct retention time as well as 2 scheduled multiple reaction monitoring (sMRM) transitions that were used as quality control criteria for clear identification. Therefore, we are able to distinguish each estrogen (even stereoisomers) by the chromatographic separation and the sMRM, demonstrating that our method is highly specific. This method has been applied to microdissected brain samples. Initially, we used a songbird model because songbirds have high levels of aromatase and 17β-estradiol in specific brain regions. We were able to simultaneously quantify multiple estrogens in small amounts of brain sample (1-2 mg) in brain areas that regulate aggression such as the hypothalamus and the nucleus taeniae (homologous to mammalian amygdala). We examined seasonal changes of estrogens in the brain and blood. Future work will apply this method to mouse, rat, and human samples and expand the panel of estrogens examined. Our ultra-sensitive assay is essential for small animal models, where estrogen measurement is extremely challenging because of the limited amount of brain tissue. This novel technique will also have wide-ranging applications for basic research and clinical testing, including estrogen measurement in humans with low estrogen levels, such as men, pre-pubertal children, and post-menopausal women.

Title: Novel approach for cell-type specific profiling of HPTMS and corresponding gene expression

Authors: *D. K. FISCHER, M. D. CARPENTER, K. S. CZARNECKI, E. A. HELLER; Univ. of Pennsylvania, Philadelphia, PA

Abstract: Recent evidence shows that histone post-translational modifications (HPTMs) regulate gene expression via chromatin accessibility and transcription factor recruitment. However, the functional relevance of these HPTMs remains elusive. Here, we applied novel methods to establish a methodology for transcriptional and epigenetic profiling of specific neuronal cell types in mouse brain. Transcription differs in the two distinct subtypes of GABAergic medium spiny neurons (MSNs) within the nucleus accumbens. MSNs express either D1 dopamine receptor (Drd1) or adenosine 2A receptor (A2a). Drd1 and A2a expression define the direct and indirect motor output pathways, respectively, and express distinct genes in response to rewarding stimuli. We established transgenic mouse lines that express an affinity tagged nuclear receptor (GFP- Sun1 fusion) in dopamine Drd1- or A2a-containing MSNs. To initiate the protocol, the bilateral caudate/striatum of male and female mice from these mouse lines were subjected to affinity isolation of nuclei tagged in specific cell types (INTACT) protocol. Nuclei were then subjected to cleavage under targets and release using nuclease (CUT&RUN) or quantitative PCR (qPCR). Using this approach, we were able to bioinformatically profile multiple HPTMs and gene expression in specific cell-types of a single bilateral mouse striatum. Here, we present data from our INTACT into CUT&RUN or qPCR optimization protocols, unveiling a robust method of cell-type specific quantification of HPTMs and corresponding gene expression.

Title: Novel mitochondria marker for staining formaldehyde fixed cells and tissue sections

Authors: *A. E. KALYUZHNY[1], J. TAYLOR[2], A. PTAK[2], P. WOOD[2], D. MILLER[2], H. MAPLE[2];
[1]Bio-Techne, Minneapolis, MN; [2]Bio-Techne, Inc., Minneapolis, MN

Abstract: There are many mitochondrial-targeted fluorescent proteins and fluorescent dyes available to researchers to study the function of mitochondria in live cells. Unfortunately, live-cell probes tend to lose their fluorescence after fixing cells with chemical fixatives including formalin and formaldehyde, making these mitochondria trackers incompatible with immunohistochemistry and in situ hybridization. To overcome this problem, we have developed a novel mitochondria marker, MT-5, for labeling mitochondria in fixed cells and tissues. MT-5 is a bright, far-red fluorescent probe (655 nm excitation/669 nm emission) that localizes in the mitochondria and is highly photostable: it retains brightness in stained samples stored for several weeks and after prolonged fluorescence imaging. MT-5 works equally well on frozen and paraffin-embedded tissue sections and does not cross-react with cell nuclei or the plasma membrane. In addition, MT-5 can be combined in multiplex immunohistochemistry experiments using fluorescent antibody-conjugates with non-overlapping excitation and emission spectra. We present data demonstrating the use of MT-5 on rat and mouse brain tissue sections using different concentrations and incubation time. This optimized protocol provides researchers a fast, one-minute incubation at 200nM resulting in strong, long-lasting mitochondrial staining.

Title: A Genetically Encoded Fluorescent Sensor for monitoring Sonic Hedgehog (Shh) Signaling

Authors: *S. L. BERNAL[1,3], A. H. KOTTMANN[4,3], S. URIBE-CANO[2,3];
[1]Cognitive Neurosci., [2]Neurosci. Collaborative, The Grad. Center, CUNY, New York, NY; [3]Dept. of Molecular, Cell. and Biomed. Sci., City Univ. of New York Sch. of Med. (CSOM), New York, NY; [4]Physiology, Pharmacol. and Neurosci., City Univ. of New York, New York, NY

Abstract: Shh signaling is critical for the development, maintenance and function of the central nervous system. Shh acts in a concentration dependent manner and 1.8 fold changes in Shh signaling strength can result in vastly different biological outcomes as evidenced by Shh dependent cell fate determination during development. Shh signaling is spatially highly restricted and affects cellular physiology within seconds to hours. For example, we have shown previously that the precise spatial and temporal integration of multiple sources of Shh in the pMN domain of the developing spinal cord is critical for the switch from neurogenesis to oligogenesis (Starikov et al., bioRXiv; doi: https://doi.org/10.1101/534750). Further, we have shown that

mesencephalic dopamine neurons (DAN) in the adult brain engage in neuronal co transmission using Shh. Here, activity dependent release from of Shh from DAN impinge on cholinergic neurons of the striatum and affect the rate of reinforcement learning in the normal brain and the formation of dyskinesia in parkinson's models (Malave et al.; bioRXiv: https://doi.org/10.1101/2020.03.09.983759). To determine how moment to moment changes in Shh signaling strength are interpreted by Shh receiving cells and integrated with other extra cellular signals, tools need to be generated that allow quantifying Shh signaling strengths with subcellular spatial and millisecond temporal resolution. We have developed an activation-based biosensor for Smoothened, the G-protein coupled receptor (GPCR) downstream effector of Shh signaling in target cells. Guided by the prior design of GPCR-Activation Based (GRAB) sensors and analysis of their sequence homology, we inserted a circularly permutated (cp) GFP module into the third intracellular loop of Smoothened via HiFi assembly. The sensor was characterized in HEK293 cells with Smoothened pharmacology, using a vector that produces a Smoothened receptor with a non-fused GFP as a control. Our results demonstrate the sensor achieves physiologically relevant affinity and specificity, with sub-second kinetics. My poster will present the biophysical characterization of this novel recombinant SmoGRAB sensor and validation of its ability to detect physiological relevant dynamics of Shh signaling in vitro.

Abstract: Using microRNA-target chimeras to study post-transcriptional gene regulation in the mammalian brain

William T Mills IV[1], Mollie K Meffert[1,2*1]Department of Biological Chemistry and [2]The Solomon H. Snyder Department of Neuroscience, Johns Hopkins University School of Medicine

One of the most intriguing and complex questions in neuroscience concerns the molecular mechanisms by which synapses participate in learning and memory. Beginning as early as the 1960s, a growing body of evidence demonstrates that new protein synthesis is required for learning and long-term memory formation.[1] Further, local protein synthesis at synapses has been shown to participate in plasticity and perturbations in translation are associated with disorders of cognitive function such as autism.[2,3] The realization of the proximity of protein synthesis to the sites of synaptic transmission, and its disruption in disease, has underscored the importance of

understanding the nature of post-transcriptional regulatory mechanisms that shape the complement of proteins at synapses.Since their discovery in 1993, microRNAs (miRNAs) have been appreciated for their breadth of function as post-transcriptional regulators by translation inhibition and transcript destabilization.[4] miRNAs regulate neuronal plasticity and dendritic spine morphogenesis, are implicated in higher-order brain functions such as memory and cognitive dysfunction, and proteins involved in miRNA biogenesis and function are found near synapses.[1] The evolutionarily conserved let-7 family of miRNAs has emerged as a critical mediator of post-transcriptional gene regulation in many growth-related processes and is highly abundant in mature differentiated neurons.[5-6] Work from our lab and others has shown that let-7 miRNA levels can be regulated by neuronal activity,[7-9] however, an unambiguous determination of the critical *in vivo* mRNA targets of let-7 and other miRNAs has not been previously possible. This project employs a modified version of the Argonaute-Crosslinking and Immunoprecipitation (Ago-CLIP) technique to generate miRNA-target chimeric RNAs to investigate critical mRNA targets and small RNA regulatory mechanisms governing protein synthesis in the mammalian brain.

Abstract: Serotonin (5-HT) is a phylogenetically conserved monoamine neurotransmitter, critical for mood control, reward processing, and sleep-wake homeostatic regulation. Malfunction of the 5-HT system is also involved in depression, addiction, compulsivity, and other neurological diseases. Indeed, drugs targeting central serotonergic activity have been used to treat virtually every psychiatric disorder, with the best example being the use of selective serotonin reuptake inhibitors (SSRIs) for depression. Yet, despite the importance of 5-HT, our understanding of cell-specific 5-HT signaling during behaviors is very much lacking, in part due to our inability to measure 5-HT *in vivo* with high sensitivity and spatiotemporal resolution. Here, using molecular engineering, we developed genetically-encoded 5-HT sensors by coupling cpEGFP or cpmApple with 5-HT receptors. Upon 5-HT binding, the chimeric receptor changes its conformation which leads to a subsequent fluorescent signal increase from the embedded cpEGFP or cpmApple, therefore reporting the 5-HT level. We named this kind of sensors "the GPCR Activation Based sensors for 5-HT'', short for $GRAB_{5\text{-}HT}$. With iterative engineering, we developed a series of $GRAB_{5\text{-}HT}$ sensors with high specificity and sensitivity. Furthermore, we demonstrated $GRAB_{5\text{-}HT}$ sensors could be applied in multiple organisms, including *Drosophila* and mice for reliable detection of 5-HT *in vivo*. Thus, these series of tools would enhance our understanding of the 5-HT signaling dynamics and mechanisms in the complex nervous system.

Title: In-vitro and ex-vivo detection of biomolecules through fast scan cyclic voltammetry

Authors: *H. RAFI, A. G. ZESTOS;
American Univ., Washington D.C., DC

Abstract: FSCV, or fast scan cyclic voltammetry, is a novel electrochemical technique that can measure the oxidation and reduction of various molecules and proteins. They are oxidized/reduced at very specific voltages which serve as a "molecular fingerprint" for detection. Used in FSCV are carbon fiber microelectrodes, or CFMEs; in-house made electrodes composed of a glass capillary tube and 7-micron thin carbon fiber. Not only are these electrodes biocompatible and able to detect molecules and neurotransmitters with high spatiotemporal resolution but can be coated with polymers to enhance said detection. Previous studies from our lab have shown that coating the electrode with synthetic polymers, can increase sensitivity to a desired transmitter. In the current project, we look at a novel carbon fiber, multiarray electrode manufactured by our colleagues at University of Michigan. This novel electrode can simultaneously detect neurotransmitters through four channels, enabling use in multiple locations. We determine if there is improved detection for dopamine between the multi array and CFMEs and whether multiplexing can be achieved via the multiarray for biomolecules such as dopamine, serotonin, and adenosine. Results from these experiments will not only determine if the multiarray is superior to CFMEs, but if simultaneous detection and identification of biomolecules is possible. It is crucial to have highly sensitive electrodes for accurate measurements which allow for applications in in-vivo, for example, with measuring elicited release of dopamine in an animal model.

Title: Structural Properties of the Ciona intestinalis (L.) Connectome

Authors: *C. BHATIA[1], L. VARSHNEY[2];
[1]Coordinated Sci. Lab., [2]1.Department of Electrical and Computer Engin. 2.Coordinated Sci. Lab. 3.Neuroscience, Univ. of Illinois at Urbana-Champaign, Urbana Champaign, IL

Abstract: The ascidian tadpole larva *Ciona intestinalis* has one of the smallest nervous systems with just 231 neurons and is the second organism after *Caenorhabditis elegans* to have a fully reconstructed anatomical connectome at the level of individual neurons and synapses. These properties make this minimal nervous system a unique model to study principles of neuronal circuits and signal flow. In our analyses, we use network science to characterize statistical and topological properties of the chemical synapse network of *Ciona intestinalis* (L.). We calculate properties of the connectome such as degree distributions and clustering coefficients to identify the connectivity and density of network organization. We also identify neurons that are most central in information processing, and network motifs that indicate there is significant reciprocity in the nervous system of this organism. We characterize rich club and diverse club neurons, which therefore have highest efficiency of connection and diversity of connection, respectively,

and may indicate functional importance in information processing and global network integration. Further, our work demonstrates that *Ciona intestinalis*, *C. elegans*, and mammalian neocortex belong to the same superfamily of networks in terms of subgraph (network motif) distribution, thereby elucidating a possible evolutionary convergence in their wiring diagram. We further use comparative connectomics to explain how statistical properties of *Ciona intestinalis* are similar to those found in *C. elegans* and mammalian neocortex and biologically interpret results. Our work proposes mechanistic bases of behavior by generating predictions on experiments involving genetic perturbations, laser ablations or monitoring neuronal activity propagation in response to stimulation. The statistical results and biological interpretation help in understanding various behaviors displayed by *Ciona intestinalis,* and in identifying key neurons responsible for the multitude of behaviors the nervous system regulates.

Title: Syconn v2: Scalable synaptic connectivity inference toolkit for volume EM

Authors: *P. J. SCHUBERT[1], S. M. DORKENWALD[2], J. KLIMESCH[1], M. S. FEE[3], W. DENK[1], J. KORNFELD[3];
[1]Electrons - Photons - Neurons, Max Planck Inst. of Neurobio., Martinsried, Germany; [2]Princeton Neurosci. Inst., Princeton, NJ; [3]Brain & Cog Sci. / McGovern Inst., Massachusetts Inst. Tech., Cambridge, MA

Abstract: The ability to acquire ever larger datasets of brain tissue using volume electron microscopy (VEM) leads to an increasing demand for reliable and fast automated analysis methods. We introduce SyConn v2, a cellular-resolution connectome analysis framework, which scales nearly linearly with the number of compute nodes and the processed volume. Importantly, it is compatible with classical HPC environments at universities or national labs and commercial cloud providers. Our framework combines synapse detection with the analysis of cell morphology and the identification of cellular organelles to extract a comprehensive connectivity matrix. Instead of VEM images, our models use a point cloud representation of the cell to perform supervised type classification, semantic segmentation of cellular compartments and unsupervised clusterings for cell type discovery. We show that point-based models are computationally efficient and competitive with previous approaches in classification accuracy (Li et al., 2020; Schubert et al., 2019). Finally, we test SyConn v2 on a > 25 million cubic µm VEM data set of brain tissue, suggesting that the architecture and design choices are sufficiently scalable for the massive data challenges that connectomics faces in the next decade.

Title: Representation learning for cortical cell types based on local peptidergic networks

Authors: ***F. BAFTIZADEH**, Y. M. MARGHI, R. GALA, M. HAWRYLYCZ, S. J. SMITH, U. SÜMBÜL;
Allen Inst. For Brain Sci., Seattle, WA

Abstract: Analysis of a large body of single-cell RNA-seq data from mouse cortex [1] allowed Smith et al [2] to predict recently the existence of dozens of molecularly distinct neuropeptidergic modulatory networks interconnecting all cortical neurons. The predicted signaling pathways are cell type specific [2], suggesting a way to relate the very extensive diversity observed in single-cell transcriptomic studies to circuit function. In particular, predicted cell-type-specific paracrine signaling can be formalized as a network where nodes represent cell types and directed edges represent the expression of genes encoding a peptide precursor protein and its cognate G-protein coupled (GPCR) in source and target types, respectively. Joint analysis of the multitude of networks with directed, non-symmetric connections is, however, quite challenging. Here we develop a method based on graph neural networks to obtain low-dimensional embeddings of the underlying directed graph structures. We demonstrate that these embeddings can accurately predict peptidergic cell type-cell type interactions and shed light on network level differences between cell types defined by their transcriptomes.

Title: Joint identification of neuron types and type-specific activity-regulated genes

Authors: *Y. M. MARGHI, R. GALA, Z. YAO, B. TASIC, U. SÜMBÜL;
Allen Inst. for Brain Sci., Seattle, WA

Abstract: The striking diversity of neurons has been appreciated since the early days of modern neuroscience. Recent advances in single-cell transcriptomics uncovered an even greater diversity than previously appreciated [1,2]. While the previous studies confirmed the existence of easily-distinguishable broad neuron classes, they also pointed towards a complicated landscape where neuron types often appear to overlap or form gradients in gene expression [1,2,3]. Therefore, a crucial step toward elucidating the neuronal circuits is to jointly identify the discrete and the continuous factors of variability controlling the identity and function of the neurons that participate in those circuits. Although significant progress has been achieved in documenting the diversity of neurons, the discrete and continuous transitions between types pose unresolved challenges [1,2,4]. Moreover, from a computational perspective, such transitions are hindered by the unknown relative abundances of the underlying cell types. Here, we propose an unsupervised computational method that identifies discrete neuron types and the continuous variability within individual types. Taking advantage of deep generative models, we developed a generative framework using coupled artificial neural networks to disentangle the discrete and continuous aspects of neuronal diversity. At its core, we pursue the idea that different states of the same neuron should still share the same discrete category [2]. We demonstrate the application of our method to a stand-alone single cell RNA sequencing dataset, which defined over 100 transcriptomic cell types in the mouse cortex [3]. Our results illustrate that our framework can jointly identify discrete types as well as type-specific, activity-regulated genes whose expression contributes to the observed gradients and refine the existing classifications of neuronal identity.

Abstract: Consistent identification of neurons in different experimental modalities is a key problem in neuroscience. Parsing complex relationships across different modalities to uncover neuronal identity is a growing challenge. Here, we present an optimization framework to learn coordinated representations of multimodal data, and apply it to a large multimodal dataset profiling mouse cortical interneurons. Our approach reveals strong alignment between transcriptomic and electrophysiological characterizations, enables accurate cross-modal data prediction, and identifies cell types that are consistent across modalities.

Title: Statistical analysis of the temporal-frontal and parieto-frontal networks in the macaque cortex

Authors: *F. GIARROCCO, B. AVERBECK;
NIH, Bethesda, MD

Abstract: The anatomical connections between architectonically defined areas of the frontal, temporal, and parietal lobes has been extensively mapped through tract tracing methods, providing a wide and complex dataset of connectivity. However, a comprehensive description of the statistical organization of the resulting networks, as well as a description of their functional architecture, has been marginally investigated. To tackle this issue, we carried out a maximum

likelihood hierarchical cluster analysis on 32 frontal, 20 temporal, and 17 parietal areas based on their inputs. This method clusters together areas that shared similar inputs, and allowed us to identify a well-defined hierarchical organization of frontal, temporal and parietal areas. Based on temporal inputs, frontal areas were divided into ten clusters, including multiple prefrontal, cingulate, premotor, and motor cortex domains. Based on frontal inputs, temporal and parietal areas were divided into six and four clusters, respectively. Temporal clusters were composed of inferotemporal, parahippocampal, hippocampal, entorhinal/perirhinal, insular, and amygdala domains. Parietal clusters were composed of ventral, lateral-medial, dorsal, and dorsal-medial parietal domains. As a general rule, areas grouped into the same cluster shared basic functional proprieties and, in most instances, were anatomically contiguous areas. Furthermore, each cluster showed a specific set of dominant inputs, which reflected its functional proprieties. Thus, we provided a new and simplified picture of the connectivity between frontal, temporal and parietal cortices, strengthening our understanding of these complex networks.

Title: Online data-driven estimation and control of nonlinear model for neuronal dynamics

Authors: *S. FUKAMI, T. OMORI;
Grad. Sch. of Eng., Kobe Univ., Kobe, Japan

Abstract: In recent years, experimental techniques in neuroscience regarding measurement and stimulus have been significantly developed. Along with this, there have been attempts to estimate the neural dynamics from measurement data. As a method for extracting the dynamics model of a neuron from data, the data-driven approach for estimating the mathematical model has been studied in the framework of Bayesian statistics. For example, statistical approaches for estimating non-linear dynamics for single neurons have been proposed.
In order to control neuronal state, a method to determine the feedback stimulus based on the estimated neuronal state has been proposed. In the previous study, the state of a neuron can be controlled more accurately by determining the control signal from the estimated value, whereas the state of neuron cannot be controlled accurately by noisy observable data. In the previous method, the state estimation is performed by assuming that the parameters of the model are known. In realistic situation, it is necessary to conduct online estimation of both parameters and state in order to determine the feedback control signal from the estimated state in the presence of

unknown parameters. However, in the usual estimation of dynamics by Bayesian statistics, estimation is performed using observed data in batch processing. In order to perform feedback control based on the estimated values, it is necessary to estimate parameters online. Moreover, the previous method is restricted to only single neurons.
In this study, we propose an online data-driven method for simultaneous realization of estimation of both parameters and states, and feedback control based on those estimated values. First, nonlinear state space model is derived for neural systems such as single neuron models and neuronal network models consisting of conductance neuron models. Next, sequential Monte Carlo methods, which is a state estimation method applicable to non-linear dynamics, is applied to the derived state space model with the feedback control. In addition, online parameter estimation is performed by using stochastic EM algorithm. A signal of feedback control is determined from the estimated hidden variables and parameters. Using the proposed method, we show that accurate feedback control can be performed by using the proposed method in the situation where the only observed value is noisy membrane potential. Furthermore, we find that the proposed method realizes accurate control of neural systems for not only single neuron but also neuronal network with multiple neurons.

Title: Evaluation of positive allosteric modulators of SK2 channels using QPatch

Authors: ***W. YU**[1], S. H. PARK[1], M. ZHANG[1], N. SALEM[2], Y.-W. NAM[2], K. PARANG[2], M. ZHANG[2];
[1]Sophion Biosci. Inc, Woburn, MA; [2]Chapman Univ. Sch. of Pharm., Irvine, CA

Abstract: Small-conductance Ca^{2+}-activated K^{+} (SK) channels mediate afterhyperpolarization in neurons and dampen the firing frequency of action potentials. Calmodulin is constitutively associated with the SK2 channels and serves as the Ca^{2+} sensor for the SK-calmodulin complex. The SK2 channel subtype plays a key role in the regulation of excitability of Purkinje cells in the cerebellum. Given their importance in Purkinje cells, SK2 channels are a promising drug target for ataxia, a movement disorder. Automated patch clamp (APC) machines, such as Qpatch, have been used in pharmaceutical industry to study drug interaction with varieties of ion channels. Over the past decade, the technology has contributed significantly to pharmaceutical research and drug discovery. Here, we report to use QPatch as a tool for testing and evaluating the

positive allosteric modulators of SK2 channels. A stable cell line of the rat SK2 channel tagged with GFP was established through transfection of HEK293 cells followed by puromycin selection and enrichment using repeated GFP fluorescence-activated cell sorting. Positive allosteric modulators were tested under whole-cell voltage clamp configuration with automated QPatch. The compounds that positively modulate the SK2 channels in the automated QPatch was further tested with the inside-out patch manual recordings. The results from automated whole-cell recordings and inside-out patch manual recordings were consistent.

Title: Whole tissue proteomics of in vitro and in vivo primed dorsal root ganglia

Authors: M. BAUTISTA, P. CHUMALA, S. DWIVEDI, G. KATSELIS, *A. KRISHNAN; Univ. of Saskatchewan, Saskatoon, SK, Canada

Abstract: Peripheral nerve injury is accompanied by immediate neurodegenerative events followed by active regeneration. In line with this, previous studies established that regenerative reprogramming of sensory neurons occurs as early as 2-3 days after injury and is associated with dynamic expression kinetics of growth regulatory molecules in the dorsal root ganglia (DRG). The early molecular changes in DRGs favoring nerve regeneration are collectively known as '*in vivo* priming' or injury-driven 'pre-conditioning' effect. The *in vivo* primed neurons outgrow extensively, and this model has been used for decades to understand the biology of nerve regeneration. A similar pre-conditioning effect was recently observed in a paradigm involving *in vitro* priming of DRGs. This new paradigm was designed independent of classical nerve injury, thus avoiding painful axotomy for animals. The objective of this study was to characterize the proteomics profile of *in vitro-primed* DRGs and compare it with that of uninjured and axotomized (*in vivo-primed)* DRGs from adult SD rats. We performed liquid chromatography-tandem mass spectrometry for the proteomics analysis and found several proteins differentially upregulated in *in vitro* primed DRGs. Of particular interest, several Ras-related proteins and the components of ubiquitin-proteasome machinery were differentially expressed after *in vitro priming*. The key transcription factor, signal transducer and activator of transcription 3 (STAT 3)

showed downregulation after *in vitro* priming, whereas it upregulated after *in vivo* priming. Similarly, mitogen-activated protein kinase (MAPK) proteins were preferentially upregulated in *in vivo* primed DRGs. Altogether, the proteomics profiling revealed differential molecular regenerative reprogramming of neurons after *in vitro* and *in vivo* priming. In conclusion, *in vitro* priming of DRGs is a valid model to explore additional molecular mediators of nerve regeneration. The proteomics database generated in this study will serve as a resource for future research aimed at developing nerve regeneration therapeutics.

Title: Cell-based delivery strategies for zinc finger proteins in preclinical animal models of Angelman Syndrome

Authors: *P. DENG[1], A. ADHIKARI[2], D. CAMERON[1], N. A. COPPING[2], J. J. WALDO[1], J. A. N. M. HALMAI[1], H. O'GEEN[4], J. A. NOLTA[3], J. L. SILVERMAN[2], D. J. SEGAL[4], K. D. FINK[1];
[1]Dept. of Neurol., [2]MIND Inst. and Dept. of Psychiatry and Behavioral Sci., [3]Inst. for Regenerative Cures, UC Davis Med. Ctr., Sacramento, CA; [4]Genome Ctr., UC Davis, Davis, CA

Abstract: Therapies based on DNA-modifying proteins such as zinc finger, transcription activator-like effectors, and CRISPR/Cas9 to regulate gene expression are becoming viable strategies to treat genetically linked disorders through manipulation of endogenous gene regulation. The identification of an effective delivery systems for these proteins *in-vivo* remain a major translational hurdle. In this work, we evaluate a mesenchymal stem/stromal cell (MSC)-based delivery system as a putative cell-based strategy for the secretion of DNA modifying proteins. MSCs are advantageous as a delivery system due to their favorable ease of culturing, immunomodulatory properties, and favorable clinical safety profile. Presently, we report the first the use of a Zinc Finger secreting MSC (ZF-MSC) in transgenic Angelman Syndrome (AS) mouse models. In our *in-vivo* work we evaluate two routes of administration for ZF-MSC - direct intracranial injection or access into the cerebral spinal fluid space. Secreted ZF protein from mouse ZF-MSC is detectable in the murine hippocampus 1-week following either intracranial or cisterna magna injection. This secreted ZF is able to activate the imprinted paternal Ube3a gene

in a transgenic Ube3a^{Yfp} reporter mouse at 1 and 3-weeks following either intracranial or cisterna magna injection of ZF-MSC. We detect high co-localization of secreted ZF protein within the CA1 and CA3 regions of the hippocampus in the Ube3a^{Yfp} reporter mouse. ZF-MSC were detectable along cerebral spinal fluid rich regions such as the lateral ventricle, 3rd ventricle, and cerebellum following either route of administration. A significant increase in Yfp+ neurons are observable 1-week following intracranial ZF-MSC administration. A significant increase in Ube3a^{Yfp} protein expression is observable in the hippocampus, midbrain, and cerebellum 3-weeks following a cisterna magna injection of ZF-MSC. An amelioration of motor deficits in rotarod and forepaw propulsion is observed 3-4 weeks following intracranial injection of ZF-MSC in the Ube3a$^{mat-/pat+}$ AS mouse. Overall the results of these studies demonstrate that ZF-MSC secrete functionally active ZF protein to activate paternal Ube3a in AS mouse models. This approach may provide a less-invasive, non-surgical means to deliver gene modifying therapies into the CNS through access of the cerebral spinal fluid injections.

Title: Novel viral vectors for infection of birds' brain cells

Authors: *S. ZOABI, Y. GUTFREUND, S. BERLIN;
Technion, Haifa, Israel

Abstract: Contemporary optical tools, such genetically-encoded calcium indicators and optogenetic actuators, provide users with exquisite means to trace, measure and manipulate cells *in vivo*, with unprecedented spatiotemporal resolution. Delivery of these *in vivo* can be efficiently obtained by use of viruses, commonly the adeno-associated virus (AAV). However, current AAVs are suitable to but a handful of species; mostly rodents. This gap has hindered the progression of studies in other animal species. We sought to bridge this gap by developing new means to introduce genetic tools to avian species, explicitly to the domestic Japanese quail (*Coturnix japonica)*. Our prime obstacle is that common viral vectors do not infect most avian models and, in the case of quails, remains untested. We first sought to develop a protocol for growing primary neuronal cultures from Quail embryos, as cultures are more suitable for high throughput screening of viral candidates. We succeeded and screened multiple viruses, *in vitro*. All viruses tested showed substantially reduced ability to infect Quail neurons. We examined the infection routes of AAVs, leading us to discover that the putative receptor for AAV1 and 2 in

Quails is different than the mammalian receptor. Educated mutagenesis was introduced to the viral capsid with the hope to improve receptor binding and infection in Quails. We produced a small library of new serotypes; of which one particular variant, denoted AAV1*, showed strikingly high infection efficiency, *in vitro*. Unexpectedly, AAV1* shows exclusive tropism to glial cells. We have established a robust culturing protocol from Quail embryos and engineered a highly efficient AAV for introducing genetic material to glia cells.

Abstract: Gene delivery to the brain with adeno-associated virus (AAV) has been a mainstay of in vivo neuroscience research and has significant therapeutic potential. However, gene delivery to the brain is typically done invasively, through surgeries that damage the studied tissues and prevent targeting of large brain regions e.g. in large animal models. Focused ultrasound (FUS) can be used to open the blood-brain barrier (BBB) to enable the delivery of AAVs into the brain from the blood. Recent studies optimized the ultrasound parameters and choice of serotypes for more efficient delivery. However, the delivery of large molecules, e.g. AAVs, remains challenging. AAV delivery requires FUS pressures close to the safety margins of the FUS BBB opening (FUS-BBBO); intravenous injection of AAVs exposes peripheral organs to the virus, leading to off-target peripheral tissue transduction. Here, we engineer a new AAV with improved brain transduction efficiency and tissue specificity after FUS-BBBO.To obtain a new AAV strain optimized for FUS-BBBO we modified a viral vector engineering method called Cre-recombination-based AAV targeted evolution (CREATE). In CREATE, a library of AAVs with mutated capsid proteins is injected intravenously into mice. When a particular AAV clone transduces a cell expressing Cre, its viral genome is modified and becomes detectable by a Cre-dependent PCR. We modified CREATE to engineer a FUS-BBBO-optimized AAV, which we called AAV.FUS. We first generated a library of viral vectors with a capsid modified by insertion of a randomized 7 amino-acid sequence between residues 588 and 589 of the AAV9 capsid. We chose AAV9 due to our preliminary studies and published work showing its efficient

gene delivery in mice. We then used FUS-BBBO to deliver the AAV library to one hemisphere of hSyn1-Cre mice that express Cre in neurons and after selection identified 5 clones most enriched in the FUS-targeted. Histological analysis revealed higher numbers of transduced cells in the brain for all candidates (20-130% improvement over AAV9) at safe ultrasound pressures. At the same time, each serotype transduced the liver less effectively (range: 13 - 643% reduction compared to AAV9). The liver is strongly transduced by many AAVs, e.g. AAV9. The top AAV.FUS candidate (AAV.FUS.3) showed a 12.1-fold improvement in overall brain-tissue specificity after FUS-BBBO. When tested the cell-type specificity of AAV.FUS candidates they have shown improved neuronal tropism when compared to AAV9.Overall, we conclude that FUS-BBBO gene delivery can be improved by engineering new AAV viral vector strain - AAV.FUS. JOS and HL contributed to this study equally.

Title: The NINDS Ultra-Rare GENe-based Therapies network: Responding to an URGenT need

Authors: *N. F. SCHOR, A. TAMIZ, A.-M. BROOME, J. MORRIS, C. BOSHOFF, M. H. SKIADOPOULOS, J. L. BACHMAN, G. LIND, W. J. KOROSHETZ;

Abstract: Gene-based therapies have begun to change the options and outcomes for patients with rare and ultra-rare genetic disorders. Availability of these therapies is limited by cost, risk of failure, challenges in manufacturing, and novel regulatory requirements. Furthermore, institutions differ widely in the resources, expertise, and risk tolerance they can apply to providing patients with such individualized therapies. NINDS seeks to create a mechanism that enables wider development and deployment of gene-based therapies. In April 2019, a workshop entitled “Advancing Gene-Targeted Therapies for Central Nervous System Disorders” was held by the National Academy of Medicine. In September 2019, a workshop entitled “Next Generation Strategies for Gene-Targeted Therapies of Central Nervous System Disorders” was held by NINDS to convene thought leaders and experts in diverse aspects of gene therapy, including target gene regulation of expression, target distribution, development of preclinical assays and models, choice of viral vector or delivery system, manufacture and scale-up, clinical trial challenges, collaborative network models, and regulatory requirements and standards. Finally, in December 2019, a meeting entitled “Facilitating Access to Gene Therapy for Rare Diseases: Opportunities for Collaboration” was held by the Foundation for NIH (FNIH) to bring together experts from the government, academia, industry, and nonprofit advocacy sectors to

prioritize challenges, such as preclinical scientific, technical, regulatory, and quality of life, for study and solution. FNIH has since launched an effort to create an atlas of adeno-associated viral vector platforms; NCATS has also initiated platform strategies with which to begin performance of gene therapy trials for systemic and neuromuscular junction disorders. The culmination of our efforts results in the ongoing formation of the Ultra-Rare Gene-based Therapy (URGenT) network - an NINDS late-stage therapy development program that aims to speed the delivery of state-of-the-art gene-based therapies to patients with ultra-rare diseases of the nervous system, standardize and harmonize best practices, and encourage innovation in clinical trials. URGenT was approved by the NINDS Council in February 2020. The network will provide, on a competitive basis, both grant funding and access to in-kind resources for planning and execution of therapeutic agent optimization, scale up and manufacture, IND-enabling studies, regulatory affairs support including IND preparation and submission, and clinical trial performance. The first requests for applications are anticipated to be issued in 2021.

Abstract: Glioblastoma (GB) is a highly aggressive and malignant glioma of the central nervous system. Despite significant improvements in surgical techniques and advancements in chemotherapy over the last few decades, the prognosis of GB has remained virtually the same. New developments in nanomedicine may fill a large void present in cancer therapeutics. Poly-

amidoamine (PAMAM) dendrimers are nanomolecules whose properties and ionic charge can be adjusted for GB treatment. While traditional PAMAM dendrimers have a toxic amine surface, we have developed a de novo method to synthesize G4 PAMAM dendrimers with a modified surface (G4-90/10) consisting of 90% OH and 10% NH2. Their small size (4 nm) and ability to solubilize hydrophobic molecules, facilitating cargo delivery, make them ideal candidates for nanomedicine. One such cargo under exploration for the treatment of GB is the polyphenol curcumin. It has many reported anticancer effects but has been largely unsuccessful in clinical trials due to its poor bioavailability, solubility, rapid degradation, and systemic elimination. Curcumin degradation products, however, are highly bioavailable, and isolation of these compounds have shown promise as anticancer agents. By encapsulating curcumin in a surface modified G4 PAMAM dendrimer (D-Cys-Cur), its solubility and release kinetics are greatly improved. UV Spectrometry shows that when encapsulated in a PAMAM dendrimer, curcumin is steadily released at increasing amounts over a 24-hour period compared to curcumin in water. The goal of this study is to use curcumin degradation products or curcumin by-products (CBP), and (D-Cys-Cur) to find a dose dependent treatment in vitro and in vivo in a GL261 Red-FLuc mouse model of GB. An MTT assay was run to examine the toxicity profiles of CBP and D-Cys-Cur against Gl261 mouse GB cells, using mouse primary cortical cultures (PCCs) as a healthy control. Results show that D-Cys-Cur significantly kills GL261 cells at 0.1-, 0.2-, and 0.6-mg/mL, while showing no significant loss to PCCs at their respective doses. Additionally, an MTT assay of CBPs against GL261 mouse GB cells show significant cell death at 0.04-, 0.08-, and 0.12-mg/mL, while showing no significant loss to PCCs at their respective doses. Fifteen animals with tumors were left untreated to establish a baseline length of survivability. When CBPs are administered intratumorally in GB mice, the animals live significantly longer than the control group. Future directions will examine if this is due to a reduction in tumor size after treatment.

Abstract: Dendrimers are highly branched nano molecules that can be used to deliver drugs and biomolecules to neurons *in vitro* and *in vivo*. The delivery of therapeutic genes to the brain using dendrimers has great potential in the treatment of neurodegenerative diseases. Dendrimers are defined by three main components: a central core, an interior dendritic structure (generations G), and an exterior surface with functional surface groups. The generation G indicates the size of the dendrimers such as G1 dendrimer is 1 nm in diameter and so on. The widely used G4 100% amine surface dendrimers are found to be highly toxic to cells, due to their highly positive surface charge density. Therefore, we developed dendrimers with different surface compositions and less surface charge density (% hydroxyl/%amines ratio), such as G4-90/10, and G4-70/30. These dendrimers were found to be less toxic, due to their modified surface with less positive charge. We used five different dendrimer types with a cystamine core (such as G0 cys amine, G1 cys amine, G2 cys amine, G4 90/10, and G4 70/30) which were complexed with a pcDNA plasmid expressing a fluorescent reporter under control of a ubiquitous promoter at N/P ratios of 100:1 and 10:1. These complexes were then transfected into primary cortical neurons i*n vitro*. The first transfection included all 5 dendrimer types and was used to determine the type that expressed the plasmid with the highest efficiency. The G4-70/30 dendrimer yielded the highest transfection of plasmid into neurons when added at different concentrations at 48h following transfection. This is distinct from transductions with the adeno-associated virus (AAV) which begin to express around two weeks after transduction. We are continuing to optimize efficacy of dendrimers varying in N/P ratios.

Title: Knockout of 14-3-3β and its role in proliferation, migration and invasion in glioblastoma using the PAMAM dendrimer as a delivery vehicle

Authors: *K. GALLO[1,2,3], B. SRINAGESHWAR[4,2,3], J. GALLIEN[2,3], B. SWANSON[5], A. SHARMA[5], G. DUNBAR[3,2,6,7], J. ROSSIGNOL[4,3,2,1], J. BAKKE[4,2,1];

Lab. for Restorative Neurol., Saginaw, MI

Abstract: Glioblastomas (GB) are the most common and malignant brain tumor in adults, with an incidence rate of 5.26 per 100,000 people each year. Challenges in treating GB include resistance to the commonly used chemotherapy drug temozolomide and incomplete removal of glioblastoma stem cells following tumor resection. In previous studies, it has been demonstrated that 14-3-3β is an important protein involved in tumorigenesis and is commonly found to be upregulated throughout the initiation and progression of GB. Aiming to look further at 14-3-3β and its effects on GB, we used 14-3-3β small interfering RNA to silence the expression of this gene in U-87 MG human GB cell lines in *vitro*. Following confirmation of the knockdown using RT-PCR, we saw a decrease in proliferation occurring in the human GB cells over the span of 3 and 5 days confirming that a decrease in 14-3-3β expression may lead to a decrease in the proliferation of U-87 MG cells. To further investigate this, we are using CRISPR/Cas9 to completely knock out the expression of this protein to study its effects on proliferation, migration and invasion in U-87 MG cells. The issue of an efficient, non-immunogenic delivery system that can carry large cargo continues to be a problem in the delivery of biomolecules. To circumvent this issue, the poly-amidoamine (PAMAM) dendrimer has become increasingly popular over the years due to its water solubility, biocompatibility, and its ability to carry large cargo. However, due to their large number of cationic amine groups increasing with generation size (and cargo carrying capacity), they have been shown to have toxic effects on the lipid membrane bilayer. Specifically, the generation 4 (G4) NH_2 surface dendrimers have 64 amines that are toxic in a dosage-dependent manner. Recent modifications to traditional PAMAM NH_2 surface dendrimers to contain primarily neutral hydroxyl groups (70% -OH, 30% NH_2) instead of primary amine groups have shown to decrease previous toxicities. Additionally, we have confirmed successful transfection of the G4 70/30 dendrimers complexed with the 14-3-3β into U-87 MG cells. Following the knockdown of 14-3-3β, we plan to create a xenograft mouse model to study the effects of the knockout on survivability and tumor mass by delivering it intracranially using the generation 4 NH_2 surface dendrimer as our vehicle.

Abstract: Dendrimers are 3-dimensional nanomolecules that have branches having various chemical and biomedicalapplications. They have been shown to be effective biomolecule carriers for the CNS as they can cross theblood-brain-barrier (BBB) following systemic injections. Previous research indicates that the G4dendrimers having 100% amine surface (G4-NH2) are highly toxic to cells *in vitro* and *in vivo*, due to theirpositively charged amine groups on the surface. Therefore, to reduce the toxicity of these dendrimers, wehave modified them to have more neutral functional groups, containing only 10% of the surface coveredwith NH2 and remaining 90% of the surface covered with hydroxyl groups (-OH; G4-90/10). Our workindicates that these surface-modified dendrimers are taken up by various cultured neurons, glia, and stemcells,) and by brain cells *in vivo*. The toxicity assay shows that these modified dendrimers are less toxiccompared to the pure 100% amine surface dendrimers. Moreover, the G4-90/10 dendrimers are capableof forming complex with plasmid DNA of various sizes (6kb and 10kb) and can deliver them to differentstem cells *in vitro* and to the glia cells *in vivo*. Continuing this line of research of using PAMAM dendrimers,we also focused on delivering them to the rodent fetal brain following i.p injections to analyze their abilityto cross the BBB and the placental barrier in pregnant mice. This can be applied for future purposes bydelivering therapeutic biomolecules using PAMAM dendrimers to treat fetal diseases affecting thenervous system such as infections of Zika virus, rubella virus, cytomegalovirus, and herpes frequentlyresult in numerous neurological deficits and malformations. Finally, we also injected

the PAMAMdendrimers and their complexes with large plasmids into the rodent brain and tracked the dendrimersand the complexes using in vivo imaging system (IVIS) to analyze the longevity of the dendrimers and thecomplex into the rodent brain. Our results show that the PAMAM dendrimers can successfully formcomplex with large plasmids and were able to deliver the plasmid into the cells *in vitro* and *in vivo*.Moreover, the PAMAM dendrimers were able to cross the maternal BBB and reach the brain, however,very negligible amounts of dendrimers were found in the fetal tissue, and majority of the dendrimers werefound in the placental tissue. In conclusion, we were able to track the PAMAM dendrimers and thecomplexes in the rodent brain using IVIS showing steady clearance of these nanomolecules over time.

Title: EFhd2 brain interactome reveals its association with different cellular and molecular processes

Authors: *A. S. SOLIMAN[1], A. UMSTEAD[1,2], A. LEE[3], J. RYAN[3], J. LAMP[1,2], I. E. VEGA[1,4,2];
[1]Translational Neurosci., [2]Integrated Mass Spectrometry Unit, Michigan State Univ., Grand Rapids, MI; [3]NeuroInitiatives, Jacksonville, FL; [4]Neurol., Univ. of Michigan, Ann Arbor, MI

Abstract: EFhd2 is a calcium-binding protein that is highly conserved from human to nematodes. EFhd2 has a very dynamic structure that leads to self-oligomerization and aggregation mediated by its coiled-coil domain. We showed that EFhd2 is widely expressed in the body with predominant levels in the central nervous system. In addition, we demonstrated that EFhd2 is associated with tauopathies (e.g. Alzheimer's disease). In particular, EFhd2 co-purified with insoluble tau in a mouse model of tauopathy and postmortem brains. Our findings instigated more research to decipher EFhd2 function in the brain. Despite the strides we and colleagues have made to unveil EFhd2 function in the brain, many questions about the molecular mechanisms thereof remain unanswered. Herein, we used a proteomics approach to investigate the physiological role of EFhd2 in the brain. EFhd2 was immunoprecipitated from cortical and subcortical brain regions of $EFhd2^{+/+}$ mice, and $EFhd2^{-/-}$ mice were used as control. EFhd2-associated proteins were identified by tandem mass spectrometry. EFhd2 interactome was generated and the associated proteins were categorized into their known biological functions.

The analysis showed that EFhd2 markedly associates with proteins regulating cytoskeleton, vesicle trafficking, mitochondrial metabolism, and stress response. These findings were corroborated by examining human EFhd2 interactome from postmortem temporal cortex and cerebellum of normal-aging individuals. In fact, the human and mouse EFhd2 interactome are comparable. Interestingly, fourteen proteins that copurified with EFhd2 in both temporal cortex and cerebellum are also linked to several neurological disorders like Alzheimer's disease, Parkinson's disease, and epilepsy. Among these proteins, we found MAPT (tau), which is the main pathological culprit in tauopathies and GLUL (glutamate synthase) whose function is dysregulated in several neurological diseases. Moreover, we employed label-free quantification (LFQ) to determine proteome changes induced by EFHD2 gene deletion ($EFhd2^{-/-}$). Gene ontology analysis revealed that the differentially abundant proteins in $EFhd2^{-/-}$ mice are associated with metabolism, stress response, transport, and protein regulation compared to $EFhd2^{+/+}$ in both cortical and subcortical brain regions. Our results open a gateway to understanding the impact of EFhd2 gain- and loss-of-function on different physiological and pathological pathways.

Title: A microfluidic platform for tension driven axon elongation

Authors: ***S. C. SOUSA**[1,2], M. AROSO[4], T. SILVA[3], C. LOPES[4], P. BRITES[3], P. AGUIAR[4], M. SOUSA[2];
[1]ICBAS - Inst. De Ciências Biomédicas Abel Salazar da Univ. do Porto, Porto, Portugal; [2]Nerve Regeneration, [3]Neurolipid Biol., I3s/IBMC, Porto, Portugal; [4]Neuroengineering and Computat. Neurosci., I3s/INEB, Porto, Portugal

Abstract: During development, axonal elongation is mediated by growth cone progression. Once a synapse is established, body growth results in an increased distance between the neuronal somata and their targets. This distinct biophysical process is known as axon stretch growth (ASG). Players underlying ASG remain mostly unknown. Thus, to uncover the molecular mechanisms governing ASG, we designed a microfluidic platform (Fig.1A and B) to promote axon stretch in dorsal root ganglia (DRG) neuron explants from C57BL/6 animals grown in compartmentalized microchannels. Our microfluidic platform promotes a uniformly distributed

stretch, which is computer controlled by specifically developed firmware and software (Fig. 1C). All structural elements were 3D-printed in polylactic acid (PLA), a biocompatible polymer/plastic, whereas Arduino and C++/Qt were used for, respectively, the firmware and software controlling the stretcher stepper motor. DRG explant cultures in microfluidics have been optimized in a stretchable substrate - polydimethylsiloxane (PDMS). With this strategy we are able to mimic physiological conditions: with separated soma and neurites, which form synapses in co-culture with fibroblasts (Fig. 1D). Currently, our system is being optimized for live-cell imaging of cytoskeleton dynamics and transport, alongside with other techniques. Exploring molecular changes in response to physiological axon stretch, may provide insight into molecules that may find application in conditions where axon regeneration is needed.

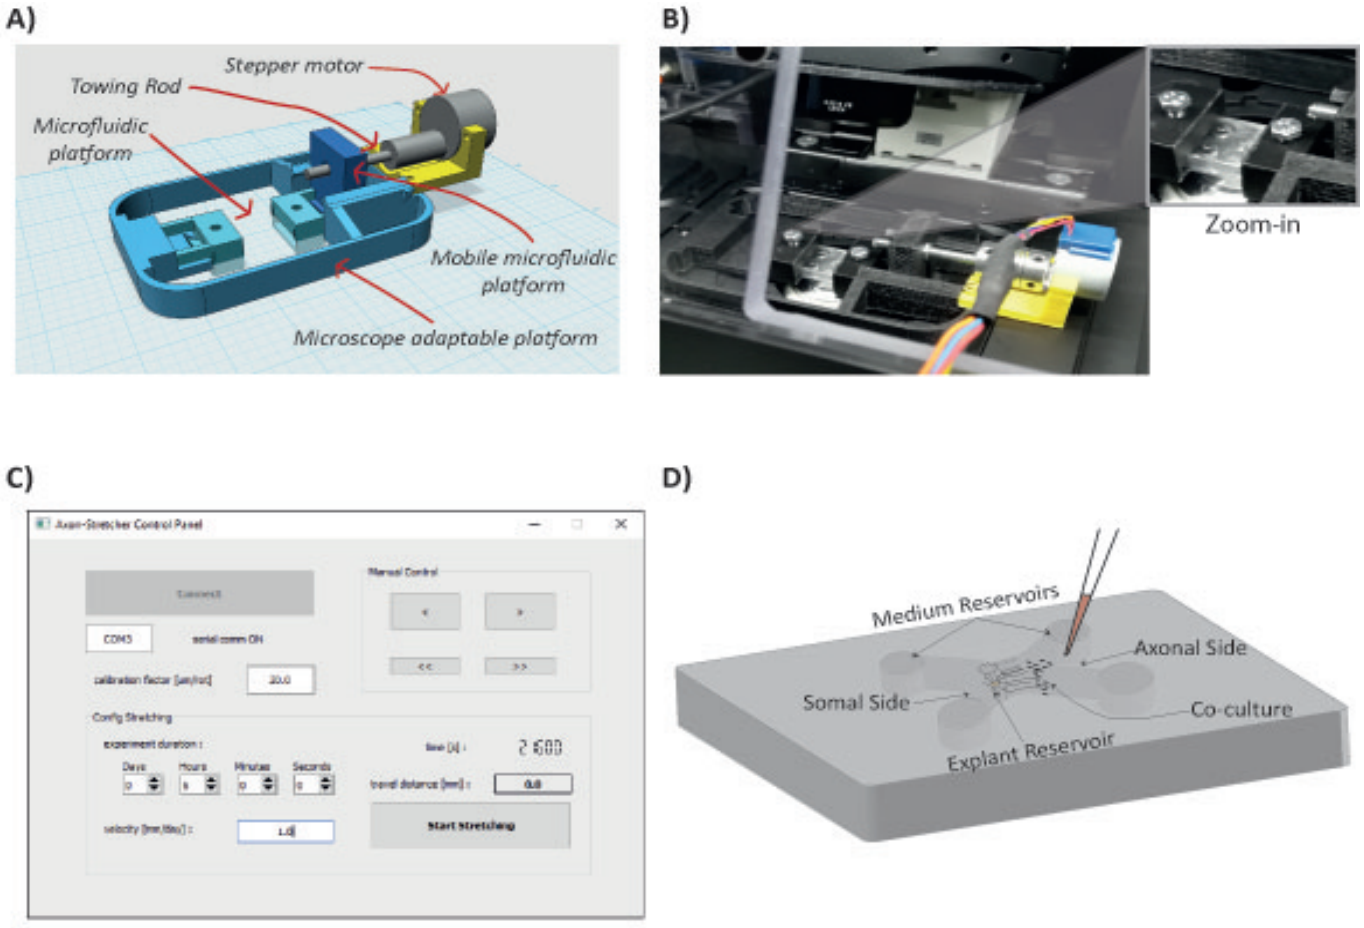

Figure 1 – Prototype of the microfluidic platform. A) 3D- schematic of microfluidic platform. B) Prototype of the microfluidic platform on the Leica SP8 microscope stand. The stretchable microfluidic platform is zoomed-in on the right. C) Control panel of the software currently being developed to control stretch rates. D) Schematic representation of the microfluidic co-culture system between DRG neuron explants and mouse embryonic fibroblasts. DRG explants will be plated in the explant reservoir (somal side) and fibroblasts plated in the axonal side to allow for a co-culture with the formation of synapses.

Title: Exploring laminar connectivity in the macaque brain

Authors: *I. SHAMIR, Y. ASSAF;
Tel Aviv Univ., Tel Aviv, Israel

Abstract: Over the past two decades, substantial progress has been made in neuroimaging of both global white matter connectivity (Sporns et al. 2005, Leemans et al. 2009, Setsompop et al. 2013), as well as cortical grey matter structure (Barazany and Assaf 2012, Lifshits et al. 2018, Shamir et al. 2019). Nevertheless, current techniques for exploring the brain's wiring diagram remain biased by the definition of the cortex as a single homogenous unit. To overcome this bias, we must expand the basic unit used in connectomics to a more descriptive representation of the heterogeneous laminar substructure of the cortex. In this study, we model and explore the macaque laminar connectome by integrating multi-modal ex-vivo magnetic resonance imaging via a simple model of laminar connectivity. The MRI acquisition includes a T1w sequence, an IR sequence performed using 3D FLASH and a DWI sequence. The model used for integration is based on a meta-analysis of histological findings concerning the interconnectivity of layers (Shamir and Assaf 2020). Our sample includes 7 macaque brains, all obtained from the Mammalian MRI (MaMI) database (Assaf et al. 2020). In order to validate our results, we revisit Felleman and Van Essen's seminal work regarding hierarchical processing in the primate cerebral cortex (Felleman and Van Essen 1991) and attempt to recreate it on the excised macaque brains. The resulting network of cortical laminar connectivity is compared in the visual cortex to Felleman and Van Essen's findings, resulting in a an accuracy level of 83%. By using an unbiased definition of the cortex that takes into account its laminar composition, we are able to use MRI neuroimaging to explore a new and more detailed laminar-level connectome.

Title: Reduced RNA integrity indicates pathway-selective mRNA degradation in post-mortem human brain tissue

Authors: ***E. S. JOHNSON**, K. E. STENZEL, S. LEE, E. M. BLALOCK;
Dept. of Pharmacol. and Nutritional Sci., Univ. of Kentucky, Lexington, KY

Abstract: Objectives. RNA degradation can be influenced by many factors (e.g., post-mortem interval, sample preparation, storage duration), and the degree to which RNA is degraded prior to quantification can affect downstream measurements (e.g., situ hybridization, RT-PCR, transcriptional profiling). Agilent Technologies introduced the RNA integrity number (RIN; 1 being the worst to 10 being the best) to help quantify and standardize degradation across samples and labs. Recent studies have shown that RIN levels are associated with mRNA quantification, though relatively little work has been done to determine whether RNA is degraded across the genome or instead is focused in certain biological pathways. **Methods/ Results.** Using raw transcriptional data (accessed through the Gene Expression Omnibus) for multiple transcriptional profiling studies of post-mortem brain tissue from different individuals, we identified a robust and selective expression profile of degradation vulnerable mRNAs. Importantly, we report that many of the pathways supported by these degradation-sensitive genes are neuronal, particularly: vesicles, mRNA transport, synapses, and mitochondria. This suggests that neuronal synaptic mRNA is particularly vulnerable to degradation. Using a mean subtraction method, we determined the most common templates a gene's RNA degradation followed and plotted the gene expression values with the template. **Conclusion.** Our data found RNA degradation causes major drops in the signal of selective mRNA species around a RIN of 6.7-7 and that there is no appreciable correlation between gene expression and RIN if RIN is $\geq$ 8.3. Second, our data suggests this effect is pathway selective, possibly having important consequences for current bioinformatic RIN correcting procedures. Finally, this may have implications for neurodegeneration research like Alzheimer's disease, where the disease itself, rather than technical issues associated with harvesting and storage, may cause pathway selective mRNA degradation.

Abstract: Neuronal cell types are classically defined by their molecular properties, anatomy, and functions. While recent advances in single-cell genomics have led to high-resolution molecular characterization of cell type diversity in the brain, neuronal cell types are often studied out of the context of their anatomical properties. To better understand the relationship between molecular and anatomical features defining cortical neurons, we combined retrograde labeling with single-nucleus DNA methylation sequencing to link neural epigenomic properties to projections. We examined 11,827 single neocortical neurons from 63 cortico-cortical (CC) and cortico-subcortical long-distance projections. Our results revealed unique epigenetic signatures of projection neurons that correspond to their laminar and regional location and projection patterns. Based on their epigenomes, intra-telencephalic (IT) cells projecting to different cortical targets could be further distinguished, and some layer 5 neurons projecting to extra-telencephalic targets (L5 ET) formed separate clusters that aligned with their axonal projections. Such separation varied between cortical areas, suggesting area-specific differences in L5 ET subtypes, which were further validated by anatomical studies. Interestingly, a population of CC projection neurons clustered with L5 ET rather than IT neurons, suggesting a population of L5 ET cortical neurons projecting to both targets (L5 ET+CC). We verified the existence of these neurons by dual retrograde labeling and by anterograde tracing of CC projection neurons, which revealed axon terminals in ET targets including thalamus, superior colliculus, and pons. These findings highlight the power of single-cell epigenomic approaches to connect the molecular properties of neurons with their anatomical and projection properties.

Title: Rnascope™ Hiplex assay and hiplexup reagents in situ hybridization assay enables high throughput multiplexed spatial mapping of diverse gene signatures and cell type specific markers across mouse brain

Authors: J. SHELDON, **M. YU**, H. LU, H. ZONG, B. ZHANG, *J. V. PULLIAM, X.-J. MA; BioTechne, Newark, CA

Abstract: Transcriptomic research has ushered into an era of single cell technologies that are crucial for both classifying and characterizing known and novel cell populations of complex heterogenous tissues. However, such techniques are limited by the use of dissociated cells that result in the loss of spatial organization of these cell populations, thus requiring a highly multiplexed approach that can interrogate gene expression at a single cell resolution while retaining the morphological context. We sought to utilize the RNAscope HiPlex^{TM} assay with HiPlexUp reagents to resolve and spatially map diverse gene signatures identified by single cell RNA sequencing (scRNAseq) and known neuronal cell-type specific markers. With the previous HiPlex-12 reagent workflow, we spatially mapped the novel medium spiny neuronal (MSN) D1 and D2 subtypes identified by scRNAseq (Gokce *et al*, *Cell Rep*, 16(4):1126-1137, 2016). Our new HiPlexUp reagent workflow enables extension of the previous workflow for simultaneous detection of up to 48 targets on a single tissue section. This iterative target detection process allows for a highly sensitive and specific mRNA visualization without compromising the structural integrity of the tissue morphology. In addition to visualizing the previously confirmed major and minor D1 and D2 MSN subtypes (*Drd1, Htr7, Pcdh8, Th, Synpr, Crym, Wfs1, Calb1, Drd1, Cnr1*, and *Foxp1*) in the mouse striatum, we also visualized neuronal markers (*Fam84b, Lhx6, Crh, Vip, Tac1, Moxd1, Slc6a1, Sst, Chrna2, Gad2, Slc32a1, Gria1, Grin1, Cx3cr1, Chrm1, Chrm3, Oprd1, Chrnb2, Gabr2, Vglut1, Vglut2, Gad2, Calb2*, and *Pvalb*) and ubiquitously expressed genes that served as positive control (*Polr2a, Ppib, Ubc, Hprt, ActB, Tubb3, Bin1, Ldha, Gapdh, Pgk1, Bhlhe22*, and *Cplx2*) of the mouse brain. The markers were expressed across various region of interests such as the olfactory bulb, caudate putamen, hypothalamus, and cerebral cortex. These diverse expression patterns serve as an invaluable tool is understanding the region-specific functional significance of these diverse neuronal genes. Lastly, we demonstrated the utility of our HiPlex image registration software resolving this 48-plex data by zoning into our targets of interest. In conclusion, single-cell transcriptomics combined with spatial mapping by the RNAscope technology is well suited for resolving

heterogeneous tissues at cellular resolution and providing insights into cellular organization and function of diverse cell types in both healthy and disease states

Title: Mirnascope a novel in situ hybridization technology for the detection of small regulatory rnas with spatial and morphological context

Authors: M. MATA[1], **A. SAHAJAN**[2], *L. WANG[2], B. ZHANG[1], X.-J. MA[1];
[1]Advanced Cell diagnostics, Newark, CA; [2]ACD a bio-techne brand, Newark, CA

Abstract: microRNAs (miRNAs) are 18 to 22 nucleotide small regulatory RNA molecules that are expressed in a tissue, cell-type, and cell-state specific manner. miRNAs regulate gene expression in developing neuronal cells and are implicated in pathogenesis of many neurological disorders, neuroinflammation and immune regulation. Attempts at studying miRNAs have relied on small RNA sequencing approaches, microarray, and qPCR. While these methods deliver bulk expression levels, they do not provide detailed spatial information for miRNA expression. Additionally, existing small RNA ISH technologies suffer from poor reproducibility and sensitivity, extensive optimization at the level of sample pretreatment, target probe hybridization, and post-hybridization. This emphasizes the need for a technology that can reliably detect cell-specific small RNA species in the brain and support biomarker discovery and small RNA therapeutics. To address this need ACD developed an RNA *in situ* hybridization (ISH) method known as miRNAscope™ for detection of miRNAs and small RNAs. It is a "Ready-to-Use" small RNA detection ISH assay supplied with universal tissue pretreatment reagents and needs zero target probe optimization. As proof of concept, miRNAscope probes specific for human Hsa-miR-124-3p, mouse Mmu-miR-124-3p-S1, Mmu-miR-138-3p, Mmu-miR-128-5p, rat Rnu-miR-let7b-5p were designed and its expression was evaluated in brain. A control scramble probe was used to determine background signal. The miRNAscope assay demonstrated high sensitivity and specificity for the cell-specific miRNA detection for the targets highlighted above, demonstrating the functionality of this assay. In summary, miRNAscope is an RNA ISH assay for the detection of small RNA species with unparalleled detection sensitivity and specificity, enabling morphological information with single cell resolution. The assay will improve our understanding of small RNA species in their native context and will elucidate their associated gene regulatory networks involved in health and disease.

Title: Dissecting neurodegeneration mouse models with an automated high-plex spatial platform

Authors: B. COOK, I. OH, R. YIN, **M. OTERO**;
Rebus Biosystems, Santa Clara, CA

Abstract: Single-cell RNA sequencing (scRNA-seq) has fundamentally expanded our understanding of tissue composition and heterogeneity. While this methodology enables unbiased and comprehensive identification of cell types based on their transcriptomic profiles, it does not provide positional information in the tissue architecture context. Rebus Biosystems has developed a highly automated platform that combines Synthetic Aperture Optics (SAO), fluidics engineering and data processing to enable multiplex analysis of gene targets across large tissue sections with minimal user intervention. Here, we used the Rebus Biosystems platform to quantify expression levels of 31 target genes across three experimental conditions. First, we obtained fresh frozen mouse brain sections from two transgenic lines modeling a neurodegenerative disease and a third wild-type line serving as a control. We mounted one section from each of the three conditions (genotypes) on the same glass coverslip. Sections mounted together corresponded to the same antero-posterior levels of the hippocampus and adjacent somatosensory cortex. We ran nine of these three-section arrays to acquire single

mRNA molecule quantitative data for 31 genes using on-system cyclic single-molecule RNA fluorescence in situ hybridization (smFISH) chemistry. Detected mRNA spots were automatically assigned to individual DAPI-stained nuclei to render a single-cell gene-expression matrix. Like with scRNA-seq approaches, cell-type associated genes were used for unbiased classification of single cells into several distinct neuronal and glial cell types. Then, the spatial information was used to further dissect each cell type into distinct anatomical compartments and explore spatial relationships between cells. The expression levels of disease-associated genes were compared across experimental conditions, for each cell type and anatomical structure individually. The combination of single cell gene expression and spatial data allows for fine dissection of tissue heterogenicity, while the balanced tissue-array design minimizes technical variability and enables powerful statistical comparisons.

Title: Pathfinder, open source software for analyzing spatial navigation search strategies

Authors: ***M. B. COOKE**[1], T. O'LEARY[2], P. HARRIS[2], R. MA[2], R. E. BROWN[4], J. S. SNYDER[3];
[1]Dept. of Neurosci., [3]Dept. of Psychology, [2]Univ. of British Columbia, Vancouver, BC, Canada; [4]Psychology & Neurosci., Dept. of Psychology and Neurosci., Halifax, NS, Canada

Abstract: Spatial navigation is a universal behavior that varies depending on goals, experience and available sensory stimuli. Spatial navigational tasks are routinely used to study learning, memory and goal-directed behavior, in both animals and humans. One popular paradigm for testing spatial memory is the Morris water maze. Researchers typically express learning as a function of the latency to escape, though this reveals little about the underlying navigational strategies. Recently, a number of studies have begun to classify water maze search strategies in order to clarify the precise spatial and mnemonic functions of different brain regions. However, despite their usefulness, strategy analyses have not been widely adopted due to the lack of software to automate analyses. We developed Pathfinder, an open source application for analyzing spatial navigation behaviour. Here we show Pathfinder's performance on a sample dataset, where it effectively characterized highly-specific spatial search strategies used during the trials. Our software provides support for inputs from commonly-used, commercially-available

and open-source software packages, is optimized for classifying search strategies, and can also be expanded easily to work with other species and spatial navigation tasks. Pathfinder has the ability to automatically determine the platform location as well as the size of the pool and related pool parameters. It can generate heatmaps of trials, analyze navigation with respect to multiple goal locations, and can be easily updated to accommodate future developments in spatial navigation behaviours.

Title: Apinatomy infrastructure for multiscale connectivity

Authors: ***T. H. GILLESPIE**[1], N. KOKASH[3], M. C. SURLES-ZEIGLER[1], M. E. MARTONE[2], B. DE BONO[4];
[2]Neurosci., [1]UCSD, La Jolla, CA; [3]RUDN Univ., Moscow, Russian Federation; [4]Auckland Bioengineering Inst., Univerity of Auckland, Auckland, New Zealand

Abstract: A key challenge facing many large neuroscience projects is how to integrate data across a wide diversity of species and spatial and temporal scales. We face this in the NIH

SPARC project as we build systems for researchers to discover data about the peripheral nervous system and other organ systems on the basis of its potential physiological relevance to the organ systems they research. A central element of our approach is the use of the ApiNATOMY toolkit that supports data integration over a multiscale connectivity model of cells, tissues, and organs. ApiNATOMY consists of a knowledge representation and knowledge management tools that enable topological and semantic modeling of process routes and associated anatomical compartments in multiscale physiology. Domain experts provide model specifications in a semi-structured format based on templates for common topological structures (such as neural arborizations, etc.). ApiNATOMY tools then expand the specifications into a graph that can be visually manipulated, serialized, and integrated with other knowledge bases such as the NIF-Ontology and the SPARC Knowledge Graph.
ApiNATOMY models are annotated using the same vocabularies as datasets, allowing the connectivity knowledge to be leveraged to enhance navigation, classification, and search for data. For instance, if a researcher is designing a procedure on the Middle Cervical Ganglion (MCG), ApiNATOMY connectivity provides the means to discover existing data along the route of neurons passing through the MCG that could help plan the experiment.
Here we present our work on infrastructure for ApiNATOMY to make its connectivity models more FAIR (Findable, Accessible, Interoperable, and Reusable). This includes an interactive graphical web application, services to support identifier resolution, and tools to query linked metadata, discover datasets, track provenance, etc. We use a generalizable approach to make application specific JSON data structures FAIR by using JSON-LD to convert them to RDF. This approach has greatly reduced the complexity of the system and has made it easier to maintain.

Title: Analysim - a web platform for collaborative data sharing and analysis

Authors: H. DINH, D. THOMAS, A. DOLOC-MIHU, ***C. GUNAY**;
Sch. of Sci. and Technol., Georgia Gwinnett Col., Lawrenceville, GA

Abstract: AnalySim is a website developed from scratch to help people create and share new projects that can include different types of datasets and analysis methods already implemented in the system. AnalySim aims to help with data sharing, data hosting for publications, interactive visualization, collaborative research, and crowdsourced analysis. It is especially designed for specialized for datasets with many changing parameters and recorded measurements, such those in computational neuroscience. Analysim provides tools that are specific for parameter search,

but at the same time allows to run custom code. Offering these features on an interactive web platform improves visibility of one's research and helps the reviewing process by allowing to reproduce others' analyses. In addition, it fosters collaborative research by providing access to others' public datasets and analysis, creating opportunities to ask novel questions, guide one's research, and start new collaborations or join existing teams. Analysim can be said to provide a "social scientific environment", which include features such as forking or cloning existing projects to customize them and tagging or following researchers and projects. In addition, one can filter datasets, duplicate analyses and improve them, and publish findings via interactive visualizations. In summary, Analysim is a Github-like tool specialized for scientific problems - especially when they are large and complex as in parameter search.

Title: Common cell type nomenclature for the mammalian brain: a systematic, extensible convention

Authors: ***J. A. MILLER**, N. W. GOUWENS, B. TASIC, F. COLLMAN, C. T. J. VAN VELTHOVEN, T. E. BAKKEN, M. J. HAWRYLYCZ, H. ZENG, E. S. LEIN, A. BERNARD; Allen Inst. for Brain Sci., Seattle, WA

Abstract: The advancement of single cell RNA-sequencing technologies has led to an explosion of cell type definitions across multiple organ systems. Consortia like the BRAIN Initiative Cell Census Network (BICCN) and the Human Cell Atlas (HCA) have begun to standardize and centralize the intake of data and associated metadata from these projects; however, organization of cell types has largely been left to individual investigators, resulting in widely varying nomenclature and limited alignment between taxonomies. To facilitate cross-dataset comparison, the Allen Institute created the Common Cell type Nomenclature (CCN) for matching and tracking cell types across studies, allowing comparison of matched cell types between any two taxonomies, including a reference taxonomy. This concept is qualitatively similar to gene transcript management across different genome builds. The CCN can be readily applied to new or established taxonomies without changing cell type names previously assigned in an analysis or publication. Finally, the CCN proposes conventions for assigning accurate yet flexible cell types names in the mammalian cortex as a step towards community-wide effort to organize multi-source, data-driven information related to cell types taxonomies from any organ system or organism. To demonstrate its utility, the CCN was applied here to diverse cell type datasets

derived from multiple quantifiable modalities and several species. User-friendly executable code for applying the CCN is available on GitHub (https://github.com/AllenInstitute/nomenclature).

Title: Stimulating Peripheral Activity to Relieve Conditions (SPARC) Anatomy Working Group: Enriching ontology development

Authors: ***M. C. SURLES-ZEIGLER**, T. H. GILLESPIE, T. SINCOMB, M. E. MARTONE; Neurosci., UCSD, La Jolla, CA

Abstract: The Stimulating Peripheral Activity to Relieve Conditions (SPARC) program is a collaborative effort funded by the US National Institutes of Health to improve our understanding of the circuitry responsible for visceral control to develop the next generation of neuromodulation devices to treat conditions. SPARC comprises a consortium of researchers obtaining data on autonomic nervous system (ANS) connectivity between end organs and the central nervous system and the SPARC Data and Resource Center (DRC), which is fielding an infrastructure and tools for making these data available for use in models and simulations. As part of the DRC, we are developing FAIR vocabularies for annotating SPARC data, circuitry maps, and models. As anatomy forms the basis for this mapping effort, we have implemented an anatomical term pipeline that facilitates the use of anatomical terms from community ontologies like UBERON and FMA while augmenting these vocabularies with new terms as needed. New terms are needed when missing from community ontologies due to relatively poor coverage of the ANS.

Additionally, SPARC annotation spans several spatial scales, requiring even more precise anatomical annotations. In order to ensure that new anatomical terms are accurate and used consistently across these contexts, the SPARC Anatomy Working Group (SAWG) was formed comprising anatomical experts who provide an independent review and arbitration of SPARC's anatomical terminology. As part of this process, the SAWG developed a term request pipeline that enables SPARC investigators to regularly submit anatomical terms to the SPARC vocabularies housed within the InterLex database, an online database for viewing and building ontologies (https://scicrunch.org/sawg/). After review, appropriate terms will be contributed back to the community ontologies, thus improving their coverage of the PNS. Therefore, this project describes the novel process of triaging and standardizing anatomical terms and illustrates the

urgent need to contribute to community ontologies to enhance peripheral nervous system coverage.

Title: Blocking cross-species secondary binding when performing double immunostaining with mouse and rat primary antibodies

Authors: *G. XIONG[1], S. MAO[2], B. N. JOHNSON[1], N. A. COHEN[3,4], A. S. COHEN[1,5]; [1]Anesthesiol. and Critical Care Med., Children's Hosp. of Philadelphia, Philadelphia, PA; [2]Neurol., Renmin Hospital, Wuhan Univ., Wuhan, China; [3]Philadelphia Veterans Affairs Med. Ctr., Philadelphia, PA; [4]Otorhinolaryngology—Head and Neck Surgery, [5]Anesthesiol. and Critical Care Med., Perelman Sch. of Medicine, Univ. of Pennslyvania, Philadelphia, PA

Abstract: Immunostaining is a powerful technique and widely used to identify molecules in tissues and cells, although critical steps are necessary to block cross-reactivity. Here we focused at an overlooked cross immunoreactivity issue where the secondary antibody (secondary) cross-reacts with the primary antibody (primary) from a different species. We first confirmed the previously reported cross-species binding of goat anti-mouse secondary to rat primary. This was accomplished by staining with a rat primary against glial fibrillary acidic protein (GFAP) and visualizing with goat (or donkey) anti-mouse secondary. We then further revealed the converse cross-species binding by staining with a mouse primary against neuronal nuclear protein (NeuN) and visualizing with anti-rat secondaries. We speculate that mouse and rat primaries share antigenicity, enabling either secondary to recognize either primary. To block this cross-species binding in double staining experiments, we compared 3 protocols using mouse anti-NeuN and rat anti-GFAP, two primaries whose antigens have non-overlapping distributions in brain tissue. Simultaneous staining resulted in cross-species astrocytic staining (anti-mouse secondary to rat anti-GFAP primary) but no cross-species neuronal staining (anti-rat secondary to mouse anti-NeuN primary). Cross-species astrocytic staining was missing after sequential same-species staining with mouse anti-NeuN primary, followed by rat anti-GFAP. However, cross-species astrocytic staining could not be diminished after sequential same-species staining with rat anti-GFAP primary, followed by mouse anti-NeuN. We thus hypothesize that a competition exists between anti-mouse and anti-rat secondaries in their binding to both primaries. Single staining for NeuN or GFAP visualized with dual secondaries at different dilution ratio supported this hypothesis.

Title: An implantable kinematic headplate for repeatable submicron skull positioning in mice

Authors: ***S. J. KIM**, B. B. SCOTT;
Psychological & Brain Sci., Boston Univ., Boston, MA

Abstract: Head immobilization is widely used in neuroscience studies to facilitate sensory stimulus control, behavioral monitoring, and neurophysiological recordings. Fixation strategies that provide mechanical stability and repeatable positioning over time or across instruments are particularly important for cellular resolution imaging or manipulation experiments. Headplates inspired by kinematic mounts enable precise micron-scale stability and position repeatability in rats (Rich et al. 2018). Here we sought to develop a head-restraint system capable of submicron registration accuracy that is small enough to be worn by mice. To achieve these goals, we designed a headplate and clamp based on the Maxwell kinematic coupling system (Slocum 2010). The clamp consisted of an aluminum mount with three vee grooves, oriented at 120 degrees relative to each other. The headplate was a stainless steel triangle, weighing 2.2 grams, with three half spheres at the triangular vertices, designed to mate with the vee grooves. Neodymium magnets attached to the clamp were used to provide the clamp force. We assessed the registration accuracy of the system using super resolution two-photon (2P) imaging of fluorescent microspheres fixed to the headplate following repeated attachments of the headplate., Registration accuracy (root mean square [RMS] displacement) for the solid stainless steel headplate was 1.35μm in x, 1.42μm in y, and 0.28μm in z. Scanning electron microscopy of the half spheres revealed mesoscale ridges and grooves in the metal surface, which could affect registration accuracy. Replacement of the stainless steel half spheres with ruby spheres improved repositioning accuracy to 0.17μm in x, 0.32μm in y, and 0.21μm in z. Mechanical stability of the headplate was assessed by 2P imaging of hippocampal pyramidal neurons of implanted, head fixed mice on a running wheel. RMS displacement was less than 4μm microns along horizontal (x) and vertical (y) axes of the imaging plane, and was small enough to be corrected by standard image registration algorithms. These results suggest that the mechanical stability of the headplate and clamp are sufficient for cellular resolution imaging in awake, behaving mice. We anticipate that the headplate clamp system reported here may facilitate experiments in mice where high precision and stability are required, such as imaging experiments involving voluntary head restraint (Kampf et al. 2010), time-lapse developmental studies, or registration of the same subject across multiple instruments.

Title: Neuroanatomical Differences Between Brain Lobes Of Adults and Hatchlings Of Octopus maya

Authors: *H. SANCHEZ-CASTILLO[1], **P. GARCÍA-ANDALUZ**[2], A. GONZÁLEZ-NAVARRETE[4], D. B. PAZ-TREJO[3], F. VERGARA OVALLE[4];
[1]Univ. Nacional Autonoma De Mexico. Fac Psicologia, Mexico City, Mexico; [2]Univ. Nacional Autonoma de Mexico, CDMX, Mexico; [3]Univ. Nacional Autonoma de Mexico, Mexico City, Mexico; [4]Univ. Nacional Autónoma de Mexico, Mexico City, Mexico

Abstract: Octopuses are proposed as a good animal model for studying cognition and behavior because of their wide behavioral repertoire and complex neuroanatomy, however, the Octopus Maya, an endemic specie from Mexico, is not fully studied yet. Even though their lifespan is relatively short, previous findings state that hatchlings are born with a fully developed brain and exhibit similar behavior to adults, hence they can be used on experimental procedures since early life stages. Yet, some behavioral differences between young and adult specimens have been observed in octopuses breed in captivity, and more information is needed to elucidate the underlying causes. Brain organization, neuronal growth and overall system maturation have been seen as a crucial factor on behavioral refinement in other animal groups, therefore, in this study we compared neuroanatomical characteristics between brain lobes of adults and hatchlings of octopus maya, including quantity, type and distribution of neurons through light microscopy. We found that lobes of 1 month post-hantching specimens only have the equivalent of 36% of the amount of neurons present in adults. In addition, most neurons in young specimens are small cells arranged in 1 cellular layer, while adults exhibit 3-4 cellular layers comprised of small and large cells. These findings show the potential relevance of studying the developmental characteristics of octopus neurobiology, to improve the standardization of this emerging model of complex behavior and cognition.

Abstract: Current functional neuroimaging techniques, such as functional magnetic resonance imaging, rely on indirect consequences of neural activity (the hemodynamic response). With the advances in transgenic rodent technology and photoacoustic (PA) imaging, we propose a more direct method to map and quantify activated neurons using a Fos-LacZ transgene reporter system in rats. Fusion of Fos with the lacZ gene gives active (Fos+) cells the ability to cleave pro-chromogenic substrates, such as X-gal, into PA-detectable products. In this study, we quantified the neuroactivity-based PA signal in Fos-LacZ transgenic rats following cued fear conditioning using various routes of administration of X-gal to determine optimal *in vivo* PA imaging parameters and facilitate longitudinal analyses.Homozygous Fos-LacZ Wistar female and male rats underwent acquisition of cued fear conditioning immediately followed by X-gal administration through intrathecal, intravenous, or intraperitoneal routes 60 or 90 minutes (route dependent) after fear conditioning. Twenty-four hours later, rats were anesthetized and a cranial window was created in the skull. PA imaging of Fos-dependent neuroactivity in the medial prefrontal cortex (mPFC) *in vivo* was immediately conducted followed by transcardial perfusion to allow for subsequent validation with PA imaging of brains *ex vivo*. All PA imaging used an 18.5 MHz, 128 element L22-14v linear array ultrasound transducer to record PA signal produced by pulsed laser illumination directed with custom fiber optic cables. PA intensity within the mPFC *in vivo* and *ex vivo* of acquired images were then quantified using Matlab.We report quantified *in vivo* and *ex vivo* PA images acquired after multiple routes of X-gal administration demonstrating PA intensity differences between fear conditioned animals and vehicle controls.Using this novel approach, we propose a method of longitudinally monitoring activated (Fos+) neurons *in vivo* with high resolution and specificity. Our studies report the feasibility of all tested routes of X-gal administration with the best results reported from intrathecal administration. We then continued our exploration of this route to report preliminary *in vivo* imaging which will drive our future studies.

Title: The AxCaliber connectome - investigating the axon-diameter weighted human brain network using MRI

Authors: *H. GAST, Y. ASSAF;
Sagol Sch. of Neurosci., Tel Aviv Univ., Tel Aviv, Israel

Abstract: Considered to have a major role in the ability to define brain's function, the history of neuroscience is replete with attempts to understand the wiring pattern of the brain. Yet, one of the major drawbacks in studying the connectome, is how to weight its connections. In this study, we introduce AxCaliber3D method, under developing in our lab, to assess axon diameter distribution in the brain. Being related to the conduction velocity in axons (Ritchie, 1982), we intend to define the conduction-velocity based connectome of the human brain. We believe that this newly defined connectome, might provide a better ground for connectome properties estimation. 50 participants were scanned for a high resolution T1 MPRAGE, a high angular resolution diffusion imaging (HARDI) and a multi b-shell AxCaliber. We analyzed scans using AxCaliber3D, an under-development method for assessing axon-diameter distribution. In AxCaliber3D, we divide the analysis into two parts: Estimating hindered diffusion and fiber orientations (from the HARDI acquisition); and estimating the relative contribution of each of axonal components to the obtained signal, for 160 different axon components (0-20 μm). The diffusion within the axon are modeled based on the work of Vangelderen et al. (1994). We then performed Deterministic Maximum Direction Getter and CSD tractography, using Dipy library. Based on Schaefer et al.'s (2018) atlas, we labeled brain areas as nodes and weighted edges by the average number of tracts, FA values or axon-diameter between each pair of nodes, to compute connectivity matrices. We used Pearson correlation to compared the FA weighted and axon-diameter weighted connectomes, we were able to show that for some cases the two weighting methods demonstrate a positive correlation, in others a negative correlation and some nodes' pairs connections are not correlated at all. The different patterns between the two diffusion-based values, asses that the AxCaliber3D method measures a unique property of the brain's tracts, thus revealing a new tier in the human brain connectome. Moreover, while weighting edges using the number of tracts or the axon-diameter, connectivity matrices showed two different networks, as well as distinct node's properties distribution. Our results show different distributions of node's centrality measures (i.e. the node's degree and clustering coefficient) for the two connectomes. Being notably different from the so far explores weighted anatomical connectomes, the axon-diameter based connectome could expand our knowledge regarding the human brain and the complex network that upholds it.

Abstract: The prefrontal cortex (PFC) evolved greatly in primate lineage to enable highly complex cognitive behaviors, laying the basis for humanity. At the core of its function lies the intricate connectional network of cortical and subcortical brain regions. To gain insight into the architecture of such network, we performed a comprehensive mapping of PFC projections using marmosets as the model animal. We have now obtained 44 high-quality datasets with anterograde tracer injections into major PFC subdivisions, including dorsolateral and orbitomedial PFCs, putative frontal eye field as well as a few premotor areas. Each dataset covers the whole brain with >650 images of axon-level resolution (xy resolution; 1.3μm/pixel, z resolution; 50 μm/section). It offers both parcellation-based and parcellation-free measurements of tracer signals in a standardized 3d space for comparison across samples. Using this resource, we were able to model topographic projections of corticothalamic and corticostriatal terminals at high accuracy. Furthermore, by modeling the cortical surface by a stack of layer-specific surface map, we were able to quantitatively characterize the columnar convergence of axon terminals, which have been known for decades as a characteristic feature of primate PFC.

Title: Inter- and Inner- Connectivity Balance in The Human Brain

Authors: *R. KRUPNIK[1], Y. YOVEL[2], Y. ASSAF[3];
[1]Sagol Sch. for Neurosci., [2]Sagol Sch. of Neurosci. and Sch. of Zoology, [3]Sch. of Neurobiology, Biochem. and Biophysics and Sagol Sch. of Neurosci., Tel Aviv Univ., Tel Aviv, Israel

Abstract: The connectome has a great impact on the brain's function, as its structure affects the speed and efficiency of information transfer. As such, brain networks are expected to have an organization that minimizes wiring costs while maintaining conductivity speed. A recent study spanning a variety of mammals showed consistent connectivity across species, explained by the fact that species with highly connected hemispheres appear to have weaker inter-hemisphere connections. While this phenomenon is harder to pinpoint in humans due to a smaller variability, we hypothesized that a similar phenomenon will be found across humans. Analyzing this phenomenon in the human brain allows us to compare network structures more easily. Thus, we can find anatomical and functional origins of this phenomena, an exploration that could not be done between species. This research was conducted on the HCP young adult dataset (N=970), including structural and diffusion MRI scans of pairs of monozygotic and dizygotic twins, non-twin siblings and other subjects. We performed multi-shell multi-tissue CSD based tractography on all subjects and computed structural connectivity matrices for each. Hemispheric connectivity was assessed by the network connectivity, and inter-hemispheric connectivity by the ratio of commissural tracts of the overall brain. To further examine the biological origins of this phenomenon, local connectivity measures were computed in order to examine their effect on the phenomenon. We observed a correlation (r^2 =0.25, $p<0.001$) between hemispheric efficiency and the commissural ratio. In node analysis, a strong connection was found between each node's centrality in the network and its effect on the balance. Rich club nodes, such as the precuneus, superior frontal and temporal cortices and the hippocampus, contribute highly to the phenomenon. Comparing the connectomes of monozygotic and heterozygotes siblings revealed higher hereditary values for commissural ratio (h^2=90%) than hemispheric efficiency (h^2=83%) and significant cross-twin-cross-correlation. Our results point to a trade off between inter intra hemispheric connectivity. In contrast to previous studies in mammals, here we explore the regional and hereditary basis of this phenomenon. These findings emphasize studies showing increased intra-hemispheric connections in subjects with agenesis of the corpus callosum, suggesting a reorganization of connections to balance the brain connectivity. This variability in hemispheric connectivity may underlie the specific abilities of an individual. Thus, further focus on the cognitive and behavioral implications of these findings is needed.

Title: A multimodal connectomic atlas of the mouse brain

Authors: *G. A. JOHNSON[1], M. CHEN[2,3], J. COOK[4], G. COFER[4], J. GEE[2], R. LAOPRASERT[4], Y. QI[4], L. WHITE[5], N. WANG[3], P. STAREWICS[6], R. WILLIAMS[7]; [1]Radiology, Duke Univ., Durham, NC; [2]Radiology, U Penn, Philadelphia, PA; [3]Radiology, Indiana Univ., Bloomington, IN; [4]Radiology, [5]Neurobio., Duke, Durham, NC; [6]Resonance Res., Billerica, MD; [7]Genet., Univ. of Tenn, Knoxville, TN

Abstract: Introduction: We present a multimodal connectomic atlas of the mouse brain that merges diffusion tensor images (DTI) magnetic resonance histology (MRH) at 15 μm isotropic resolution and light sheet microscopy (LSM) of the same brain registered into a common space (CCFv3).Methods: MRH was performed at 9.4 T using a novel compressed sensing pipeline. Brains were cleared/stained using LSM. LSM data were acquired with stains for Syto16 NeuN and MPB. LSM data were registered to MRH at full resolution. The CCFv3 atlas was registered to the MRH using diffusion-weighted (DWI) and fractional anisotropy (FA) images.Results: The MR/DTI datasets are ~ 600,000-times higher resolution than the human connectome and 250-fold higher when adjusting for total brain volume between human and mouse. We were successful in co-registering the CCFv3 atlas and LSM data to the MRH. Since the MRH data are acquired with the brain in the skull, there is almost no distortion from perfusion-fixation and no artifacts from cranial dissection, tissue sectioning and histological processing. The availability of multiple MRH contrasts—axial diffusivity (AD), radial diffusivity (RD), DWI, FA—all of which are inherently registered to the same space, provides anatomical and cytoarchitectural landmarks that are consistent with the CCFv3 atlas. The resolution index of the connectome data, that is, the product of angular and spatial resolution ($3.7x10^7$) is five orders of magnitude higher than clinical scans allowing quantitative comparison between DTI and ABA mouse brain connectomes. The combination of MRH and LSM provides the most accurate geometric correction possible with a comprehensive anatomical connectome for the same specimen. The atlas is providing a powerful, multidimensional platform for global surveys of structural, functional, behavioral, and connectomic variation, including a comprehensive evaluation of the BDX panel of transgenic mouse strains.

Title: Exploring the spatial efficiency of the brain utilizing the mouse connectome

Authors: ***N. R. SMITH**[1], A. BORZOU[3], S. MILLER[2], J. KASPER[2], J. HOMMEL[2];
[1]Sch. of Med., [2]Dept. of Pharmacol. and Toxicology, Univ. of Texas Med. Br., Galveston, TX;
[3]Dept. of Physics, Syracuse Univ., Syracuse, NY

Abstract: The mammalian brain is a complex set of highly interconnected, yet anatomically and functionally distinct, regions. Together, these brain regions are organized into a functional neural network, but it remains unclear what factors drive this organization. One possible factor driving the spatial orientation of discrete brain regions is the structural connectivity of the network which promotes efficient function, where a network is efficient if regions that are well-connected are placed closer together. However, a limited understanding of structural connectivity and efficiency of brain networks in mammalian systems confounds our understanding of the brain's organization. The Allen Mouse Brain Connectivity Atlas provides a high-resolution structural connectivity map of mouse brain regions derived from a series of viral tracing experiments. With these data, we explored our hypothesis that regions which are highly interconnected are located

proximal to each other resulting in an efficient spatial organization that is related to the network connectivity. To test this hypothesis, we composed a model of the mouse brain by first simplifying complex brain region geometry to spheres while maintaining original structure volume. Then, using accompanying axonal projection volume data from the Atlas, we defined the spatial-connective efficiency for the placement of brain regions in 3D space as the volume of axonal projections between each region divided by the distance between regions. With this parameter defined, we utilized the SciPy optimization library to derive a solution for the maximal spatial-connective efficiency, and therefore the optimal theoretical placement, of 157 wild-type mouse brain regions with connectivity data from 499 viral tracing experiments and compared it to the actual mouse brain. Through this comparison, we found that the mouse brain's connectivity correlates to the physical localization of brain regions, suggesting that the brain's spatial organization is partly driven by the efficiency of the network connectivity.

Title: A multiscale brain map derived from whole-brain volumetric connectome reconstructions

Authors: *C. A. BRITTIN[1], S. J. COOK[2], D. H. HALL[3], S. W. EMMONS[3], N. COHEN[4]; [1]Mem. Sloan Kettering Cancer Ctr., New York, NY; [2]Biol., Columbia Univ., New York, NY; [3]Albert Einstein Col. of Med., New York, NY; [4]Univ. of Leeds, Leeds, United Kingdom

Abstract: Understanding how brain structure and function combine to generate behavior is a major goal of systems neuroscience. We present a multi-scale connectome and complete brain map of the *C. elegans* main neuropil, the nerve ring. We integrate our volumetric reconstruction of serial-sectioned EMs from 1 L4 larva and 1 young adult brain with corresponding synaptic and gap junctional connectomes. Exploiting bilateral symmetry of the neuropil, we generate 4 lateral datasets and assess the reproducibility of membrane contacts across datasets (M^{δ}), where δ=[1,4] labels the reproducibility degree. We find M^{δ} bimodally distributed, with high and low reproducibility peaks, and predict distinct populations of precisely-targeted versus variable contacts. Synaptic contacts (C^{δ}) on reproducible membrane contacts are also bimodal, pointing to significant variability in synaptic connectivity. We model membrane and synaptic contact distributions with 3 parameters: the target contact fraction, f<50% , precision, p>90%, and specificity (contact avoidance), s>20%, showing that <50% of synaptic contacts are precisely

targeted. Applying cluster analysis to reproducible M^4 (as proxies for core) contacts, we identify 5 spatial clusters of neurites (Figure A) that support similarly modular synaptic circuitry. Most neurons form predominantly intra-module contacts but 33 neurons are cross-modular and often exhibit reproducible microscale features linked to synaptic specialization. We posit that parallel information processing modules integrate over parallel sensory pathways before converging onto a recurrent distributed subcircuit, and construct a cellular resolution 3-layer modular brain map that accounts for 83% of core (C^4) contacts (Figure B). The *C. elegans* brain map is reminiscent of the layered cortical connectivity and its bio-inspired analogue - Residual Networks. The nested architecture supports both core, conserved, and variable, individual structures. Conserved features point to robust principles of brain organization that likely generalize across nervous systems.

Abstract: How the brain works depends on its neuronal network wiring. A comprehensive understanding of the brain is not possible without revealing its wiring diagram at a single synapse level. Mapping neuronal circuits in mammalian brains requires reconstruction of large

brain samples at spatial resolution corresponding to the size of synapses, e.i. ~20-40 nm. Optical microscopy has been the most powerful technique in the neuroscience arsenal due to its low cost, wide usage in biological sciences and ability to read out information-rich molecular signals. However, conventional optical microscopes have the spatial resolution of optics limited by diffraction of light. To address this issue, we developed an integrated imaging method for optical connectome microscopy with unprecedented resolution and scales. The method based on a modified ExM protocol that enables physical magnification of large brain tissue samples by 8 times in linear dimension. The high expansion factor allows us to achieve ~40 nm resolution using conventional microscopy techniques. The method is compatible with standard fluorescent proteins and antibody staining enabling multiplex imaging of neuronal morphology and pre- and post-synaptic densities in mouse brain. Using a versatile tiling light-sheet microscope we imaged the entire primary visual cortex region of a mouse at 100 nm resolution. In addition, the developed technique is compatible with whole mouse brain preparation as well as intact C.elegans worms. We believe that our method will enable fast and cost-efficient acquisition of whole-brain optical connectome at a single synapse resolution for the model organisms. The successful delivery of the method would significantly facilitate the study of how the brain works by creating complete connectome maps.

Campus, Howard Hughes Med. Inst., Ashburn, VA

Abstract: The Mushroom Body (MB) is a well-characterized associative memory structure within the *Drosophila* brain. Although previous studies have analyzed MB connectivity and provided a map of inputs and outputs, a detailed map of the downstream targets is missing. Using the genetic anterograde transsynaptic tracing tool, *trans*-Tango, we identified divergent projections across the brain and convergent downstream targets of the MB output neurons (MBONs). Our analysis revealed at least three separate targets that receive convergent input from MBONs: other MBONs, the fan shaped body (FSB), and the lateral accessory lobe (LAL). We describe, both anatomically and functionally, a multilayer circuit in which inhibitory and excitatory MBONs converge on the same genetic subset of FSB and LAL neurons. This circuit architecture provides an opportunity for the brain to update information and integrate it with previous experience before executing appropriate behavioral responses.

Title: Mapping spinal cord and brain targets of colonic extrinsic nerves in the mouse.

Authors: *A. M. HARRINGTON[1], V. WANG[1], J. HARRIS-JANSON[1], A. MCGOVERN[2], S. B. MAZZONE[2], S. BRIERLEY[1];
[1]Flinders Univ., Adelaide, Australia; [2]Dept. of Anat. and Neurosci., The Univ. of Melbourne, Carlton, Australia

Abstract: Aim: Identify the central circuits into which extrinsic nerves from the distal colon convey nociceptive signalling in the mouse. **Methods:** Male and female adult mice underwent retrograde tracing from the distal colon using cholera toxin subunit b (CTb). CTb labelled sensory neurons were quantified within CLARITY cleared dorsal root ganglia (DRG, T9-S2) and nodose ganglia (N=6) after four days. CTb labelled projections were identified in spinal and medulla sections (N=5) after seven days. Anterograde trans-neuronal tracing with herpes simplex virus 1 expressing EGFP (HSV-H129-EGFP) was performed from the distal colon wall. Neuronal expression of EGFP was identified within spinal and brain sections after 72-120 hours (N=4/time). To identify brain regions engaged by colonic nociceptive stimuli the number of neurons activated by noxious *in vivo* colorectal distension (N=5) was compared to that evoked by innocuous (N=5) and no distension (N=5). Immunolabelling for phosphorylated MAP kinase (pERK) was used to identify activated neurons. **Results:** Colonic CTb-labelled neurons were present in the DRG, peaking in L1 and S1, and nodose ganglia. CTb-labelled projections were observed in the spinal cord dorsal horn, spanning T11-L1 (in lamina I/ V and in lateral tracts of

Lissauer) and L6-S2 (in lamina I, dorsal grey commissure and lateral tracts into the sacral parasympathetic nuclei (SPN)), and within the medulla (nucleus tractus solitarius (NTS) and area postrema). CTb-labelled cell bodies were present in the intermediolateral nuclei (IML), SPN and dorsal motor vagal nuclei (DMV). 72-96 hours after colonic injection, EGFP-expressing neurons were observed in the spinal cord dorsal horn spanning T11-L1 (lamina I, IML and around the central canal) and L6-S2 (laminae I-V, dorsal grey commissure and SPN) and within the caudal and rostral ventrolateral medulla (VLM) and the rostral ventromedial medulla (RVM). After 120 hours, EGFP-labelling was present in the DMV, NTS, hindbrain locus coeruleus (LC), sub-coeruleus, Barrington's nucleus, lateral parabrachial nucleus (lPbN) and pontine reticular A7. Labelling was also evident in the hypothalamic paraventricular nucleus, periaqueductal gray (PAG), thalamic nuclei and somatosensory motor cortex. Of the brain regions in which EGFP-neurons were observed, noxious CRD evoked a significant increase in neuronal activation relative to innocuous distension in the VLM, RVM, LC, lPbN, PAG and medial thalamic nuclei. **Conclusion:** These data localised colonic input within the spinal cord dorsal horn and medulla dorsal motor vagal complex and the subsequent brain circuits into which colonic nociceptive stimuli is conveyed.

Title: Mapping neuroanatomical structures labeled in histologic sections to a whole brain standardized atlas coordinate system

Authors: *N. J. O'CONNOR[1], B. S. EASTWOOD[1], P. J. ANGSTMAN[1], A. D. LEDUC[1], C. R. GERFEN[2], J. R. GLASER[1];
[1]MBF Biosci., Williston, VT; [2]Natl. Inst. of Mental Hlth., Bethesda, MD

Abstract: Advances in molecular neuroanatomical tools have expanded the ability to map specific neuron subtype populations and their connections in the context of behavioral or pathological patterns of neuronal activity. Analysis of connectivity and neuronal activity across whole mouse brains that have been registered to a reference atlas reveals the functional organization of brain circuits related to behavior and pathologies that can be compared across animals, experiments, and laboratories. Here we present advances to our previous technique[1] for reconstructing images of mouse brain sections labeled with standard histochemical techniques into whole-brain volumes and registering those brain volumes to the Allen Mouse Brain Common Coordinate Framework (CCF) to enable automatic delineation of brain

regions.Specifically, the process for accurate registration to the CCF accounts for artifacts due to histological cutting, mounting, and fixation. A transform is estimated for a section that contains clear landmarks, and this transform is then propagated to other sections with linear and nonlinear refinements that preserve the histologic sectioning model. We present a quantitative comparison between our updated algorithms and a single 3D transformation of aligned serial section volumes. Manually placed fiducial markers in the experimental brain sections and in corresponding anatomies in the CCF are used to assess matching accuracy. Examples are provided of whole-brain analysis of connectivity using trans-synaptic rabies labeling of neurons providing inputs to Cre-expressing neuron subtypes and of analysis of behaviorally relevant brain circuits using fos labeling of activity in neurons correlated with specific behaviors. For analysis, coronal brain sections are reconstructed into a 3D volume, labeled neurons are automatically marked using a multiple scale feature detector assisted by a deep neural network, and brain sections and marked neurons are registered to the CCF. The number of detected neurons in each of the 2500 brain structures in the CCF are tallied, allowing for quantitative analysis between mice.

Title: Estimation of protein turnover in mouse brains over multiple spatial scales with cell type specificity

Authors: *B. MOHAR, N. P. SPRUSTON, K. SVOBODA;
HHMI Janelia Res. Campus, Ashburn, VA

Abstract: Cells continuously synthesize and degrade their proteins (turnover), supporting cellular functions over a wide range of temporal and spatial scales. The brain presents special

challenges for studying turnover, due to its morphologically expansive neurons and the need to maintain synaptic weights used to store memories that may last as long as the lifetime of the animal. Thus, the dynamics of protein turnover may vary across brain regions, cell types, and subcellular compartments. Studying protein turnover in the nervous system requires a method that overcomes the brain's pharmacologically privileged status, and assesses protein turnover at very high spatial resolution and over large spatial and temporal scales. We tackled these challenges by tagging proteins with a self-labeling enzyme that covalently attaches a fluorescent ligand. We then measured turnover using a pulse-chase strategy with orthogonal fluorescent dyes. We screened dyes to maximize brain bioavailability, and characterized their temporal profile with in-vivo measurements and modeling. By combining this method with post-hoc immunofluorescence, we quantified cell-type and brain-region specific turnover of the nuclear protein MeCP2, as well as subcellular compartment-specific turnover of a glutamate receptor subunit, which turned over faster in the soma than in dendrites and spines. This new method enables high-resolution, brain-wide measurements of protein turnover in-vivo.

Abstract: Optical recording with voltage-sensitive dye (VSD) was developed in the early 1970s. Developments of imagers for VSD recording in the 1980s-90s have enabled us to record the dynamics of neural activities in the brain. Due to small fractional changes in VSD fluorescence upon membrane potential change in brain slice preparation, one must do averaging or accumulating of the signal over several trials to get clear signals, or in most cases to avoid photon shot-noise. Our improvements in optics and slice preparation handlings have improved this situation — they have allowed us to record much more data. We successfully recorded optical response every 200 ms, recording every 60 seconds at 0.1 ms/frame (10 kHz) for over 12 hours, without photo-damaging or photo-bleaching in area CA1 of mouse hippocampal slice upon Shaffer collateral stimulation, enabling us to record late-phase LTP. Each single-shot imaging trial has enough S/N without averaging.
The successful single-shot repetitive recording allows us to find "rare" network activity among many trials. This network activity occurred only rarely but was imaged clearly. One was the activity spread from the perirhinal cortex (PC) to area CA2 of the hippocampus. In the series of consecutive recordings, most of the recording only shows the spread between the PC and the entorhinal cortex (EC). On only rare occasions, the PC activity was followed by an activation in area CA2 of the hippocampus and then spread to the CA1 region in parallel with the spread to EC. The neural excitation transmission between two regions has been predicted from the anatomical study but was difficult to record with electrophysiological recording. This kind of probabilistic or quantal communication between regions in the brain could be substantial. Because of the evident propagation shown in the imaging system, even though it was rare, the spread is not just noise or fluctuation. The single-shot recording was also useful to see oscillations in the neural circuit. We present oscillatory activity in the hippocampus from CA2 to CA1 and PC-EC connection and long-range activity in the cortex. Because we could record those events with the wide-field optics, we argue that wide-field imaging with VSD is a handy tool in seeking unique network activity in the brain slice preparation.

Title: Quantitative analysis of 1700-nm three photon red-shifted calcium imaging in the mouse brain

Authors: *C. WU, A. MOK, T. WANG, D. OUZOUNOV, W. GU, M. WARDEN, C. XU; Cornell Univ., Ithaca, NY

Abstract: Three-photon calcium imaging with combination of genetically encoded calcium indicators (GECIs) have allowed measurements of activity in large populations in deep brain regions. To achieve deeper depth and parallel applications, red-shifted GECIs were emerging as a useful tool. However, current red GECIs are not well quantified in large-scale neural activity imaging which entails a careful balance between recording fidelity and tissue heating.
We calculated and experimentally verified the excitation pulse energy to achieve the minimum photon count required for the detection of calcium transients in jRGECO1a-expressing neurons for 1064-nm two-photon and 1650-nm three-photon excitation, respectively. Brain tissue heating by continuous three-photon imaging was simulated with Monte Carlo method and experimentally validated with immunohistochemistry. We observed increased immunoreactivity with 75 mW excitation power at 0.8-, 1.0- and 1.2-mm imaging depths. Our analysis presents a translatable model for the optimization of three-photon red protein calcium imaging based on experimentally tractable parameters.

Title: Bioluminescent genetically encoded indicators of neuronal activity

Authors: E. D. PETERSEN[1], G. SANTANA[2], F. ST-PIERRE[3], N. C. SHANER[4], A. GILAD[1]; [1]Michigan State Univ., East Lansing, MI; [2]Florida Intl. Univ., Miami, FL; [3]Neurosci., Baylor Col. of Med., Houston, TX; [4]Neurosciences, UCSD, La Jolla, CA

Abstract: Genetically encoded optical sensors and advancements in microscopy have revolutionized the scientific toolbox used for answering complex biological questions especially in terms of studying brain activity. However, there remains a need to develop new tools for reporting neuronal activity *in vivo* within deeper structures. We expect this can be achieved by replacing the fluorescent elements of the existing biosensors with bioluminescent producing elements. This will bypass the need of external light sources to illuminate the sensor and overcome limitations such as limited light penetration depth, light diffraction and tissue heating that are all caused by the excitation light used for fluorescent imaging. We are building on recent advancements in two fields: genetically encoded optical sensors for real-time sensing changes in neurotransmitters levels or voltage; and genetic evolution of new enzymes that produce

biological luminescence at unprecedented intensities. We have engineered a variety of bioluminescent voltage indicators (bGEVIs) and bioluminescent neurotransmitter indicators (bGENIs) by adapting sensing domains used in fluorescent indicators and incorporating bioluminescent producing luciferases. We have currently created bioluminescent indicators that report membrane depolarization, glutamate and dopamine with increases in luminescence. Our voltage indicator has a 60% increase in luminesce when mammalian cells are depolarized. Our glutamate indicator has a 255% increase and our dopamine indicator currently has a 20% increase in response to neurotransmitter presentation when expressed in mammalian cells (HEK cells). We expect these indicators to perform well for imaging neuronal activity in deep brain structures with imaging equipment that is readily accessible to researchers.

Abstract: Endocannabinoids (eCBs) are retrograde neuromodulators that play an important role in a wide range of physiological processes; however, the release and in vivo dynamics of eCBs

remain largely unknown, due in part to a lack of suitable probes capable of detecting eCBs with sufficient spatiotemporal resolution. Here, we developed a new eCB sensor called $GRAB_{eCB2.0}$. This genetically encoded sensor consists of the human CB1 cannabinoid receptor fused to circular-permutated EGFP, providing cell membrane trafficking, second-resolution kinetics, high specificity for eCBs, and a robust fluorescence response at physiological eCB concentrations. Using the $GRAB_{eCB2.0}$ sensor, we monitored evoked changes in eCB dynamics in both cultured neurons and acute brain slices. Interestingly, in cultured neurons we also observed spontaneous compartmental eCB transients that spanned a distance of approximately 11 μm, suggesting constrained, localized eCB signaling. Moreover, by expressing $GRAB_{eCB2.0}$ in the mouse brain, we readily observed foot shock-elicited and running-triggered eCB transients in the basolateral amygdala and hippocampus, respectively. Lastly, we used $GRAB_{eCB2.0}$ in a mouse seizure model and observed a spreading wave of eCB release that followed a Ca^{2+} wave through the hippocampus. Thus, $GRAB_{eCB2.0}$ is a robust new probe for measuring the dynamics of eCB release under both physiological and pathological conditions.

Title: A family of genetically-encoded GRAB sensors for detecting neuropeptides in vitro and in vivo

Authors: *H. WANG[1], T. QIAN[1], L. WU[1], Y. LI[1,3,4,2];
[1]State Key Lab. of Membrane Biology, Peking Univ. Sch. of Life Sci., [2]Peking-Tsinghua Ctr. for Life Sciences, Acad. for Advanced Interdisciplinary Studies, Peking Univ., Beijing, China; [3]Chinese Inst. for Brain Res., Beijing, China; [4]PKU-IDG/McGovern Inst. for Brain Res., Beijing, China

Abstract: Neuropeptides are key signaling molecules in endocrine and nervous system, regulating virtually all physiological processes, ranging from food ingestion, sleep & circadian rhythm, to pain sensation and social behaviors. To understand their important functions in vivo, it is critical to be able to monitor neuropeptide dynamics with selectivity, sensitivity and good spatiotemporal resolution. One major hindrance to the above goal is the lack of direct, sensitive and non-invasive probes to report these bioactive peptides *in vivo.* Here, by tapping into GPCRs

for human neuropeptides, we developed a toolbox of GRAB (GPCR activation based) sensors for neuropeptide Y (NPY), vasopressin (VP), oxytocin (OT), somatostatin (SST), corticotrophin releasing factor (CRF), neurotensin (NT), cholecystokinin (CCK), vasoactive intestinal peptide (VIP) and substance P. These fluorescent sensors utilize native human GPCR ligand binding pockets as neuropeptide sensing modules and circular-permutated GFPs as optical reporters. We have developed sensors with ultra-good selectivity for neuropeptides, with nano molecular affinity, up-to 1500% dF/F fluorescence increase upon cognate ligand application. In addition, these GRAB sensors have minimal downstream G protein coupling, or arrestin coupling, compared to their original GPCR scaffolds. OT sensor and CRF sensor are able to faithfully report electric stimuli induced cognate peptide release in acute brain slices. We are validating these peptide sensors in slice & in vivo and extend the sensor development strategy to cover more neuropeptides in human body. The further development of these sensors and their deployment will likely significantly enhance our understanding of neuropeptide function and regulation in physiological and pathophysiological conditions.

Title: Development and applications of novel genetically-encoded histamine sensors

Authors: *M. LI[1,3], H. DONG[1,3], T. QIAN[1,3], Y. LI[1,3,2,4];
[1]State Key Lab. of Membrane Biology, Sch. of Life Sci., [2]Peking-Tsinghua Ctr. for Life Sciences, Acad. for Advanced Interdisciplinary Studies, Peking Univ., Beijing, China; [3]PKU-IDG/McGovern Inst. for Brain Res., Beijing, China; [4]Chinese Inst. for Brain Res., Beijing, China

Abstract: Histamine (HA) is an important biogenic monoamine, involved in many crucial physiological processes, including immune responses, sleep-awake regulation and cognitive function. In the central nervous system, HA is mainly released from histaminergic neurons in the tuberomammillary nucleus (TMN), acting on a number of brain regions to execute its function. Despite of undisputable function of histaminergic transmission, how HA release is regulated in the brain is poorly understood, in part due to lacking of sensitive methods to monitor the dynamics of HA non-invasively with good cell specificity and high spatial-temporal resolution, especially *in vivo*. Here, we developed genetically-encoded HA sensors by tapping into cpEGFP and histamine receptors (HRHs), which are G protein coupled receptors (GPCRs). We screened different HRHs and used structure-guided semi-rational screen to yield a set of genetically-encoded HA biosensors with different dynamic ranges. We named these sensors GPCR-Activation-Based sensors for HA, or $GRAB_{HA}$ for short. The first generation of $GRAB_{HA}$, which is based on human histamine H_4 receptor, exhibited specific HA-induced fluorescence response ($\Delta F/F_0$ ~400%) with high ($GRAB_{HA1h}$, EC_{50} ~20 nM) or medium ($GRAB_{HA1m}$, EC_{50} ~200nM) apparent affinity. The $GRAB_{HA}$ sensors were validated in HEK293T cells and cultured cortical neurons regarding the properties of fluorescence response, kinetics, affinities and molecular specificity. Fiber photometry recording in freely moving mice with virus-mediated $GRAB_{HA}$ expression revealed the endogenous HA release during sleep-wake cycles. Further continuous optimization led to the identification of second generation of HA sensors based on water bear histamine H_1 receptor, named $GRAB_{HA2m}$, with more than 2-fold improvement in fluorescence response and faster kinetics. These HA sensors would likely enhance our understanding of complex histaminergic neuromodulation *in vivo* in both physiological and pathological conditions.

Abstract: The purinergic transmitter adenosine 5' triphosphate (ATP) plays a critical role in both central and peripheral nervous systems, and the ability to directly measure ATP dynamics is essential for understanding its physiological and pathological functions. Here, we developed a fluorescent GPCR-Activation-Based ATP ($GRAB_{ATP1.0}$) sensor. with ultrasensitive fluorescence response to extracellular ATP in multiple cell types ($\Delta F/F_0$ values of 500% to 1000%), and exhibits subsecond kinetics, nanomolar to micromolar affinity and enables subcellular detection of ATP. Using $GRAB_{ATP1.0}$ sensor, we monitored distinct patterns of ATP release, including the spontaneous ATP release, mechanical stimulation evoked ATP release and hypotonic stress evoked ATP release, in the primary hippocampal cultures. In zebrafish *in vivo*, we detected injury induced ATP release, and revealed its correlation with microglia migration after injury. In mice, we characterized a spatially selective ATP releasing event after systemic inflammation induced by lipopolysaccharide (LPS) using two-photon imaging, and we monitored ATP dynamics during sleep-wake cycles using fiber photometry. Together, we developed a new ATP sensor for monitoring extracellular ATP dynamics.

Title: Registration across in vivo neuronal imaging modalities: miniature microscopes to high resolution microscopes

Authors: *S. GULATI, K. ZITELLI, A. STAMATAKIS;
Inscopix, Palo Alto, CA

Abstract: Inscopix's miniscopes allow neuroscientists to record and manipulate large-scale calcium (Ca2+) dynamics in genetically defined populations of neurons at single-cell resolution in freely behaving animals over months. This is crucial to understanding and investigating the correlative and causal link between neural circuits and behavior. Adding the ability to register data from freely moving imaging experiments to data from high resolution confocal or multi-photon imaging will begin to provide crucial links between activity dynamics and anatomical, molecular, and/or connectivity profiles of distinct neuronal populations. To enable this goal, we have developed a Multimodal Image Registration and Analysis (MIRA) platform that fully integrates calcium imaging using miniaturized microscopes with high-resolution laser scanning microscopes. Here, we use the MIRA platform to record and register contralaterally-projecting medial prefrontal cortical (mPFC) neurons (labeled with tdTomato and imaged with a ZEISS Airyscan confocal), within the broader mPFC circuit during free behavior (imaged with an Inscopix nVista miniscope). To ensure we are recording from the same focal plane, we designed a confocal adapter that allows the experimenter to make the nVista system parfocal with the Airyscan. Freely-behaving Ca2+ imaging is first performed with the nVista platform, followed by head-fixed recordings with the Airyscan. After acquiring data from the two imaging modalities, we extract functional cell maps from each Ca2+ imaging data set using Inscopix Data Processing Software. To align the cell maps from both microscopes, we combine cell maps with structure images containing blood vessel patterns and shared landmarks. The different scale, rotation, and elastic deformations between the images are then corrected and aligned using the bUnwarpJ algorithm. After alignment, the same cells are registered from the different imaging modalities. The freely behaving calcium cell map is then overlaid with the static red cell map generated with the Airyscan, allowing for the identification of the subset of contralateral-projection mPFC neurons. Importantly, the registration method described here can be expanded to other high-resolution imaging modalities such as multiphoton microscopes.

Title: 'Light-guided sectioning' for precise localization and 3D visualization of in situ optical implants

Authors: *A. KAHAN, A. GREENBAUM, M. J. JANG, J. E. ROBINSON, J. R. CHO, X. CHEN, P. KASSRAIAN, D. A. WAGENAAR, V. GRADINARU;
Biol. and Biol. Engin., Caltech, Pasadena, CA

Abstract: In the last two decades, there has been a significant increase in the use of implanted optical devices to control and monitor neuronal activity *in vivo*. However, *post hoc* examination of the implant location is commonly achieved via 2D histology, which often suffers from distortion and loss during tissue processing. To address this, we developed a 3D method that allows *post hoc* labeling and clearing of tissue that preserves the size of the tissue while leaving the optical implant unperturbed. By coupling the implant to a light-emitting diode, the implant itself can serve as a light guide for removal of redundant tissue (light-guided sectioning, LiGS). The residual tissue, including the tissue-implant interface, is then processed as a whole for further investigation. This enables the precise location of the optical implant to be determined as well as the identification of tissue changes at the implant site. LiGS can also be used for accurate cell registration of *ex vivo* histology with single-cell two-photon calcium images obtained through GRIN lenses. We anticipate that LiGS will provide valuable additional information in any experiment that uses optical implants and will increase reproducibility through well-defined fiber-to-target localization.

Title: A Novel Pressure Regulating Brain Imaging Implant For Ultra-Large Field-of-View Microscopic Imaging in NHPs

Authors: *O. CABALLERO;
SUNY Downstate Med. Ctr..

Abstract: Several problems challenge mesoscopic imaging in the brain: 1) Difficulty with positioning high-NA objectives near the brain; 2) Creating a flat imaging window against the surface of the brain; 3) Adjusting the imaging window in the face of changes in swelling and pressure in the brain; 4) Preventing growth of dura and biofilms that obscure the imaging window; 5) Follow-on MRI imaging of the animal post-implantation. We propose here an ultra-large window radiolucent implant to address these issues. Our approach provides a 2 cm diameter window for non-human primates (NHPs) that regulates pressure and employs a stable, strong, and thin design. The system is mechanically modeled and stress-tested to achieve access to the brain by large objectives, with design features that allow for manual repositioning of the imaging lens. To optimize the distance between the objective and the brain, we prioritize a thin implant design. A strong radiolucent implant is created using PEEK plastic, a strong, thermoresistant and biostable material. We heighten strength of the chamber's attachment to the skull by using titanium screws that are normal to the surface of the bone at each point. The implant design has several parts and contemplates a potential method to maintain pressure on the brain. This method uses an engineered silicone mount to maintain even pressure of the imaging window on the brain's surface, despite brain motion. The mechanical properties of the silicone are manipulated to closely resemble that of brain tissue to be more biomimetic and act as a cushion for motion. This method also allows for the manual repositioning of the cover slip to create a flat imaging window. Lastly, our approach prevents dural growth by blocking the migration of migratory biofilm-forming cells; we hypothesize that use of dynamic pressure maintenance on the brain is key to this method's success. We are also investigating methods to elongate the longevity of the implant and imaging site, such as silver sputtering on implants and blue light therapy. These methods have produced an ultra-large field of view with 2P image results in <60,000 neurons. As such the chambers are expected to enhance recording window longevity and may prove to be a critical advance in NHP and human brain imaging.

Abstract: Targeting specific subsets of peripheral pathways of the autonomic nervous system will enable new avenues to study organ control and develop new disease therapies. Vagus nerve stimulation (VNS) has shown many therapeutic benefits but current approaches involve imprecise electrical stimulation that gives rise to adverse effects, while the functionally relevant pathways are poorly understood. One method to overcome these limitations is the use of optogenetic techniques, which facilitate highly specific neural communication with light-sensitive actuators (opsins). Opsins can be targeted to cell populations of interest based on the location of viral delivery and genetic control of expression. Here, we tested whether retrograde adeno-associated virus (rAAV2-retro) injected in the heart can be used to selectively express opsins in vagus nerve fibers controlling cardiac function. Furthermore, we investigated whether perturbations in cardiac function could be achieved with photostimulation at the cervical vagus nerve. Viral injection in the heart resulted in robust, primarily afferent, opsin reporter expression in the vagus nerve, nodose ganglion, and brainstem. Photostimulation using both one-photon stimulation and spatially-selective stimulation using two-photon holography was tested on the pilot-cohort of injected mice, using a GRIN-lens incorporated nerve cuff. Changes in heart rate, surface electrocardiogram, and respiratory responses were observed in response to both one- and two-photon photostimulation. The results demonstrate feasibility of retrograde labeling for organ targeted optical neuromodulation.

Title: Optogenetic inhibition of the external globus pallidus in normal and parkinsonian monkeys

Authors: *K. S. HEFFERNAN[1], X. HU[2], T. WICHMANN[3], A. GALVAN[3];
[1]Yerkes Natl. Primate Res. Ctr. and Grad. Neurosci. Program, [2]Yerkes Natl. Primate Res. Ctr., [3]Yerkes Natl. Primate Res. Ctr. and Dept. of Neurology, Sch. of M, Emory Univ., Atlanta, GA

Abstract: Based on extracellular recordings obtained in vivo, neurons in the external globus pallidus (GPe) of parkinsonian animals have lower average firing rates and increased bursting

compared to normal animals. However, recent work in rodents has demonstrated differences in the parkinsonian-related changes that occur in arkypallidal and prototypical GPe neurons. It is currently unknown whether these differences are also seen in non-human primates and how such changes in GPe firing rates impact activity in the putamen and subthalamic nucleus (STN).Here, we characterize the effects of inhibitory opsin Jaws in the GPe of rhesus monkeys. Two monkeys received chronic recording chambers aimed at the GPe. We injected AAV5-hSyn-Jaws-EYFP into the GPe (post-mortem histology showed that Jaws were expressed in neuronal terminals and remain stable for many months). To examine the effects of inhibition of GPe terminals in the putamen and STN, we obtained recordings of putamen and STN neurons during 500ms light pulses to activate the inhibitory opsins. Recordings were also performed in the GPe, to examine the efficacy of the opsins. Extracellular electrophysiologic recordings were conducted while the animals were awake, using tungsten electrodes coupled to 200um optic fibers and standard recording procedures, while the monkeys were sitting on a primate chair. In one of the monkeys, recordings were conducted before and after induction of stable parkinsonism with MPTP. For each cell, we generated peri-light-stimulus time histograms to analyze the proportion of light-responsive neurons. We analyzed firing rates for the 500ms before stimulus onset ('control') and for the 500ms of stimulus duration ('light-stimulated'). For each structure we used paired t-tests to compare differences in firing rates between control and light-stimulated periods (for normal and parkinsonian conditions separately).In approximately half of the GPe neurons, changes in firing rate were seen in both normal and MPTP-treated monkeys. The change in firing rates between control and light-stimulated conditions was comparable in normal and parkinsonian conditions. No effects were seen in putamen neurons in normal or parkinsonian conditions and minimal effects were seen in STN neurons in both conditions. Although our results suggest that optogenetic silencing of GPe terminals in STN and putamen has little effect on the firing rates of these structures, other parameters of firing could be modulated by the pallidal inputs.

Title: Stimulation-induced functional connectivity change in brain networks is mediated by the existing structure: An optogenetic study in non-human primate cortex

Authors: *J. BLOCH[1], *A. GREAVES-TUNNELL[2], E. SHEA-BROWN[3], Z. HARCHAOUI[4], A. SHOJAIE[5], A. YAZDAN-SHAHMORAD[6];

Abstract: Aberrant functional connectivity underlies many neural disorders from schizophrenia to epilepsy. Neural stimulation has been proposed as a means to rewire brains towards healthier connectivity. Research investigating the stimulation-induced functional connectivity change (SIFCC) has primarily analyzed how connectivity between stimulation sites changes as a function of stimulation delay. Here, we challenge this approach by revealing that the cortical network structure is the primary controlling feature of SIFCC, and that changes it underlies are not localized to the stimulation sites but spread over the surrounding cortical network.
We obtain network-level recordings from a large-scale (1cm^2) array of 96 micro-electrocorticography (μECoG) electrodes in the non-human primate (primary sensorimotor cortex in two subjects. We stimulate the cortex using optogenetics in a paired pulse protocol and quantify the functional connectivity over the network before, during, and after stimulation. We then develop a nonparametric statistical regression model to assay the contribution of a wide set of stimulation and network characteristics for predicting SIFCC. We parameterize the stimulation protocol with features such as delay, anatomical locations of electrodes, and relevant distances between electrodes and stimulation sites. Similarly, we parameterize cortical network structure by extracting from neural recordings a diverse set of graph metrics such as degrees of direct and indirect connectivity between electrodes, average connectivity strength to the network, and covariances of connection patterns.
By testing the prediction accuracy of models fit on subsets of these features we elucidate their importance in controlling the network SIFCC. First, we observe that while stimulation protocol features are statistically significant predictors, they have poor explanatory power (R2~0.05). We then augment the model with the network features and find that the network structure is much more important than the stimulation protocol in determining SIFCC (R2~0.50). Finally, we repeat these analyses with a time-varying model and find that the input-output relationships linking protocol and network features to SIFCC temporally vary as the cortex is being stimulated.
In this work we investigate for the first time how neural stimulation interacts with pre-existing cortical networks to drive network SIFCC. We demonstrate that the structure of the network is the primary controlling factor of SIFCC. This observation opens the door to more powerful and accurate stimulation interventions for the treatment of neural disorders.

Abstract: Introduction: Neurovascular coupling is frequently compromised in neurodegenerative conditions and contributes to their progression. Two-photon fluorescence microscopy (2PFM) coupled with optogenetic activation allows for controlled neuronal activation and direct vascular observation (Shih et al., 2012). We here present a deep learning platform for high-throughput quantification of neurovascular coupling in mice based on 2PFM data. **Methods:**8 Thy1-ChR2-YFP mice, injected with TexasRed, were imaged on a FVMPE-RS system. Image stacks covered 509x509μm lateral FOV at 0.99 μm resolution from the surface to 500 μm below, at 2.64 μm resolution. Stacks were acquired in pairs, before and after stimulation (458 nm wavelength at 20% power, 250 μm diameter cylinder in center of FOV) for quantification of vascular changes. We trained a 3D Unet CNN (Goubran et al. 2019) on these data. 5 image stacks were used for training and 3 withheld for validation. The model achieved an F1 score of **0.83 (±0.01)**. Segmentation masks were filled and skeletonized using an iterative thinning method. Vessel diameters were mapped onto skeletons via the distance transform of the segmentation mask. Graphical representations of the skeletons were aligned before and after stimulation. Images segmented for analysis were not involved in updating the machine learning model. **Results and Discussion:**Six regions of interest in 12 image stacks from 3 mice whose data were not used for training of the segmentation model were used for analysis **(Fig.1, A):** 1632 vessel segments across the 3 mice were analyzed. The CNN's output aligned well qualitatively to the raw data on these 3 test mice **(Fig. 1, B)**. Photostimulation-induced vessel caliber changes were observed in **(Fig. 1, C, D)**. Viscous resistance () for each vascular segment was calculated at both timepoints. The network showed an increase in vascular volume **(Fig.1, E, F)** and thus an average decrease in vessel resistivity **(Fig.1,G,H,I)**, with 98% of the net volume increase attributed to capillaries, and 53% of the overall volumetric changes.

Abstract: A common electrophysiology technique used in neuroscience is patch clamp: a method in which a glass pipette electrode facilitates single cell electrical recordings from neurons. Typically, patch clamp is done manually in which an electrophysiologist views a brain slice under a microscope, visually selects a neuron to patch, and moves the pipette into close proximity to the cell to break through and seal its membrane. While recent advances in the field of patch clamping have enabled partial automation, the task of detecting a healthy neuronal soma in acute brain tissue slices is still a challenging step that is commonly done manually. To overcome this obstacle and progress towards full automation of patch clamp, we combined the differential interference microscopy optical technique with an object detection-based convolutional neural network (CNN) to detect healthy neurons in acute slice. Utilizing the YOLOv3 convolutional neural network architecture, we achieved a 98% reduction in training times to 18 minutes, trained on an annotated data set of 1138 neurons. We also compared networks trained on unaltered and enhanced images, achieving up to 77% and 72% mean average precision, respectively. This novel, deep learning-based method accomplishes automated neuronal detection in brain slice at 18 frames per second with a small data set, rapid training time, and high precision. The addition of this technology during live-cell imaging for patch clamp experiments can not only improve manual patch clamping by reducing the neuroscience expertise required to select healthy cells, but also help achieve full automation of patch clamping by nominating cells without human assistance.

Title: Machine learning-based pipette correction for automatic patch clamp in vitro

Authors: *M. M. GONZALEZ[1], M. C. YIP[1], C. F. LEWALLEN[1], M. J. ROWAN[2], C. R. FOREST[1];
[1]George W. Woodruff Sch. of Mechanical Engin., Georgia Inst. of Technol., Atlanta, GA; [2]Dept. of Cell Biol., Emory Univ., Atlanta, GA

Abstract: Patch clamp electrophysiology is a common technique used in neuroscience to understand individual neuron behavior, allowing one to record current and voltage changes with submicron and sub-millisecond spatiotemporal resolution. While patch clamp experiments produce high fidelity electrophysiology data, the technique is onerous and labour-intensive. Despite the emergence of automated patch clamp systems, the crucial step of identifying the pipette location and carefully placing it within 1-2 micrometers of a cell membrane remains a bottleneck for the success rate of whole-cell experiments. Specifically, when patching in acute brain slices, the inherent light scattering from brain tissue makes automatically identifying the pipette tip a non-trivial problem that is not easily solved with traditional image processing methods. Here we used a convolutional neural network (ResNet101) to identify and correct the pipette position during automated patch clamp experiments. This deep-learning based pipette detection method improved the cell detection success rate and whole-cell success rates by 71% and 59% respectively compared to the state-of-the-art cross correlation method, as well as reduced the average time for pipette correction by 81.2%. This improvement has to potential to ultimately enable real-time correction of pipette position during patch clamp experiments with similar accuracy and quality of recording to manual patch clamp.

Title: Correlations of electrode parameters and recording performance in chronic epicortical implants

Authors: M. F. PORTO CRUZ[1,2], I. G. VASILAS[1], E. ZUCCHINI[2,3], L. FADIGA[2,3], ***T. STIEGLITZ**[1];
[1]Biomed Microtechnol Lab, IMTEK & IMBIT, Univ. of Freiburg, Freiburg, Germany; [2]Ctr. for Translational Neurophysiol. of Speech and Communication (IIT), Ferrara, Italy; [3]Section of Human Physiol., Univ. of Ferrara, Ferrara, Italy

Abstract: Electrocorticography (ECoG) has particularly gained strength in the recent years as ultra-conformable grids featuring neuron-sized electrodes have allowed to extend the frequency band from local field potentials (LFPs) to spike-like activity. Diverse methods have been proposed to effectively improve the performance of microelectrodes, one of them being the use of conductive polymers such as PEDOT to reduce the electrochemical impedance between electrode and tissue. Nonetheless, the relation between electrode impedance and signal quality still remains a topic of debate. To address the issue, we have collected *in vivo* electrode impedance and ECoG recordings from eight rats implanted with micromachined, ultra-conformable grids at implantation day and after 3, 6 and 12 weeks and have assigned electrochemical features and recording features to each single reading. The eight implants - one per rat - had electrodes with 10 µm and 100 µm in diameter and platinum, iridium oxide and PEDOT/PSS as electrode coatings. Spearman correlation coefficients were computed across all features and have shown that the root mean square (RMS) of the recorded signal in the high frequency band (above 300 Hz) strongly correlates with the thermal noise (ρ= 0.73) and anti-correlates with the interface capacitance (ρ=-0.66). Electrode material highly influenced the correlations between the performance parameters. Platinum had the strongest coefficient correlations between thermal noise and high band RMS, followed by iridium oxide. PEDOT had the weakest coefficients. Interestingly, spike counts and peak-mean ratio (PMR) from peri-event histograms showed no significant correlation to electrochemical features, suggesting that, once provided a reliable tissue-electrode contact via ultra-conformability, impedance does not explain high frequency performance. Looking at implantation day only, thermal noise and high band RMS remained highly correlated but, differently from the chronic scenario, both PMR and spike counts showed an anti-correlation to the high band RMS, indicating a larger contribution of thermal noise in the acute scenario. Scarring reactions reduce desired signals, as well as non-desired biological artefacts. Therefore, the signal-to noise ratio might stay constant along the weeks. Thermal noise, which is proportional to the real part of the *in vivo* impedance, seems not to be the main part of signal deterioration at higher frequencies. Reliable material-tissue interfaces matter more.

Title: Monolithically integrated microfabricated stainless steel neural probe platform for high-resolution recording in non-human primates

Authors: *Z. AHMED[1], J. REDDY[1], I. KIMUKIN[1], T. TEICHERT[2], M. CHAMANZAR[1]; [1]Carnegie Mellon Univ., Pittsburgh, PA; [2]Univ. of Pittsburgh, Pittsburgh, PA

Abstract: Non-human primate (NHP) brain is a very helpful model system for translational studies. Electrophysiology recording in non-human primates with high spatio-temporal resolution can facilitate our understanding of the neural basis of brain function and dysfunction in humans. Despite significant recent advancements in developing tools for high resolution neural recording in rodents, progress in developing scalable, high-density, and robust neural interfaces for recording from the larger NHP brain has been comparatively limited. Silicon-based rodent neural probe technologies benefit from the well-established nanofabrication technologies. The large NHP brain requires probes with extremely large aspect ratios, i.e., several centimetres long with small cross-sections to minimize tissue damage. However, the brittleness and fragility of silicon makes longer silicon neural probes vulnerable to breakage in large NHP brains. Stainless steel, on the other hand, is bio-compatible, highly fracture-resistant and has high modulus of elasticity making it a promising material platform for NHP probes. However, microfabrication and micromachining technology for stainless steel is challenging and fairly underdeveloped. As a result, commercially-available stainless-steel probes are mostly manufactured and assembled using expensive manual methods and have low channel-densities and are very expensive. To address these challenges, we have designed a neural probe based on a combination of stainless steel and Parylene C that can be implemented using a scalable microfabrication process . We have demonstrated 8 cm long neural probes with upto 102 channels densely distributed channels over a 300 μm wide shank. The rigid stainless steel shank enables reliable insertion and the flexible polymer cable reduces tethering forces from skull fixtures. We will discuss the design and implementation of these hybrid rigid-flexible neural probes as well as their in vitro characterization. This hybrid Parylene-stainless steel device platform enables the design of robust implantable brain interfaces for large animals with the potential for clinical translation.

Inst., Stanford, CA

Abstract: Anatomical, physiological, and transcriptomic studies suggest a diverse range of neuronal cell types. However, current *in vivo* methods—such as clustering on waveform features—only differentiate between broad- (BS) and narrow-spiking (NS) neurons. This gap between 'known' and 'observable' *in vivo* diversity limits our understanding of how cell types shape behavior. Here, we developed a new method (WaveMAP) that combines non-linear dimensionality reduction (UMAP) with graph clustering on spike waveforms and show that it better reveals candidate cell classes *in vivo*. We applied WaveMAP to extracellular waveforms recorded with U-probes from macaque dorsal premotor cortex (PMd) during a decision-making task. WaveMAP revealed that BS and NS classes are comprised of at least three and five sub-classes of neurons. These sub-classes had distinct physiological, functional, and laminar distribution properties. First, the BS neuron sub-classes had low firing rates (FR), late choice-selectivity, and broad laminar distributions concentrated in middle layers—hallmarks of excitatory pyramidal cells. Second, two sub-classes of NS neurons had high FR, early choice-selectivity, and strong decision-related responses. The laminar distribution of these neurons was also consistent with our layer-specific histological counts of calbindin-/calretinin- and parvalbumin-positive inhibitory interneuron densities respectively. Third, an NS sub-class had identical FR and functional properties as candidate excitatory neurons—consistent with findings that PMd excitatory neurons possess biophysical machinery capable of producing narrow spikes.

Fourth, another NS sub-class had FR, functional properties, and triphasic waveforms consistent with excitatory axons in deep layers. Fifth, WaveMAP sub-classes explained heterogeneity in decision-related properties of PMd neurons over and above our previously reported laminar differences. Notably, candidate cell types were not identifiable with traditional Gaussian mixture models that operate on derived features of the waveform (e.g., trough-to-peak and waveform width). WaveMAP produced more candidate cellular sub-classes and these sub-classes were also better separable. In summary, WaveMAP provides previously unavailable access to candidate cell types *in vivo*. Combining opto-tagging with WaveMAP will provide further insight into whether these candidate cell types are consistent with populations of excitatory and inhibitory neurons. WaveMAP will therefore enable more precise investigation of microcircuit dynamics during behavior in species where genetic access to cell types is difficult.

Title: A Multiplexed Active Digital Implantable Neural Probe

Authors: *X. HE[1], S. LIU[2], S. KARGARRAZI[1], V. CHEN[1], M. CHAMANZAR[1], L. PILEGGI[1];
[1]Carnegie Mellon Univ., Pittsburgh, PA; [2]Analog Devices Inc, Wilmington, MA

Abstract: Implantable neural probes have been extensively used as an important tool in neuroscience research. Implantable probes can record single unit action potentials and local field potentials from brain tissue with amplitudes ranging from tens of micro-volts to hundreds of micro-volts. Recently, silicon-based neural probes have been designed based on complementary metal-oxide-semiconductor (CMOS) technology. With the feature sizes that are possible with existing CMOS technology, neural probes can be designed to incorporating active elements such as low noise amplifiers and multiplexers within the area of a single electrode site on the probe. Neural signals can then be amplified and multiplexed at hundreds of sites along the probe shank. The traces along the probe shank are shared to transmit the recorded neural signals. Although this approach heavily expands the total number of recordable channels, the number of simultaneous recording channels is still limited. Therefore, only a sub-group of channels can be recorded simultaneously. In this work, we designed and fabricated a novel active digital neural probe in which the analog neural signals in the spikes band (i.e., 300 Hz - 10 kHz) are detected at the recording sites and then digitized and multiplexed over a common transmission line. The

probe integrates analog-front-end (AFE) circuitry under each recording electrode for instant neural signal quantization. Only one signal trace is needed to transmit the aggregate digitized neural data. Our prototype design features 113 recording electrodes over a 2.2 mm long shank that can all be recorded simultaneously. Each recording channel takes an area of 75 μm × 68.4 μm on the probe shank and each electrode is 15 × 15 μm^2. Each channel can be individually selected to be in the ON or OFF state, as needed. Measurements show that the recording system achieves an input referred noise of 12.43 μV_{rms} in the spikes frequency band, with the dynamic range of ±750 μV. The power consumption is measured to be 12.76 μW/channel. The number, density and the arrangement of the recording sites can be scaled and customized in our design. The design and in vitro characterization of these neural probes are discussed.

Title: Axontracking assay: automatic identification and functional characterization of axons by high-density microelectrode array technology

Authors: B. CLEMENT, ***M. FISCELLA**, N. BIYANI, E. GRONSKAYA, D. JÄCKEL; MaxWell Biosystems, Zurich, Switzerland

Abstract: Axons are the output projections of neurons that conduct action potentials towards other neurons in a network[1]. Axonal dysfunction plays a central role in neuronal pathophysiologies such as Parkinson's Disease[2] and Amyotrophic Lateral Sclerosis[3]. Therefore, access to axonal physiology is crucial to study information processing in neuronal networks and to discover cures for human neurological disorders.High-density microelectrode array (HD-MEA) technology[4,5] enables in-vitro recordings of extracellular axonal action potentials in primary rodent neurons[6] and human iPSC-derived neurons[7], long-term and label-free. In this work, we present the MaxLab Live[8] AxonTracking Assay, a software package for automatic detection and functional characterization of subcellular axonal physiological signals, across hundreds of neurons within a neuronal network.
MaxLab Live AxonTracking Assay features toolsets to record and analyze axonal signals, identify individual cells and to compute and export physiological neuronal metrics. In a first step, tens to hundreds of neurons are simultaneously recorded while the HD-MEA sensor area is scanned for signals of axonal outgrowth. Next, the detected spikes of the recorded neurons are sorted by clustering signal features from close-by electrodes spanning the action potential initiation site. The spike sorting results are used to reconstruct the spike-triggered average extracellular waveform over the entire array area for every identified cell. An unsupervised object tracking algorithm is then applied to detect the traveled path of action potential signal

propagation, thus identifying individual axonal branches and the morphology of neuronal outgrowth per cell. Finally, identified signal paths are used to compute branch-level and single-cell assay metrics, such as axonal conduction velocity and total axon length.
In conclusion, the presented MaxLab Live AxonTracking Assay combined with HD-MEA technology enables to access novel electrophysiological parameters of neurons, which can be used as metrics for new functional phenotype studies and drug screenings.

Title: Recording performance of low-impedance coatings for neural probes: an in vitro and in vivo comparison

Authors: *C. BOEHLER[1], R. LILJEMALM[2], C. LEWIS[3], T. STIEGLITZ[2], M. ASPLUND[1]; [1]Dept. of Microsystems Engin. - Bioelectronic Microtechnology, [2]Dept. of Microsystems Engin. - Biomed. Microtechnology, Albert-Ludwigs-University, Freiburg, Germany; [3]Brain Res. Inst., Univ. of Zurich, Zurich, Switzerland

Abstract: Implantable microprobes enable researchers and clinicians to tap into the signalling pathways of the nervous system to diagnose and treat diseases, understand basic functions, or offer neuroprosthetic rehabilitation. In order to provide high quality recordings, a variety of electrode materials has been developed, focussing in particular on low-impedance coatings to improve the performance of small electrode sites. Whether the lowest possible impedance, as

determined *in vitro*, also translates to the best possible recording performance *in vivo*, has to date not been clarified. We here address this question by implementing four electrode materials on the same flexible shank, comparing *in vitro* characterization with chronic performance measures *in vivo* (16 weeks). Flexible probes (polyimide 10µm thick, electrodes 12µm diameter/ pitch 45µm) were used as test platform to evaluate the recording performance of different low-impedance materials. Iridium Oxide (IrOx), nanostructured platinum (nanoPt) and PEDOT were deposited in an alternating pattern on the probes, allowing direct comparison among all materials including smooth Pt (Fig. 1). The electrochemical properties were determined before the coated probes were implanted into mouse cortex for recording evaluation. PEDOT electrodes had the overall lowest impedance followed by IrOx and nanoPt (Fig. 1), all orders of magnitude lower than bare Pt. For single unit activity (SUA), yield and amplitude were found to be substantially higher for the low-impedance materials indicating a direct correlation between recording quality and electrode impedance. Low-impedance coatings moreover greatly reduced movement related artefacts in local field potential (LFP) recordings, contributing to improved robustness in experiments with awake and moving animals. Last, but not least, low impedance materials allow for electrode area to be reduced so that few electrodes can be replaced with many, offering better opportunities for spike sorting and correlative analysis and improving prospects for clinical use of precision bioelectronics.

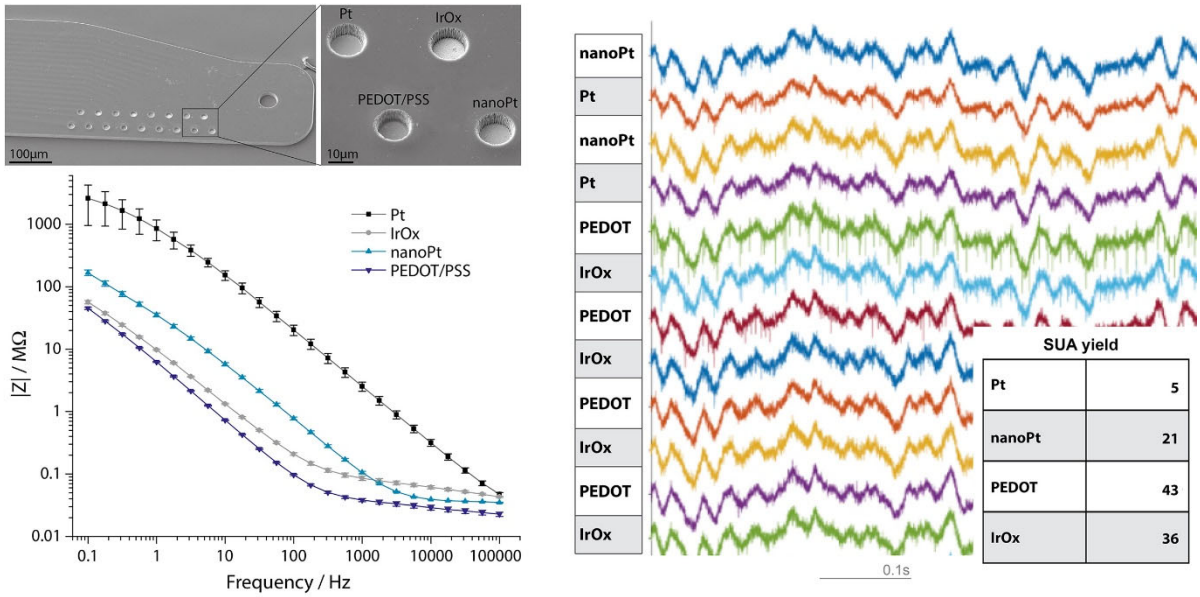

Figure 1: SEM image of a flexible polyimide thin-film probe providing a dense array of electrode sites for performance evaluation of different low-impedance materials on the same probe (top left). Impedance spectroscopy data (measured *in vitro*) shows a significant difference among individual electrode materials (bottom left). Representative *in vivo* data verifying high recording quality when using low impedance materials for SUA and LFP recordings (right).

Abstract: Mapping the excitability of motor cortex muscle representations using transcranial magnetic stimulation (TMS) and surface electromyography (EMG) has been used to study motor function in clinical and healthy human populations since the early 1990s. Recently, the development of a rapid TMS mapping technique, enabling the assessment of a cortical map in as little as two minutes, has greatly improved the time resolution that is attainable in TMS mapping studies. This may be particularly useful in studies where tonic or phasic muscle contraction introduces myoelectric manifestations of muscle fatigue to the surface EMG signal that is used to obtain TMS maps. The purpose of the present study is to determine whether it is feasible to simultaneously assess TMS map characteristics and EMG features during a prolonged isometric fatiguing task using high-density surface EMG (HDsEMG). The participant was a right-handed female volunteer (age = 20 yrs). At three discrete timepoints during a 23-minute isometric biceps brachii contraction at 5% of maximum voluntary EMG level, fast TMS maps and muscle HDsEMG maps were simultaneously obtained. Each map set was obtained over a 3-minute period at 0, 10 and 20 minutes. Cortical maps were assessed by delivering 100 TMS stimuli at random locations within a 6x6cm region of the scalp over the primary motor cortex at a rate of 0.5 Hz. The muscle potential evoked by each TMS stimulus was recorded by a 64-channel HDsEMG patch placed over the muscle belly. Relative to 0 minutes, the area of the cortical excitability map increased by 591mm^2 and 511mm^2 at 10 minutes and 20 minutes, respectively. The TMS map center of gravity also moved laterally at 10 minutes (1.5 mm) and 20 minutes (3.2 mm), while shifting less than 1 mm in the anterior-posterior direction (10 min: anterior 0.8 mm, 20min: posterior <0.1 mm). The spatial distribution of background muscle EMG activity was also assessed. The distribution of the mean rectified signal across the HDsEMG grid during the 250 - millisecond interval prior to each TMS pulse was averaged across the 100 map trials. The center of the EMG activity distribution along the medial-lateral and proximal-distal axes of the HDsEMG patch was located by taking the weighted average of the activities from each of the grid coordinates. The center of the distribution shifted medially (10 min: 0.1mm, 20min: 0.4 mm) and distally (20min: 0.2 mm) relative to 0 minutes. This case study highlights the feasibility and potential utility of combined HDsEMG and rapid TMS mapping for studies involving muscle fatigue. Future studies with sufficient sample sizes will be necessary to interpret the observations made in this case study.

Title: Large-scale recordings from the rat hippocampus using a 3D Parylene-based multi-electrode array

Authors: ***W. JIANG**, X. WANG, H. XU, E. MENG, D. SONG;
USC, Los Angeles, CA

Abstract: Large-scale monitoring of resolvable neuronal activities from multiple hippocampal sub-regions of behaving animals provides valuable insights into neurobiological mechanisms underlying learning and memory. However, current state-of-the-art probes such as microwire and silicon devices are much stiffer than brain tissue, which largely increases the chance of inflammation. Parylene C is a promising alternative structural and insulation material for building neural interfaces with reduced mechanical mismatch between tissue and implants. Furthermore, it can achieve high density of recording contacts as silicon devices. With high spatial and temporal resolution, Parylene-based multi-electrode array advances the possibilities for studying the anatomically distributed sub-circuits in the hippocampus. In our previous work, a 64-channel Parylene-based multi-electrode array with 8 shanks was developed and applied to chronic recording of the hippocampus in behaving rats. In our current work, a novel 3D Parylene-based probe consisting of 16 (2x8) shanks with a 250um spacing was developed. Each shank contains 8 platinum electrodes and thereby has a total of 128 electrodes. To aid insertion, dissolvable polyethylene glycol (PEG) brace was employed to temporarily support the flexible probe. One 3D Parylene probe was successfully implanted at 2.6mm posterior to the bregma and 2.4mm lateral to the midline at a depth of 4.4mm, and it was angled ~30 degrees from the midline to match the septal-temporal axis of the hippocampus. On the day of implantation, 12 out of 16 shanks from 2 arrays recorded single and complex neuronal signals from hippocampus. 59 units were captured from hippocampus through 4 electrode clusters arranged on the probe. 6 shanks recorded 8 units from CA1 while 9 shanks recorded 51 units from CA3. The histology showed that the shanks were straightly inserted in the first 2.5mm. They began to deviate from the midline of the probe when they were further advanced, which was due to the different dissolving rates on the surface of the PEG block. Severe bleeding around the implantation site was shown in the brain slices. It suggested the shanks might hit blood vessels during the insertion. This could explain why the captured units were less around the CA1 region. This preliminary result demonstrated the feasibility of implanting 3D flexible polymer probe to deep brain structures for large-scale recordings. In the next step, different insertion methods will be investigated to ensure straight insertion of the probes. The large-scale 3D Parylene probe will be

tested both acutely and chronically for recording from multiple hippocampal regions in behaving rats.

Title: Mea measurement in cerebral organoid

Authors: R. YOKOI, Y. ISHIBASHI, N. MATSUDA, ***I. SUZUKI**;
Tohoku Inst. of Technol., Sendai, Japan

Abstract: We have been developing a method for predicting seizure liability of drugs using in vitro cultured human iPSC-derived neurons. However, it is necessary to approach the in vitro to in vivo extrapolation (IVIVE). As one approach to IVIVE, an assessment method using a human brain organoid that mimics the three-dimensional structure is considered to be effective. In this study, we attempted to detect the response to convulsants by MEA measurement using human cerebral organoids. We detected the responses to convulsants in cerebral organoids and found that features appear in low frequency components of MEA data. Wavelet analysis revealed that the frequency intensity from the θ wave to the β wave component significantly increased in a dose-dependent manner. This is a result that enables comparison with in vivo brain waves. This study demonstrated that MEA measurement using human brain organoids may be a method that can approach in vitro to in vivo extrapolation in prediction of seizure liability of drugs.

Title: Diamond electrodes for minimally invasive and long-term recordings of neuronal network activity

Authors: ***N. BERTRAM**[1], B. CHANG[2], A. HAN[3], R. W. BERG[1];
[1]Dept. of Neurosci., Univ. of Copenhagen, Copenhagen, Denmark; [2]Nanolab, [3]Mechanical Engin., Tech. Univ. of Denmark, Lyngby, Denmark

Abstract: The coordinated activity of neurons gives rise to all output of the nervous system, yet the network logic is still an elusive scientific topic. Electrodes can be used to investigate this network logic as well as an interface for neuroprosthetic devices. Such electrodes should demonstrate longevity, mechanical strength, and preserve sensitive tissue, hence the material biocompatibility is of utmost importance. Diamond as a material has many extraordinary properties for tissue interfacing: extreme durability, chemical inertness, low surface friction and superior mechanical strength, which allows design of very small physical dimensions. Despite a great interest in artificially grown diamond thin films, the use of diamond is limited in the field of neuroscience. The aim of this study is therefore to produce long-term durable and minimally invasive diamond electrodes, while still capturing the extracellular activity of hundreds of individual neurons. Specifically, we aim to decrease the state-of-the-art probe dimension by an order of magnitude from few tens of microns to below 8 μm and down to 2 μm i.e. the scale of mammalian cell nuclei. The first prototype aims for 16 shanks with 8 electrodes on each (128 electrodes total). Hot filament chemical vapor deposition provides polycrystalline diamond on a silicon base as our starting point. We adapt techniques from the microchip industry, so that diamond can easily fit into a long history of silicon processing. The challenge is partially to overcome the chemical inertness of diamond; we have established an oxygen plasma etching scheme for freely manipulating diamond into CAD-drawn shapes and micron-sized thicknesses. We have functionalized diamond surfaces with platinum electrodes in well-defined patterns of 5 μm widths via lift-off photolithography and e-beam evaporation. However, deposition parameters such as temperature must be carefully considered for defect-free depositions. Full diamond-encapsulation of platinum patterns has also been demonstrated with etched electrode access. Results are verified via optical microscopy, scanning electron microscopy, and atomic force microscopy. This experimental work is ongoing, but these prototype results show promise for future in-vivo testing of functionality and biocompatibility. Beyond assisting in fundamental neuroscience, this work has many interesting perspectives for long-term durable brain-computer interfaces and neuroprosthetics.

Title: Advances in Polymer Microelectrode Array Technology

Authors: ***K. SCHOLTEN**[1], J. ORTIGOZA-DIAZ[1], D. SONG[2], E. MENG[1];
[1]Biomed. Engin., [2]Ctr. for Neural Engin., Univ. at Southern California, Los Angeles, CA

Abstract: Microwire arrays and silicon-based microelectrode arrays (MEAs) made large-scale recording of single neural units possible, and standardization and commercialization of these technologies led to their integration into neuroscience research worldwide. Mounting evidence suggests the rigid structure of these devices can compromise the electrode-tissue interface, limiting their usefulness for chronic recordings. Flexible MEAs made from compliant polymers can mitigate tissue damage and offer greater compatibility with optical and magnetic imaging; adoption of this technology has been slow, due to long-standing limitations of existing polymer MEA technology, including low channel count, bulky packaging, and lack of standardization in fabrication and implantation. By adapting semiconductor manufacturing methods to the biocompatible polymer Parylene C we have developed a new generation of polymer-based MEAs for neural recording. Our devices consist of a transparent polymer backbone, 100× softer than silicon or metal, supporting micropatterned metal recording sites. These Parylene MEAs have been validated *in vivo* in free-moving models for >1 year. Here we describe several advances in design, fabrication capabilities, and packaging methods, and present *in vitro* performance data. Our 'Standard Probe' design features 64 Pt recording electrodes (700μm^2, 50kΩ mean impedance at 1khz) supported across 4 Parylene C penetrating shanks (5mm length, 210µm max width), for cortical/subcortical recording in small-rodent models. MEAs are ultrasonically welded to custom-built PCBs for external connection, and dip-coated in a thin layer of polyethylene glycol as a temporary stiffener to aid insertion. Using this platform we can build Parylene MEAs of arbitrary shape and configuration. We have launched the Polymer Implantable Electrode Foundry, a shared technology resource, to proliferate custom polymer MEAs to academic users. Examples of recent MEA devices built in this manner include a 32 channel array for targeted recordings in mouse hippocampi, and 16 channel MRI compatible probes for recording in cat cortices and lateral geniculate nuclei. By disseminating these devices and the underlying technology we aim to establish polymer MEAs as a reliable tool for the neuroscience researcher.

Title: Large-scale multi-modal dura for non-human primates

Authors: *D. J. GRIGGS, J. ZHOU, K. KHATEEB, W. K. S. OJEMANN, A. YAZDAN-SHAHMORAD;
Univ. of Washington, Seattle, WA

Abstract: We aim to develop large-scale multi-modal cortical interfaces for non-human primates for the purpose of studying large-scale neural phenomena including neural disease, damage, and recovery. Non-human primates are critical for the development of translational neural technology because of their neurological and neuroanatomical similarity to humans, and their big brains serve as valuable models for studying large-scale neural processes. Interfaces which can capitalize on these opportunities, and particularly interfaces with multiple modalities for stimulation and data collection at a large-scales, pose us to unveil network-scale dynamics of both healthy and unhealthy neural systems.

We present a transparent electrocorticographic array useful for multi-modal experiments in non-human primates in both acute and chronic scenarios. The array is composed of conductive traces printed into medical grade polymer to produce an electrocorticographic array embedded into a transparent artificial dura. This array provides simultaneous neurophysiological recordings and optical access to the cortex and it has been designed to provide an effective window of optical access on the order of months. The array is the centerpiece of the interfaces we have designed to support electrocorticographic recording and stimulation, cortical imaging, and optogenetic experiments, all at the large-scales afforded by the brains of non-human primates. We have made improvements to our past work in the areas of array flexibility, corrosion resistance, and photoelectric artifact mitigation.

Electrical and optical experiments were performed bench-side and acutely *in vivo* with macaques to validate the utility of our array. To provide representative data of the *in vivo* performance, we present optical coherence tomography angiography cortical data collected through the array and electrocorticography recordings and stimulation with the array.

The results indicate that our interfaces are suitable for large-scale electrocorticography, large-scale cortical imaging techniques and, by extension, large-scale optogenetic experimentation. These interfaces prepare the way for both acute and long-term chronic experiments with complimentary data collection and stimulation modalities. When paired with the complex behaviors and cognitive abilities of non-human primates, these assets position us well to study large-scale neural phenomena including neural disease, damage, and recovery.

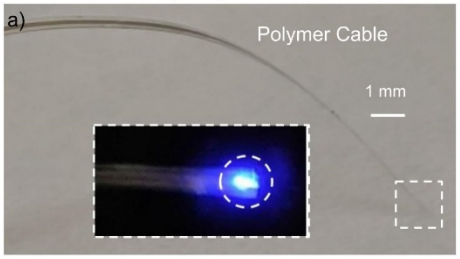
Title: Micro-led neural probes on flexible polymer substrates for bi-directional electrical and optical neural interfaces

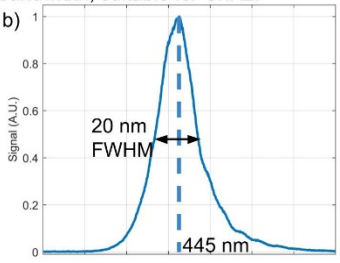
Authors: *J. W. REDDY, I. KIMUKIN, L. T. STEWART, Z. AHMED, A. L. BARTH, E. TOWE, M. CHAMANZAR;
Carnegie Mellon Univ., Pittsburgh, PA

Abstract: To enable high-resolution neural interfaces for closed-loop optogenetic experiments in deep tissue, optical stimulators and microelectrode arrays must be integrated into a single implantable device. Additionally, a fully-flexible architecture using thin-film microfabrication and flexible polymer substrates reduces tissue damage from implantable neural probes during chronic experiments. Micro-light-emitting diodes (micro-LEDs) are traditionally fabricated on rigid silicon and sapphire substrates and then either thinned to make an implantable shank, or released and transferred to a new flexible substrate. However, a monolithic fabrication process can achieve a very high device density with any desired arrangement of light sources. Here, we demonstrate our integrated neural probe platform for compact 22 µm x 22 µm micro-LEDs monolithically integrated with recording microelectrodes on a flexible Parylene C polymer substrate (Figure 1a). Parylene C acts as a flexible, biocompatible, and highly impermeable insulation and substrate material. We demonstrate gallium nitride micro-LEDs with an emission wavelength of 445 nm, suitable for stimulating Channelrhodopsin-2 (ChR2) (Figure 1b). The micro-LEDs can generate power densities up to 12.4 mW/mm2, significantly above the optogenetic threshold of stimulation for ChR2. LED arrays are shown in 1D and 2D configurations in densities of up to 400 LEDs/mm2. The high-density, high-power micro-LED stimulation raises concerns of tissue heating, since unlike rigid silicon substrates, polymers are less effective at dissipating heat. We present a thermal simulation framework to identify thermally-safe stimulation paradigms (Figure 1c). We will discuss the fabrication process, simulation results, and device validation using transgenic mice.

a) Microfabricated polymer cable containing GaN micro-LEDs in a Parylene C substrate, with single device illuminated (inset).



b) LED emission spectrum centered at 445 nm with 20 nm FWHM bandwidth, suitable for ChR2.



c) Tissue heating (°C) after 5 ms LED optical stimulation at 4.8 µW power.

Title: Label-free functional characterization of human brain organoids at single-cell resolution

Authors: S. SAJGO, G. ZORZI, ***M. J. OBIEN**;
MaxWell Biosystems AG, Zurich, Switzerland

Abstract: Three dimensional organ-like cell aggregates (organoids) that originate from human induced pluripotent stem cells (h-iPSCs) are emerging as promising tools for investigating development and disease progression, as well as for drug discovery. Organoids from h-iPSC-derived neurons recapitulate the architectures and characteristic functions of different brain areas that can be used to model human disease in-vitro. In order to adopt brain organoids for rapid and cost-effective drug screenings, it is necessary to assess their cell type composition, gene expression patterns and physiological function.
The electrical activity of brain, retina or muscle organoids can now be easily captured, label free, at single-cell resolution by using MaxWell Biosystems' high-density microelectrode array (HD-MEA) technology—MaxOne (single-well) and MaxTwo (multi-well)[1]. The HD-MEA's large sensor array, featuring 26,400 electrodes at high-resolution enables recording of neuronal activity across different scales, from the network level, single-cell level, down to the sub-cellular level.
Three different neuronal assays have been implemented in the software, MaxLab Live, and used to evaluate the spontaneous activity of brain organoids. (A) The ActivityScan Assay allows detection and identification of all active areas in the organoid. Firing rate and amplitude of the action potentials can be extracted. (B) The Network Assay enables the analysis of network bursts and synchronicity, indicating formation of connectivity between neurons. (C) The AxonTracking assay identifies single neurons and provides metrics such as axonal conduction velocity.
In this work, we present results from organoids modeling different brain compartments and will demonstrate the potential of HD-MEA technology for characterizing the physiological function of human brain organoids and for testing compounds.

Title: Development and characterization of an in vitro synaptic propagation assay using optogenetics and multiwell microelectrode array technology

Authors: *D. C. MILLARD, A. NICOLINI, F. GOODFELLOW, H. HAYES;
Axion Biosystems, Inc., Atlanta, GA

Abstract: Synaptic connections are a fundamental building block of neuronal function, enabling neuronal circuits to process and relay information downstream via action potential propagation. Indeed, many neurological disorders involve impaired connectivity between distinct brain regions. However, traditional in vitro "disease-in-a-dish" neuronal models comprise only a single neuronal circuit, whereas animal models are too costly and complicated to facilitate a screen on compounds or genetic edits that affect synaptic propagation. Here, we describe the development and characterization of a simple in vitro assay of synaptic propagation between two distinct neural circuits. First, an easy-to-use, two-compartment silicone insert was added to each well of a 6-well microelectrode array (MEA) plate. Cryopreserved rodent primary cortical neurons were prepared and seeded into each compartment of the silicone inserts. An adeno-associated virus was added to transduce the cells of each compartment with a distinct optogenetic construct (Chronos vs. Chrimson). After two days in vitro, the silicone insert was removed and the networks allowed to mature. The development of functional network activity (e.g., activity, synchrony, oscillations) was monitored every 2-3 days throughout the cell culture period. Activity and synchrony developed first (~7-10 days) within the networks originally defined by the two-compartment silicone insert, followed by the propagation of network activity from one compartment to the other (~14-17 days). Optogenetic stimulation was used to selectively stimulate one network at a time within each well of the plate while the electrophysiological activity was monitored from the second network. The evoked synaptic propagation was evaluated for each well at baseline, after treatment with either the vehicle control or a cocktail of synaptic blockers (CNQX, APV, Bicuculline), and then following washout. The effect of the synaptic blockade was quantified as the probability and delay of synaptic propagation in response to the optogenetic stimulus. These results support the continued development and use of in vitro neuronal models and MEA technology for drug toxicity and safety assessment, evaluation of phenotypic disease-in-a dish models, and cell development.

Title: Observing neuronal ensemble based on synaptic connectivity estimation on high-density microelectrode array

Authors: *T. ASAHINA, K. SHIMBA, C.-H. CHANG, K. KOTANI, Y. JIMBO;
The Univ. of Tokyo, Tokyo, Japan

Abstract: Neuronal ensemble is important because it is an essential unit of information processing in the brain. One of the major problems about neuronal ensembles is difficulty of observation. Neuronal ensemble consists of tens of thousands of neurons and the large number of neurons makes it difficult to record the whole activity of neuronal ensemble. In this study, we developed a novel method to estimate activities of unobserved neurons from local spike recordings. Using the proposed method, we observed multiple patterns of neuronal ensembles from extracellular spike recording. A computational model was established to estimate summation of functional synaptic connectivity to a single recorded neuron from many other neurons. When a neuronal ensemble is activated, single recorded neuron receives synaptic inputs from many surrounding neurons of which the neuronal ensemble consists. Under the assumption that every recorded neuron receives inputs simultaneously from all neurons in the active neuronal ensemble, the summation of synaptic connection to each recorded neuron was estimated based on membrane potential calculations. By using this estimation method, optimal connectivity summation patterns can be obtained reflecting activities of all recorded neurons for a long term. The proposed method was applied to spike trains which were recorded from cultured neuronal networks to distinguish multiple neuronal ensembles. Spike trains were recorded from rat cortex neurons cultured on high-density microelectrode array. Neuronal activities were recorded from four samples around a month of their culturing. Spike trains were recorded from 1,024 electrodes for more than twelve hours for each sample. Synchronized bursts were detected from spike trains and the synaptic connectivity summations were estimated for each detected burst. The estimated synaptic connectivity summation patterns were regarded as feature values of the bursts. As a result, transitions from one active neuronal ensemble to another active neuronal ensemble were observed in the form of synaptic connectivity summation pattern changes. Moreover, the observation of multiple neuronal ensembles from only 50 electrodes using the proposed method was as clear as the observation from 1,024 electrodes using a simple conventional method (clustering based on basic statistics of bursts). And the observation of multiple neuronal ensembles from 1,024 electrodes using the proposed method was clearer. From this result, we conclude that the proposed method is useful for estimating neuronal ensemble activity in wide areas from local recordings.

Title: Morphological and electrophysiological phenotypes in Angelman syndrome iPSC/hESC-derived neurons

Authors: *D. GORKA[1], J. BLOOM[2], C. SIROIS[2], L. LOEW[3], E. LEVINE[2], S. CHAMBERLAIN[1];
[1]Dept. of Genet. and Genome Sci., [2]Dept. of Neurosci., [3]Dept. of Systems Biol., Uconn Hlth., Farmington, CT

Abstract: Angelman Syndrome (AS) is a neurodevelopmental disorder characterized by motor dysfunction, intellectual disability, severe seizures, absent speech, and a happy demeanor. The disorder is caused by a deletion or mutation of the maternally inherited allele of *UBE3A*. The paternal copy in the brain cannot compensate for this loss because it is subject to silencing via genomic imprinting by the *UBE3A* antisense transcript (*UBE3A-ATS*). Using AS patient specific derived induced pluripotent stem cells (iPSCs) and their neuronal derivatives as a model system, we sought to identify phenotypic differences between human AS neurons and healthy control neurons to pinpoint the primary cellular deficits in AS in order to potentially reveal how neuronal physiology contributes to the neurological and behavioral deficits in individuals with AS. Using CRISPR/Cas9, we have generated two distinct isogenic AS and control human pluripotent stem cell pairs. For the first pair, we correct a C to T transition resulting in a phenylalanine to serine missense mutation in the maternally-inherited copy of *UBE3A* in iPSCs derived from a 7-year old male with AS. This missense mutation kills the enzymatic activity of *UBE3A* but causes no reduction in RNA or protein levels. The second isogenic pair was generated by deleting the maternal copy of *UBE3A* in H9s, a female human embryonic stem cell (hESC) line. Whole cell patch clamping was used to assess electrophysiological phenotypes in forebrain cortical neurons derived from these two isogenic pairs. Both isogenic pairs showed that AS neurons displayed a more depolarized resting membrane potential and impaired action potential firing compared to their isogenic control. Confocal imaging to interrogate morphological differences in the isogenic pairs found that mature AS neurons have a decreased density of dendritic protrusions, decreased soma size, and decreased dendritic branching compared to their isogenic control. Altogether, these findings identify novel cell intrinsic and network-dependent cellular phenotypes in human AS neurons and provide a framework for identifying the neuronal deficits that contribute to the human AS symptomology. These data also

provide a phenotypic readout that may be able to more accurately predict the effectiveness of different drug treatments in ameliorating AS-related deficits.

Title: Impaired Neural Induction and Neuronal Differentiation in a Novel Cerebral Organoid Model of NIBP Syndrome

Authors: *B. BODNAR, Y. LIN, Y. ZHU, W. HU;
Ctr. for Metabolic Dis. Research, Dept. of Pathology and Lab. Med., Lewis Katz Sch. of Med. at Temple Univ., Philadelphia, PA

Abstract: NIBP (NIK-and-IKK2-binding protein; also known as TRAPPC9), is an important mediator of both NFκB signaling and protein transport/trafficking. Increasing clinical evidence shows that homozygous mutations of *NIBP/TRAPPC9* has been linked to a novel autosomal recessive intellectual disability syndrome, NIBP Syndrome. Patients with NIBP Syndrome exhibit various symptoms including intellectual disability, developmental delays, microcephaly, dysmorphic facial features, and obesity. While clinical findings suggest this is due to absent or decreased levels of functional NIBP protein, the cellular mechanisms underlying this phenotype is still unclear. In order to elucidate the pathogenesis resulting from NIBP deficiency, we generated cerebral organoids (COs) from induced pluripotent stem cells (iPSCs) derived from three NIBP Syndrome patients and two healthy subjects as controls. While there were no significant differences in iPSC propagation or embryoid body formation between patient and control lines, there were robust differences in CO formation and maturation. Control COs readily formed neuroepithelial tissue and neural stem/progenitor cells (NSC/NPC) during neural induction and matured in a typical fashion, but patient COs often formed numerous abnormal sizes and shapes, had decreased neuroepithelial tissue, and grew more slowly or died off, suggesting an impairment of neural induction. Intriguingly, there was varying degree of severity of impairment and structural change among different patient COs. To further examine the impact of NIBP deficiency on neural lineage differentiation, some COs were dissociated after neural induction to generate monolayer NSCs/NPCs. The control NSC/NPCs readily formed neurospheres or differentiated into neural cells including neurons with long thin processes projecting outwards; however, patient NSC/NPCs displayed very little morphological changes, with most projections being bipolar or unipolar, suggesting impaired neural differentiation. Long-term neuronal differentiation/maturation studies showed impaired neural network and

synaptic plasticity, with the majority of patient NSCs/NPCs failing to differentiate into mature neurons. In conclusion, we find evidence of neurogenic deficits related to NIBP Syndrome in an innovative, novel, and clinically relevant model in an effort to help elucidate pathogenic mechanisms underlying a serious neurodevelopmental disorder.

Abstract: Across many contexts, including sleep, anesthesia, and the vegetative state, EEG delta waves (1 – 4 Hz) are a signature of unconsciousness. How is it then that children with Angelman syndrome (AS), a genetic disorder caused by dysfunction of *UBE3A*, display extremely high voltage delta activity while awake and conscious? AS is highly penetrant for intellectual disability, epilepsy, and motor delays, yet children with AS display a rich spectrum of behaviors that indicate conscious awareness. Understanding this paradox (an EEG signature of sleep accompanying wakeful behavior) is important for deriving robust EEG markers of covert consciousness in unresponsive brain-injured patients with disorders of consciousness (i.e., what EEG features, if not delta power, reliably indicate that a person is unconscious?). To investigate this mystery, we looked at EEG signal complexity as an alternative marker of conscious state. We compared the modified multiscale entropy (mMSE) and the generalized multiscale Lempel-Ziv complexity (gMLZ), two measures of signal complexity, between wakefulness and sleep (within-subject) in 23 children with AS and 23 age matched TD controls (mean age of 68 months, both groups). 19 channel EEGs were bandpass filtered 0.5 – 45 Hz and artifact reduced. We averaged both complexity measures across 19 channels and 20 timescales. mMSE and gMLZ

both showed a significant ($p < 0.005$) main effect of sleep and group x sleep interaction (two-way repeated measures ANOVA), but only gMLZ showed a significant main effect of group. Complexity values indeed differentiate sleep from wakefulness in AS, but the separation (as measured with mMSE) is not as large as TD, and the mean awake level of complexity in AS (as measured with gMLZ) is still less than the sleeping level of complexity in TD, suggesting that complexity does not benchmark conscious level consistently across groups. Next, using regularized logistic regression, we trained a binary classifier on complexity values from 35 AS EEGs and then validated the model on 41 TD EEGs (these were larger, non-age matched cohorts). The classifier yielded 71.4% sleep/wake accuracy for AS and 92.7% accuracy for TD; the higher accuracy for TD was likely due to a simpler feature space boundary that differentiated sleep/wake for this group. We conclude that although the absolute level of complexity in AS may erroneously suggest that children are unconscious while awake, biomarkers of conscious state in AS nonetheless appear to generalize to healthy controls, as demonstrated using logistic regression. The paradoxical cortical dynamics in AS may therefore serve as a crucible for validating biomarkers of conscious state.

Title: Chronic intermittent theta burst stimulation (iTBS) effects on adult hippocampal neurogenesis in males and females

Authors: ***T. ZHANG**, B. ASKARI, A. KESICI, E. M. GUILHERME, F. VILA-RODRIGUEZ, J. S. SNYDER;
Univ. of British Columbia, Vancouver, BC, Canada

Abstract: Intermittent theta burst stimulation (iTBS) is a promising form of non-invasive stimulation therapy for a variety of psychiatric illnesses. Currently, iTBS is administered similarly across males and females, but it is not known whether iTBS's mechanism of action is affected by patient sex. As hippocampal neurogenesis plays a critical role in stress adaptation and antidepressant course of action, we examined adult hippocampal neurogenesis in male and female mice following a chronic iTBS protocol similar to those used in the clinics. Although chronic iTBS does not exert dramatic effects on neurogenesis, we found that there is a trend for a

greater population of immature neurons after iTBS in males, but not females. Females do not respond to iTBS with respect to any hippocampal neurogenesis related measures. There is no effect on iTBS on the survival of neurons born one week before stimulation for either sex. We also examined the morphology of new-born neurons and found that iTBS produced a trend for a slight decrease in spines in stimulated animals compared to sham stimulated animals. New neurons generated in either sex have normal morphology, similar to non-stimulated control animals, with the exception of females overall have lower total dendritic length compared to males. Otherwise, all comparisons between male and female new-born neurons are consistent with each other, indicating that baseline neurogenesis levels and new-born neuron morphological features are comparable between sexes. Our findings suggest that iTBS's primary target on neuroplasticity may not be adult hippocampal neurogenesis, however, there may be physiological differences of new-born neurons that are influenced by iTBS that remains to be further explored.

Sch. of Med., Stanford, CA; [8]Univ. of Toronto, Toronto, ON, Canada; [9]Structural Genomics Consortium (SGC) Toronto, Toronto, ON, Canada

Abstract: Drug development in Alzheimer's disease (AD) has been marked by repeated failures. Increasing evidence supports the need for a diverse portfolio of therapeutic and diagnostic targets in order to effectively reduce the burden of AD. The Emory-Sage-SGC TREAT-AD Center was established with the aim at developing drugs for a diverse portfolio of therapeutic approaches to break the cycle of failure, by focusing on research advances in two key areas. One focus is to cast a wider net and develop drugs that target the multifaceted dysregulation in the brains of AD patients, rather than two key pathological hallmarks. The second is using open scientific

practices to speed up drug development for new therapies. The Emory-Sage-SGC TREAT-AD Center has identified a diverse set of novel AD targets derived from systems biology studies within the Accelerating Medicines Partnership in AD (AMP-AD) consortium and further evaluated using data from multiple AD consortia and existing literature. Targets nominated through the AMP-AD consortium were mapped to mechanistic hypotheses and prioritized based on unbiased bioinformatic assessments across multiple lines of evidence. Hypotheses prioritized in the initial evaluation included those relating to immune function, endocytosis, and retromer-mediated endosomal protein sorting. To engage the research community to pursue emerging targets in AD, the center is generating and openly distributing experimental tools for use in target validation to advance or reject therapeutic hypotheses. Distribution of all data and Target Enabling Packages that include expression constructs, knockout cell lines, assays, antibody validation data, and crystal structures for 20 proteins identified within these mechanisms will be publicly shared through standard repositories and cataloged on the Agora website, a data visualization portal funded by the NIA and developed by Sage Bionetworks. The open drug discovery approach of TREAT-AD is aimed to de-risk potential AD therapeutics to support industry investment by catalyzing robust and independent evaluation of a diverse portfolio of promising yet untested AD therapeutic hypotheses.

Title: Retinal hyperspectral changes in a mouse model of Parkinson's disease

Authors: *C. T. O. NGUYEN[1], P. TRLIN[1], K. K. N. TRAN[1], V. H. Y. WONG[2], D. ZHAO[1], J. K. H. LIM[3], D. I. FINKELSTEIN[4], A. METHA[1], B. V. BUI[1], P. BEDGGOOD[1];
[1]Optometry and Vision Sci., [2]The Univ. of Melbourne, Parkville, Australia; [3]Flinders Univ., Adelaide, Australia; [4]Florey Inst. of Neurosci., Parkville, Australia

Abstract: Purpose: The retina is an accessible out-pouching of the central nervous system and may reflect cortical changes that occur with Parkinson’s disease (PD). In vivo hyperspectral imaging is a non-invasive means to image the retina and has shown promise as an indicator for central nervous system conditions in animal models and human patients. This is the first study to evaluate whether hyperspectral imaging is altered in a well-characterized mouse PD model of

alpha-synuclein overexpression and whether this changes with advancing age. **Methods:** A transgenic mouse model of alpha-synuclein deposition (A53T) and wild-type littermates were assessed at 6 and 14 months old (n = 10-24 / group). Hyperspectral imaging of the retina centred around the optic nerve head was conducted from 320 to 680nm in 5 nm steps (TILL Polychrome V light source, Andor Neo cMOS camera). Images were registered and blood vessels and optic nerve head were masked to isolate retinal regions of interest. Normalized spectral reflectivity was analysed using two-way ANOVA with Bonferroni correction for multiple comparisons (Prism, GraphPad), and with principle components analysis (PCA; MATLAB, MathWorks). **Results:** Six-month-old A53T mice exhibited statistically significant wavelength-selective changes using two-way ANOVA ($p < 0.05$), and a genotype effect on spectrum shape using PCA ($p < 0.05$; sensitivity 0.88, specificity 0.59). Fourteen-month-old A53T mice showed statistically significant interaction effects (two-way ANOVA; $p < 0.001$) with increased reflectivity at shorter wavelengths (< 500nm) and decreased reflectivity at longer wavelengths (> 600nm). Spectral shape differences bordered on significance using PCA ($p = 0.08$), with specificity and sensitivity of 0.75 and 0.40, respectively. Healthy ageing changes to hyperspectral imaging were examined by comparing the 6- and 14-month-old wild-type control mice. A different pattern of hyperspectral reflectivity was observed in healthy aging, with a statistically significant interaction effect ($p < 0.001$) indicating greater reflectivity at longer wavelengths (> 600nm) with advancing age. This healthy aging effect was confirmed in a separate control cohort of aging mice. **Conclusion:** A transgenic mouse model of alpha-synuclein overexpression exhibits an alteration in spectral reflectivity of the retina at mid and advanced stages of PD. The hyperspectral signature exhibited with advancing alpha-synuclein deposition is distinct from normal healthy ageing.

Title: Ultra-reflectivity as a novel ocular biomarker in mice models of Parkinson's and Alzheimer's diseases

Authors: *V. H. Y. WONG[1], H. LEE[1], D. ZHAO[1], K. K. N. TRAN[1], B. V. BUI[1], D. I. FINKELSTEIN[2], C. T. O. NGUYEN[1];
[1]Univ. of Melbourne, Parkville, Australia; [2]Florey Inst. of Neurosci., Parkville, Australia

Abstract: Purpose: Early biomarkers for neurodegenerative diseases, such as Parkinson's disease (PD) and Alzheimer's disease (AD) are needed. Optical coherence tomography (OCT) has the capability to detect changes within the eye, where retinal nerve fibre thickness alteration is present in PD and AD. This study explores the possibility that in addition to changes in tissue thickness, retinal alpha-synuclein (α-syn) and amyloid beta (Aβ) deposition may change OCT reflectivity or "ultra-reflectivity".
Methods: Two transgenic murine models were used: a human α-syn overexpression model of PD (A53T mice) and an Aβ accumulation model of AD (5xFAD mice). Sedated (ketamine: xylazine mix 80:10 mg/kg, i.p.) A53T mice were assessed at 6 and 14 months of age (n=15-17/group) and 5xFAD mice were assessed at 3, 6 and 12 months of age (n=11-12/group) and compared with their respective wild-type (WT) littermates. Three adjacent OCT B-scans (OCT2, Spectralis) across the optic nerve head (768 A-scans, axial resolution: 3.87µm, lateral: 10.29µm) were analysed to measure ultra-reflectivity at the retinal nerve fibre layer (RNFL) and the outer nuclear layer (ONL). Two-way ANOVA with Sidak correction for multiple comparisons (Prism, GraphPad) was used to compare groups.
Results: ONL reflectivity was elevated in A53T mice compared to WT_{PD} littermates ($p = 0.026$), particularly at 6 months of age. RNFL reflectivity was also significantly reduced in A53T mice compared to WT_{PD} littermates ($p = 0.011$), particularly at 14 months of age ($p = 0.003$). As such, when the difference between RNFL and ONL reflectivity is calculated ("ultra-reflectivity" = RNFL reflectivity - ONL reflectivity) there was a significant decrease in reflectivity in A53T mice at both 6 and 14 months of age ($p = 0.035$ and 0.014, respectively). There was no genotype difference in RNFL and ONL reflectivity between 5xFAD and WT_{AD} mice ($p = 0.785$). Ultra-reflectivity profiles changed in both 5xFAD and WT_{AD} ($p = 0.041$) when comparing across 3 and 12 months of age.
Conclusion: Our study demonstrates that RNFL and ONL reflectivity are useful tools in following the neurobiological changes within the eye. A53T mice exhibited changes in ultra-reflectivity measures, whereas 5xFAD mice did not. Further studies are required to better understand these reflectivity changes in relation to α-syn related pathology and normal healthy aging.

Title: Neurotheranostic for MR imaging of dopamine transporters and treatment of dopaminergic neurodegeneration

Authors: *G. VITALIANO[1], C. ADAM[2], G. ZEBALLOS[3], F. VITALIANO[4];
[1]McLean Hospital/ Harvard Med. Sch., Belmont, MA; [2]McLean Hosp., BELMONT, MA;
[3]McLean Hosp., Belmont, MA; [4]ExQor Technologies, Boston, MA

Abstract: Neurotheranostics (NTs) show great promise for diagnostic imaging and treatment of neurodegenerative disorders. NTs consist of combined CNS diagnostic and therapeutic agents and can be used to enhance MRI sensitivity and molecular targeting by delivering superparamagnetic iron oxide (SPIO) contrast agents along with antibodies. However, NTs cannot cross an intact blood-brain-barrier (BBB) limiting their use in neurology/psychiatry. Our goal was to develop a novel NT for targeted, noninvasive delivery of DAT-antibody (DAT-Ab), SPIO, and brain-derived neurotrophic factor (BDNF) to dopamine brain regions.
NTs were synthesized by conjugating DAT-Ab and SPIO for MRI (plus BDNF for treatment) to Clathrin carrier using polyethylene glycols (PEGs) at 1:1:1:1 molar ratio, and NT's size and structure were characterized. For 7 days, iTat mice received intraperitoneally doxycycline (100 mg/kg/day) to induce neurotoxic HIV-Tat protein expression. Concurrently, Tat+ mice received intranasally (i.n.) saline or NTs (BDNF, 300 µg/kg/d). For MRI, wild-type C57BL/6J mice received one dose of i.n. saline or NTs (SPIO, 68pmol, 50µL). Four hours after the last NT/saline dose, mouse brains were prepared for immunohistochemistry or *ex-vivo* MRI. Voxel-wise R2* relaxation rates were obtained using a series of gradient-echo images (TR=1.5 s, TE=3.2, 4, 5, 6, 7, 8, 9, 10 ms; 128x128 in -plane matrix; 0.2 mm resolution; 64 slices at 0.5 mm thickness; 7 averages). R2* values in the striatum (STR), substantia nigra (SN) and visual cortex (vCTX), a control region with low DAT expression, were calculated.
The iron-stained brain slices contained NTs in brain regions rich in DAT (e.g., STR). Striatal tyrosine hydroxylase densities were higher (P=0.0467) in NT vs. saline treated Tat+ mice. MRI studies of NT with DAT-Ab-SPIO revealed that R2* values were significantly higher in the STR (p=0.0010) and SN (p=0.0007) compared to vCTX in animals that received NTs, but not in saline treated animals. NTs significantly increased R2* in the STR (p<0.0001) and SN (p=0.0002) compared to saline without significantly altering R2* in the vCTX.
NTs successfully bypassed the BBB and delivered adequate concentrations of SPIO and BDNF to neurons expressing DAT in the mouse brain. NTs enabled DAT detection using MRI, and rescued striatal tyrosine hydroxylase-positive fibers from HIV/Tat neurotoxicity. Thus, Clathrin-based NTs could assist in early detection and treatment of neurodegeneration and in monitoring disease progression and recovery processes.

Title: Design and Development of Proteolysis Targeting Chimera against Cytoplasmic TDP-43 in Neurodegeneration

Authors: *K. G. BHAVSAR;
Indian Inst. of Technology, Gandhinagar, Gandhinagar, India

Abstract: Neurodegenerative disorders (ND) are increasingly recognized as the major cause of disability and deaths, currently affecting 47.5 million people globally with dementia in people aging 60 or above. One common feature linked to mostly all ND is the misfolding and aggregation of certain proteins, which generates the cascade of pathological events leading to failure to protein homeostasis in the physiological state. TAR DNA binding protein 43 (TDP-43), is one such protein responsible for Amyotrophic Lateral Sclerosis (ALS) and Frontotemporal lobar degeneration (FTLD). Physiologically TDP-43 is a regulator of gene expression, RNA processing, etc. However, the mutation in TDP-43, leads to the excess deposition and formation of misfolded toxic protein aggregates in the cytoplasm of the cell, leading to disease. The aggregation-prone proteins are pharmacologically difficult to target because of their misfolded and disordered structure. To tackle this stumbling block, we contemplated the Targeted Protein Degradation approach and developed a peptide-based Proteolysis Targeting Chimera (PROTAC) against aggregated TDP-43 degradation. PROTAC is a heterobifunctional molecule, composed of two different binding domains connected by a linker. One is for engaging an E3 ubiquitin ligase and the other for the binding to targeted protein. E3 ligase recruitment leads to the ubiquitination of targeted protein, and recognition by the Ubiquitin proteasome system for the degradation. As a protein quality control system, the UPS plays a key role in the degradation of misfolded or aggregated proteins and maintaining protein homeostasis. Our objective is to study the degradation potential of cytoplasmic mutated TDP-43 utilizing synthesized peptide-PROTAC Synthesis of the peptide-PROTACs was done via Fmoc-base solid-phase peptide synthesis methodology. The purity and characterization of the molecule were checked using RP-HPLC and MALDI mass spectrometer. TDP-43 recombination protein expressed and purified in *E.Coli* bacterial culture was performed. The Cell penetration study of the synthesized PROTAC was performed in the SH-SY5Y neuroblastoma cell line using confocal microscopy. Further, the cell viability assay was done using the MTT Assay and analyzed. Further experiments including the protein expression in SH-SY5Y cell lines are currently in process. The preliminary studies performed on peptide-PROTAC were seen to be promising and further evaluation needs to be done. Conclusion: We believe that the synthesized novel PROTAC will regulate the aggregated cytosolic TDP-43 towards the selective degradation, utilizing inherent cellular UPS.

Title: Location-specific gene co-expression modules in peripheral blood implicate neutrophilic, monocytic and lymphocytic response to spontaneous human Intracerebral Hemorrhage

Authors: B. KNEPP[1], A. YEE[1], G. JICKLING[1,2], F. RODRIGUEZ[1], K. NG[1], X. ZHAN[1], N. ALOMAR[1], M. HAKOUPIAN[1], H. AMINI[1], P. CARMONA-MORA[1], H. HULL[1], B. P. ANDER[1], F. R. SHARP[1], ***B. STAMOVA**[1];
[1]Univ. of California, Davis Sch. of Med., Sacramento, CA; [2]Univ. of Alberta Dept. of Med., Edmonton, AB, Canada

Abstract: Intracerebral Hemorrhage (ICH) occurs within the cortical (lobar) or deep intraparenchymal brain regions. Deep ICH tends to be caused by hypertension, while Lobar ICH tends to be caused by cerebral amyloid angiopathy. Since peripheral immune cells respond to ICH and contribute to damage and repair, we examined whether peripheral blood gene co-expression networks differed between Deep and Lobar ICH patients. Whole-genome gene expression for 28 ICH patients (19 Deep, 9 Lobar) and 33 Vascular Risk Factor Controls (VRFC) was examined on HTA 2.0 microarrays. Weighted Gene Co-Expression Network Analysis was performed on 10,200 protein-coding genes and generated 31 co-expressed gene modules. Of these, 7 were significant ($p < 0.05$) in a Lobar ICH vs VRFC contrast and 6 in Deep ICH vs VRFC (Fig. 1). There were 3 significant modules (Fig. 1) common between the two. They were significantly enriched in monocyte- and neutrophil-specific genes. Additionally, one of these modules was also enriched in T Cell-specific genes. The Lobar ICH-specific modules were enriched in monocyte, neutrophil and B-cell specific genes, while one of the Deep ICH-specific modules was enriched in T cell specific genes. The Lobar- and Deep ICH-common modules were overrepresented (adj. $p < 0.05$) in inflammatory pathways such as Interleukin-(1,2,6,10,12, and 17A), Inflammasome, Neuroinflammation, Acute Phase Response, and B Cell Receptor Signaling. Lobar unique modules were also overrepresented in Phagosome Formation, Granulocyte Adhesion and Diapedesis, and PI3K Signaling in B Lymphocytes. Deep ICH-unique modules were overrepresented in T Cell pathways, such as Th1 and Th2 Activation, T Cell Exhaustion, and T Cell Receptor Signaling. Our current data suggest common and specific monocyte, neutrophil, T-cell, and B-cell involvement in Lobar and Deep ICH. Collectively, these results give additional evidence for a specific pathophysiology and transcriptome architecture

based on ICH location. Our exploratory findings may guide the search for location-specific potential therapeutic targets.

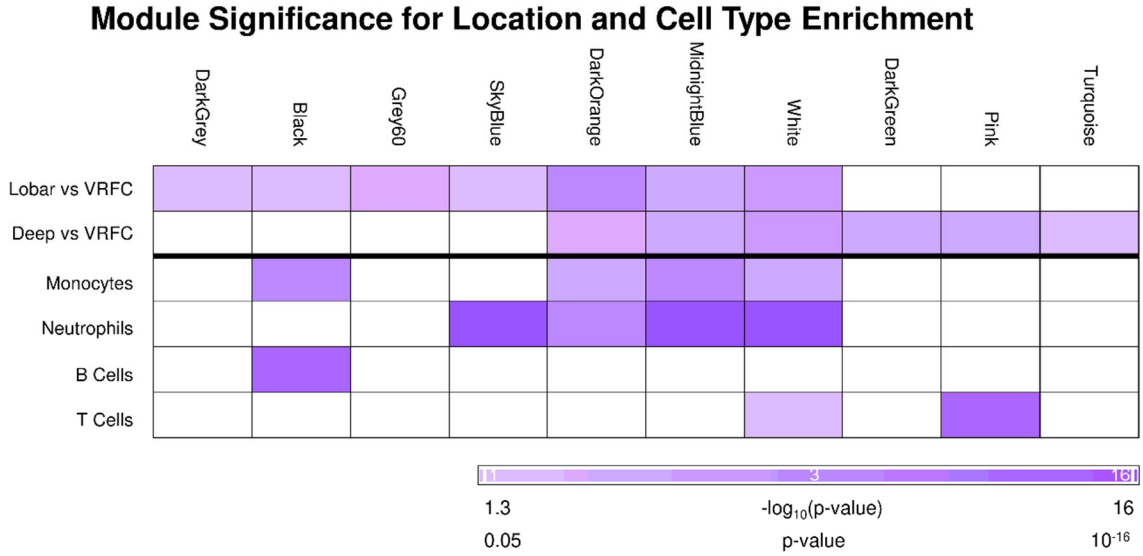

Figure 1 Module significance for ICH location as well as cell type enrichment of all modules significant to at least one location comparison. Shaded boxes show -$\log_{10}$(p-value); white boxes represent non-significance. Location comparisons were done on an ANCOVA that accounted for the covariate Age. Cell type enrichment was found using hypergeometric probability testing based on module's overlap with known cell type specific gene lists.

Title: Artificial intelligence assisted feature selection for novel and translatable quantitative electroencephalography biomarker discovery

Authors: L. GOU[1], D. J. GRAZIANO[3], *M. M. SIDOR[4], B. MAGNUSSON[2];
[1]Novartis Pharma AG, East Hanover, NJ; [2]Novartis Pharma AG, Basel, Switzerland; [3]Novartis Inst. of BioMedical Res., Cambridge, MA; [4]Deepcure Inc., Boston, MA

Abstract: Electroencephalography (EEG) is a noninvasive neuroimaging technique that records small voltage fluctuations at the scalp that result from the summed activity of the underlying cortical neurons. EEG biomarkers play a valuable role in the early diagnosis of many neurological disorders, in the monitoring of disease progression, and for determining the effects

of pharmacological treatment on the brain. However, canonical quantitative EEG (qEEG) biomarkers are often limited to pre-defined frequency bins (designated as Greek letters such as alpha, theta, and gamma waves) that impose constraints and bias data analyses. As such, there is an urgent need for identifying more sensitive and robust qEEG biomarkers. In this analysis, we built a machine learning model to enable the unbiased detection of novel EEG biomarkers that takes into account the temporal dynamics of the EEG signal. This is especially important in cases where spectral differences are not expected to be static, such as for pharmacological biomarker discovery, whereby pharmacodynamic effects are dependent on the drug's pharmacokinetic profile, and in cases of brain-state dependent spectral changes. Given the temporal dynamic of EEG signals, we used a recurrent neural network (RNN) model to ingest and capture the time-series EEG data and to automatically select optimal qEEG features. We developed and implemented various time-series data augmentation techniques to increase the size and diversity of training data for robust and generalizable training of the RNN models. We also evaluated different model architectures and hyperparameters. As a result, we achieved a reliable model with high classification performance. By analyzing the feature importance, specific frequency bins were obtained as potential qEEG biomarkers in a genetic mouse model with relevance to bipolar disorder and schizophrenia. We are currently integrating our models with an Amazon Web Services-based Streamlit processing and visualization pipeline to identify novel EEG biomarkers over hundreds of mice with an easy to use, scientist-friendly interface.

Title: Structural neuroadaptative changes as a consequence of alcohol use disorder: A pilot study.

Authors: *D. A. VALDEZ[1], A. LÓPEZ-CASTRO[1], S. ALCAUTER[2], E. GARZA-VILLARREAL[3];
[1]Univ. Nacional Autónoma De México (UNAM), Querétaro, Mexico; [2]Inst. De Neurobiologia. Univ. Nacional A, Queretaro, Mexico; [3]Univ. Nacional Autónoma de México (UNAM), Querétaro, Mexico

Abstract: Alcohol use disorder (AUD) is a complex neuropsychiatric condition that combines behavioral, neurobiological, and psychosocial alterations. The development of AUD has been characterized as a three-stage cycle. We need behavioral models that capture AUD aspects. These three stages can modeled in animals with the assumption that they emulate the human AUD characteristics. Longitudinal neuroimaging analysis of structure may help us understand

the neuroadaptive changes in the brain as a consequence of AUD. We implemented a pre-clinical AUD, the Intermittent-Access Ethanol 2-Bottle-Choice Drinking Paradigm (IA2BC). The model started in P45 with n=3 (2 female) Wistar rats with continuous-Access 10%-20% ethanol on a 12-hour reversed light/dark cycle (7 am). Brain structutral images were acquired using a Bruker 7T MRI scanner with a 2x2 surface array rat coil using a FLASH sequence. First acquisition was before the IA2BC model as baseline, and the second MRI acquisition was after finishing the 20 sessions (45 days) of ethanol intake. All images were preprocessed by: center image, denoising, and N4-Bias Field Correction. We used deformation-based morphometry to create Jacobian maps per subject and time point using an in-house pipeline, Two Level DBM based on ANTS based on Fisher atlas parcellation, with mixed model GLM and correction for multiple comparisons using an FDR 5%. The main alcohol intake (g/kg/24hrs) was 3.64 ± 0.66 (mean/sd). We found local structural changes after 20 sessions of alcohol consumption in several brain regions. When evaluating the changes in deformation-based morphometry in rats, in both logistic models we did not find any significant coefficients of brain changes related to a specific stage. Conclusions We found robust local neuroadaptive structural changes related to chronic voluntary alcohol use in a small sample of Wistar rats. Our future study will include a sample of 48 rats as well as functional connectivity analysis and immunofluorescence techniques to understand the functional microstructural neuroadaptive changes related to AUD.

Title: Clinical predictions in CNS drug discovery based on in vivo systems response profiles and non-linear machine learning methodology

Authors: K. GRANBOM[1], F. WALLNER[2], P. SVENSSON[2], *S. HOLM WATERS[2], J. KULLINGSJÖ[2], N. WATERS[2], A. ANDERSSON[3,4];

Abstract: Background
The Integrative screening Process, ISP, is a CNS drug discovery platform based on in vivo phenotypic profiling (Waters et al, ACS Chem Neurosci, 2017). Systems response profiles capturing pharmacological effects on neurochemistry, behaviour and gene expression are uniformly collected for all test compounds of interest, and analysed by linear dimensionality reducing methods such as principal component analysis (PCA) and partial least squares regression (PLS). This approach enables visualization of trends and clusters among therapeutic classes, as well as prediction of therapeutic class for novel compounds, while maintaining full transparency regarding underlying biological effects and differences in response profiles. However, non-linear features, such as non-monotonous dose response patterns are less well modelled. In this work we wanted to explore if non-linear methods could capture more information and improve the models and predictions.
Methods
Nonlinear analysis methodology was applied for the analysis of multidimensional in vivo pharmacological dose-response data (post mortem neurochemistry in several brain regions, behavioural patterns) on a broad array of CNS therapeutics and exploratory compounds from different therapeutic or mechanistic classes. Kernel PLS and t-distributed stochastic neighbor embedding (tSNE) were applied for dimensionality reduction and visualization. Classification of compounds into clinical classes based on therapeutic usage was performed using multinomial logistic regression as well as random forest and multi-layer perceptron networks. Based on performance metrics (precision, recall, F1 score), the best performing classifier was applied on a separate set of 85 compounds.
Results and conclusion
Results from nonlinear dimensionality reduction methods yielded similar results, compared to linear methods. However, in particular t-SNE modelling resulted in somewhat different clustering and appears promising to build upon in further applications. The best performing classification method, the perceptron network, shows results corresponding to well known effects for 71% of the compounds evaluated. Moreover, classifications of 12% of the compounds indicate potentially unknown effects, which are interesting and could be a springboard for further

analysis. In conclusion, based on in vivo phenotypic response profiles, non-linear classification methods, in particular multilayer perceptrons, performed well in terms of correct classifications, and further, indicated potential new classes of interest in several cases, suggesting use eg for drug repurposing purposes.

Title: Driving progress in biomarkers of neuropsychiatric disease: RAPID-Dx's metabolomic cross-platform comparison study

Authors: *L. CHABY[1], H. C. LASSETER[2], A. THOMPSON[1], T. VAUGHAN[1], L. LANCASHIRE[1], M. HAAS[3], A. JEROMIN[1];
[2]Dept. Psychology, [1]Cohen Veterans Biosci., Cambridge, MA; [3]Cohen Veterans Biosci., New York, NY

Abstract: *Objectives*: Biomarker discovery and validation will require large scale 'omics investigations across diverse populations, yet the integration and replication of 'omics data remains a key challenge in neuropsychiatric research. To determine replicability and reliability of analytical approaches in leading biomarker modalities and facilitate analysis at the scale needed for biomarker discovery, Cohen Veterans Bioscience - through its Research Alliance for

Precision Therapeutics, Innovation and Diagnostics (RAPID-Dx) Program - is conducting cross-platform comparisons in multiple domains of interest for neuropsychiatric disease, with findings in inflammation recently published (Lasseter, et al. *Cytokine X* 2020). Current efforts are directed at metabolomics, which provides a global assessment of metabolites resulting from biochemical activity and can be a powerful tool for understanding complex mechanisms of disease.
Methods: We conducted a systematic literature review of metabolomics efforts in PTSD to structure an evaluation of technical performance and dynamic range of metabolomics assay platforms. Clinical and healthy control biospecimens as well as technical standards were utilized for comparisons across and within platforms. Coverage and platform performance was mapped for metabolites implicated in PTSD through (i) case-control studies and (ii) genome-wide association studies (GWAS) of PTSD.
Results: Our systematic review revealed that prior efforts in PTSD have largely relied on discovery-based approaches and workflows. PTSD findings varied across metabolomics techniques, but emphasized essential and long chain fatty acids. Of metabolites implicated in PTSD, platform coverage ranged from 25-80%. For metabolites associated with PTSD GWAS loci, e.g. PARK2, coverage varied from 5-90%. Technical performance varied across analytical workflows; for example, coefficients of variation (CV%) within assays for duplicate PTSD samples ranged from 0.4-76.1%.
Conclusion: The metabolomics cross-platform comparison will help identify the best assay platforms to discover the metabolomic signature of PTSD. Further, this work has generated a metabolomics database to facilitate recommendations across clinical states. Together with findings from the RAPID-Dx inflammatory-markers cross-platform comparison, this study highlights the importance of considering assay performance in interpreting and designing biomarker studies. RAPID-Dx will continue conducting cross-platform comparisons across domains of interest for neuropsychiatric disease, with planned evaluations for transcriptomics and epigenetics.

Title: Development and characterization of in vitro perineural invasion model to study peripheral nerve-cancer cell interaction

Authors: *S. DWIVEDI, M. BAUTISTA, A. KRISHNAN;
Dept. of Anatomy, Physiology, and Pharmacol. & Cameco MS Neurosci. Res. Centre,, Univ. of Saskatchewan, Saskatoon, SK, Canada

Abstract: Perineural invasion (PNI) is the invasion of cancer cells in and around nerves influencing the pathological characteristics of malignant tumors, usually associated with low survival rate and poor prognosis of patients. PNI is often characterized by neuropathic pain, sensory and motor dysfunction, paralysis and disfigurement. The mechanism associated with PNI is not well-understood due to lack of relevant *in vitro* models. We developed for the first time a 3D culture model that recapitulates the PNI features observed *in vivo*. Our approach involves co-culture of thoracic or lumbar dorsal root ganglia (DRG)-nerve explant with cancer cells in Matrigel. Using the breast cancer cells MDA MB 231 and prostate cancer cells DU145, we demonstrated that seeding the cells at specific orientation and distance from the nerve ending promotes PNI *in vitro*. Visualization of nerve invaded cancer cells was done by immunostaining of cancer cells using cytokeratin or by using e-GFP tagged cancer cells. Characterization of PNI events over two weeks showed selective migration of cancer cells towards nerve endings by interacting with neurites and glial cells during the initial days of culture. By 7-10 days, the cancer cells surrounded the entire DRG-nerve. Fluorescence microscopy of cytokeratin stained/eGFP labelled cancer cells in DRG-nerve sections demonstrated the presence of cancer cells within nerve layers. The number of cells within the nerve layers increased in a time-dependent manner over two weeks. The changes in sensory axons and glial cells that are in contact with cancer cells within nerves were visualized using NF200 and GFAP/S100beta staining. We also confirmed the proliferation status of nerve-invaded cancer cells in contact with axons/glial cells using the cell proliferation marker Ki67 and by visualizing BrdU uptake. Overall, this new model will serve as a tool to study the fundamental mechanism/s of PNI. This model will also serve as a screening tool for developing PNI therapeutics for the management of cancers.

Title: Modeling and Characterization of Single Cytoskeleton Filaments

Authors: *E. ALVA;
Univ. of Texas At San Antonio.

Abstract: A variety of biological functions of cytoskeletal filaments involve the formation of high order structures such as bundles and network arrangements which mainly depend on their individual electrostatic, semi-flexibility, and polymerization degree properties, as well as, the biological environment. In this presentation, we introduce an unprecedented modeling and characterization of single cytoskeleton filaments. We combined accurate models and multi-scale theories to characterize polyelectrolyte properties of actin filaments including the electric potential and charge, electrophoretic mobility, filament length distribution, semi-flexibility, and

hydrodynamic size.
Additionally, we performed Dynamic Light and Electrophoresis Scattering experiments on actin filaments in solution at dilute concentrations to measure their diffusivity (hydrodynamic sizes) and electrophoretic mobility (surface electric potentials) in physiological conditions. We optimized the formulation by adjusting some, otherwise unknown, atomistic-scale parameters to reproduce the experimental results. We used several polymerization buffers and pH electrolyte solutions to characterize these actin filament properties in a variety of biological conditions. Our preliminary results on the diffusion coefficient show a correlation between the nucleation/elongation and the ATP concentration. A buffer with high concentration of ATP resulted in a high diffusion coefficient of, i.e. 6.44 ± 0.153 um^2/s, in contrast to a lower diffusion coefficient of, i.e. 1.39 ± 0.0714 um^2/s, using less amount of ATP. Based on the theoretical approach, we concluded that high ATP concentration results in faster nucleation of G-actins followed by a faster formation of short actin filaments. This, in turn, generates a high diffusion coefficient. Whereas, lower concentrations of ATP result in longer nucleation times of G-actins. This forms longer actin filaments which lead to lower diffusion coefficient values.

Title: Multi-scale modeling of morphologically realistic neurons under transcranial magnetic stimulation

Authors: *S. SHIRINPOUR[1], N. HANANEIA[2], J. ROSADO[3], C. GALANIS[4], A. VLACHOS[4], P. JEDLICKA[2], G. QUEISSER[3], A. OPITZ[1];

Abstract: Transcranial Magnetic Stimulation (TMS) of the dorsolateral prefrontal cortex is currently utilized as a non-invasive neuromodulation tool for the treatment of depression. Nevertheless, the basic mechanisms underlying TMS effects at the neuronal level are largely unknown. Since the recording of single-unit activity *in vivo* during TMS is challenging in

animals, and typically not possible for humans, modeling is an important tool to investigate the neuronal response to TMS.Here, we develop a new multi-scale pipeline (*NeMo-TMS*) for modeling TMS effects across spatial scales. On the macro-scale, we generate a realistic head model from MRI that includes multiple tissue types (white matter, grey matter, cerebrospinal fluid, skull, and scalp) and use the SimNIBS software to simulate the electric field induced in the brain for a given TMS coil position and orientation using Finite Element Method (FEM). Afterward, simulated electric fields from the previous step are coupled with morphologically realistic neuronal models. These models are solved by discretizing the neuronal branches into small compartments and by numerically solving the cable equation and channel dynamics in the NEURON environment. These neuron-scale simulations allow investigating membrane voltage (depolarization/hyperpolarization), action potential initiation and propagation, field intensity, and orientation necessary for modulating neuron response, etc. Then, we incorporate the membrane voltage data to simulate the calcium concentration induced by voltage-gated calcium-channels at the subcellular scale by solving the calcium dynamics equations. This step is important for understanding neural plasticity due to rTMS protocols. In this study, we also provide results to demonstrate how different neuron types behave distinctly for the same external electric field and therefore make a case for the importance of such multi-scale realistic modeling of neurons. Our pipeline can facilitate research as a tool for hypothesis testing and prediction technique for experiments. Additionally, modeling has the potential to be used for calculating the dose needed for efficient treatment in clinical applications.

Title: Towards biophysically-based neuromorphic computing at scale: Markov abstractions of electochemical reaction-diffusion in synaptic transmission

Authors: *M. WAGNER[1,2], T. M. BARTOL[2], T. J. SEJNOWSKI[2], G. CAUWENBERGHS[1]; [1]Dept. of Bioengineering, UCSD, La Jolla, CA; [2]Salk Inst., La Jolla, CA

Abstract: Progress in computational neuroscience towards understanding brain function is challenged both by the complexity of molecular-scale electrochemical interactions at the level of individual neurons and synapses, and the dimensionality of network dynamics across the brain covering a vast range of spatial and temporal scales. Our work abstracts the highly detailed, biophysically realistic 3D reaction-diffusion model of a chemical synapse to a compact internal

state space representation that maps onto parallel neuromorphic hardware for efficient emulation on very large scale, and offers near-equivalence in input-output dynamics while preserving biologically interpretable tunable parameters.Methods: We initially built a physically realistic stochastic 3D reaction-diffusion system in containing all major components for presynaptic vesicle release variability in response to a stimulus input using MCell. The model included realistic geometry for a CA3-CA1 Schaffer collateral en passant synapse with parameters set from experimental data. The CA3-CA1 Schaffer collateral was chosen as it is highly studied experimentally and is important for learning and memory [5, 6].
We modelled an action potential input followed by the stochastic opening and closing of voltage-dependent calcium channels (VDCCs) located on the membrane resulting in calcium influx into the presynaptic bouton and calcium diffusion, binding to calbindin and calcium sensors, and removal due to plasma membrane calcium pumps (PMCA pumps). These factors directly determine the quantity of neurotransmitters released and thus the strength of the synaptic connection. Abstracting this for computational efficiency, we created a series of Markov state transitions to fully realize the system with multiple internal states done in Python allowing for a biophysically tunable model of synaptic connectivity implementable in neuromorphic architectures.

Title: Long-range coordination patterns in cortex change with behavioral context

Authors: ***D. DAHMEN**[1], M. LAYER[1], L. DEUTZ[2], P. A. DABROWSKA[1], N. VOGES[3], M. VON PAPEN[1], T. BROCHIER[3], A. RIEHLE[3], M. DIESMANN[1], S. GRÜN[1], M. HELIAS[1]; [1]Juelich Res. Ctr., Juelich, Germany; [2]Univ. of Leeds, Leeds, United Kingdom; [3]Inst. de Neurosciences de la Timone (INT), CNRS - Aix-Marseille Univ., Marseille, France

Abstract: The cerebral cortex is a network of subnetworks that is organized on various spatial scales. Understanding how neurons communicate at the different scales is crucial for

understanding brain dynamics and function. On the microscopic scale the connectivity stems mostly from local axonal arborizations, suggesting coordination is strongest between nearby neurons in the range of a few hundred micrometers. Yet recent studies found activity of neurons across much larger distances to be organized in manifolds. The emergence of such manifolds relies on complex coordination patterns between neurons. We here analyze multi-electrode recordings of resting-state activity in macaque motor cortex that indeed show strong positive and negative spike-count covariances between neurons that are millimeters apart. To understand the origin of such coordination we develop a conceptually novel network theory that combines the spatial extent and heterogeneity of the connectivity with fluctuations of activity treated beyond the mean-field approximation. This quantitative theory uncovers a simple and ubiquitous mechanism that generates long-range correlation patterns despite short-range connections: the heterogeneity of connections causes a dynamical network state that emphasizes cooperation of neurons by multi-synaptic interactions. The mechanism does not rely on specific connectivity structures, but emerges in spatially organized networks with even random connectivity. The theory not only explains the experimentally observed shallow exponential decay of the width of the covariance distribution at long distances, but also predicts that neuronal coordination patterns can change in a state-dependent manner. We confirm this prediction by comparing activity in macaque motor cortex across different behavioral epochs of a reach-to-grasp experiment. Our results explain how spatially extended neural manifolds can emerge from the local network connectivity.

Title: Interplay between feedback and mutual Inhibition increases network flexibility via a multi-cusp bifurcation.

Authors: *A. J. WHITE[1], B. LIU[2], C.-C. LO[3];
[2]Inst. of Physics, [3]Inst. of Systems Neurosci., [1]Natl. Tsing Hua Univ., Hsinchu City, Taiwan

Abstract: One of the most intriguing properties of recurrent neural circuits is their flexibility. This flexibility extends far beyond the ability to learn, but includes the ability to use learned procedures to respond to novel situations. Here using a various sized spiking neuron models, we

show how networks with recurrent inhibition are key in expanding the functionality of the circuit, far beyond what feedback inhibition alone can accomplish. By adding mutual inhibition to small neural motifs, decision-like functionality is off-loaded onto the inhibitory sub-network. This frees up recurrent excitation for working memory. More importantly, feedback inhibition and mutual inhibition work synergistically to allow a plethora of central pattern generators to coexist with decision networks. This allows for quick, robust and flexible external control, without changing any synaptic weights. Taking advantage of dynamical system theory and bifurcation analysis we show mutual inhibition adds to the number of cusp bifurcations that can coexist in the system. This multi-functionality allows robust control of the underlying multi-cusp bifurcation structure by using bias current to push the system through lower co-dimension bifurcations. Thus changes in bias current can quickly switch between different functionalities including 8 different logical operations with 3 different classes of inputs, distinguishing between differences in magnitude, timing, and phase. Furthermore we uncovered several types of central pattern generators, working memory, and chaos. Finally, we showed that the underlying multi-cusp explains why mutual inhibition increases the information storage (Shannon entropy) of larger neural networks. Moreover, the location of the multi-cusp bifurcation in parameter space is near the optimal information capacity for the network.

Abstract: The hippocampus is a brain region involved in a spectrum of tasks such as learning, memory and spatial navigation. Cellular and network dysfunction of the hippocampus is implicated in a number of neurological disorders. In order to better understand the computations performed by the hippocampus and how those computations become abnormal in pathological conditions, it is essential to construct a biophysically realistic, large-scale circuit model of the hippocampus and study its spatiotemporal activity patterns. As a first step, we undertook a massive literature search to compute the total number and the distribution of diverse neuron types in the CA1, CA3 and dentate gyrus of the mouse hippocampus. Most of our assumptions were derived from experimental literature on the mouse hippocampus. We overcame missing

data by adapting relevant literature on the rat hippocampus. Our results indicate that the molecular make up and the morphology of a significant number of GABAergic neurons in the mouse CA1, CA3 and dentate gyrus remain uncharacterized. We also report that the mouse CA1 is much denser than the rat CA1 and identified significant cell type-specific differences between the two species. In conclusion, our work could provide a solid foundation for constructing a large-scale model of the mouse hippocampus and enable predictions on its involvement in brain function and dysfunction.

Title: A firing-rate computational model of the mouse dorsal lateral geniculate nucleus: the effects of cortical feedback

Authors: ***S. CHAWLA**[1,2], J. D. GOODWIN[2], R. H. L. NATARAJAN[2], S. R. SCHULTZ[2]; [1]King's Col. London, London, United Kingdom; [2]Dept. of Bioengineering, Imperial Col. London, London, United Kingdom

Abstract: The lateral geniculate nucleus (LGN) has traditionally been viewed as a passive relay station transmitting visual information from the retina to the cortex. However, recent literature suggests it may modulate retinal signals before reaching the cortex and thus play a key role in information processing. To better understand the role of cortical feedback in the LGN, we constructed a firing rate model based on experimental mouse LGN data. We created two instances of a high-level firing-rate model of the early visual system based on the extended difference-of-gaussian model, with only one including a thalamocortical loop. The cell populations, comprising of retinal ganglion cells (RGC), LGN relay cells, and primary visual cortex (V1) cells, were modelled as 2-dimensional layers using the python package pyLGN. Connecting kernel functions transmitted visual information between cell populations. Receptive field (RF) data collected experimentally in mice was used as the feedforward kernel between the RGCs and the relay cells. The RFs were modelled to have two spatially shifted and rotated bivariate Gaussian components, each varying temporally in strength according to a Gaussian function. Fullfield grating patterns were fed into the RGCs as Stimuli and we compared the spatiotemporal tuning curves of the model's relay cells with their experimental counterparts by calculating their Pearson correlation coefficient. Cells with correlation values of greater than +0.5 were considered to have been accurately modelled. Without cortical feedback, 149 of 417 cells had their spatial tuning properties accurately predicted; the addition of cortical feedback reduced this to 144 of 417. The model predicted temporal properties more accurately, with 207 of 417 cells being well modelled without cortical feedback, and 204 cells being accurately

modelled with feedback. Due to the blanket application of cortical feedback, accuracy reduced overall, though many individual cells' behaviour converged to the experimentally observed behaviour. This could evidence literature suggesting cortical feedback may neither be uniformly nor constantly applied to all relay cells. Alternatively, this may highlight our model's limitations, and future work should incorporate the addition of multiple thalamocortical loops.

Title: Input representation and processing in a computational model of the rat primary somatosensory cortex

Authors: *S. BOLAÑOS-PUCHET, A. ECKER, C. POKORNY, J. ISBISTER, V. SOOD, M. GEVAERT, P. KUMBHAR, A. ARNAUDON, L. KANARI, W. VAN GEIT, H. MARKRAM, J.-D. COURCOL, M. REIMANN, S. RAMASWAMY;
EPFL - Blue Brain Project, Geneva, Switzerland

Abstract: In recent years, simulation of large-scale computational models of the cortex has emerged as a promising way to study neural processing. However, due to computational costs and difficulty of parametrization, detailed reconstructions have so far been restricted to small volumes of tissue representing isolated cortical columns. In this work, we present a data-driven computational model of the primary somatosensory cortex of the rat built with the aim of gaining insights into how sensory inputs are represented and processed in the cortex at a region-wide level. The model consists of 4.2 million biophysically detailed neurons of 60 different morphological types and 212 different morpho-electrical types, distributed across 8 sub-regions encompassing the entirety of the non-barrel primary somatosensory cortex, and connected with 9.1 billion synapses featuring short-term dynamics. This circuit was built using our previously established methodology, now extended to reproduce the actual geometry of tissue based on the representation of somatosensory regions in a digitized rat brain atlas. Beyond local connectivity, two projection systems have been built: thalamocortical afferents that allow for extrinsic controlled input, and between-region connectivity which provides intrinsic feed-forward and feedback pathways between the various somatosensory sub-regions. After an initial exploration of the emerging dynamical behavior of the circuit with different simulation parameters, an *in vivo*-like working state was found. This state is characterized by asynchronous activity but sits

close to the transition to the synchronous regime, and is where *in vivo*-like behavior has been previously observed. Under these conditions, we analyzed the response of the circuit to realistic thalamocortical input spike trains in different spatial configurations to study phenomena such as input representation, distributed cortical processing and horizontal propagation of activity. Additionally, we investigated the interactions between the various somatosensory sub-regions by comparing simulations with and without between-region connectivity. These initial results provide a starting point for further studies in sensory cortical processing using this circuit to test hypotheses, compare with experimental findings, and make useful predictions.

Title: Data-driven analysis of information transfer in cortical neural circuit model with extracellular electric field

Authors: *N. MATSUMOTO, T. OMORI;
Grad. Sch. of Eng., Kobe Univ., Kobe, Japan

Abstract: Recent experimental studies suggest that the extracellular electric field influences information processing in neural systems. Previous theoretical studies showed that neuronal responses in single neurons are controlled by the effect of extracellular electric field. However, it is still unclear what kind of effect the extracellular electric field has on signal transmission in neuronal networks of the cortex.
In this study, we propose a mathematical model of cortical neural circuits that introduces a mechanism that can provide electric fields from outside the cell, and investigated the effects of extracellular electric fields on the neural circuits by numerical simulations. The neural circuits in the proposed model are designed to represent the layered structure of the cerebral cortex. We apply the mechanism of extracellular electric field to the cortical neural circuit and develop a model that can simulate the neural circuit by considering the extracellular electric field. We consider not only a uniform (constant) DC electric field but also a periodically oscillating AC electric field with a specific frequency.
In order to investigate the effect of extracellular electric field on cortical neural circuit, we

performed simulations using the proposed model. To quantify information transfer between cortical layers, we utilized an information theoretic index called normalized transfer entropy. The simulation result showed that the normalized transfer entropy between some layers decreased, whereas the normalized transfer entropy between other layers increased. We also found in specific cortical layers that the change in normalized transfer entropy depends on the frequency of applied extracellular electric field; there may exist optimal frequency for enhancing the normalized transfer entropy, and the effect of extracellular electric field on normalized transfer entropy is modulated depending on internal connectivity of the neural circuits. Our results suggest that the extracellular electric field may control the information transfer between layers in cortical networks.

Title: Multiple bumps enhance robustness to noise in continuous attractor networks

Authors: ***R. WANG**[1], L. KANG[2];
[1]Univ. of California, Berkeley, Berkeley, CA; [2]Neural Circuits and Computations Unit, RIKEN Ctr. For Brain Sci., Wako, Japan

Abstract: A central function of continuous attractor networks is encoding continuous variables and accurately updating their values through path integration. To do so, these networks produce localized bumps of activity that move coherently in response to inputs. In the brain, continuous attractors are believed to underlie grid cells and head direction cells that maintain periodic representations of space. However, path integration and various types of periodic tuning can be achieved with any number of activity bumps, and the consequences of producing more or fewer bumps are unclear. To address this problem, we construct continuous attractor networks with different bump numbers and assess their ability to path-integrate in the presence of noise. Single-bump networks with more neurons exhibit greater diffusive motion, which would lead to increased error. However, accuracy can be rescued by introducing multiple activity bumps, which suppresses noise-induced diffusion. Our findings may be particularly salient for large, noisy biological systems, such as the mammalian grid cell network, which could employ multiple attractor bumps to avoid massive error.

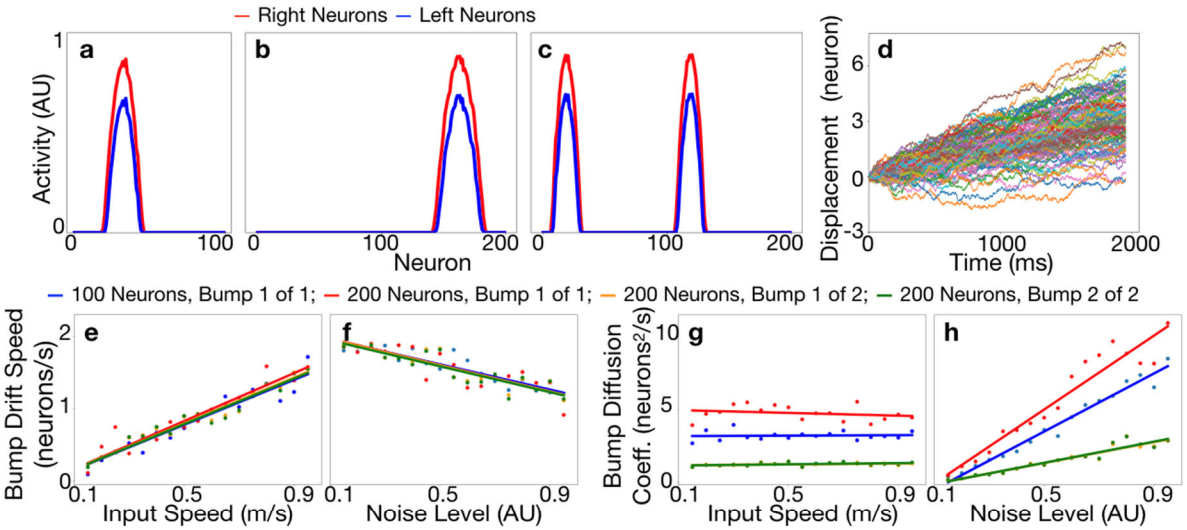

Figure 1: (**a-d**) Bump profiles and motion. (**a-c**) Activity snapshots of networks with (**a**) 100 neurons per population and one bump, (**b**) 200 neurons per population and one bump, (**c**) and 200 neurons per population and two bumps. (**d**) Bump trajectories for 100 replicate simulations that demonstrate noise-induced diffusion relative to the average drift. (**e-h**) Path integration and robustness to noise. Points indicate averages over 100 simulations and lines indicate linear fits. (**e**) At fixed noise level 0.5 AU, bump drift speed is proportional to input speed, which allows for unbiased path integration. (**f**) At fixed input speed 1 m/s, bump speed decreases at higher noise levels. As in **e**, all networks share the same bump speeds. (**g**–**h**) Noise-induced diffusion of bumps increases with neuron number but decreases with multiple bumps. Values for each bump in the two-bump network are almost equivalent. (**g**) Fixed noise level 0.5 AU. (**h**) Fixed input speed 1 m/s.

Title: Reliability of EEG functional connectivity based modular network organization

Authors: ***P. NAGY**[1,2], B. TÓTH[1], I. WINKLER[1], Á. BONCZ[1];
[1]Inst. of Cognitive Neurosci. and Psychology, Res. Ctr. For Natural Sci., Budapest, Hungary;
[2]Dept. of Measurement and Information Systems, Budapest Univ. of Technol. and Econ., Budapest, Hungary

Abstract: A large number of fMRI studies have reported that large-scale brain networks are organized into separated but interacting modules, typically studied in resting-state. Modularity is assumed to reflect functional segregation within the integrated network and is thought to confer robustness and adaptability to brain connectivity networks. However, fMRI data capture functional relations among brain regions on a timescale of seconds, making it difficult to link networks with cognitive functions, while MEG data remains relatively scarce. The present study aims to explore the reliability of large-scale network modularity as measured with resting-state

EEG rhythms (0.5-80 Hz) on a large sample of young healthy adults (N=202; mean age= 22.4). We tested whether stable resting-state networks could be identified with EEG on the individual and the group-level and if those networks could be characterized with a shared modular structure. Phase synchrony (PLV; iPLV) and amplitude envelope correlation (AEC) was calculated to estimate functional connectivity between reconstructed cortical signals in five frequency bands (delta 0.5-4Hz; theta 4-8 Hz; alpha 8-13 Hz; beta 13-30 Hz; gamma 30-80 Hz). Modularity was defined using multislice community detection, with resolution parameters estimated against randomized (null) data. Individual reliability was assessed by halving the resting state data and group-level reliability by randomized subgroups. Our results reveal a stable modular organization occurring during rest irrespective of connectivity measures, with moderate correspondence to structures reported with different modalities. Observed modularity of connectivity might play an important role in state and trait processes of cognitive functioning.

Abstract: Imaging Trigeminal Neuralgia Pain: Insights from Combining AI and Granger Causality

Yun Liang[a], Qing Zhao[a], John K. Neubert[b], Mingzhou Ding[aa]*J. Crayton Pruitt Family Department of Biomedical Engineering, University of Florida [b] Department of Orthodontics, University of Florida*

AbstractTrigeminal neuralgia (TN) is a severe and disabling chronic facial pain condition. It is considered one of the most severe pain conditions, often called the “suicide disease,” but presently available therapies for TN are mostly ineffective or inadequate. Both the unpredictable response to treatment and variability in long-term clinical outcomes in TN strongly suggest that a range of peripheral and central mechanisms underlying TN pain remain to be understood. This study aims to achieve two objectives. Objective 1 is to identify the regions in the brain that underlie TN pain. Objective 2 is to characterize how these regions interact to produce TN pain perception. Functional MRI (fMRI) data were recorded from TN patients (N=54) while they rated their pain levels in real-time using a tracking ball. Analytically, recognizing the limitations of traditional data analysis techniques (e.g., fMRI activation analysis), we turned to AI-inspired technology. In particular, a deep neural network (DNN) was designed and implemented, which

was able to take fMRI data as input features to predict the moment-to-moment fluctuations of pain levels with high accuracy (R=0.84). Importantly, from the DNN model, a set of brain regions, including the thalamus and the dorsal anterior cingulate cortex (dACC), were derived as signature centers of TN pain. Applying Granger causality analysis to fMRI data from the thalamus and dACC, we further showed that thalamus->dACC causal influence, but not dACC->thalamus causal influence, predicted daily experienced pain levels (R=0.55), consistent with the known physiology that the thalamus is a key brain structure in linking nociceptive sensory input to pain perception and dACC is a key brain structure for perceiving pain.

Title: Microelectrode recordings from an A-delta fiber in dorsal root ganglion: A computational study

Authors: L. R. MADDEN, R. D. GRAHAM, S. F. LEMPKA, *T. M. BRUNS;
Biomed. Engin., Univ. of Michigan, Ann Arbor, MI

Abstract: Dorsal root ganglia (DRG) are discrete targets for neuromodulation to treat various conditions, such as bladder incontinence and chronic pain, due to the presence of sensory neurons that innervate specific dermatomes. DRG neurons are pseudounipolar, meaning they have a stem axon that protrudes from the cell body that splits into a peripheral branch that extends out to the body and a central branch that enters the spinal cord. The stem axons of larger neurons in the DRG have been found to have a long, tortuous path known as a glomerulus. The electrophysiological impact of the glomerulus on extraneural recorded waveforms of DRG neurons is unknown. Understanding the unique electrophysiology of DRG neurons would inform neuromodulation therapies that target them, such as for closed-loop monitoring. Here, we created a computational recording model of a DRG and a sample A-delta fiber within it. We constructed an anatomically-accurate multi-compartment model of an A-delta fiber that included the soma, glomerulus, and stem axon (Figure). We built a finite element model (FEM) of the DRG, surrounding tissues, and a microelectrode shank with multiple recording sites. We then used a two-step reciprocity-based approach to simulate an extraneural recording from the DRG. We varied the active electrode site in order to explore the effect of distance between the recording electrode and the neuron. The results of this model may provide key insights into how the electrophysiological properties of DRG neurons influence neural recordings. Additionally, this model may inform electrode development and closed-loop neuromodulation techniques for both

in-vivo experiments and clinical applications by providing a method of examining DRG electrophysiology under various therapeutic conditions.

Title: Deconvolution and Analysis of Responses in Alternating Event Related fMRI Designs

Authors: ***S. DAS**[1,2], M. DING[3], G. R. MANGUN[1,2];
[1]Ctr. for Mind and Brain, [2]Dept. of Psychology, Univ. of California Davis, Davis, CA; [3]J Crayton Pruitt Family Dept. of Biomed. Engin., Univ. of Florida, Gainesville, FL

Abstract: Functional magnetic resonance imaging (fMRI) uses blood oxygen level-dependent (BOLD) signals to index brain activity. Event-related fMRI approaches are especially useful in experimental studies because it enables the measure of different events of interest in studies of perception, cognition, and action. However, because the time course of the BOLD signal is slow (being on the order of several seconds) compared to the millisecond time course of the underlying neural activity, significant challenges arise for fMRI design and analysis, especially when events (e.g., stimuli) are presented closely in time. One key goal is to improve the

efficiency with which the underlying hemodynamic response evoked by one event type can be detected and estimated, and distinguished from other events. The use of experimental methods such as event randomization and strategic sequencing of events can alleviate some of these challenges, they are more difficult to employ in some experimental designs, where the event sequences follow a non-random order, as occurs in typical cued attention paradigms, separating cue events from target and response events is more complicated. We address these issues using simulation, by manipulating design parameters to determine optimal design structures. Our model includes nonlinear and transient properties of fMRI signals that might be expected in certain experimental designs. We also included a more realistic noise component in our model, using the package *fmrisim* (Ellis et al., 2020, PeerJ). Our study investigated the dependence of fMRI signal optimization on several design parameters: Inter-Stimulus-Interval (ISI), different transient properties, and proportion of null events. Our results show optimal ISI ranges for alternating event sequences. We found that it is difficult to simultaneously optimize both detection power (ability to detect a signal) and estimation efficiency (the ability to model the hemodynamic function). We demonstrate how the inclusion of null events is critical for detection power at shorter ISIs. In contrast, there is a direct relationship between the proportion of null events and estimation efficiency. Our study provides additional information to be used to design optimal experimental paradigms for alternating event sequences. Through our assumption of a practical nonlinear model for the refractoriness of the blood flow, implementation of a realistic noise model, and taking into account the various transient properties, we have presented a theoretical structure that can provide insight into how the performance of an alternating event sequence in fMRI studies varies based on different parameters of the design.

Abstract: Diffusion-weighted imaging (DWI) has uncovered important white matter characteristics tied to development, aging, disease, and even individual differences. These discoveries suggest the massive potential of DWI to non-invasively detect explicit neurobiological properties, beyond what is possible within the realm of conventional neuroimaging. Moreover, recent advances in both DWI acquisition and analysis have enabled us to detect *in vivo* microstructural features of gray matter as well. However, little is known about

how different cellular landscapes may contribute to these metrics, especially in gray matter. Understanding the possible cytoarchitectural signatures of these measures would enable us to non-invasively estimate type-specific cell counts, potentially resulting in a very powerful clinical diagnostic tool as well as a mechanism for longitudinal tracking of effects in animal models. Here, we used a combination of diffusion-weighted imaging, brain clearing, light-sheet microscopy, and a high-resolution cell atlas of the mouse brain (Erö et al., 2018), to determine the link between diffusion images and the underlying neurobiology. We observed that different regions display unique, reliable relationships between cell counts and diffusion metrics. Moreover, we found that these relationships remained consistent across both *in vivo* and *ex vivo* diffusion imaging. We then used the robustness and exclusivity of these associations to create region-specific models to predict counts of both neurons and glial subtypes using the Extra Trees machine learning algorithm.

Title: Effects of resolution and scale on segmentation of Nissl-stained rat brain tissue images via convolutional neural networks

Authors: *A. ARNAL[1], O. FUENTES[1], A. M. KHAN[2];
[1]Univ. of Texas At El Paso, El Paso, TX; [2]Dept. of Biol. Sci. and Border Biomed. Res. Ctr., Univ. of Texas at El Paso, El Paso, TX

Abstract: There are numerous efforts to automate the delineation of rat brain regions from rat brain tissue images. A leading approach is to use convolutional neural networks (CNNs) to model anatomical variability and, ultimately, to determine cytoarchitectonic boundaries. Currently, it is not clear what scale or resolution of the input tissue images offer the most information for these models to exploit. In this work, we test a fully convolutional architecture, U-Net, with inputs of different scales and resolutions of Nissl-stained rat brain tissue images to segment the fornix at the level of the lateral hypothalamic area. Specifically, we reduce either the resolution or the scale of the original images, which results in brain tissue images with less detailed cytoarchitectural information. We consider the intersection over union metric between the model prediction and ground truth segmentation to determine the best model from these data-reduced images and show that the network attains the highest intersection over union when it has access to cytoarchitectural information. Further, our results are consistent with recent work on

CNNs in that our trained models are more sensitive to texture by predicting boundaries that follow the fornix's texture and which deviate from the ground-truth elliptical shape determined by a human expert. Our work provides valuable insight into the optimal input needed to train convolutional neural networks designed to automate the delineation of cytoarchitectural boundaries from Nissl-based images of the brain.

Informatics, [8]Neurosci., Yale Univ., New Haven, CT

Abstract: EEG/MEG are currently the only methods to non-invasively record human neural dynamics with millisecond temporal resolution. These signals are correlated with nearly all healthy and pathological brain functions. However, it is still extremely difficult to infer the underlying cellular and circuit level origins without simultaneous invasive recordings. This limits the translation of EEG/MEG signals into novel principles of information processing, or into new treatment modalities for pathologies. As such, there is a pressing need to relate the macro-scale signals to their underlying meso-scale generators. To address this limitation we built the Human Neocortical Neurosolver (HNN): an open-source software tool to help researchers and clinicians without formal computational modeling or coding experience interpret the neural origin of their human EEG/MEG data (https://hnn.brown.edu). HNN provides an intuitive graphical user interface (GUI) to an anatomically and biophysically detailed model of a neocortical brain

circuit, with layer specific thalamocortical and cortical-cortical drives. Unique to HNN is an underlying neural model that accounts for the biophysics generating the primary electric currents underlying EEG/MEG signals, enabling visual and statistical comparison of model output to source localized data (in nAm). Users can change model parameters in the GUI for testing hypotheses on signal differences under varied experimental conditions or in patient populations. Further, visualizations are shown of detailed circuit activity including layer specific responses, cell spiking activity, and membrane voltages. We describe the development and application of HNN, including updated online resources for learning and installing HNN on all major platforms. We give an overview of ongoing expansions, including conversion of the model to the NetPyNE specification (allowing circuit architecture modifications in the GUI), visualization of LFPs, and model parameter optimization to match data features. We highlight the uniqueness of HNN among other software for EEG/MEG modeling. In total, HNN represents an unprecedented tool for the EEG/MEG community to translate their human signals to underlying neural dynamics.

Title: Development of an automated high-throughput machine learning pipeline for phenotypic classification based on rodent quantitative electroencephalography

Authors: F. SHENG[1], ***D. J. GRAZIANO**[1], E. J. MA[2], M. XIAO[3], H. HOEFLING[4], M. M. SIDOR[5];
[2]Data Sci. & Statistical Learning, [3]AD Data Sci., [1]NIBR, Cambridge, MA; [4]Scientific Data Analysis - Machine Learning and Quantitative Analysis, NIBR, Basel, Switzerland; [5]Deepcure, Boston, MA

Abstract: Electroencephalography (EEG) is a non-invasive and translational method to record brain activity across species, with robust alterations in the EEG frequency spectra found across several neurological diseases. Indeed, such alterations are being increasingly explored in transgenic rodent models to identify disease-associated biomarkers. Conventional analysis of EEG frequency spectra, however, often divides the spectra into arbitrary and discrete frequency bins (i.e. alpha, theta, gamma) whereby subtle differences that span the spectrum or that straddle traditional frequency bounds can be missed. In this context, machine learning (ML) offers an advantage that enables the unbiased selection of features for classification purposes. Here, we present an automated high-throughput ML pipeline for rodent EEG spectral analysis. The

pipeline was divided into three parts: feature extraction, feature selection, and classification. Continuous EEG data was collected from 32 wild-type and transgenic mice using wireless telemetry. Power spectral density (PSD) estimates were computed from 0.5-90Hz using the fast-fourier transform (Hanning window, 1024 nfft samples, 50% overlap). Both unbinned (~2Hz resolution) and traditional frequency bin (e.g. alpha, theta, gamma) PSD estimates were used for model training. Performance across random forest, linear discrimination analysis, support vector machine, and hierarchical clustering models were compared using 5-fold cross validation with 1000 iterations on stratified training and test data. The best-performing model, a combination of random-feature elimination with an underlying SVM model combined with a decision tree classifier, correctly classified rodent genotype using unbinned PSD estimates with 93% accuracy and a F1 score of 89% using data from a representative resting state EEG phenotyping experiment. Moreover, novel biomarkers were identified using a ML approach. Parallel computing optimization in a High-Performance Computing (HPC) environment, reduced processing time to a few minutes on a standard personal computer. The pipeline is highly modular, whereby additional feature selection or classification models can be included. Our results demonstrate that ML can uncover novel biomarkers and achieve a speed, scope, and scale that would be unachievable using conventional EEG analytical methods.

Title: Quantifying changes in complexity of the event related response to sensory stimuli in different states of arousal

Authors: *A. DALLAVECCHIA, F. MICHELI, J. FROHLICH, D. TOKER, M. M. MONTI; Dept. of Psychology, UCLA, Los Angeles, CA

Abstract: Complexity measures have traditionally been applied to resting state electroencephalography (EEG) as a way to quantify the dynamic, nonlinear changes in the signal. While there has been some interest in porting these techniques into the event-related response (ERP) space, the computational and temporal requirements for complexity measures have limited their spread into this field. However, a new measure has been developed, called the *perturbational complexity index* (PCI), that quantifies the complexity of an EEG response to single pulse transcranial magnetic stimulation (TMS). While this new measure originated in TMS-EEG, new work has already applied a modified version of this measure to multisensory and unisensory ERPs. It is still unclear however how well this measure, along with its new iteration (PCIst), tracks consciousness and arousal when applied to sensory ERPs as compared to TMS evoked responses. Importantly, PCIst and the original PCI differ in how the complexity of

the data is measured, with the former measuring the distance between the baseline and response signals, and the latter using Lempel-Ziv to measure the compressibility of the data. In this preliminary study, left median nerve somatosensory evoked potentials (SEPs) and auditory evoked potentials (AEPs) were delivered while subjects rested with eyes open and eyes closed in a within-subjects design to test the sensitivity of a variety of PCI measures to slight changes in arousal. Here, we report that while cluster permutation paired t-tests showed ERP level changes only for AEPs, there was a significant reduction in complexity of the responses as measured by Lempel-Ziv PCI for both ERP conditions ($F(1,16)=25.92$, $p<0.001$) and only for SEPs with PCIst (post-hoc comparison, Scheffe corrected, $p<0.001$) in low arousal. Therefore, while the Lempel-Ziv PCI appears to follow the expected direction of effect for both ERPs—complexity decreases as arousal decreases, as seen in the TMS-EEG experiments, PCIst appears to be sensitive to these changes only for one ERP condition (SEPs). In conclusion, we recommend using Lempel-Ziv based PCI when attempting to measure differences in arousal using the complexity of sensory evoked responses.

Title: Neuroscience Gateway - Large Scale Data Processing and Modeling Using High Performance and High Throughput Computing Resources

Authors: S. SIVAGNANAM[1], K. YOSHIMOTO[1], A. DELORME[1], R. MARTINEZ[1], D. TRUONG[1], M. KANDES[1], S. YEU[1], S. MAKEIG[1], T. CARNEVALE[2], ***A. MAJUMDAR**[1]; [1]Univ. of California San Diego, La Jolla, CA; [2]Yale Univ., New Haven, CT

Abstract: Since its inception in 2013, the Neuroscience Gateway (NSG) reduces technical and administrative barriers that neuroscientists face in accessing and using high performance computing (HPC) resources needed for large scale neuronal modeling projects. NSG provides about twenty neuroscience software that require and run efficiently on high performance computing (HPC) resources. Since around 2017 experimentalists such as cognitive neuroscientists, psychologists, biomedical researchers started to use NSG for their neuroscience data processing, analysis and machine learning work. Data processing workloads are more suitable on high throughput computing (HTC) resources where single core jobs run to process

individual data sets of subjects. NSG is adapting to the needs of experimental neuroscientists by providing HTC resources, in addition to already successfully serving the computational neuroscience community. To support data processing workload NSG is adding new functionalities such as transfer/store of large data, processing of data by multiple users, visualization of data, HTC of data etc. In addition NSG is becoming an environment where neuroscience software developers can test, benchmark, and scale their newly developed software and eventually disseminate their software via the NSG. NSG is also being integrated with the NEMAR (NeuroElectroMagnetic data Archive and tools Resource) project which is a data and tools archive focused on EEG data. It will extract EEG data deposited on the OpenNeuro archive and then allow researchers to search, visualize and process EEG data. NSG's EEGLAB data processing pipeline, will be used for large scale EEG data processing on high throughput supercomputing and cloud resources. The presentation will describe: (i) how NSG has been successfully serving both the computational neuroscience community, and the experimental neuroscience researchers; (ii) new features that are added to make it a suitable and efficient dissemination environment for lab-developed neuroscience software. NSG has a growing user base, and provides an easy to use and an open environment, and allows large scale computing on powerful compute resources. It has a well-established training and outreach program, and a functioning user support system.

Title: Convolutional Neural Network Predicts Impairment Scores for Repetitive Movement Measurements

Authors: *A. SURESH[1], J. R. BRASIC[1], M. E. HERNANDEZ[2];
[1]Johns Hopkins Univ., Baltimore, MD; [2]Univ. of Illinois at Urbana-Champaign, Urbana, IL

Abstract: Objective: To develop a machine-learning based method to predict motor impairment scores of repetitive movement measurements.
Methods: A dataset containing repetitive movement measurements from patients with Parkinson's disease (PD) and age- and sex-matched control participants was used (Harrigan et al., 2020). Movements included finger tapping, toe tapping, and pronation-supination. A low-cost, accelerometer-based protocol (McKay et al., 2019) was administered to obtain the movement measurements from the extremities of participants. A trained examiner scored the movements live (McKay et al., 2019; Goetz et al., 2008). For each trial, ten-second segments of accelerometer signals were selected and images were generated using their continuous wavelet

transforms (CWTs) and short-time Fourier transforms (STFTs). Image classification was performed using a convolutional neural network, GoogLeNet in MATLAB (The Math Works, Inc., 2020). The CWT images and STFT images were divided into two classes: low (corresponding to ratings 0-1) and high (corresponding to ratings 3-4). An equal number of images were selected randomly from each class and used for classification. An 80-20 split for training and validation images was chosen. The network's ability to correctly classify validation images determined its accuracy score.

Results: The network had a 92% accuracy in predicting new CWT images and a 97% accuracy in predicting new STFT images into low (0-1) and high (3-4) classes.

Conclusion: Image classification performed by a GoogLeNet generates a high level of accuracy in predicting the impairment score of repetitive movements measured by accelerometers. This technique has significant potential for the evaluation of movements in patients in telemedicine and for the tracking and monitoring of movements through embedded accelerometers in wearable devices. It also provides the foundations for the identification of electronic signatures pathognomonic for PD to facilitate the diagnosis, monitoring, and treatment of PD and other movement disorders.

Abstract: Primate research is a pivotal step in the progression of medical research from animal models to human trials. This is especially true in neuroscience and neural engineering where nonhuman primates (NHP) have been highlighted as an ideal preclinical model for understanding brain function. In most NHP neuroscience experiments, neurosurgical measures are required for the implantation of devices such as head posts, stimulation and recording chambers, electrode arrays, and optical windows. Current practices for headpost implantation, surgical craniotomy, and fluid injection use methods for surgical preparation that carry a degree of unavoidable uncertainty. This comes from an inability to visualize and test the physical compatibility of complex components and anatomy prior to neurosurgery.In this work, we outline a method for surgical preparation that allows for the practical planning of a variety of neurosurgeries in NHPs solely using data extracted from magnetic resonance imaging (MRI). This protocol allows for the generation of 3D printed anatomically accurate physical models of the brain and skull, as well as an agarose gel model of the brain that replicates some mechanical properties of the brain. These models can be obtained from MRI using brain extraction software for the brain model, and custom code for the skull. The preparation protocol takes advantage of state-of-the-art 3D printing technology to combine models of the brain and skull with neuroprostheses. With the addition of a craniotomy using the custom code, the skull and brain models can visualize brain tissue inside the skull, enabling better preparation for surgeries.Using the methods outlined in the protocol, the accuracy of the 3D printed brain, skull, and craniotomy placement were successfully validated through a comparison to the original MRI scan. The gel brain was additionally used to visualize delivery of a mock viral vector through the craniotomy of a skull model. By preoperatively fitting a headpost to the physical model of the skull we successfully reduced the time required for the headpost implantation surgery by 40% and greatly reduced the risk of operative complications. Unlike previous publications in surgical preparation, this protocol offers a novel, unimodal method requiring only an MRI scan that can additionally visualize and prepare for surgical injection using the various gel molding components. The

applications of these methods are designed for surgeries involved in neurological stimulation and recording as well as injection in NHPs, but the versatility of the system allows for future expansion of the protocol, extraction techniques, and models to a wider scope of surgeries.

Title: Evaluation of different statistical procedures to estimate coupling between oscillatory phase and behavioral response

Authors: *N. WOLPERT, C. TALLON-BAUDRY;
Dept. d'Etudes Cognitives (DEC), Ecole Normale Superieure, Paris, France

Abstract: A growing number of studies report a link between the phase of an oscillation and behavior. For instance, the phase of brain alpha oscillations at which a stimulus is presented correlates with the likelihood to detect a near-threshold stimulus. Phase-effects have been observed not only for neural oscillations but also within the cardiac or respiratory cycle. A large variety of methods has been employed for the statistical evaluation of phase effects on behavior, without rigorous investigation to determine which method is optimal for the question under study. Additionally, most studies relied on the assumption that phase-behavior would take a 1:1 relationship, i.e. with one preferred portion of the phase for each behavioral outcome (e.g., "hits" and "misses"). Here, we compare the peformance (sensitivity, False Positive rate) of five circular tests commonly used in the field of neuroscience to quantify relationships between the phase of an oscillation and a binary behavioral outcome, namely Phase Opposition Sum, Circular Logistic Regression, the Watson test, Modulation Index, and the Rayleigh test. We created semi-artificial datasets mimicking real experiments with 30 participants, where we imposed a link between a simulated behavioral outcome with the phase of a physiological oscillation. We systematically varied the strength of phase-outcome coupling, the coupling mode (1:1 to 4:1), the overall number of trials, the relative number of trials in the two outcome conditions, and evaluated different strategies to estimate phase-outcome coupling chance level, as well as significance at the individual or group level. We found that Circular Logistic Regression, Phase Opposition Sum and the Watson test are the most sensitive tests when coupling mode is 1:1. Modulation index, and to a lesser extent the Watson test, is sensitive to higher coupling modes. The Watson test is

thus a good first intention test, with a good sensitivity and low False Positive rate, some sensitivity to 2:1 coupling mode and low computational load. Modulation index, intitially designed for continuous variables but that we find useful to estimate coupling between phase and a binary outcome, should be preferred if coupling mode is higher than 2:1. Phase opposition Sum, coupled with a resampling procedure, is the only test retaining a good sensitivity in the case of a large imbalance in the number of occurrences of the two behavioral outcomes. The results of this systematic evaluation directly generate recommendations to analyze data for phase-behavior coupling in future studies.

Title: Memory-tasks using rapid-serial visual presentation paradigm to inform brain-computer interface error correction

Authors: ***A. W. CHIU**, D. H. HUGHES, L. M. JILEK, M. E. JACOBS;
Biol. and Biomed. Engin., Rose-Hulman Inst. of Technol., Terre Haute, IN

Abstract: One of the applications of the brain-computer interface (BCI) is to help people with neuromuscular deficiencies to communicate effectively. Many of these BCI speller systems employ various visual presentation paradigms that allow users to construct and edit sentences but are limited by the oculomotor deficiencies of the target population. In this study, we implemented a modified rapid-serial visual presentation (RSVP) paradigm and evaluated features to allow for an intuitive means for BCI spellers to quickly identify and correct errors. Fifteen healthy individuals with no prior experience with RSVP software or similar speed-reading tools were recruited. OpenBCI 16-channel Mark IV system with Cyton and Daisy was used for data acquisition. Subjects were asked to complete 240 trials of a modified working memory free recall task to assist in identifying relevant features that can be used to illustrate possible errors during BCI spelling tasks. Each trial involved a presentation phase (PP), where subjects were shown a list of words, and a response phase (RP), where subjects were shown a single word. The PP lists contained 4 words (120 trials) or 10 words (120 trials) and subjects were asked to memorize the words as they flashed on the screen. Words were presented at 200 to 420 words per minute (WPM) (3.3 to 7 Hz) and the flash rate was randomly chosen for each trial with an equal number of trials being presented via each flash rate. During the RP subjects were instructed to press different buttons depending on whether the RP word had appeared on the PP list. Only responses within 4 seconds are considered. Although event-related potentials (ERPs) such as N400 and P600 are often used in language comprehension tasks, they are more aligned with

sensitive to the degree of semantic expectancy, and comprehension, and are not relevant features for BCI error identification. Time-dependent Generalized Hurtz Exponent (GHE) for each EEG channel was used to identify the difference between conditions where RP mismatch occurred. Significant changes in both alpha and theta activity were found depending on the number of words in PP. Taken independently, none of these features were sufficient in classifying whether an error occurs. However, using machine learning techniques, the accuracy of identification could be enhanced up to 65% at 200 WPM but down to 50% at 420 WPM, suggesting that presentation speed also played a huge factor.

Title: A comparison of active marker and deep learning based marker-less tracking of human motion in 3D

Authors: ***M. MORO**[1], M. CASADIO[2], L. MROTEK[3], F. ODONE[1], R. RANGANATHAN[4], R. SCHEIDT[3];
[1]DIBRIS - MaLGa Ctr., [2]DIBRIS, Univ. of Genova, Genova, Italy; [3]NeuroMotor Control Lab., Marquette Univ., Milwaukee, WI; [4]Dept. of Kinesiology, Michigan State Univ., East Lansing, MI

Abstract: Measuring quantitative information about human motion is fundamental to understand how our central nervous system controls and organizes movements and is essential to many fields including motor control/learning, rehabilitation, and sport biomechanics. Currently, for scientific use, the study of human motion is commonly done through marker-based techniques and motion capture systems. These methods are the gold standard because they are precise and reliable. However, they are expensive, time consuming and the use of markers or wires can affect the naturalness of the motion in some real-world contexts. Marker-less video-based techniques are an alternative to these methods. They are less expensive and can be used to record performers in their natural settings. Unfortunately marker-less techniques appear to be less precise, although a systematic and detailed comparative analysis of recent models have yet to be explored. The aim of this work is to implement and evaluate a video-based marker-less system to quantitatively study human motion in three dimensions (3D).To examine performance in a real-world context, we studied violin players of a wide range of ages and capabilities. We acquired the kinematics of these violinists repeatedly playing a G scale arpeggio. For the marker-less system, the setup included three RGB cameras (Mako G125). We used a motion capture system (Optotrak 3020) with 6 active markers placed on the violin and 4 placed on the bow to validate the marker-less

system.We first trained a state-of-the-art deep learning algorithm (DeepLabCut) to automatically detect the (x,y) coordinates of landmark points in the image plane for each frame in all the videos. Then, we filtered the obtained trajectories in order to enforce spatio-temporal consistency. We reconstructed the 3D positions of the actual markers placed on the violin and on the bow combining the information from different viewpoints (stereopsis). At the end, we measured the Euclidean distances between different couples of markers in the 3D space with both actual markers and their analogues reconstructed from videos and we compute the mean and the standard deviation for each distance across different time instants. We obtained similar results in term of mean distances between marker-based and marker-less techniques (average difference < 4 mm) with a standard deviation lower than 1 mm for marker measures and around 5 mm for marker-less ones. These results suggest that marker-less systems can successfully track performance in real-world settings, although their higher variability may potentially limit their use in certain contexts.

Title: Unnecessary reliance on multilevel modelling to analyse nested data: when a traditional summary statistics approach excels

Authors: *C. B. MCNABB, K. MURAYAMA;
Sch. of Psychology and Clin. Language Sci., Univ. of Reading, Reading, United Kingdom

Abstract: Nested data structures (common in neuroscience) create dependence in the data that influences the effective sample size and statistical power of a study. Several methods are available for dealing with nested data, including the summary statistics (SS) approach and multilevel modelling (MM). Recent publications have heralded MM as the best method for analysing nested data, claiming benefits in power over SS approaches (e.g. the *t*-test). However, when data are not cross-nested and cluster size is equal, conventional analysis with the SS approach is actually mathematically equivalent to MM. This equivalence has been established in statistical literature and made use of in popular neuroimaging software such as FMRIB Software Library (FSL) and Statistical Parametric Mapping (SPM). However, the merits of the SS approach have not been well recognised in neuroscience beyond that context. We conducted statistical simulations demonstrating equivalence of MM and SS approaches for analysing nested data and provide support for the utility of the conventional SS approach in nested experiments. We demonstrated that losses in power attributed to the use of the SS approach in previous

publications (Aarts, Verhage et al. 2014, Aarts, Dolan et al. 2015) are unsubstantiated and due to inappropriate use of the log-likelihood test in MM. This method increased study power at the cost of inflated type 1 error (Fig. 1), attributable to singular fit errors when intraclass correlation was low (ICC=.1) but independent of these errors when intraclass correlation was high (ICC=.5). Use of restricted maximum likelihood estimation, however, resulted in power and error rates comparable to the SS approach, indicating that the formerly mentioned benefits in power with MM are in fact a myth.

Figure 1. Type 1 errors associated with log-likelihood ratio test and SS approach; a) including all 10,000 simulations; b) excluding simulations that resulted in singular fit or convergence warnings.

Title: Neural silences can be localized rapidly using template head models

Authors: *A. CHAMANZAR, M. BEHRMANN, P. GROVER;
Carnegie Mellon Univ., Pittsburgh, PA

Abstract: Rationale: The diagnosis and treatment of many neurological disorders can benefit from non-invasive and rapid monitoring of abnormal neural activity. We recently proposed a

method, called SilenceMap, for the detection and localization of neural "silences" in the brain using scalp electroencephalography (EEG). "Silences" are regions in the brain with suppressed neural activity, which can model conditions such as hypoxic, necrotic, or lesioned tissue in brain injuries and stroke. In situations where there is limited or no access to advanced imaging techniques such as magnetic resonance imaging and computed tomography, having access to a fast-to-apply monitoring system for assessment of neural damage is vital. This paper explores the possibility of silence localization in the brain based on a template head model and scalp EEG recording. Methods and Results: In a recent study, we tested the performance of SilenceMap on three male pediatric patients with lobectomy, where the structural MRI scans of these patients were used to extract the real head models for lead-field matrix estimation. We used a standard EEG grid with 128 electrodes to record EEG signals during visual and rest tasks. SilenceMap successfully (maximum distance error of 13mm) localized the regions of silence using fewer than 3 minutes of EEG recording. In the current work, a template head model is extracted using an MRI scan of a healthy individual (intact brain) using an open source MRI dataset. Using this template head model, along with the scalp EEG recording, SilenceMap localizes the correct regions in the brain. However, slight performance reduction is observed in silence localization using a template head model (see the attached Figure). Conclusions: This study further validates the capability of SilenceMap in localizing and monitoring neural silences in the brain, even without having access to any structural information of the brain, since use of template head models results in only a slight performance reduction. This paves the way towards fast and reliable monitoring of neural silences in emergency situations.

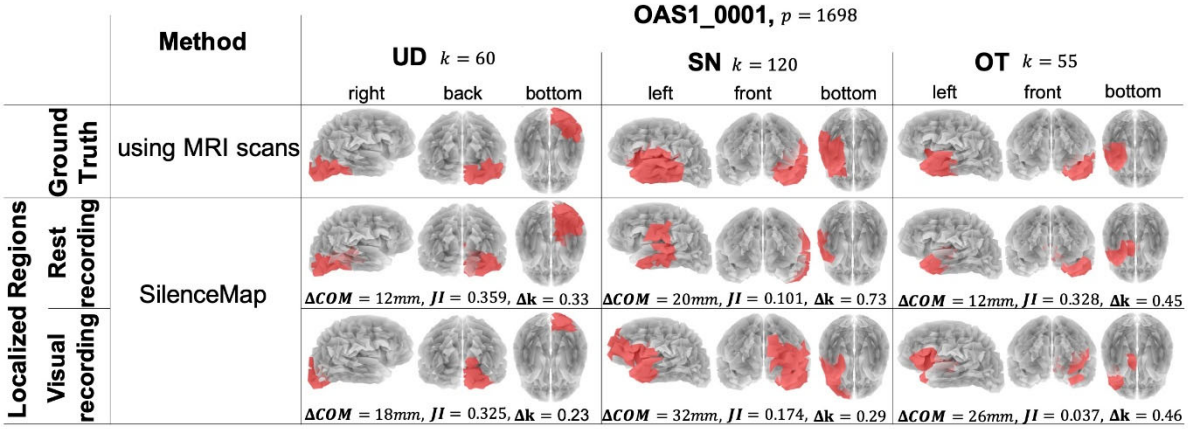

Fig. Performance of SilenceMap in both the rest and the visual recording conditions, using a template head model: the first row shows the extracted ground truth regions of silence (red regions) overlaid on the resected cortical region of three patients based on a symmetric brain model extracted from the structural MRI scan of a healthy individual in an open source dataset (OAS1_001 in OASIS1[1] dataset); the second and third rows show the performance of SilenceMap, based on the Rest and Visual recordings respectively, through both visual illustration (red regions) and using performance metrics of center-of-mass (COM) distance (ΔCOM), Jaccard Index (JI), and size error (Δk). p is the total number of sources in each brain model, and k is the size of ground truth region of silence. The results show only small reduction in the silence localization performance using a template head model in comparison with the results using the structural MRI scans of each patient (see Fig. 3 in Chamanzar, et al., 2020[2])

Title: Implication of disregarding the fundamental characteristics of neural signals

Authors: *A. NOURMOHAMMADI[1,2], P. BRUNNER[3,4,2];
[1]Natl. Ctr. For Adaptive Neurotechnologies, Albany, NY; [2]Biomed. Sci., SUNY Univ. at Albany, Albany, NY; [3]Nat. Ctr. for Adapt. Neurotechnologies, Albany Med. Col. / Wadsworth Ctr., Albany, NY; [4]Sch. of Med., Washington Univ., Saint Louis, MO

Abstract: The large scale electrophysiological signals recorded from the cortex or scalp encompass valuable information about neuronal activities and are thus widely used in brain research. The inherent complexity of these signals has urged neuroscientists to adopt sophisticated analysis tools and methods, mostly developed in other disciplines such as Digital Signal Processing and Economics. While applying such analysis approaches can be instrumental in processing neural data, lack of proper understanding about their underlying assumptions and treating them as 'black box' can be detrimental. The majority of methods and techniques in commonly used analysis pipelines are based on certain ideal assumptions about the input data, which are often incongruent with the nature of brain signals. Our research aims to address this profound issue and shed light on the ramification of lack of such consistency. To accomplish this, we investigated the fundamental characteristics of large-scale electrophysiological signals, their presence under different physiological conditions, and the optimum methods for their quantification. Our study hypothesized that fundamental signal characteristics play a critical role in choosing appropriate analysis approaches. To test this hypothesis, we applied widely used techniques to simulated and real neural data. Our results demonstrate that a lack of concordance between the premise of the processing methods and inherent signal attributes can be misleading and introduce dire analytical confounds in the context of different neuroscientific applications. We hope this study serves as a guideline for neuroscientists and encourages them to be cognizant of the essential attributes of neural data in each experiment and meticulous about choosing the proper analysis technique.

Title: A standardised framework for re-referencing strategies of human intracranial electrophysiological data.

Authors: ***G. PARISH**[1], F. ROUX[1], L. KOLIBIUS[2], R. CHELVARAJAH[3], D. T. ROLLINGS[3], V. SAWLANI[3], H. HAMER[4], S. GOLLWITZER[4], G. KREISELMEYER[4], M. TER WAL[1], B. STARESINA[1], M. WIMBER[2], S. HANSLMAYR[2];
[1]Univ. of Birmingham, Birmingham, United Kingdom; [2]Univ. of Glasgow, Glasgow, United Kingdom; [3]Queen Elizabeth Univ., Birmingham, United Kingdom; [4]Univ. Hosp. Erlangen, Erlangen, Germany

Abstract: In recent years human electrophysiological studies, particularly intracranial and human single neuron studies, have become increasingly popular as the field grows in funding and stature. It is important, therefore, that there is some form of standardisation that enables comparison between studies and findings. Such studies inherently rely on the analysis of electrical signals that are emitted by the combined neural circuitry of the brain. These electrical signals must be recorded in relation to some grounding signal, meaning that this reference signal will play a large role in the resultant waveforms that are ultimately recorded. At the point of recording, there is a general understanding that typical grounding sources will help to minimise surrounding electrical interference whilst not removing much of the original signal. For this reason, grounding references are often situated around the periphery of the head or skull of the subject being recorded from. However, neuroscientific studies often employ another step of re-referencing, whereby a single or amalgamation of electrodes or micro-wires are selected as grounding references. In theory, this is pursued to further increase the signal to noise ratio. However, it is often the case that a re-referencing strategy is chosen to remove signals that are undesirable for the hypothesis in question. Re-referencing might be achieved in any number of ways that are currently preferred by the field, whether it is the subtraction of an average set, an independent-component, an electrode situated near white matter or the skull, or a bi-polar subtraction of each electrode from its neighbours, amongst others. Preferred strategies are often employed on a case-by-case basis, rather than being prescribed from a standardisation of re-referencing methods. We feel that this can murky the underlying theory behind secondary re-referencing, potentially leading to disagreements and an inability to reproduce findings across studies. As such, we here explore a human episodic memory paradigm to assess the effect of a variety of popular re-referencing techniques on resultant oscillatory signals and spike-field coherence, using intracranial EEG data collected from 16 subjects. By comparatively analysing

time-frequency space and the degree to which spikes conform to oscillatory signals, we here hope to provide a standardised framework for human intracranial re-referencing methods. Our aim is to aid colleagues in selecting an appropriate strategy for their hypothesis, such that the field can engage in more transparent and comparable experimentation.

Title: Development of an application for real-time acquisition and synchronization of data from operative patient monitoring instruments

Authors: K. PUTHUVEETIL[1], ***A. VENKATESAN**[2], R. HANG[1], D. J. KRUSIENSKI[1]; [1]Biomed. Engin., [2]Biol., Virginia Commonwealth Univ., Richmond, VA

Abstract: Successful outcomes during surgery critically depend on a variety of instruments in theoperating room for monitoring and regulating patients' vitals. It is common to employ trainedclinicians or teams solely dedicated to specific monitoring modalities, such as cardiopulmonaryperfusion, neuromonitoring, or anesthesia, for instance. The surgeon intimately relies on theseclinicians to maintain patient vitals and to communicate any irregularities seen in their respectivemodalities. While an active dialog about the readings from the individual instruments ismaintained between the clinicians and surgeon during the case, the signals are often notsystematically synchronized or permanently recorded. Such synchronization and recording haveseveral advantages beyond creating an archival record, such as using the data to betterunderstand and model the impacts of the interventions during a case on the vitals and patientoutcomes. The ultimate objective of this research is to not only synchronize monitoring but alsoto enable offline analysis for improved automated event detection. An application that supportsrecording from a multichannel analog-to-digital converter or via serial ports was developed. Theapplication allows for a simple configuration of device communication parameters, enabling datacollection from any medical devices with an analog or RS232 output, like those for transcranialdoppler and perfusate flow/blood parameter monitoring modalities in our test case. Theapplication also allows clinicians to make time-stamped annotations about events of interest,which can then be used to identify trends in signal characteristics during proceduralabnormalities. The synchronized, annotated, multichannel data can be stored and used for laterinspection or analysis. In our test case in partnership with VCU Health, the recording applicationwill be used to track annotations and record signals from neuromonitoring

instruments, amongothers, during cardiac surgery. The collected data will be used to evaluate the efficacy of theneuromonitoring system used by the hospital in improving patient outcomes.

Title: Phase-contrast micro computed tomography for vasculature imaging in post mortem human brain stem

Authors: *J. LEE[1], A. MACK[2], T. SHIOZAWA-BAYER[2], K. SCHEFFLER[1], F. DI LILLO[3], R. LONGO[4], G. TROMBA[3], G. HAGBERG[1];
[1]Max Planck Inst. for Biol. Cybernetics, Tübingen, Germany; [2]Inst. of Clin. Anat. and Cell Analysis, Eberhard Karls Univ. Tuebingen, Tübingen, Germany; [3]Elettra - Sincrotrone Trieste S.C.p.A., Trieste, Italy; [4]Univ. of Trieste, Trieste, Italy

Abstract: Studying the vasculature in the human brain using classical histology can be challenging due to the necessity for high quality, stained tissue slices. Here, we propose to use phase-contrast micro computed tomography (microCT) for identifying the vasculature in the unstained, paraffin-embedded brain. With a phase contrast technique, which incorporates the phase shift of the X-rays, we could obtain edge enhanced images from the tectum of the midbrain. Human brain stems were provided by the University of Tübingen Body Donor program. Samples were fixed in formaldehyde for a minimum of 4 weeks and then were embedded in paraffin. Acquisitions were made at the SYRMEP beamline of the Elettra Synchrotron Facility in the “white-beam” configuration mode, illuminating the sample with a mean energy of 22 keV. The samples were measured with a rotation angle of 180° with a total of 3600 projections. We scanned 4 samples in 4.9µm pixel size (detector-to-sample-distance, DSD: 90cm) and 2 samples in 0.9µm pixel size (DSD: 20cm). We applied Paganin’s phase retrieval algorithm for signal-to-noise ratio improvement and filtered back projection for image reconstruction. Vessels were automatically segmented using; a median filter, non-local means denoising, a variance filter followed by thresholding and opening. Vessel volume within the superior colliculus was calculated using 0.9µm pixel size data. Figure 1 shows that the vessel structure segmented from microCT matches the structure revealed by Indian ink staining in a previous study (Durvernoy, H. M., 1978.). Within the superior colliculus, vessels project from the surface towards the cerebral aqueduct in a parallel manner. Within the superior colliculi, vessel volume made up a mean of 3.47 % (SD= 0.53%) of the tissue. These findings show that phase contrast microCT is suitable for investigating the vasculature of post mortem human brain.

This method can also be used for vessel tracing in three dimensional space and analyzing features such as length, diameter and branching.

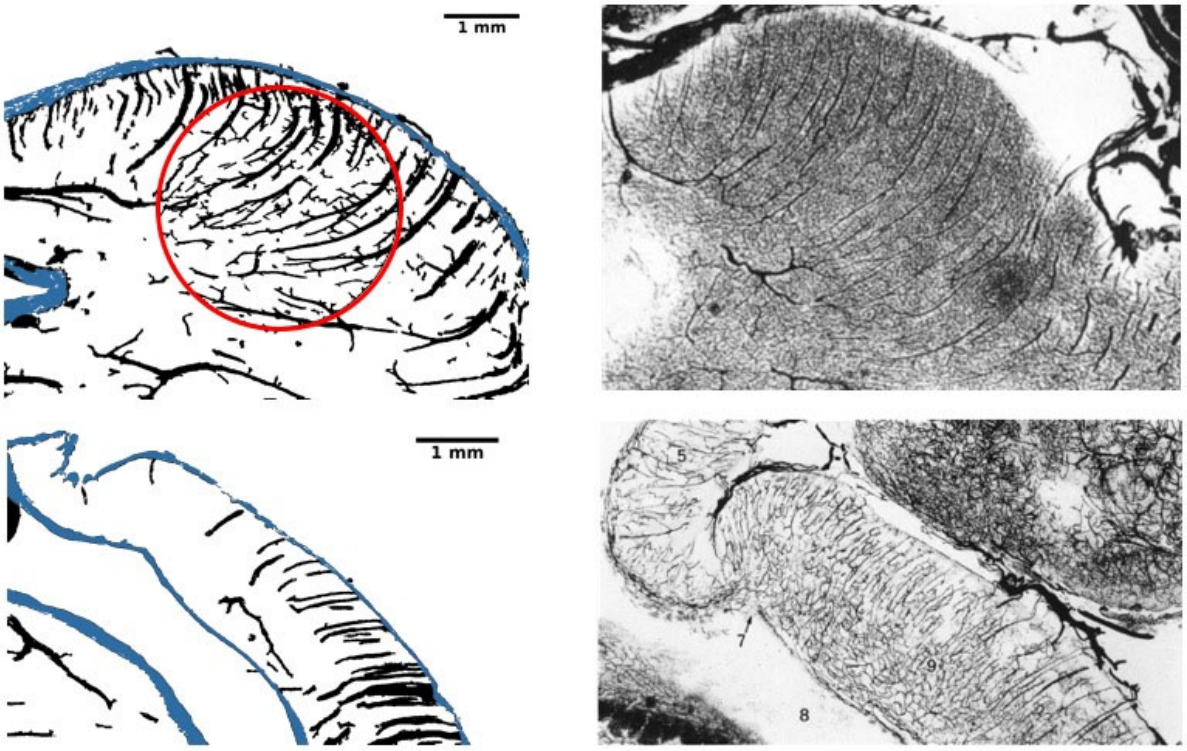

Figure 1. Top: Vessel structure in the superior colliculus from microCT (left) and Indian ink stain (right) in a transversal plane. In the left image, the vessel structure segmented from 0.9 micron resolution microCT is shown inserted in the red circle. Bottom: Sagittal plane of the vasculature in medial tectum from microCT (left) and Indian ink stain (right). (Indian ink stain images are adopted from Durvernoy, H. M., 1978.)

Title: Network-based r-statistics software for longitudinal (unbalanced) brain networks

Authors: *Z. GRACIA TABUENCA, S. ALCAUTER;
Univ. Nacional Autonoma De Mexico, Queretaro, Mexico

Abstract: The brain can be modeled as a set of interacting elements, allowing its characterization from a systems perspective using network science. In particular, Zalesky et al. (2010) proposed Network-Based Statistics (NBS), a mathematical approach that applies statistical inferences at the (sub-)network level, with a trade-off between the control for false positives and higher statistical power than mass univariate approaches (e.g., FDR). Nevertheless, NBS relies on the general linear model (GLM) which limits its application to longitudinal samples, in particular, to unbalanced samples, that is, with a variable number of sessions per subject. We developed a publicly available software (an R-package), NBR (Network-Based R-statistics), that performs mixed-effects models (LME) in the NBS framework, allowing the exploration of unbalanced longitudinal samples. We then tested GLM- and LME-NBS in the SWU-SLIM database, which is publicly available at the International Neuroimaging Data-sharing Initiative (INDI). The dataset includes 333 participants (145 males; 17-28 years old.) with two (n=212) or three (n=121) sessions each. All sessions include a resting-state fMRI scan and psychometric data. State anxiety scores and brain connectivity matrices were used. GLM and LME tested the edgewise brain-behavior relationship for balanced (424 matrices) and unbalanced (787 matrices) samples, respectively. Significance was assessed based on permutation tests including 1000 permutations restricted to within-subject swapping.
The LME approach found a significant subnetwork, which includes the cingulum, the frontal, parietal and occipital lobes, and the cerebellum (pFWE = 0.001), while GLM found no significant results (pFWE = 0.355).
In summary, we developed an R package that implements LME for NBS. We showed that LME-NBS overpowers GLM-NBS when dealing with unbalanced longitudinal samples. This is relevant given that missing data is very common in longitudinal studies, and balanced testing could dramatically undermine statistical power. Besides, we were able to show a brain network related to anxiety symptoms that vary over time, which would not be identified using standard methods. Considering the growth of longitudinal studies in neuroscience, we anticipate this method being potentially useful in the field.

Title: Shoulder Motion Evaluation in Patients with Cervical Spinal Cord Injury via Inertial Measurement Unit-based System

Authors: *R. BRAVI[1], S. CAPUTO[2], S. JAYOUSI[2], A. MARTINELLI[2], L. BIOTTI[2], I. NANNINI[3], E. J. COHEN[1], E. QUARTA[1], S. GRASSO[1], G. LUCCHESI[3], G. RIGHI[3], G. DEL POPOLO[3], L. MUCCHI[2], D. MINCIACCHI[1];
[1]Dept. of Exptl. and Clin. Med., [2]Dept. of Information Engin., Univ. of Florence, Florence, Italy; [3]Spinal Unit, Azienda Ospedaliero-Universitaria Careggi, Florence, Italy

Abstract: In an attempt to achieve functional independence of individuals with cervical spinal cord injury (CSCI), several rehabilitation programs or surgical interventions have been developed to restore shoulder range of motion (ROM) [1]. In clinical settings the gold standard for measuring joint ROM in patients with CSCI is the goniometer, a portable, inexpensive, quasi-objective tool [2,3]. However, the need for more objective methods when evaluating motor parameters appears to be of great importance. The aim of the study was to test the validity of a wearable Inertial Measurement Unit (IMU) sensor system by comparing the accuracy of the IMU system to goniometer method in measuring shoulder ROM [4]. Eight participants with CSCI completed four shoulder movements (forward flexion, abduction, and internal and external rotation) on dominant shoulder. Each movement was assessed with a goniometer and the IMU system by two testers independently. The extent of agreement between each tester's goniometer and IMU measurements was assessed with intra-class correlation coefficients (ICC) and Bland-Altman 95% limits of agreement (LOA). Additional analysis compared agreement between tester's goniometer or IMU measurements (inter-rater reliability) using ICC's and LOA. Preliminary results showed that goniometer and IMU measurements had excellent levels of agreement for all tested movements; however, LOAs were found high. Inter-rater reliability was found excellent between the IMUs measurements, while it was found lower between tester's goniometer. LOAs were found high also when agreement between tester's goniometer or IMU measurements were compared. The current study provides preliminary evidence of the concurrent validity of a wearable IMU sensor system for assessing shoulder movements in patients with CSCI. This can be a potential monitoring and clinical diagnostic tool to be widely used in clinical settings at the service of specialized personnel supporting spinal cord injured subjects.

Title: Mathematical Model of Motion Sickness: Capturing the Effect of the Prediction of Exogenous Motion

Authors: *T. WADA;
Ritsumeikan Univ., Kusatsu, Japan

Abstract: Computational models for estimating motion sickness build in prior studies do not capture the fact that the predictability of the exogenous motion patterns affects the sickness. This study presents a new computational model that includes the effect of the predictability of the dynamics of the exogenous motion stimulus on the motion sickness. The new model combines a conventional observer-theoretic sickness model with a sub-model representing human features of online learning of motion dynamics and the future prediction using a recursive Gaussian process regression. Using the proposed model, a simulation experiment was conducted to calculate the predicted motion sickness incidence under the condition that a human was moved horizontally for 900s, in which the motion was composed of repetitions of 9 m back-and-forth movement and a pause. As a motion factor, the direction and timing of the motion were changed as follows: predictable (M_P), the direction of the motion and duration of the pause (8 s) were fixed; direction unpredictable (M_dU): the pause duration was fixed as in (M_P), but the motion direction was randomly determined; and timing unpredictable (M_tU), the motion direction was fixed as in (M_P), but the pause duration was random between 4-12 s. The results demonstrated that the predicted MSI for (M_P) was smaller than those of (M_dU) and (M_tU). Results agreed with the actual sickness observed during an experimental study with human participants conducted under motion conditions similar to our simulation. No significant difference in the predicted MSI was found when using the conventional model. This demonstrated that the proposed model effectively captured the effect of human motion prediction on motion sickness.

Title: Nih funded nitrc's triad of services: software, data, compute

Authors: *D. N. KENNEDY[1], C. HASELGROVE[2], A. PAULSON[3], A. CROWLEY[4], N. PREUSS[5];
[1]U. Massachusetts Med., Worcester, MA; [2]Univ. of Massachusetts Med. Sch., Worcester, MA;

[3]The Paulson Venture, Huntington Beach, CA; [4]TCG, Inc, Washington, DC; [5]Preuss Enterprises Inc., Miami, FL

Abstract: Aim of Investigation: NeuroImaging Tools and Resources Collaboratory (NITRC) is a neuroinformatics knowledge environment for MR, PET/SPECT, CT, EEG/MEG, optical imaging, clinical neuroinformatics, computational neuroscience, and imaging genomics tools and resources.
Methods: Initiated in 2006 through the NIH Blueprint for Neuroscience Research, NITRC's mission is to foster a user-friendly knowledge environment for the neuroinformatics community. By continuing to identify existing software tools and resources valuable to this community, NITRC's goal is to support its researchers dedicated to enhancing, adopting, distributing, and contributing to the evolution of neuroinformatics analysis software, data, and compute resources.
Results: Located on the web at www.nitrc.org, the Resources Registry (NITRC-R) promotes software tools and resources, vocabularies, test data, and databases, thereby extending the impact of previously funded, neuroimaging informatics contributions to a broader community. All services freely downloadable, NITRC-R offers over 1,300 public resources; NITRC-Image Repository (NITRC-IR) offers 17 data projects, 11,559 subjects, and 13,282 imaging sessions, and NITRC Computational Environment (NITRC-CE) provides cloud-based computation services downloadable to local machines or via commercial cloud providers such as Amazon Web Services.
Conclusions: In summary, NITRC is an established knowledge environment for the neuroimaging community where tools and resources are presented in a coherent and synergistic environment. NITRC is a trusted source for the identification of resources in this global community. With over 9,790 citations on Google Scholar, NITRC has supported over 34,560 registered users, served up 11.4 million total, and of that, 9.9 million data downloads, to over 1.4 million users generating 3.1 million sessions. In addition to untold downloaded Virtual Machines, NITRC-CE currently supports over 250 subscriptions on AWS Marketplace running over 365,400 compute hours. We encourage the neuroinformatics community to continue providing valuable resources, design and content feedback and to utilize these resources in support of data sharing requirements, software dissemination and cost-effective computational performance.

Title: A Python-based pipeline for computational modeling of peripheral nerve electrical stimulation

Authors: *E. D. MUSSELMAN, J. E. CARIELLO, W. M. GRILL, N. A. PELOT;
Biomed. Engin., Duke Univ., Durham, NC

Abstract: Electrical stimulation of peripheral nerves is used to treat a variety of diseases and to restore function following injury. However, translation of therapies to the clinic can be unsuccessful despite promising preclinical data, particularly if differences in nerve morphology require distinct cuff designs and stimulation parameters to achieve target responses. Computational modeling of nerve stimulation enables robust quantification of the effects of stimulation parameters and optimization to design device geometries and stimulation parameters to achieve desired responses to stimulation.

We developed an open-source computational modeling infrastructure to automate the complex, multi-step simulations of the responses of fibers within individual-specific nerves. The pipeline uses Python, the COMSOL API for use with Java, and NEURON, and all model parameters are defined in JSON files. Model inputs, such as nerve morphology, coordinates of nerve fibers, and stimulation waveforms, are prepared in Python. In COMSOL, extracellular potentials are computed along the length of model fibers seeded in the three-dimensional representation of the nerve and cuff electrode. Extracellular potentials along each fiber are applied as a time-varying signal in NEURON, and Python is used to analyze and plot simulation outputs (e.g., thresholds). The pipeline increases the accessibility of model-based design for peripheral nerve interfaces and enhance reproducibility of modeling data. Researchers will be able to plan and interpret results from surgical interventions using our tools that are essential for achieving model accuracy: automated nerve geometry representation from images of segmented histology or user-defined nerve and fascicles sizes and locations, a library of parameterized cuff electrode parts for assembling custom nerve interfaces, integration of published biophysical nerve fiber models (e.g., MRG model of myelinated fibers, Tigerholm model of unmyelinated fibers), and parameterized stimulation waveforms.

Computational modeling is a critical tool to determine and control the input-output relationship between applied electrical stimulation and the complement of nerve fibers that are activated or blocked. This simulation pipeline enables large-scale simulations with a platform that is user-friendly, expandable, and thorough in its feature set.

Abstract: Local field potentials (LFP) provide rich information about population dynamics across neural networks for neuroscientific studies and therapeutic applications. Yet, the invasiveness of LFP and incomplete cortical coverage limit the acceptability and usage of LFP-based brain-machine interface (BMI). Here, we introduce the NeuroBondGraph Network (NBGNet), a deep learning method to infer forward and inverse dynamics between neural activities in different modalities. When applied to the macaque cortical datasets, the bi-directional translation modeling accurately estimates LFP from brain signals recorded from intracranial macroelectrodes (ICME) and vice versa. To validate the predictive power and stability of NBGNet, we utilized multiple metrics: (1) scale-dependent measures such as root mean squared error to determine how close the predictions and the ground truth were, (2) cross-correlation to evaluate the similarities between them, and (3) phase synchrony to quantify the phase difference between them. The presented analysis could significantly improve the performance of LFP-based closed-loop neuroprosthetic applications without increasing the LFP channel count. Furthermore, our predictive models have future clinical utility by illuminating the brain computations in multi-scale networks to facilitate the development of clinical devices and rehabilitative therapies.

Title: Particle swarm optimization of ionic conductances identifies models of varied c-fiber subpopulations

Authors: *B. J. THIO, N. D. TITUS, N. A. PELOT, W. M. GRILL;
Biomed. Engin., Duke Univ., Durham, NC

Abstract: C-fibers constitute the vast majority of axons within peripheral nerves, but their small diameters prevent application of voltage clamp to characterize their membrane properties. Previous C-fiber models only replicated a subset of experimental conduction responses for

specific C-fiber subpopulations. We created a library of novel isoform-specific ion channel models and used particle swarm optimization to reverse engineer underlying C-fiber membrane properties of two C-fiber subpopulations. The resulting optimized models of autonomic and cutaneous C-fibers reproduced a broad range of experimentally measured electrophysiological properties including conduction velocity, chronaxie, and the dynamics of the paired pulse recovery cycle. As further validation, we simulated activity dependent slowing (ADS), a property not included in model optimization. The models exhibited ADS that closely matched published experimental data for autonomic (1.5-1.8% slowing in model vs. 1.9-2.2% slowing in experiment) and cutaneous fibers (12.7-16.1% slowing in model vs. 13.8-20.7% slowing in experiment). Finally, we simulated the fidelity of action potential activation of the C-fibers to pulse trains of extracellular stimulation at rates ranging from 2 to 10,000 pulses per second which is of interest in understanding the mechanisms of pain. Both fiber types exhibited conduction failure starting at 10-20 pulses per second and conduction was blocked by kilohertz rate stimulation. The resulting C-fiber models constitute an important tool for understanding the mechanisms of nerve fiber responses to electrical stimulation and designing novel neuromodulation interventions. Additionally, the novel reverse engineering approach of the particle swarm optimization framework can be applied to generate models of other neurons where electrophysiological data are available but voltage clamp data are not.

Title: Investigating the reliability of fast motor maps at varying motor threshold intensities

Authors: ***S. FOGLIA**[1], C. TURCO[2], A. J. NELSON[2];
[1]Biomed. Engin., [2]Dept Kinesiol, McMaster Univ., Hamilton, ON, Canada

Abstract: The organization of the primary motor cortex (M1) can be non-invasively assessed using transcranial magnetic stimulation (TMS) combined with frameless stereotaxic brain navigation. Traditionally, this technique requires stimulation of M1 in a grid-like pattern at predefined targets, delivering 3-5 stimulations per site with an interstimulus interval (ISI) of at least 5s. Various characteristics of these motor maps can be explored such as area to visualize the somatotopy of M1. However, the time required to produce these maps (~20 min per map) reduces the feasibility of this technique in more time sensitive protocols, such as fatigue studies or clinical brain tumor mapping. Van de Ruit (2015) recently developed a new way of collecting these maps, termed “fast motor maps”, that relies on delivering TMS pulses to pseudo-random locations within a 6x6 cm space overlaying M1. This technique improves map acquisition time

(~3 minutes per map) and is reliable within a session when performed at 120% resting motor threshold (RMT). No study however, has examined fast motor map reliability at more than one stimulus intensity. Higher TMS test intensities have been shown to decrease variability and improve reliability for MEP responses. The primary purpose of the present study was to investigate the reliability of fast motor maps as a function of TMS intensity using both relative and absolute reliability statistics. Intrasession reliability was assessed in 12 healthy participants for maps acquired at 110, 120, and 130% RMT in the right and left FDI muscles, before and after a 2-hour rest period. Relative reliability was assessed using the intraclass correlation coefficient (ICC) to quantify the degree to which individuals in the sample differed from one another and how well these differences could be distinguished by the measurement/test. Absolute reliability, measured with standard error of measurement (SEMeas), was used to estimate the distribution of repeated measures around the true score of the individual. Results illustrated that maps collected at 130% RMT exhibited the greatest level of absolute and relative reliability for area. Specifically, map area was moderately reliable for both RFDI (ICC 0.72, SEMeas 22%) and LFDI (ICC 0.73, SEMeas 15%) muscles at 130% RMT. Map area at 120% RMT was poor and moderately reliable for RFDI (ICC 0.42, SEMeas 34%) and LFDI (ICC 0.6, SEMeas 18%) respectively. These results demonstrate that higher stimulation intensities are required to elicit the most reliable motor map using the fast mapping technique.

Title: A new neuromechanic semantic of turning using fuzzy spinors for quantum-like electric-charge relocation in intact brains: a non-classic, electromagnetically sensitive and delicate probabilistic process

Authors: *J. F. GOMEZ-MOLINA;
Intl. Group of Neuroscience, IGN:N(S,E,P).

Abstract: INTRODUCTION. Excitable tissues are more probabilistic but more organized, delicate and sensitive at the subcellular and sub-millisecond level than previously thought. They present new phenomena in relation to electroneutrality as well as capacitive and ephaptic effects that need to be revisited (Savtchenko et.al. 2017). The LFP, EEG and MRI-techniques cannot longer be understood in terms of deterministic equations for co-activated cells but in terms of open, activation and relocation probabilities of coactivated ion channels and electrically charged particles (Gomez 2003, 2016). Electrophysiological and inflammatory activation states need to be defined not only in terms of mitochondria, neurons, glia and vascular cells but also in terms of

free radicals and unpaired electrons in order to apply appropriately the equations (Gomez 2020 NIH Rehab). New circuit or single-particle models can be developed to describe possible forms of signaling with electronic unbalances (in charge, spin and pairing) associated to membranes and macromolecular networks of ion channels or the cytoskeleton. Here we present some elements to facilitate new models. -METHODS. Simplified toy-models based on fuzzy math and probabilistic approaches. Analysis of sensolocomotion and turning in ants, humans and robots during climbing against gravity. -RESULTS. Some elements of the Schrodinger's equation, Spinors and (de)fuzzification are used to revisit controversies, explore wave-like propagation of states, exotic and generalized forms of charge relocation and long-range electric signals. -DISCUSSION. Modern physical models are complex, too difficult and abstract (Gomez and Ricoy H-abstract SfN 2020). Tests with new non-invasive biophysical and neuromechanical experiments are needed. CONCLUSIONS. 1. The concept of spinors of Pauli-Dirac can be applied to charge relocation (discontinuous changes in vector position) in the brain. 2. To understand electromagnetism in general we need: i) new logic and probabilistic expressions ii) new kind of experiments in biophysics and psychophysics iii) an intuitive semantics with this new phenomenology. iv) more sensible techniques (QFT-type?) to model, measure and stimulate probabilistic molecular signals. 4.Recent finding showing high sensitive of neurons to electromagnetic fields, critically multiply the measurement problem in physics, making us to assume a more humble epistemological attitude. This has important consequences in the design of non-invasive research, from the subcellular (electron transfer signaling, quantum dots, nanosensors) to the system (NMR/EPR, neuroprothesis, EEG/MEG, TMS) level.

Title: Microstructural variation in the human striatum using non-negative matrix factorization

Authors: *C. ROBERT[1], R. PATEL[1], N. BLOSTEIN[1], C. STEELE[3], M. CHAKRAVARTY[2]; [2]Dept. of Psychiatry, Biol. and Biomed. Engin., [1]Douglas Mental Hlth. Univ. Institute; Univ. of McGill, MONTREAL, QC, Canada; [3]Dept. of Psychology, Univ. of Concordia, MONTREAL, QC, Canada

Abstract: The striatum is a deep grey matter nucleus involved in various neurological and neuropsychiatric disorders. Although the functional role of the striatum has been broadened, its tissue microstructural organization and variation remain poorly known. Here, we developed a normative multimodal, data-driven microstructural parcellation of the striatum and explored how variation from the normative model relates to motor and cognitive performance as well as demographics. We used a subset of the multimodal MRI data along with behavioural/demographic data from the Human Connectome Project Young Adult dataset

(n=333, age: 22-35). We assessed microstructure using mean diffusivity (MD), fractional anisotropy (FA) and the ratio between T1- and T2-weighted structural MRI data (T1w/T2w; putative marker of myelin). We extracted spatially distinct components representing patterns of covariance in microstructure across subjects using non-negative matrix factorization (NMF). NMF decomposed a vertex-wise matrix with each subject's metric as columns and voxels as rows. Using the stability and accuracy of NMF clusters in a split-half analysis, we identified 5 striatum components. Then, we used partial least squares (PLS) to link inter-individual variation in the striatal components to selected behaviours and demographics. We found four significant latent variables (LV, $p<0.05$), two for each the left and right striatum. The first left LV (left LV1, 57% variance explained) was associated with young age, male sex and increased MD across all 5 components. Left LV2 (29%) correlated with young age, female sex, decreased FA in components 1, 3, 5 and decreased T1w/T2w in all components. Right LV1 (58%) correlated with young age, male sex and increased MD across all components. Right LV2 (31%) was associated with young age, increased FA in all components and increased T1w/T2w in components 1, 3. Our findings suggest distinct microstructural patterns in the human striatum that relate to demographics. Our work also highlights the gain in clusters' stability when using multimodal versus unimodal metrics.

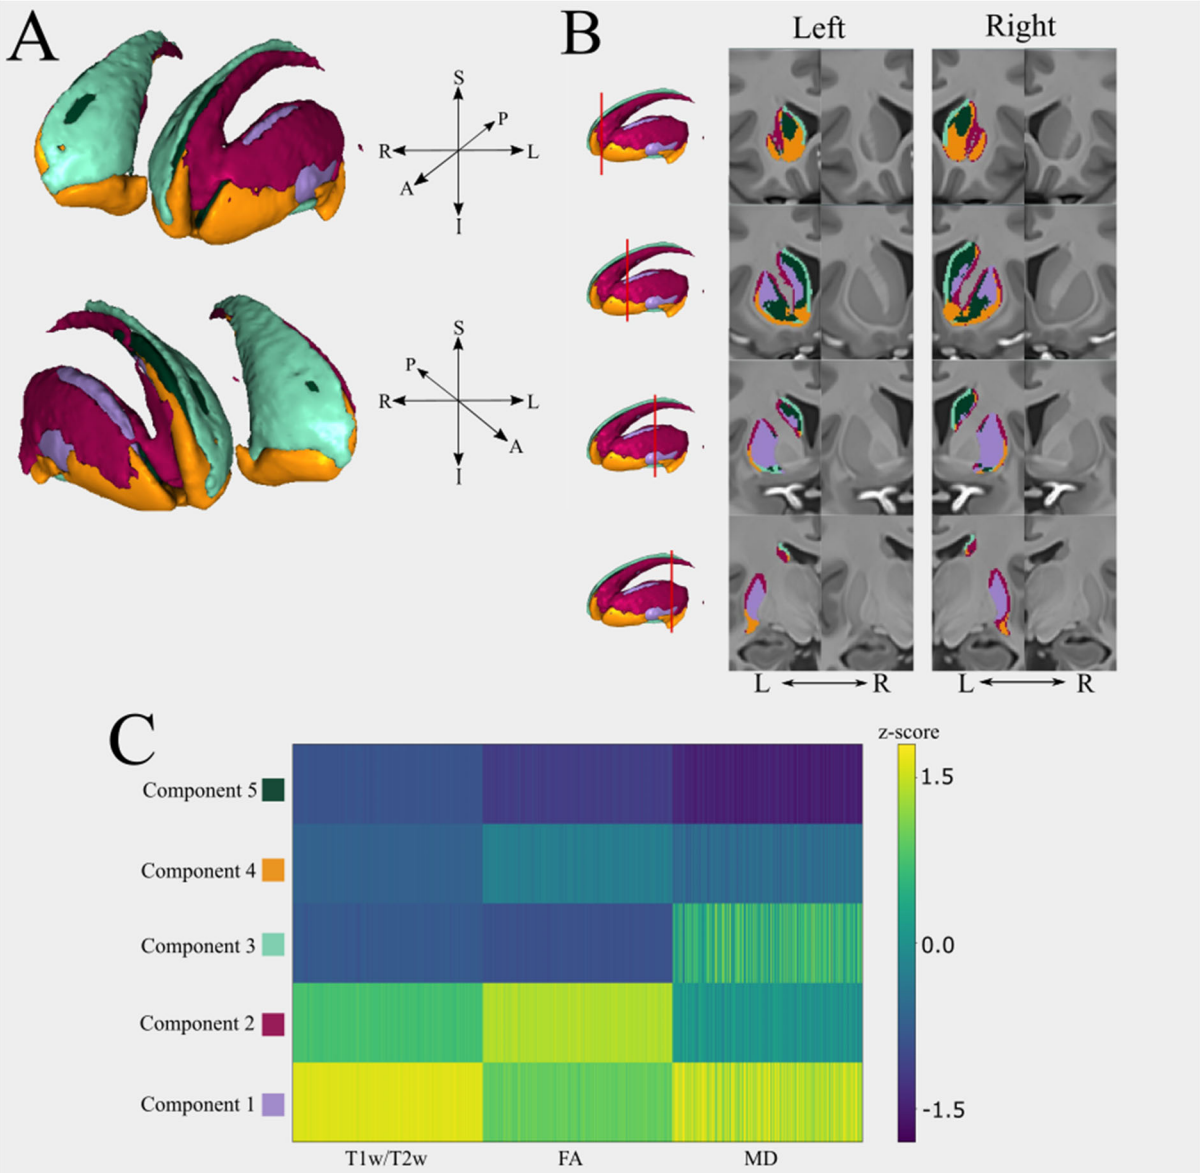

Figure 1: A) 3D rendering of the 5 components solution (A: anterior; P: posterior; S: superior; I: inferior; R: right; L: left). B) Coronal slices showing the labelled and unlabelled (side-by-side columns) of the left and right striatum. C) Weight matrix output from NMF of the left striatum, showing how the microstructural metrics weight into each component (the right weigth matrix is similar).

Title: Application of the novel object recognition test in Wistar rats by the use of the MOTUS software

Authors: *M. ALVARADO[1], P. GONZÁLEZ[1], V. HERNÁNDEZ[2], A. LEÓN[2];
[1]Inst. de Neuroetologia, Xalapa, Mexico; [2]Lab. de Psicología Comparada, Xalapa, Mexico

Abstract: The study of animal behavior can be carried out using different behavioral tests. The novel object recognition test (RON) is relevant because it assesses short-term (MCP) and long-term (MLP) memory. The use of software for behavioral tests has shown advantages by facilitating and presenting results in greater detail. This study describes the use of software (MOTUS) on animal behavior, analyzing its performance on the RON test, through the detailed exposition of the path that the rodent follows and the interaction with objects (Familiar Object and Novel Object). Route graphs, accumulated time in regions, speed and distance to each of the objects are obtained. In the present work, 6 male rats of the Wistar strain without any treatment were used at the age of P120. For the behavior test a 90x90x50 cm sand was used and there were three objects: the familiar object (pyramid) and two novel objects (cube and cylinder), which were selected and placed at a distance of 20 cm from the corner to the sand and 50-60 cm between them (Ordoñez, 2013; Aubele *et al*., 2008; Goulart *et al.,* 2010). The test was carried out in four sessions (habituation, training, MCP and MLP), each session lasted 5 min. The MOTUS program worked with X, Y coordinates which were previously obtained using the idTracker software. For the graphic representation of the results were indicated in the software: the specific coordinates of the objects in addition to the size of the sand. In the MCP session it was obtained an average percentage of 8.66% in the latency interaction and 58.84% on frequency interaction with the novel object while of the familiar object it was 4.59% and 41.15% respectively, the relevant objects distance graph was generated by this information. On the other hand, in the MLP session it was obtained a percentage of 11.30% by the latency interaction with the novel object and a 64.62% on frequency interaction while of the familiar object was 3.59% and 35.79% respectively. In addition, the software is freely accessible and has provided information on the average speed, distance traveled and acceleration, thereby prove to be an effective, practical and easy software for monitoring behavioral dynamics in the RON test and, potentially, with other behavioral test. https://www.uv.mx/ceicah/proyectos-academicos/desarrollos/motus/ (León *et al.,* 2020).

Title: Precision dynamical mapping using topological data analysis reveals a unique Transition State at rest in highly sampled individuals

Authors: *M. SAGGAR[1], J. M. SHINE[2], R. LIEGEOIS[3], R. RAUT[4], T. O. LAUMANN[4], A. Z. SNYDER[4], N. U. F. DOSENBACH[4], D. A. FAIR[5];

Abstract: Even in the absence of external stimuli, neural activity is both highly dynamic and organized across multiple spatiotemporal scales. The continuous evolution of brain activity patterns during rest is believed to help maintain a rich repertoire of possible functional configurations that relate to typical and atypical cognitive phenomena. Whether these transitions or "explorations" follow some underlying arrangement or instead lack a predictable ordered plan remains to be determined. Although innovative approaches have been previously developed to reveal the temporal structure underlying transitions in the brain at rest, several methodological and data quality issues precluded the development of a clear understanding of network dynamics at the individual level. Here, we overcame these limitations by examining the dynamic states during intrinsic brain activity using Topological Data Analysis (TDA) on a maximally denoised precision neuroscience dataset - The Midnight Scan Club (MSC). This dataset comprises of ten highly sampled individuals, with >5 hours of resting state fMRI data per individual and individualized parcellations of each brain. Without temporal averaging or sliding windows, our TDA-based approach mapped whole-brain resting state volumes onto a set of individually defined intrinsic dynamical manifolds or "state spaces". For reliability, all reported results were validated using split-half cross validation. Further, multivariate autoregressive and phase randomized null models were used to examine how topological properties of the revealed landscape were driven by linear versus non-linear properties of the data. Using our TDA-based approach, we observed a rich topographic landscape in which the transition of activity from one network to the next involved a large shared attractor-like basin, or "transition state", where all networks were represented equally prior to entering distinct network configurations. The intermediate transition state and traversal through it seemed to provide the underlying structure for the continuous evolution of brain activity patterns at rest. In addition, differences in the manifold architecture were more consistent within than between subjects, providing evidence that this approach contains potential utility for precision medicine approaches.

Title: A computational control scheme for self-adjustment brain system

Authors: *J. KANG[1,4], J. EO[2], H.-J. PARK[4,1,2,3];
[1]Dept. of Nuclear Med., [2]BK21 PLUS Project for Med. Sci., [3]Dept. of Psychiatry, Yonsei Univ. Col. of Med., Seoul, Korea, Republic of; [4]Inst. of Human Complexity and Systems Sci., Yonsei Univ., Seoul, Korea, Republic of

Abstract: Treatment of brain disease is difficult due to the complexity of the brain. Computational frameworks, which can simulate dynamics of the before and after treatment brains, have been developed to resolve this problem. However, in these frameworks, self-adjusting nature of brain system after treatments has not been fully considered and the brain system was only regarded as a passive responding system. Thus, an initial plan of treatment may not always the best solution. In the present study, we propose a computational framework for optimal control of the self-adjustment brain system.
To describe brain dynamics, we adopted dynamic causal model (DCM) [1] which can generate experimental observation signals from neural activities of the models. We modeled the plasticity of the effective connectivity of the neural system after the treatments. Two types of plasticity, activity-dependent plasticity and homeostatic plasticity, were implemented as the brain's self-adjustments, and neural system was updated by self-adjustments after each treatment.
The solutions for optimal control of the brain were explored with considerations of the brain self-adjustments. Considering various clinical treatments, we set several restrictions such as one treatable node which mimics transcranial magnetic stimulation (TMS), global treatment which mimics medications, and mixed treatments (simultaneous treatments of TMS and medications). In the present scheme, first, using neuroimaging data, the effective connectivity of the brain system was estimated by DCM. Then, applying the treatment and self-adjustment rules, we simulated observation signals of updated system, and explored the best solution that can generate similar observation signals of target brain system. To estimate system parameters of self-adjustments, we used signals that were obtained from previous treatment.
To test our scheme, we used hippocampus systems of mutant and wild-type mice that were analyzed in our previous study [2], where the effective connectivity of the rodent's hippocampus circuitry were estimated by using DCM of the voltage-sensitive dye imaging (VSDI).
Simulation results showed that optimal control of the abnormal mutant system successfully approached to the signals of the normal wild type under restrictions that mimic various clinical treatments. We believe that the proposed computational framework of the self-adjustment system could help optimal control of the dynamic brain after treatment.

Title: Automated scaling and segmentation of mouse mesoscale cortical maps using machine learning.

Authors: *D. XIAO[1], B. FORYS[1], M. VANNI[2], T. MURPHY[1];
[1]Univ. of British Columbia, Vancouver, BC, Canada; [2]Univ. de Montréal, Montréal, QC, Canada

Abstract: Understanding the basis of brain function requires knowledge of cortical operations over wide spatial scales, and quantitative analysis of brain activity in well-defined brain regions. Matching an anatomical atlas to brain functional data has traditionally been a labor-intensive procedure that precludes high-throughput analysis. We have developed an automated machine learning-based registration and segmentation approach for quantitative analysis of mouse mesoscale cortical images. We fine-tuned a pre-trained deep learning model to identify nine cortical landmarks using a wide-field calcium imaging dataset from more than 400 GCaMP transgenic mice. A fully convolutional network was trained to delimit brain boundaries. We present the methodology to automatically register and align mesoscale cortical images as MesoNet, a robust and user-friendly analysis pipeline using pre-trained models to segment brain regions as defined in the Allen Mouse Brain Atlas. This Python-based toolbox can also be combined with existing analysis methods to cluster distinct cortical activity motifs.

Title: The SPARC Data Structure: serving the peripheral nervous system research community funded under SPARC

Authors: *A. E. BANDROWSKI[1], A. PILKO[1], T. GILLESPIE[2], M. SURLES-ZEIGLER[2], G. PINE[2], T. SINCOMB[2], P. L. PASCUAL[2], D. RAWOOL[2], I. B. OZYURT[2], J. K. BOLINE[4], J. S. GRETHE[5], M. E. MARTONE[3];
[1]UCSD, SAN DIEGO, CA; [3]Neurosci., [2]UCSD, La Jolla, CA; [4]Informed Minds Inc, Walnut Creek, CA; [5]Ctr. for Res. in Biol. Systems, Univ. of California San Diego, La Jolla, CA

Abstract: The Stimulating Peripheral Activity to Relieve Conditions (SPARC) program is a NIH funded project to fund, collect, and curate various peripheral nervous system data for inclusion into an open data portal, https://sparc.science. 28 awards have been funded over 4 years to groups from 19 universities and 4 companies; it was necessary to develop a consistent structure to organize, label, and annotate data. The project is composed of investigators who generate data, 4 data handling cores (data storage, data curation, mapping, and simulation), as well as investigators who are building stimulators that will eventually be used to intervene with peripheral nervous system disorders.
The SPARC Data Structure, SDS (https://github.com/SciCrunch/sparc-curation/releases), is derived from the Brain Imaging Data Structure (BIDs). BIDs is a simple folder structure with predictably named metadata files that enables investigators to align data files and describe them in a consistent manner. The SDS is also a simple folder with metadata files, but it allows inclusion of data modalities such as RNASeq, immunohistochemistry, in addition to imaging. Like BIDs, the top level folder includes standardized metadata description files, containing specific information about subjects as well as general dataset details, and unlike BIDs samples, and finding specific information. All four of these files are created from standard templates designed by the curation team and approved by the SPARC data structure committee. Each folder includes data files, named in a consistent manner with the metadata files and includes a manifest describing additional details about the files.
As each dataset is submitted by investigators, it is checked by an automated tool (SDS Validator https://github.com/SciCrunch/sparc-curation), which produces a set of errors and warnings. An upload assistant, SODA (https://github.com/bvhpatel/SODA), is a desktop application designed to organize data automatically for the SPARC investigators. Curators work with dataset authors to eliminate the errors and reduce the warnings, ensuring that every dataset is properly structured, contains appropriate metadata elements, and is machine readable. The current SPARC portal contains 55 datasets, as of November 12, 2020, and an additional 186 datasets are in process. Each released dataset has a descriptive image, a structured abstract, curation notes, a set of machine readable data files aligned to SDS structure.
The SDS should improve the usability of SPARC data.

Abstract: Ultrasonic vocalizations (USVs) are known to reflect emotional processing, brain neurochemistry, and brain function. USVs in the 22-28 kHz and 50-55 kHz frequency range are widely recognized forms of social and emotional expression in rodents. 22-28 kHz USVs reflect negative affect status and are initiated by regional activation along the ascending mesolimbic cholinergic (ACh) pathways. 50-55 kHz USVs reflect positive affect status and are initiated by regional activation along the mesolimbic dopaminergic (DA) pathway. Collecting and processing USV data is manual, time-intensive, and costly creating a significant bottleneck by limiting researchers' ability to employ fully effective, and nuanced experimental designs, and serving as a barrier to entry for other researchers. Duvauchelle et al (2013, 2014) addressed this bottleneck by developing WAAVES, an automated USV assessment program that utilizes a decision tree architecture. Unfortunately, WAAVES requires manual threshold calibration for each unique environmental context reducing its benefit to the wider research community. Last year at SFN we introduced a new automated USV scoring algorithm, WAAVES+ that is environment- and animal-agnostic. WAAVES+ uses supervised and unsupervised machine learning techniques to detect, isolate, parameterize, group, and classify USVs. In this poster, we present the detailed process that we utilized to further optimize WAAVES+ 2.0. First, we developed an Amazon Web Service (AWS) back-end framework for storage and automated analysis of USV files with an intuitive user interface using the React framework (Javascript). The main processing script can be run both on AWS (where a run is triggered by uploaded files) and via local resources providing the ability to gather data from many sources simultaneously without disrupting the development cycle. Program updates and new analytics can be deployed to all users directly and instantaneously via the website. We have also modified the call detection program (Python) for off-line batch processing of USV audio files that can provides the developer with a number of useful data metrics and statistics. Third, we hand scored several hundred minutes of new USV files from multiple recording environments into 17 rat and 9 mouse call categories. We are currently developing a machine learning approach that utilizes these data in an ongoing and

iterative fashion to improve call detection and call classification capabilities via reinforcement learning algorithms that continue to improve WAAVES+ 2.0 performance based on user feedback.

Title: Evaluating methods for estimating geometry of neural representations

Authors: *H. KEGLOVITS, A. BHANDARI, E. CHICKLIS, D. BADRE;
Brown Univ., Providence, RI

Abstract: There is growing recognition that the geometry of neural population representations place important constraints on cognitive function and behavior. Representational geometry refers to the relationships among the firing patterns of a population across its inputs. One key feature of the geometry is its dimensionality, defined as the number of unique axes required to fully specify the position of all the firing patterns of a population across all conditions of a task. Representational dimensionality has been shown to correlate with behavior in highly trained monkeys, but has not been systematically studied in humans. A major obstacle to bridging human and animal studies in this domain is that we presently lack techniques to estimate representational dimensionality non-invasively in humans, using methods like fMRI and EEG. Recently, Rigotti & Fusi (2016) proposed a method for leveraging repetition suppression (RS) effects in fMRI to estimate representational dimensionality. However, the impact of realistic hemodynamic effects would be on these estimates was not considered. In this study, we sought to address this gap and validate the method in realistic neural-to-BOLD simulations of repetition suppression effects using efficient trial sequences which could be feasibly given to human subjects. We employed a model of repetition suppression to simulate neural firing patterns of known dimensionality and used a standard gamma function to simulate hemodynamic responses to these firing patterns. We then employed a previously developed cross-validated singular value decomposition method to estimate the dimensionality of the recovered signal from the BOLD response, which was evaluated against the known underlying dimensionality of the neural firing patterns. Results from our simulations provide a validation of the method and systematically demonstrate that the method is useable, but the robustness of dimensionality estimations is affected by three main factors: neural and fMRI noise, correlated history effects of the BOLD

signal, and the shape of the input matrix used to test dimensionality. Each of these factors drives a bias toward under-estimation of the true representational dimensionality in the neural signal. We discuss ways to mitigate these effects and achieve better dimensionality estimations through careful study design.

Title: Meso-scale structure of population spiking dynamics as revealed by correlation and filter estimation in a computational model of rat hippocampus

Authors: ***G. J. YU**, J.-M. C. BOUTEILLER, T. W. BERGER;
Biomed. Engin., USC, Los Angeles, CA

Abstract: Investigations into the meso-scale connectivity of hippocampus have revealed a spatial modularity that is dependent on axonal anatomy and may provide a means to identify higher-level functional units beyond the neuronal and microcircuit levels. These meso-scale functional units have yet to be fully explored. Two methods - spatio-temporal correlation and Laguerre-Legendre basis functions - were used to predict the spatial and dynamical properties of putative higher-level functional units using spiking data generated by a large-scale and multi-scale neuronal network mode of the rat hippocampal entorhinal-dentate-CA3 system. The network contained 112 000 entorhinal neurons, 120 000 dentate granule cells, and 25 000 CA3 pyramidal cells. The neuronal models were distributed along the septo-temporal and transverse axes to represent the full hippocampal volume which was necessary to accommodate the meso-scale connectivity. The connectivity of neuronal network was constrained using anatomical data that characterized the size and shape of projections and their topographical organization. The first method for identifying a meso-scale functional unit was the correlation map. The correlation map was constructed by computing pairwise temporal correlations which were then sorted based on the relative distance between the neuron pairs. The second method was to represent the transformation of neural spiking using Laguerre and Legendre basis functions which account for the temporal and spatial properties, respectively. Both the correlation map and Laguerre-Legendre filters used spiking activity for their analysis and characterized the functional similarity of neurons in space and time. Both methods captured the spatial size and shape within which neural spiking was related, thereby estimating the spatial size and shape of the functional unit. Finally, both methods contain a temporal aspect which captures the dynamics of the functional unit. Key differences are that correlation is acausal and linear, and Laguerre-Legendre is causal and nonlinear. The results suggest that neural modules are not discrete but change over a

continuum depending the subpopulation of neurons being observed and are dependent on the topography of the connectivity. The characterization of these meso-scale functional units offers a method to understand how information within a neural system is processed and distributed throughout a network.

Title: Modularity measures of functional brain networks predict individual differences in delayed recognition memory

Authors: *M. B. ZHOU, Q. LIN, M. CHUN;
Yale Univ., New Haven, CT

Abstract: Long-term memory (LTM) is crucial to daily functioning, and individuals show a large variance in LTM capacity. In this study, we ask: to what extent does the functional organization of the brain explain individual differences in a widely studied form of LTM, delayed recognition memory (REC)? Recent work has adopted tools from graph theory to examine how modularity, the degree to which the brain can be divided into distinct modules, is related to cognition (Bertolero et al., 2018). Using fMRI data from n-back tasks and recognition memory data from the Human Connectome Project (n=708), we explored how different modularity properties of nodes in the brain may relate to individual differences in REC. More specifically, we focused on two properties that describe distinct aspects of network functioning: diversity (the extent to which a node has diverse connections with different modules; measured with participation coefficient [PC]) and locality (the extent to which a node has more connections within their own modules; measured with within-module degree [WMD]). To investigate if node diversity and locality are related to REC, we built a predictive model with these two measures and validated it in a leave-one-out cross-validation scheme. For PC, we first correlated the PCs of each node with REC across the subjects within the training sample and selected nodes whose PCs were correlated with REC. We then correlated each subject's PCs with the group-based PC-behavior correlation map of the selected nodes. This value represents how optimized this subject's PCs among the selected nodes are for REC performance. The same procedure was repeated for WMD. We then used linear regression to relate the PC and WMD optimality measures with REC performance in the training sample. This model was used to predict the REC score in the left-out test subject based on their modularity measures. This predictive model significantly predicted individual differences in REC (Pearson's $r = 0.26$, $p < .001$). In addition, we found that the node diversity of the Medial Frontal network contributed most to the prediction, while the node locality of the Frontoparietal, Visual I, and Visual Association networks contributed most to the prediction. Interestingly, for nodes in the Default

Mode network, both diversity and locality played important roles in the prediction of REC. Using recognition memory as an example, our findings extend previous work on how the modularity of brain is related to cognition and demonstrate the utility of using graph-theory-based measures to reveal how the modularity of brain networks is related to individual differences in LTM performance.

Title: Computational tools for rapidly visualizing large-scale activity with single-neuron, single-spike resolution in simple brains

Authors: J. W. BROWN, E. S. HILL, W. N. FROST;
Stanson Toshok Ctr. for Brain Function and Repair, Rosalind Franklin Univ., North Chicago, IL

Abstract: Despite its unceasing activity and centrality in an animal's moment-to-moment existence, the brain operates invisibly. While functional imaging techniques like fMRI and a range of optical electrophysiological methods can provide both large-scale and granular insights and into neurophysiology, achieving simultaneous resolution of brain activity at both of these scales with high temporal resolution to yield a "complete" picture of real-time brain function remains a challenge. Simple nervous systems comprising relatively few, large, mostly superficial, and individually identifiable neurons enable electrophysiological investigations and analytical approaches that allow single-neuron, single-spike readouts over significant portions of those nervous systems. Here, we describe and illustrate several computational tools we have recently developed to visualize and animate optical data collected in the brains of gastropod mollusks, including that of *Berghia stephanieae*, a new model system and the subject of a current BRAIN Initiative U01 collaboration. Data are collected using a photodiode array imaging at 1,600 Hz and the fast, absorbance voltage-sensitive dyes RH155 and RH482. Following implementation of a previously developed method for blind-source separation of optical signals into individual neuronal activity traces using independent component analysis, we employ an automated algorithm to map individual neuronal signals onto the neurons that generated them in an image featuring a significant percentage of the imaged brain. Further code animates these maps to generate audiovisual "playbacks" of the networks encoding specific behaviors with high spatiotemporal resolution. Through the use of a previously developed community detection algorithm, we can furthermore highlight the specific activity patterns of functional neuronal ensembles over the course of a behavioral program. Together, these tools constitute an ultra-fast workflow that can produce same-day insights about single-cell activity and network organization

across large portions of a nervous system, enabling a range of subsequent analyses and allowing for analysis-driven follow-up electrophysiology in just-imaged preparations.

Title: Modeling of Neural Spike Pattern Transformation as Classification of Binary Images with a Convolutional Neural Network

Authors: B. J. MOORE[1], *D. SONG[2];
[1]Biomed. Engin., [2]USC, Los Angeles, CA

Identification of causal relationships of neural activity is an important problem in neuroscience and neural engineering. Past work has shown that cognitive processes such as memory formation rely on transformations of spatio-temporal patterns of spikes across different neural populations. Such transformations are nonlinear dynamical, and cannot be captured by linear models or generalized linear models. Shallow nonlinear models, including generalized functional additive models (GFAM) and multi-input multi-output models, have attempted to capture this nonlinearity with some success. Alternatively, Convolutional neural networks (CNN) can capture complex nonlinearity and abstract low-level and high-level features in natural images via the use of deep layers of nonlinear activation functions. It thus holds the promise of modeling complex neural spike transformations underlying cognitive processes.We treat spatio-temporal patterns of past input spikes as binary images and use a CNN to predict spiking in a single output neuron in a binary classification task. We generate synthetic data using a GFAM with multiple neurophysiologically inspired functions (kernels) and a probit link function. This creates a probability of spiking over time in the output neuron that is passed to a threshold to produce a binary neural time series representing spikes. A sliding window generates binary training images from this time series that are passed to a CNN with multiple layers of convolution with filters convolving over the time domain to capture temporal nonlinearity. Results show the CNN is able to achieve a high correlation between the predicted probability of spiking in the output neuron and the true probability of spiking in the output neuron for the data generated with a generalized functional additive model. Most importantly, the CNN is able to recover the ground truth kernels used to generate the probability of spiking in the output neuron during synthetic data generation. This shows that CNNs show promise in discovering the functions that determine neural spike transformations. Based on the CNN's validation via a GFAM, our current work includes validation of our approach with data generated with more complex nonlinear kernels as well as further validation with animal data.

Title: Quantitative analysis of entorhinal cortical axonal arbors characteristics and its impact on axonal arbor growth using ROOTS algorithm

Authors: *S. FARZAD[1], T. MILLARD[1], C. BINGHAM[2], G. J. YU[1], J.-M. C. BOUTEILLER[1], G. LAZZI[1], T. W. BERGER[1];
[1]Biomed. Engin., USC, Los Angeles, CA; [2]Biomed. Engin., Case Western Reserve Univ., Cleveland, OH

Abstract: The advancement of computation and neuronal modeling in recent years has facilitated the study of neural tissue systems with increasing biological realism. Many model-based neuronal studies neglect axons and focus predominantly on dendrites and soma. However, because axons are often preferentially activated by extracellular electrical stimulation, relying on models that only focus on dendritic/somatic morphologies may result in overestimation of activation thresholds. Further, explicitly represented axonal arbors greatly facilitate spatiotemporal analysis of activity conducted through fiber systems and circuits. Ruled-Optimum Ordered Tree System (ROOTS) is a generative algorithm that yields unique and highly realistic axon terminal arbors constrained by user-specified morphometric parameters. ROOTS enables construction of population models for the analysis of the influence that microscale structures and branching patterns have on spatiotemporal patterns of activity in the presence of extracellular electric fields. However, the effects of the morphometric parameters on the final construction of increasingly complex axon arbors are unknown. Using a volume reconstruction of rat dentate gyrus and ~30 000 postsynaptic target locations in that volume, ROOTS was used to generate a three-dimensional entorhinal cortical axon arbor using multiple combinations of morphometric parameters. The resulting arbors were characterized using methods that have been applied for neural dendrites, e.g. total length, direct vs. path ratio, branch length, branching order and angle, and compared with experimental values. Correlation analyses reveal the relations between the various ROOTS morphometric parameters and the resulting emergent morphological properties of the arbors. The correlations discovered in this work can then be used to guide what morphometric parameters for axon arbors beyond the entorhinal cortex.

Title: Creation of an automated registration and analysis pipeline for whole rat brain serial two photon tomography images

Authors: *A. D. AJAY[1,2], J. P. MEEKS[4,1,3,2], A. TAVAKKOLI[5], D. M. O. RAMIREZ[1,2]; [1]Dept. of Neurol., [2]Peter O'Donnell, Jr. Brain Inst., [3]Dept. of Neurosci., Univ. of Texas Southwestern Med. Ctr., Dallas, TX; [4]Univ. of Rochester Sch. of Med. and Dent., Rochester, NY; [5]Dept. of Psychological and Brain Sci., Dartmouth Col., Hanover, NH

Abstract: Serial two-photon tomography (STPT) combines high throughput image acquisition and serial tissue sectioning to generate high resolution whole brain images. Such images have been widely used in studies involving cellular distribution and connectomics in mouse. We and others have earlier developed robust automated pipelines to quantify whole mouse brain volumetric image data acquired on the TissueCyte 1000 STPT system, but to date a similar pipeline did not exist for rat brain. Here, we report the development of a modified registration pipeline to allow for effective automated quantification of rat brain STPT datasets. The new pipeline incorporates a rat brain average template which was created using STPT images as well as annotations derived from the Waxholm Rat MRI atlas. Whole rat forebrain images were acquired using STPT at 0.875um/pixel lateral resolution and 100um axial resolution resulting in 150 serial sections per brain. In total, 15 rat brains were imaged. The MRI reference atlas template in the Waxholm coordinate space for the Sprague Dawley rat brain (WHS-SD MRI) was obtained from the Neuroimaging Tools and Research Collaboration website and the images were pre-processed in order to generate a STPT image based reference template to perform single modality image registration. First, the WHS-SD MRI reference atlas was scaled to match the STPT data size and all the input datasets were registered to this reference using SimpleElastix registration workflow for global and local registration. An initial average template was created from the 6 best registered samples and the workflow was performed iteratively in three steps until the majority of the input datasets registered accurately with the intermediate average template. The final template from the iterative process contained clearly defined anatomical features and resulted in more precise alignment of the individual brain samples. Next, the annotation atlas was rescaled to match the average template and was corrected for gaps due to resizing using ITK-snap software. Finally, we applied signal segmentation to the input fluorescent brain images using a the “Pixel Classification” applet in ilastik, generating probability maps that estimate signal density in registered brains. The adapted analysis pipeline utilizing the newly created rat brain average template and modified reference atlas will be a useful resource for large scale volumetric imaging projects in rats.

Title: The accurate localization method of the amygdala neural activities using magnetoencephalography and the advanced brain source imaging methods

Authors: *S. KANG[1], M. SHIM[2], C.-H. IM[3];
[1]Univ. of Missouri-Kansas City, Kansas City, MO; [2]Korea Univ., Sejong, Korea, Republic of; [3]Hanyang Univ., Seoul, Korea, Republic of

Abstract: The amygdala is a key subcortical brain structure in the appraisal of stimulus relevance, including those of emotional stimuli. The knowledge of the human amygdala comes from fMRI and PET studies, but they do not provide enough temporal resolutions required for analysis of temporal dynamics of the neural responses. Most amygdala neurons are pyramidal cells, the main sources of the magnetoencephalography (MEG) signal from the brain. Although the pyramidal cells in the amygdala nucleus do not show a laminar organization, it is possible that the activation of subpopulations of these cells may produce a non-zero net current dipole source that can be detected in the scalp-level MEG signals. Despite recent MEG studies of subcortical source imaging, the noninvasive MEG-based brain source imaging methods for the amygdala are still not well established due to limited accuracy in the conventional source estimation methods. We developed a MEG source localization pipeline that integrates anatomical structures obtained from T1-weighted individual MRIs and diffusion tensor imaging (DTI) tensor information, which can provide a more accurate estimation of inhomogeneous conductivity associated with white matter fiber structures. Given the subcortical structures that are located underneath of white matters, we hypothesized that the utilization of the DTI tensor information of white matter will substantially improve the source localization accuracy of the amygdala and other subcortical brain structures. We used the Minn-WashU Human Connectome Project (HCP) data, including10 individuals' T1, DTI, and 256 channel MEG data collected using 248 magnetometer sensors during resting state. We created synthetic MEG data by adding simulated neural activities of the amygdala and the primary visual cortex that varied in terms of the temporal width, amplitudes, and temporal overlaps between the subcortical and cortical brain activities to the original resting MEG signals that were preprocessed. We evaluated the source localization accuracy of the amygdala activities across the results with and without DTI-based inhomogeneous WM conductivity information as well as those obtained with the boundary element method (BEM) and finite element method (FEM) head models. We found substantially higher source localization accuracy of the amygdala with the DTI and FEM methods compared to those with the other methods. In particular, when we used both DTI and FEM methods, the amygdala source localization error was very low (<.5 cm). By combining the multimodal neuroimaging data and the advanced head modeling techniques, it is possible to obtain highly accurate MEG source imaging of the amygdala.

Title: The risk of progression to dementia and cognitive characteristics in MCI participants: a cohort study using the NACC database

Authors: *F. ZHOU, V[1], X. ZHANG[2], X.-H. ZHOU[1,3];
[1]Dept. of Biostatistics, Sch. of Publ. Hlth., Peking Univ., Beijing, China; [2]Macau Univ. of Sci. and Technol., Macau, China; [3]Dept. of Epidemiology, Natl. Alzheimer's Coordinating Ctr., Univ. of Washington, Seattle, WA

Abstract: Objectives: We estimated the incident density and rate ratio of dementia in mild cognitive impairment (MCI) participants who were cognitively normal (CN) at the baseline and compared the cognitive characteristics of these MCI with different outcomes.**Methods**: Data were from the National Alzheimer's Coordinating Center (NACC), gathered from 32 Alzheimer's Disease Centers. A cohort of 2,180 participants with CN at baseline and progressed to MCI was established from 2005 to 2019, and follow-up their outcome. The Cox proportional hazards model was used to estimate risk factors associated with the progression of dementia.**Results**: Five hundred thirty-two participants progressed to dementia during the follow-up (108.5 per 1,000 person-years), 441 cases of them were Alzheimer's disease (AD, 89.9 per 1,000 person-years), another 305 participants converted from MCI to CN. Compared with 65-70 age group, rate ratio of dementia increase from 1.73 (95% CI: 1.11, 3.05) aged 70-75 to 4.25 (95% CI: 2.84, 7.39) aged more than 90, and AD rate ratio from 2.34 (95% CI: 1.37, 5.10) to 6.34 (95% CI: 3.91, 13.85). After adjusting for other confounding, a higher risk of progression to dementia was observed in elderly married women with a low level of education. Specifically, hazard ratios (HR) is 1.28 (P=0.0206) for female, 1.15 (P=0.0306) for education level (≤12, 13-16 vs. ≥17), 1.36 (P=0.0041) for married and 1.28 (P<0.001) for age (compared with 65-70 age group). Moreover, a significant risk factor for dementia was identified in participants with an APOE ε4 allele (HR=1.696, P<0.001). Although there was no significant difference between amnestic and non-amnestic MCI participants, the risk was reduced in participants with single-domain MCI (0.651, P<0.001). In addition, MCI participants progressed to dementia had a higher proportion of language and executive affect compared with participants converted from MCI to CN (21.24% vs. 14.43% and 42.48% vs. 33.11%). There is no significant difference in the effects of attention and visuospatial.**Conclusions**: This study providing information about the risk of progression to dementia in MCI individuals. Given these risk factors, this may provide helpful guidance to health-care providers on MCI prevention and screening.

Title: Functional connectivity profiles predict trial-by-trial success in a navigation task

Authors: ***R. F. WOODRY**, E. R. CHRASTIL;
Neurobio. & Behavior, Univ. of California, Irvine, CA

Abstract: Functional connectivity between brain regions reveal network properties that reflect cognitive differences across tasks, individuals, and groups. Connectome-based Predictive Modeling (CPM) is increasingly used to predict how brain states fit these functional connectivity patterns, which provides novel insights into psychological traits. However, CPM has not yet been used to analyze task performance, especially at the trial level. Here, we tested the performance of four machine learning models and three task-based functional connectivity metrics to predict individual trial-by-trial behavioral performance during a navigation task. The first-person navigation task consisted of two phases: exploration and test. In the exploration phase the subject was instructed to explore and find all 9 objects within a maze. In the test phase, objects were masked and subjects were instructed to locate target objects on a trial-by-trial basis. The test trials lasted approximately 30 seconds each - much longer than a standard cognitive task - providing a rich timeframe to examine the dynamics of connectivity. Task-based fMRI time-series were extracted and binned into time windows bound by the start and end times for each individual trial. Trial connectomes were computed using correlation, partial correlation, covariance, and tangent space connectivity metrics. These connectomes were fed into a linear Support Vector Machine (SVM) classifier and fit to trial accuracy. For predicting accuracy during a trial, the SVM performed better than chance across all functional connectivity metrics. Notably, in line with previous connectome model studies, tangent space functional connectivity outperformed other functional connectivity metrics. We find that CPM is a promising tool for investigating trial-by-trial connectome contributions to task performance. These findings suggest that functional network communication during test can be used as a marker for success.

Title: Fully-automatic Ultrasound-based Neuro-navigation Approach for Functional Ultrasound Imaging the vascular brain GPS

Authors: *M. NOUHOUM[1,2], J. FERRIER[2], B. OSMANSKI[2], S. PEZET[1], M. TANTER[1], T. DEFFIEUX[1];
[1]Physics For Med., Paris, France; [2]ICONEUS, Paris, France

Abstract: Functional ultrasound (fUS) is a recent imaging technique capable of mapping cerebralvascular network but also to capture indirectly neuronal activity with very high sensitivity.One remaining hurdle is the expertise required to position the probe and identify brainstructures solely based on 2D vascular images, especially when it comes to oblique non-coronal and non-sagittal slice.Here we develop and validate a fully-automatic and integrated approach combiningacquisition of 3D multi-slice ultrasensitive Doppler imaging of the mouse brain and itsonline automatic registration to the reference 3D anatomical atlas from the Allen brainInstitute for neuro-navigation and for guided injection in deep brain.Using Iconeus One scanner driving a 15MHz probe mounted on a motorized setup,successive 2D transcranial ultrafast Doppler images were acquired in a male C57BL/6mouse anesthetized with 1.5% isoflurane. The resulting 3D vasculature can be alignedoffline on any atlas and then used online as a template for automatic non-rigid datasetsregistration within experiments using an iterative optimization algorithm based onintensity matching of big vessels.Despite a 400 µm spatial resolution in the elevation direction, Doppler images registrationhad an average accuracy (n=20 estimations for each marker) of 156±52 - 129±62 - 109±43- 103±20 µm for four vascular landmarks compared to ground-truth estimates fromdifferent days and acquisitions by an expert neuroanatomist. During the experiments, agood matching with the Allen reference atlas was obtained under 2 minutes. Combinedwith a 4-axis motorized system, the software was used to automatically position the probefor functional imaging to an oblique plane including both the primary visual and barrelfield cortex. Whisker and visual stimulations revealed strong activation of both corticalareas, validating the slice positioning.The proposed functional ultrasound “on the fly” neuro-navigation approach allowsautomatic brain navigation and positioning, ensuring standardized experiments andprotocols for non-experts.

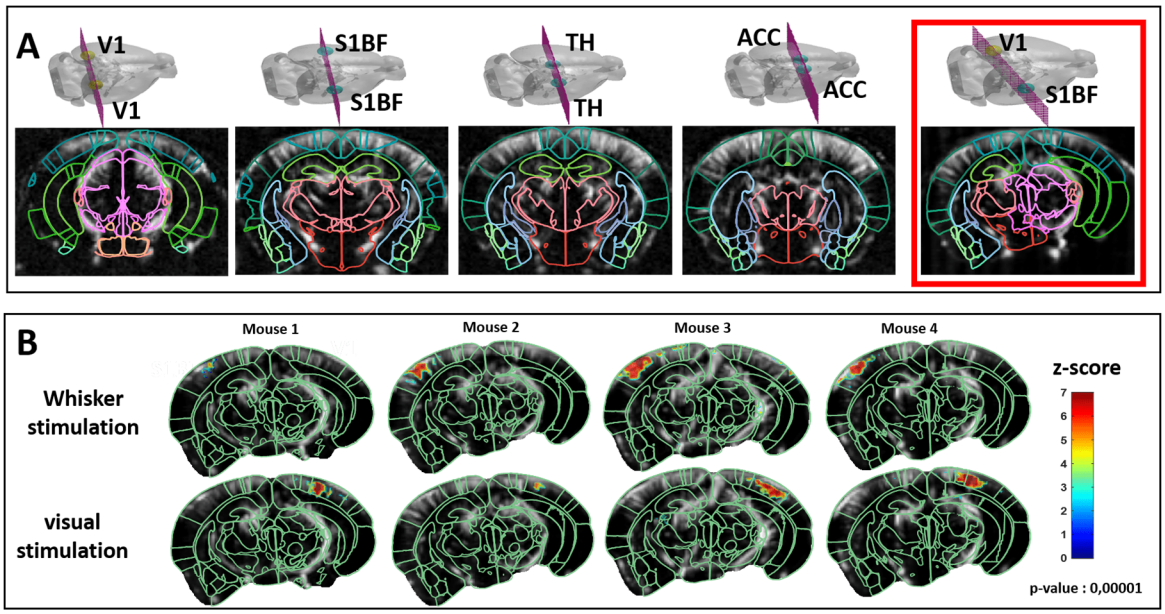

Fig6. **Transcranial functional imaging session. A.** Automatic online positioning guided by Allen brain Atlas. **B.** Functional imaging after automatic position on an oblique plane encompassing both V1 and S1BF. Activation map obtained by computing z-score based on generalized linear model with Bonferroni correction is superimposed on baseline image

Title: Liftpose3d, a deep learning-based approach for transforming 2D to 3D pose in laboratory animals

Authors: *A. GOSZTOLAI[1], S. GUNEL[1], M. P. ABRATE[1], D. MORALES[1], V. LOBATO RIOS[1], H. RHODIN[2], P. FUA[1], P. RAMDYA[1];
[1]EPFL, Lausanne, Switzerland; [2]Univ. of British Columbia, Vancouver, BC, Canada

Abstract: Markerless 3D pose estimation has become an indispensable tool for kinematic studies of laboratory animals. Most current methods compute 3D pose by multi-view triangulation of deep learning-based 2D pose estimates. However, triangulation requires multiple, synchronized cameras per keypoint and elaborate calibration protocols that hinder its widespread adoption in laboratory studies. In this talk, I will describe LiftPose3D, a deep learning-based method that overcomes these barriers by lifting 2D poses from a single camera view into 3D poses. Our method builds on a state-of-the-art deep neural network architecture designed to lift 2D human

poses without requiring temporal information, or a skeletal graph. I will demonstrate how specific data transformations and adaptations to network training enable accurate 2D-to-3D pose lifting with significantly less training data, across a wide range of animals, from different camera angles, and in stereotyped and non-stereotyped behaviors. These transformations also enable our method to work despite self-occlusions in freely behaving animals and weakens the effect of outliers in training data. I will illustrate this versatility by applying it to multiple experimental systems using flies, mice, and macaque monkeys and in circumstances where 3D triangulation is impractical. Additionally, LiftPose3D networks can be adapted to different experimental domains by matching pose statistics across datasets and by coarse-graining the network across image resolutions. In fruit flies, I will demonstrate how this allows one to use pre-trained networks to obtain 3D poses in experiments, where multi-camera triangulation was previously not possible. Thus, LiftPose3D permits high-quality 3D pose estimation in the absence of complex camera arrays, tedious calibration procedures, and despite occluded keypoints in freely behaving animals.

Abstract: Manual analysis of biomedical images by researchers and pathologists is time intensive, requires extensive training, and is prone to introduce bias and error. Unintentional bias and attentional limitations during analysis of biomarkers can underlie poor reproducibility of findings in biomedical research and potentially introduce errors to clinical diagnostics. These problems are significant barriers to delivering the most beneficial evidence-based medicine, developing effective medical treatments, and promoting public confidence in scientific inquiry. We developed a software program to improve automation and standardization of image analysis,

called “Pipsqueak,” which significantly increases data reliability between image raters and decreases the time required for analysis by more than 100-fold. However, suboptimal conditions, like high background staining, off-target structures, overlapping or clustered biomarkers, and atypical morphologies, can lead to artifacts and consequently to inaccurate results and erroneous conclusions when using the first generation of Pipsqueak. Here, we used machine learning to tune several convolutional neural networks to accurately detect the staining in a wide variety of representative cell types, including by *Wisteria floribunda* agglutinin, 8-oxo-dG, parvalbumin, cFos, DAPI, red blood cells, and human sperm. We demonstrate significantly increased inter- and intra-rater reliability of tissue sample analysis and decreased analysis time for multiplexed biomarkers. The integration of machine learning capabilities into our Pipsqueak AI technology produces an adaptive, near real-time, biomedical image analysis platform that quickly and accurately identifies biomarker targets. Pipsqueak AI is available now as an integration to ImageJ/FIJI (https://Pipsqueak.ai), and is capable of returning hundreds of accurate cellular target detections to the user within 300ms of image upload. Our end goal is for this software platform to accurately detect a wide range of novel biomarkers, beyond those tested here, by utilizing innovative transfer learning and adaptive modeling techniques.

Title: BehaviorDEPOT: A novel tool for automated behavior classification and analysis in rodents

Authors: *C. J. GABRIEL, B. JIN, Z. ZEIDLER, L. A. DENARDO;
Physiol., UCLA, Los Angeles, CA

Abstract: Detailed classification of animal behavior is essential to understand the underlying neural substrates. Behavioral neuroscience relies on analysis of video recordings for behavioral classification, which is traditionally labor-intensive or dependent on expensive software packages with limited capabilities. Recent development of open-source tools has automated the extraction of animal poses from video recordings. However, automatically classifying animal poses into behavioral categories remains challenging, requiring both programming experience and skilled manual annotation for validation. To overcome these barriers, we developed BehaviorDEPOT (DEcoding behavior based on POsitional Tracking), a software package which imports animal pose data (from DeepLabCut or similar), to automatically identify behavioral bouts based on custom classifiers and analyze behavioral statistics in user-defined ways. We provide classifiers for freezing, rearing, jumping, and walking, yet BehaviorDEPOT is customizable for inclusion of additional classifiers. To accommodate a variety of experimental designs, BehaviorDEPOT optionally applies custom spatiotemporal filters which allow users to quantify behaviors occurring in a particular location, during a particular epoch, or during the intersection of the two. BehaviorDEPOT also features modules that support new rater training and measure inter-rater reliability. These features help users generate reliable 'ground truth' human labels, regardless of the behavior type, which is an essential first step for developing behavioral classifiers. The inter-rater reliability module will thus be a useful tool for scientists classifying and quantifying behavior irrespective of application. Finally, to reduce user reliance on expensive computer workstations, we also include pre-trained DeepLabCut networks for rodent pose tracking in standard behavioral arenas. BehaviorDEPOT provides a simple, flexible, automated pipeline to move from raw pose tracking to reliably quantifying task-relevant behaviors.

Title: An Accessible Automatic Cell Counting Methodology Using Trainable WEKA Segmentation in ImageJ Validated on Mouse Cortex Microglia

Authors: *T. KATARAS[1], H. SINGH[2], J. KOURY[2], M. KAUL[2];
[1]Genetics, Genomics and Bioinformatics, [2]Biomed. Sci., Univ. of California, Riverside, Riverside, CA

Abstract: Counting cells is a cornerstone of tracking disease progression in neuroscience. A common approach for this process is having trained researchers individually select and count cells within an image, which is not only difficult to standardize but also very time-consuming. Digital images have become both easier to take and to store, allowing an automatic cell counting methodology to vastly reduce analysis time. We present an automatic cell counting method for microglia and validate it against trained expert's hand counts in mouse cerebral cortex. This method leverages the Trainable WEKA Segmentation (TWS) plugin available in the FIJI distribution of ImageJ (Agranda-Carerras 2017, Schindelin 2012, Schneider 2012). This program utilizes user-selected input and image filters in a machine learning context to automatically identify objects. All processing and analysis was performed in the free ImageJ toolbox to maximize accessibility. TWS's graphical user interface makes it accessible to operate and adjust, but to perform analysis on whole datasets requires further automation through the use of macros which we have constructed within ImageJ maintain this high level of accessibility. To validate our method, we compared our automatic counts to a published, hand counted dataset of Immunofluorescence stained mouse cortex microglia (Singh et al. 2020). For this analysis, we used two genotypes, a wild-type (WT) control and a transgenic mouse model for HIV-induced brain injury (HIVgp120), which expresses the gp120 envelope protein under a GFAP promoter. HIVgp120 mice showed behavioral deficits, and increase in microglia numbers presumably caused the gp120 protein. 10X images were collected in the sagittal plane from brain slices of three 11-14 month-old male mice for each genotype with a mean of 124 microglia per image. For an automatic counting methodology to be effective, it must adapt to changes in cell morphology such as microglial activation (Lynch 2009). The auto counting strategy with TWS replicated the increase in mean microglial number in images from the HIVgp120 mice (Manual p =0.0046; Auto p=0.0002). The auto count also correlates significantly with the manual counts in both genotypes (WT p= 2.297 e^{-07}, adj. R^2= 0.65; HIVgp120 p=2.591 e^{-04} adj. R^2=0.423). The main advantage of this strategy is the much shorter time required to apply the automatic counting strategy compared to a manual count, taking less than a fifth of time. Our study demonstrates the general applicability of this accessible technique to quickly explore large amounts of image data, leaving open the possibility to audit the results by manual counting a smaller, randomly selected subset of images.

Title: DeepMReye: MR-based camera-less eye tracking using deep neural networks

Authors: *M. NAU*[1,2], M. FREY*[1,2], C. F. DOELLER[1,2];
[1]Max-Planck-Institute for Human Cognitive and Brain Sci., Leipzig, Germany; [2]Kavli Inst. for Systems Neurosci., Trondheim, Norway

Abstract: Viewing behavior provides a window into many central aspects of human cognition and health, and is an important variable of interest or confound in many fMRI studies. To make eye tracking freely and widely available for MRI research, we developed DeepMReye: a convolutional neural network that decodes gaze position from the MR-signal of the eyeballs. It performs camera-less eye tracking at sub-imaging temporal resolution in held-out participants with little training data and across a broad range of scanning protocols. Critically, it works even in existing datasets and when the eyes are closed. Decoded eye movements explain network-wide brain activity also in regions not associated with oculomotor function. This work emphasizes the importance of eye tracking for the interpretation of fMRI results and provides an open-source software solution that is widely applicable in research and clinical settings.

Title: The ΔF/F's are too small! A computational method for removing light contamination in two-photon calcium imaging

Authors: G. ZIPURSKY, B. LAU, J. L. GAUTHIER;
Swarthmore Col., Swarthmore, PA

Abstract: Two-photon (2P) imaging of calcium indicators has enabled major advances in systems neuroscience. Many applications of this technique rely on accurate estimates of ΔF/F, the change in fluorescence ascribed to each neuron. One potential source of error in ΔF/F measurements is contamination by background light, which increases the denominator (resting fluorescence) without affecting the numerator (deviations from rest). To test whether current cell finding techniques are susceptible to background light contamination, we applied them to a simulation where ground truth was known (Charles et al. 2019, Biorxiv). Surprisingly, two popular methods greatly underestimated the true ΔF/F (CaImAn, median 0.02 of true ΔF/F; Suite2P, median 0.27). Moreover, the degree of underestimation varied widely across cells

(CaImAn quartile range 0.0082-0.031; Suite2P 0.21-0.32). Underestimation could introduce unexpected errors into spike inference algorithms or analyses that try to explain variance. Inconsistent errors across cells might also obscure activity patterns, such as functional cell classes that could otherwise be identified by the amplitude of their transients.To obtain more accurate measurements of ΔF/F, we developed a technique to remove background contamination using a post-hoc computational analysis. We constructed an estimator of cell brightness at rest (ΔF/F denominator) using a simple model of 2P fluorescence. When applied to simulated data, our method estimated ΔF/F nearly perfectly on average (median 1.10) and with a tighter distribution of ratios (quartile range 0.90-1.12). When applied to real data, where ground truth is not available, our method found much higher values of ΔF/F than popular methods (median ratio 7.9, quartile range 6.9-8.9), consistent with improved background compensation. This method could improve applications of 2P imaging that rely on correctly-estimated ΔF/F and also has the potential to correct published findings.

Title: Fast neuron segmentation for two-photon imaging videos using light convolutional neural networks

Authors: *Y. BAO, S. SOLTANIAN-ZADEH, S. FARSIU, Y. GONG;
Biomed. Engin., Duke Univ., Durham, NC

Abstract: Fluorescent genetically encoded calcium indicators and two-photon microscopy help understand brain function by generating large-scale *in vivo* recordings in multiple animal models. Automatic, fast, and accurate active neuron segmentation is critical when processing these videos. Existing methods that process an entire video have speed close to the video rate but leave little or no margins for extra processing. In this work, we developed and characterized a novel method to quickly and accurately segment active neurons from two-photon fluorescence imaging videos. We used pre-processing, including spatial filtering, temporal filtering, and whitening to maximize the signal-to-noise of active neurons; we used a series of light convolutional neural networks to quickly identify features of active neurons; we used post-processing to finalize the

spatial footprints of the consistently detected neurons. We also developed an online version, which employed nearly identical schemes as the batch version, but slightly differed in the pre- and post-processing steps. We evaluated our method using cross-validations on multiple public datasets, including Allen Brain Observatory, Neurofinder, and CaImAn dataset. The batch version was more accurate and faster than existing methods in all datasets. In addition, the accuracy of our method was equal to human accuracy, and the speed was an order of magnitude faster than the video rate when executed on a commercial desktop. The difference in accuracy between our method and existing methods was enlarged when these methods processed datasets with few manual marking ground truths. We compared the online version with another existing online method on the same datasets, and our method was also significantly better in both accuracy and speed. This automated, fast, and accurate active neuron segmentation method significantly improves state-of-the-art, and the online version can open a new regime of real-time feedback neuroscience experiments.

Abstract: Analysing the behavior of individuals or groups of animals in complex environments is an important, yet difficult computer vision task. Here we present a new deep learning architecture for classifying animal behavior and demonstrate how this end-to-end approach can significantly outperform pose estimation-based approaches, requiring no intervention after minimal training. Our behavioral classifier is embedded in a first-of-its-kind pipeline (SIPEC) which performs segmentation, identification, pose-estimation and classification of behavior all automatically. SIPEC successfully recognizes multiple behaviors of freely moving mice as well as socially interacting non- human primates in 3D, using data only from simple mono-vision cameras in home-cage setups.

Title: Independent evaluation of the Harvard Automatic Processing Pipeline using multi-site EEG data from children with fragile x syndrome

Authors: *E. AUGER[1], E. BERRY-KRAVIS[2], L. ETHRIDGE[3];
[1]Univ. of Oklahoma, Norman, OK; [2]Rush Univ. Med. Col., Chicago, IL; [3]Univ. of Oklahoma Hlth. Sci. Ctr., Oklahoma City, OK

Abstract: The Harvard Automatic Processing Pipeline for Electroencephalography (HAPPE) in conjunction with The Batch Electroencephalography Automatic Processing Platform (BEAPP) is a computerized EEG data processing pipeline specifically designed for multiple site analysis of populations with neurodevelopmental disorders. This pipeline has been validated in-house by the developers but external testing using real-world datasets strengthens support for its use. Using resting and auditory event related EEG data for 100 children ages 3-6 years with Fragile X Syndrome across 6 sites using 3 different EEG systems, the current data set represents an ideal test of the new processing pipelines. Therefore, we used this rich dataset to evaluate the software's noise reduction techniques, data standardization features, and data integration in comparison to traditional manualized methods of processing. Univariate results from a significant MANCOVA indicated that the HAPPE/BEAPP pipeline resulted in greater trials retained ($F(4,24) = 5.80$, $p = 0.02$), variance retained through ICA ($F(4,24) = 39.74$, $p < 0.01$), and smaller kurtosis ($F(4,24) = 4.29$, $p = 0.049$) than a manual pipeline for task-related data. No significant differences were found in signal-to-noise ratio (SNR) although there was a trend toward greater SNR in the manually processed data ($F(1,24) = 4.16$, $p = 0.052$). We did observe an overall reduction in signal amplitude in the HAPPE/BEAPP pipeline, which is supported by the decrease in kurtosis. To further explore this, we processed simulated data in both pipelines. The simulated data was composed of simulated brain, pink noise, and real artifact. Using a paired samples t-test we determined that the correlation between the pure signal and processed data was significantly higher for the manually processed data ($M = 0.96$, $SD = 0.03$) compared to the HAPPE processed data ($M = 0.29$, $SD = 0.03$); $t(55) = 105.87$, $p < 0.01$. In conclusion, data processed using HAPPE has many benefits including less active processing time and artifact reduction without removing segments, however users should be aware of potential over-cleaning of brain signal in certain circumstances, and some manual checking of the data post-HAPPE is recommended. Importantly, SNR in the real EEG data was not significantly different between manually processed data and HAPPE processed data, so the signal amplitude reduction may not negatively affect results depending on desired outcome measures. Recommended implementation of the HAPPE pipeline for neurodevelopmental populations depends on the goals and priorities of the research.

Title: Brain time toolbox: warping electrophysiological data to detect recurrence of active cognitive processes

Authors: ***S. VAN BREE**[1,2,3], M. MELCÓN[4], M. WIMBER[1,2,3], S. HANSLMAYR[1,2,3];
[1]Ctr. for Cognitive Neuroimaging, Univ. of Glasgow, Glasgow, United Kingdom; [2]Sch. of Psychology, [3]Ctr. for Human Brain Hlth., Univ. of Birmingham, Birmingham, United Kingdom; [4]Dept. of Biol. and Hlth. Psychology, Autonoma Univ. of Madrid, Madrid, Spain

Abstract: Clock time is a human-invented measure that is entirely foreign to the brain. While cognitive processes may correlate with passed seconds, the brain organizes information according to its own internal dynamics: brain time. Neural oscillations clock windows of neural excitability and are thus a prominent brain time candidate. Crucially, oscillations are not stationary, and do not necessarily phase reset at the start of trials. This causes nonlinearities between clock and brain time. As a result, the dynamics of cognitive processes carried by oscillations are distorted in data organized by default clock time. Here, we present a toolbox that transforms electrophysiological data to be more faithful to brain time (inside-out approach), rather than projecting our notion of time onto the brain (outside-in approach). The goal of the toolbox is to uncover and analyse recurring patterns of cognitive processes clocked by oscillations. First, the toolbox performs independent component analysis on the data. Second, the user selects a component with oscillations at a frequency range (e.g. 4-8 Hz; theta) and topography relevant to the studied cognitive process (e.g. memory retrieval). Third, within the selected component, the phase of high-power oscillations is extracted. Fourth, the rest of the data is dynamically time warped based on the dynamics of the extracted phase ("brain time warping"). In effect, this transforms the time axis of the clock time data to be closer to brain time. Finally, the toolbox offers a range of analytical tools to investigate neural activity patterns relative to brain time. Temporal generalization matrices can be created which display recurring patterns of classification performance if cognitive processes operate with a similar neural code across time. The absolute amount and temporal evolution of this recurrence can be quantified and statistically evaluated. Using simulated data, we provide evidence that the toolbox can improve detection of recurrence. In addition, we present preliminary effects of brain time warping on empirical data using an attention paradigm.

Title: Overcoming heterogeneous hardware to facilitate dissemination and validation of electrophysiological experiments

Authors: ***A. BELSTEN**[1], M. ADAMEK[1,2], P. BRUNNER[1,3];
[1]Natl. Ctr. for Adaptive Neurotechnologies, Albany, NY; [2]Dept. of Neurosci., [3]Dept. of Neurosurg., Washington Univ. Sch. of Med., St. Louis, MO

Abstract: The acquisition and processing of electrophysiological signals is an essential component of many scientific and clinical experiments. However, realization of these experiments is a daunting endeavor that requires extensive programming experience to integrate the underlying hardware and often leads to experiments that only work with the hardware and software environment present in the original laboratory. Given the heterogeneity of signal acquisition devices across laboratories, this approach impedes the dissemination of electrophysiological experiments and the validation of their results. To overcome this issue, we have developed a software abstraction layer that can accommodate a wide range of heterogeneous hardware. We demonstrate this using BCI2000, a general-purpose software for brain-computer interfacing (BCI). We investigated this concept by developing appropriate interfaces that realize a software abstraction layer for three different bio-signal acquisition devices (Nihon Kohden JE-120A; Neuralynx ATLAS; and Philips GTEN 200). These devices vary in their physical, technical, and conceptual complexity. For example, the acquired signals may be provided by the hardware using synchronous or asynchronous transfer methods. Each interface was implemented in C++ for high computational performance while using the high-level functionalities of the C++ standard libraries (STL). Within BCI2000, the acquired data is stored in a standardized format and made available in real-time for subsequent signal processing and translation algorithms. The experimental paradigm then uses the resulting control signals to provide appropriate user feedback. Abstracting the bio-signal acquisition device allows the signal processing and user applications to be agnostic to the underlying hardware. This abstraction enables the scientific and clinical experiments to be independent of hardware-specific parameters, making them suitable for dissemination and validation across laboratories that use a wide range of bio-signal acquisition devices. The abstraction layers are disseminated through a central online repository, allowing investigators to download the necessary abstraction layer to run experiments on their hardware. We expect that this software abstraction layer, implemented in widely used and well-maintained platforms such as BCI2000, will enable the widespread dissemination and validation of electrophysiological experiments.

Title: Vera - a versatile electrode localization framework for invasive electrophysiological research

Authors: *M. ADAMEK[1,2], P. BRUNNER[3,2];
[1]Neurosci., Washington Univ. In St. Louis, Saint Louis, MO; [2]Natl. Ctr. for Adaptive Neurotechnologies, Albany, NY; [3]Dept. of Neurosurg., Washington Univ. in St. Louis, Saint Louis, MO

Abstract: Since the early 1900s, we've used electrophysiological recordings from electrodes placed on the brain's surface or within the brain to detect seizure foci, map functional areas prior to the resection of pathogenic tissue, or investigate brain function. These applications depend on knowing the precise anatomical locations of the implanted electrodes within the patient's brain. Determining these electrode locations is complicated by the inevitable variations in the imaging used across patients and institutions. While we can adjust the localization for each patient using appropriate methods, the imaging itself depends heavily on the institution. This is compounded by the inevitable variance in the parameters of the clinical imaging (e.g., postoperative MRI, interoperative photographs), the specifications of the implanted electrodes (material, diameter, thickness, arrangement), and the type of surgical procedure (e.g., craniotomy, minimally invasive procedure).
No software tool can currently generalize across the wide range of surgical techniques, imaging parameters, and implanted electrode types, thwarting efforts towards fully automated electrode localization, and reliable electrode projection for cohort analysis. Current software tools either only address a subset of the necessary steps for electrode localization or only work within a very narrow set of parameters. In this study, we attempt to overcome this limitation by developing a universal tool that can be customized to accommodate the variations across and within institutions while maintaining the ability to analyze data from these different institutions.For this purpose, we developed the software framework VERA, which allows customized electrode localization for a particular subject while maintaining a standardized data framework. Therefore, investigators can utilize the same tool independent of the underlying surgical techniques, imaging parameters, and implanted electrode configurations, streamlining the reconstruction process. VERA's central idea revolves around a pipeline definition file specifying individual components, each reflecting a step in the processing pipeline. With this approach, investigators can individualize VERA for their needs while ensuring compatibility across institutions. This inherent modularity encourages the development, validation, and distribution of new techniques (i.e., components) for electrode localization and promotes data sharing between institutions. With this, VERA is an invaluable tool for algorithm distribution, reproducibility, and collaborative research across multiple sites.

Title: More efficient electrode localization in EEG: A method comparison between a traditional electromagnetic digitizer and a new photogrammetric method

Authors: *K. M. JENSEN[1], C. LEE[2], S. MAKEIG[2], J. K. KROGER[1];
[1]Psychology, New Mexico State Univ., Las Cruces, NM; [2]Swartz Ctr. for Computat. Neuroscience, Inst. for Neural Computation, Univ. of California San Diego, La Jolla, CA

Abstract: While factors contributing to low spatial resolution in electroencephalography (EEG) are well-known, many researchers have derived valuable insight from attempts to associate areas of the cortex with recorded EEG signals. Inverse models of source localization rely on forward head models, the most accurate of which involve the co-registration of the actual electrode locations. When an MRI image of the head while wearing the electrodes is unavailable, electrode localization (or 'digitization') using electromagnetic position capturing wands has long been considered a gold standard. However, in recent years, many new methods for electrode digitization have appeared that may be faster, cheaper, and as or more accurate alternatives (Shirazi & Huang, 2019). Here we sought to compare the quality of electrode digitization obtained from a traditional electromagnetic position tracker with locations obtained using a new, relatively low cost photogrammetric method. Electrode digitization was obtained using a Polhemus PATRIOT from 23 participants fitted with a 128-channel BioSemi headcap prior to their participation in an EEG study. A 3D Structure Sensor (structure.io) attached to an Apple iPad was then used to capture a 3D head surface model of each participant. Later, two independent raters used the EEGLAB plug-in *get_chanlocs* to obtain electrode locations from the 3D head surface models (Lee & Makeig, 2019). Euclidean differences between the channel locations obtained from the Polhemus and the mean of the *get_chanlocs* raters' markings were calculated, returning a median difference of 2.85 mm (IQR = 2 - 3.88 mm) between methods. Median inter-rater differences between raters using *get_chanlocs* to mark electrode locations were 0.79 mm (IQR = 0.54 - 1.12 mm). While these results do not allow us to determine which method was the more accurate, they do reveal a strong similarity in the obtained electrode locations. The photogrammetric method that uses *get_chanlocs* should be considered for use as a more cost effective method for digitizing electrode locations, with accuracy comparable to that of the commonly used Polhemus PATRIOT. Further, while both methods require similar time investments from researchers, the photogrammetric method only requires the participant to sit patiently for a brief (< 5 min) scanning period. As a result, the photogrammetry method offers a ten to fifteen minute reduction in setup time for EEG studies, reducing the burden of participant fatigue, a common cause of unwanted artifacts, noise, and participant errors.

Title: Evaluating the Closed-Loop Performance of Clinical Electrophysiology Recording Systems using BCI2000

Authors: M. ADAMEK[1,2], A. BELSTEN[2], ***N. LUCZAK**[2], J. MELLINGER[2], K. REFAEY[3], P. BRUNNER[2,4];
[1]Dept. of Neurosci., Washington Univ. In St. Louis, Saint Louis, MO; [2]Natl. Ctr. for Adaptive Neurotechnologies, Albany, NY; [3]Dept. of Neurolog. Surgery, Mayo Clin. Florida, Jacksonville, FL; [4]Dept. of Neurosurg., Washington Univ. Sch. of Med., St. Louis, MO

Abstract: Electrophysiological recordings from patient populations are invaluable for understanding disease progression and identifying possible biomarkers. Access to specific patient populations can be scarce and often necessitates collaboration across institutions. Fortunately, most clinical institutions already possess electrophysiological recording systems for clinical purposes that are suitable for research. However, there is currently no turnkey system that allows investigators to leverage the existing infrastructure without dedicating substantial time and resources. Our work addresses this issue by developing a BCI2000-based turnkey system that interfaces directly with a wide range of clinical neurophysiology systems (e.g., Natus, Nihon Kohden, Neuralynx, and Blackrock). This system allows investigators to create new paradigms and efficiently distribute them to multiple clinical sites. As part of this effort, we also verify system latencies critical to the underlying research. Specifically, we investigate the variability in closed-loop performance in various real-world scenarios. In this verification study, we tested our turnkey system combined with a wide range of clinical systems running a simple audio-visual paradigm implemented entirely in BCI2000. Next, we performed the same experiment implemented using Python code, leveraging BCPy2000, and finally, using BCI2000s ability to interface with PyschoPy. In each case, we sampled the signal of an external signal generator with the clinical system. We used this external clock to trigger the paradigm's audio and visual cues while recording them with the clinical setup. This approach allowed us to measure the full system latency independent of the clinical hardware capabilities. Furthermore, we compared the direct access to the clinical data stream in BCI2000 with indirect access through the commonly used Lab Streaming Layer. We compared the resulting system latencies from these clinical systems to those of dedicated research-grade devices. Our results highlight

the differences in performance between these systems. Evaluation of recording techniques is essential to ensure rigor and reproducibility in research. Therefore, validating and benchmarking clinical systems for research purposes provides investigators with the necessary information to ensure data quality.

Title: Deep Learning neural network for the detection of oscillatory bursts in intracranial EEG

Authors: *A. V. MEDVEDEV[1], G. I. AGOUREEVA[2];
[1]Georgetown Univ. Med. Ctr., Washington, DC; [2]Fac. of Sci. and Engin., Flinders Univ. of South Australia, Adelaide, Australia

Abstract: Objective
Mechanisms of epilepsy are poorly understood and despite any available treatment approximately 30% of patients are refractory. Over the last two decades the evidence has been growing that in addition to epileptic spikes and discharges, transient oscillatory bursts (OB) of various frequencies are important indicators of seizure development and high frequency oscillations (HFOs, ripples and fast ripples) are good biomarkers of epileptogenic tissue. Those events represent a challenge to detect them due to their transient nature and, for HFOs, very small amplitude. Deep Learning (DL) neural networks provide additional tools for automated analysis of EEG. Here we present a Long Short-Term Memory (LSTM) neural network trained to detect OBs as well as spikes/sharp waves, ripple-on-oscillation (RonO) and ripple-on-spike (RonS).
Methods
We used intracranial EEG (iEEG; sampling frequency 500 Hz) from the open access database (ieeg.org; 7 patients). Spectral features (relative power within traditional frequency bands) were analyzed continuously across several one-hour iEEG records and the initial screening for event candidates was done with a novel thresholding algorithm. 1000 events of each class (theta, alpha, beta, gamma, ripples, spike/sharp wave and baseline) were visually verified and selected. A bidirectional LSTM layer network had hidden units varied from 50 to 200. Training was performed using random selections of 50-500 events (per class) while other 500 events (per class) were used for testing.
Results
The network was able to detect events of each class (not used in training) in each patient. The

average values for sensitivity/specificity were above 85-90% for all event classes. We also correlated the detected events with seizure onset zone (SOZ). Spikes (corr = 0.42, $p < 0.05$) and RonS (corr = 0.27, $p < 0.05$) showed significant correlation with SOZ in all patients while ripples correlated with SOZ in 4 out of 7 patients. The lower correlation of ripples with SOZ can be explained by the fact that clinical determination of SOZ is not based on ripples which are impossible to detect without spectral analysis.

Conclusions

The Deep Learning networks can be used for automated detection of oscillatory and epileptiform events within iEEG. Most importantly, the trained LSTM network shows generalizability detecting events with sensitivity and specificity higher than 85-90% in all patients tested. The DL networks can significantly accelerate the analysis of iEEG data and increase their diagnostic value which may improve surgical outcome in patients with localization-related refractory epilepsy.

Title: Transcutaneous vagal nerve stimulation both activates and deactivates clusters of neurons in key brainstem nuclei: A coordinate-based meta-analysis of resting state fMRI studies

Authors: *C. RIDGEWELL, W. NEUMEIER, K. J. HEATON;
USARIEM, Natick, MA

Abstract: Transcutaneous vagal nerve stimulation (tVNS) is a non-invasive method of vagal neuromodulation. Application of tVNS has demonstrated cognitive performance enhancement in healthy individuals and clinical efficacy for conditions such as epilepsy and depression. Neuroimaging techniques, such as resting state functional magnetic resonance imaging (rs-fMRI), can provide insight into the effects of tVNS on underlying neural processes but research using these techniques with tVNS is, to date, limited. Therefore, the aim of this analysis was to conduct a meta-analytic review of available rs-fMRI studies to synthesize the current body of knowledge and identify gaps in this knowledge regarding the neurological mechanisms of tVNS. Using the search query "("transcutaneous" OR "noninvasive" OR "non-invasive") AND ("vagus" OR "vagal") AND ("stimulation" OR "neuromodulation") AND ("MRI" OR "fMRI" OR "imaging")," a review of existing literature following the Cochrane Collaboration's PRISMA

guidelines (Liberati et al., 2009) identified 20 articles. Of these, 7 articles reporting data from either 1.5 or 3 Tesla rs-fMRI, including a total of 194 unique foci across 146 participants, were included in the final sample after excluding those not reporting cluster coordinates. Stimulation sites were heterogeneous ($n_{cervical} = 1$, $n_{tragus} = 3$, $n_{cymba\ concha} = 3$). A coordinate-based meta-analysis using activation-likelihood estimation (ALE) was completed to identify relevant patterns of blood-oxygen-level-dependent (BOLD) activation during tVNS and rs-fMRI compared to sham stimulation. This analysis used a full-width half maximum Gaussian blur for each coordinate focus and a minimum cluster size of $15mm^3$. A total of 1000 thresholding permutations were calculated using an uncorrected p-threshold of $p < 0.001$ and a family-wise error threshold of $p < 0.05$. Compared to sham, active tVNS was associated with both greater and decreased activation in the locus coeruleus (LC) and dorsal raphe nucleus (DRN) and also decreased activation in the nucleus of the tractus solitarius (NTS). However, changes from pre- to post-stimulation were not associated with significant clusters of functional activity for either tVNS or sham conditions, which may be due to low statistical power. Overall, these findings suggest support of previous theories regarding the effects of tVNS on underlying neural function, particularly with respect to observations of increased norepinephrine circulation, as reflected by increased LC activity following tVNS relative to sham.

Title: Auricular Vagus Neuromodulation - A Systematic Review on Quality of Evidence and Clinical Effects

Authors: *J. D. MUDGE[1], N. VERMA[1], M. S. E. KASOLE[1], R. C. H. CHEN[1], S. L. BLANZ[1], J. K. TREVATHAN[1], E. LOVETT[2], K. A. LUDWIG[1,3];
[1]Biomed. Engin., Univ. of Wisconsin-Madison, Madison, WI; [2]LivaNova, Houston, TX;
[3]Neurosurg., Univ. of Wisconsin - Madison, Madison, WI

Abstract: Background: The auricular branch of the vagus nerve runs superficial to the surface of the skin, making it a favorable target for non-invasive neuromodulation techniques. Given that auricular vagus nerve stimulation (aVNS) can be implemented non-invasively, there have been many early stage clinical trials on a diverse range of conditions and physiological outcomes, often with conflicting results.
Methods: We conducted a systematic review of 41 aVNS randomized controlled trials (RCTs) using the common Cochrane Risk of Bias tool as a framework. The Risk of Bias tool is intended

to identify deviations from an ideal RCT that may cause the effect of an intervention to be overestimated or underestimated. As is common for early stage studies, the majority of aVNS studies were assessed as having 'some' or 'high' risk of inadvertent bias, which makes interpreting their results in a broader context problematic.
Results: The reported outcomes were qualitatively synthesized across studies. There is evidence of a modest decrease in HR during higher levels of stimulation. Findings on heart rate variability conflicted between studies and were hindered by trial designs including inappropriate washout periods and multiple methods used to quantify HRV. There is early stage evidence to suggest aVNS may reduce circulating levels or endotoxin induced levels of inflammatory markers. Studies on epilepsy reached primary endpoint results similar to previous RCTs on implantable VNS, albeit with concerns over quality of blinding. aVNS showed preliminary evidence of ameliorating pathological pain but not induced pain.
Discussion: We show the need for direct measures of target engagement in aVNS. Firstly, for the determination of stimulation parameters and electrode design and placement. Secondly, direct measures of target engagement, along with consistent evaluation of the double blind, should be used to improve the design of controls in the long term - a major source of concern identified in the Cochrane analysis. Lastly, we list common improvements in reporting of results that can be addressed in the short term.
Conclusion: Direct measures of target engagement and evaluation of the double blind for the development of appropriate controls should be strived for in aVNS and is applicable to other paresthesia-inducing neuromodulation therapies, such as spinal cord stimulation.

Title: Non-monotonic kilohertz frequency (KHF) block thresholds arise from charge imbalance not waveform asymmetry

Authors: *E. PEÑA, N. A. PELOT, W. M. GRILL;
Duke Univ., Durham, NC

Abstract: Reversible block of nerve conduction using KHF electrical signals has substantial potential for treatment of disease. However, the ability to block nerve fibers selectively is limited by poor understanding of the relationship between waveform parameters and the nerve fibers that are blocked. Previous studies reported non-monotonic relationships between block signal frequency and block threshold that differed across fiber types, suggesting the potential for fiber-selective block. However, the origin of non-monotonic effects was unclear, and these findings were not replicated in a subsequent in vivo study. We hypothesized that non-monotonic threshold-frequency relationships emerge from frequency- and amplitude-dependent charge imbalances in KHF waveforms. We used high-fidelity computational models of human vagus and rat tibial nerves, as well as rat in vivo experiments, to quantify threshold-frequency relationships of rectangular waveforms with a range of asymmetries and charge imbalances. Across both models and in vivo experiments, non-monotonic threshold-frequency relationships only occurred with charge-imbalanced KHF block, and the charge imbalance was negatively correlated with changes in block threshold. In contrast, blocking with charge-balanced waveforms consistently produced monotonic threshold-frequency relationships, and the degree of asymmetry was positively correlated with changes in block threshold. Computational models of direct current equivalent nerve block revealed that non-monotonic block thresholds represented a transition from KHF block to direct current block. The models further identified complex interactions between KHF block mechanisms and direct current block mechanisms that could be understood through independent analysis of each block regime. These results suggest a mechanism for non-monotonic threshold-frequency relationships that reconciles previous contradictory studies. In addition, the analyses clarify the mechanisms of interaction between KHF and direct current block, and they demonstrate the potential for selective block of specific fiber types.

Title: Orientation relative to grey and white matter and brain region predictably shapes the response to intracranial direct electrical stimulation in the human cortex

Authors: *A. C. PAULK[1], R. ZELMANN[2], B. CROCKER[4], N. PELED[3], D. D. DOUGHERTY[1], A. S. WIDGE[5], E. N. ESKANDAR[6], D. WEISHOLTZ[7], J. LEE[7], R. M. RICHARDSON[1], G. R. COSGROVE[7], Z. WILLIAMS[8], S. S. CASH[1];
[2]Neurol., [3]Radiology, [1]Massachusetts Gen. Hosp., Boston, MA; [4]MIT, Cambridge, MA; [5]Psychiatry, Univ. of Minnesota, Minneapolis, MN; [6]Montefiore Med. Ctr., Bronx, NY; [7]Brigham and Women's Hosp., Boston, MA; [8]Harvard Med. Sch., Boston, MA

Abstract: While electrical neuromodulation is employed to treat psychiatric and neurological disorders worldwide and is used to derive functional network connectivity in the human brain, the mechanisms of electrical stimulation remain poorly understood, manifesting a highly variable range of behavioral and neurophysiological effects. Few systematic studies address the physiological effects of human brain stimulation, in large part made complicated by the massive parameter space and numerous hypotheses as to why some stimulation parameters work and some do not. The considerable stimulation efficacy variability is likely a result of a complex interaction of multiple factors, including stimulation location, injected current density, the generated stimulation field, and stimulation frequency. We examined the relationship between single pulse and trains of evoked cortico-cortico evoked potentials (CCEPs) with current amplitude, location in the brain, electrode spacing with bipolar stimulation, and stimulation location with reference to the grey-white junction across a data set of patients (N=62) implanted with electrodes for intracranial monitoring for their clinical care. We measured peak and valley amplitudes, area under the curve, and energy of the responses while accounting for location, electrode spacing, current injected, and brain location. We found separable, nonlinear responses varying with stimulation location with respect to the cortical column / white matter and especially brain region. The peak CCEP amplitude and the distance between stimulating and recording site were negatively correlated for pulses delivered in the prefrontal cortex, dorsal anterior cingulate, and temporal lobe ($p<0.014$), but not for the rostral anterior cingulate ($p>0.297$), showing a regional specificity to stimulation spread (Wilcoxon signed rank test; N=49). In addition, stimulation sites with above-threshold (5 standard deviations above the baseline) responses across the brain were significantly closer to the grey-white matter boundary compared to sites with below-threshold responses with stimulation in the lateral prefrontal cortex ($p<0.001$) but, interestingly, not the cingulate, temporal lobe, or orbitofrontal cortex ($p>0.001$, Wilcoxon rank sum test; N=49). These results demonstrate that there are consistent location and stimulation frequency effects, and differences, on neural responses even in areas which are considered ‘similar’ in density, connectivity, neural morphology, and cortical architecture (e.g. rACC and dACC). These findings have significant implications for how stimulation is applied as a therapeutic tool.

Title: Multi-scale simulation of neuronal polarization by conventional and high-definition transcranial direct current stimulation (tDCS)

Authors: *A. S. ABERRA[1], A. LOPEZ[2,3], W. M. GRILL[1,3,4,5], A. V. PETERCHEV[1,3,5,6];
[1]Dept. of Biomed. Engineering, Pratt Sch. of Engin., [2]Dept. of Mathematics, Trinity Col. of Arts and Sci., [3]Dept. of Electrical and Computer Engineering, Pratt Sch. of Engin., [4]Dept. of Neurobiology, Sch. of Med., [5]Dept. of Neurosurgery, Sch. of Med., [6]Dept. of Psychiatry, Sch. of Med., Duke Univ., Durham, NC

Abstract: tDCS shows promise as an inexpensive, painless, and noninvasive technique for modulating brain activity by applying weak currents via scalp electrodes and has numerous potential clinical and research applications. However, it is unclear how specific electric field (E-field) distributions polarize different subcellular elements of the diverse range of cell types in cortex.
We used a multi-scale model of layer-specific, morphologically-realistic cortical neuron models (NEURON), embedded in a finite element method head model of the E-field (SimNIBS), to simulate steady-state polarization generated by conventional M1-SO tDCS (7x5 cm) and 4x1 "high-definition" HD tDCS. We quantified polarization in the somatic, axonal, and dendritic compartments of layer 1 neurogliaform cells, L2/3 pyramidal cells (PCs), L4 large basket cells (LBCs), L5 PCs, and L6 PCs in the M1 hand knob. We also used a uniform E-field approximation to estimate the tDCS-generated polarizations.
With matched peak E-field magnitude (0.5 V/m), 1.8 mA conventional tDCS (C) produced slightly stronger, more diffuse polarization, peaking in the central sulcus, while 2.0 mA HD tDCS produced peak polarization in the gyral crown, reflecting their respective E-field distributions. Both montages generated regions of depolarization and hyperpolarization beneath the M1 electrode and within each neuron. All neurons experienced higher peak axonal and dendritic polarizations than somatic polarization, with peak somatic polarization between cells in the L5 and L6 PCs (C: -0.057 - +0.082 mV, HD: -0.052 - +0.077 mV), peak axonal polarization in the tangentially oriented L2/3 PC axon terminals (C: -0.68 - +0.92 mV, HD: -0.78 - +0.82 mV), and peak dendritic polarization in the basal dendritic terminals of the LBCs (C: -0.17 - 0.21 mV, HD: -0.19 - 0.19 mV). These trends were consistent with the uniform E-field simulations. We used the polarizations from the uniform 1 V/m E-field to estimate the tDCS generated polarizations by matching the E-field direction to the somatic E-field vector for each neuron

position and scaling linearly by the amplitude, which yielded <6.83% median percent error and <57.8% mean percent error. Therefore, the uniform E-field approximation can capture broadly the polarization distribution, but may produce large errors in some regions.
These results suggest polarization of pre- and postsynaptic compartments of both excitatory and inhibitory cortical neurons may play a larger role in tDCS neuromodulation than somatic polarization, and these effects cannot be predicted by considering the E-field distribution alone.

Title: Epidural cerebellar stimulation drives widespread neural synchrony in the intact and injured motor cortex

Authors: ***N. DANIELSEN**[1], A. ABBASI[1], J. LEUNG[2], S. PATEL[2], T. GULATI[1,3,4];
[1]Ctr. for Neural Sci. and Med., [2]Cedars-Sinai Med. Ctr., Los Angeles, CA; [3]Bioengineering, UCLA Samueli Sch. of Engin., Los Angeles, CA; [4]Med., UCLA David Geffen Sch. of Med., Los Angeles, CA

Abstract: Introduction: Cerebellar electrical stimulation has shown promise in improving motor recovery post-stroke in both rodent and human studies. Past studies have used motor evoked potentials (MEPs) to evaluate how cerebellar stimulation modulates ongoing activity in the cortex, but our understanding of its effects remains limited. Here we used invasive electrophysiological recordings from the rodent primary motor cortex (M1) to assess how cerebellar stimulation modulates neural activity at the level of single neurons as well as at the level of mesoscale dynamics, both in intact and stroke-injured M1. **Methods:** We recorded single unit spiking and local field potentials (LFPs) in M1 or peri-infarct M1, contralateral to the stimulated cerebellum in adult Long Evans rats (10 intact and 4 stroke) under ketamine-xylazine anesthesia. In the injured group, stroke was induced via a photothrombotic model and the neural activity was recorded immediately anterior to the stroke site. **Results:** Our results show that post-stimulation, the firing rates of a majority of M1 neurons changed significantly with respect to their baseline rates. We observed this in both healthy and stroke-injured rats. These firing rate changes were diverse in character, as the firing rate of some neurons increased while others decreased. Furthermore, cross-correlation analysis showed a significant increase in coincident firing amongst neuronal pairs. Interestingly, this increase in synchrony was unrelated to the direction of firing rate change. We also found that neuronal ensembles derived through principal

component analysis were more active post-stimulation. Lastly, we found that cerebellar stimulation increased low-frequency power (< 4Hz) in M1 LFPs during the stimulation, but this increase did not persist post-stimulation. **Conclusion:** Thus, we conclude that cerebellar stimulation caused significant, long-lasting changes in the activity patterns of cortical neurons (in the intact or injured M1) by altering firing rates, boosting neural synchrony and increasing neuronal assemblies' activation strength. Our study provides evidence that cerebellar stimulation can directly modulate cortical dynamics in intact and stroke-injured rats.

Title: Investigating early neural responses during transcranial magnetic stimulation in non-human primates

Authors: ***N. D. PERERA**[1], S. SHIRINPOUR[1], I. ALEKSEICHUK[1], G. LINN[2], C. E. SCHROEDER[2,3], A. Y. FALCHIER[2], A. OPITZ[1];

Abstract: Transcranial Magnetic Stimulation (TMS) is a non-invasive neuromodulation technique commonly utilized in brain research and clinical applications such as major depression and ADHD. Despite its widespread use, the underlying neuronal mechanisms of TMS and how it modulates brain activity is obscure. It has been debated that some of the TMS evoked responses could be a result of peripheral effects rather than direct neural activation. To this end, we recorded brain activity from an anesthetized monkey with implanted electrodes projecting from visual area (V2) to frontal eye field (FEF), secondary auditory cortical (AUD) and temporal (TE) regions in the left hemisphere. The exact locations of electrode contacts were determined by co-registering post- and pre-surgery MR images. Biphasic single-pulse TMS was delivered over the left prefrontal cortex. A sham protocol was executed by tilting the coil away from the head to mimic the auditory response. Stimulation intensities were set to 70% and 90% of the maximum stimulator output. Concurrent electrical activity from cranial muscle depolarization was measured using needle electrodes. Data from muscle activity was processed by removing the TMS artifact and performing time locked averaging to verify the duration of muscle activity

immediately following TMS pulse. We preprocessed the neural data by removing channels contaminated with large noise through visual inspection, removing the TMS and the muscle artifacts (calculated from EMG data), interpolating, down-sampling to 1 kHz and bandpass filtering at 0.1-50 Hz. For analysis, we performed time-locked averaging across trials and time-frequency representation relative to the baseline prior to stimulus presentation. Preliminary time-frequency results indicate that under TMS condition, low frequency (4-7 Hz) activity is suppressed in frontal contacts of FEF electrode (located in caudate nucleus) in contrast to sham condition. This effect is not observed in frontal contacts in AUD electrode (located in auditory belt) or TE electrode. Furthermore, contacts of AUD electrode in auditory belt reveal consistent low frequency oscillations in both TMS and sham conditions, which is attributed to the auditory response to the 'click' sound. This provides preliminary evidence that the modulatory effects of TMS are localized and result mainly from direct neural activation with little or no peripheral stimulation. Future research directions include quantification of direct and indirect TMS effects and isolating early neural activity by blocking cranial muscle activity. This will enable us to distinguish between direct neural response and secondary stimulation effects.

Title: Studying the mechanisms of plasticity following ischemic stroke and cortical stimulation in non-human primates

Authors: *J. ZHOU[1], K. KHATEEB[1], Z. IP[1], A. YAZDAN-SHAHMORAD[2];
[1]Bioengineering, [2]Bioengineering and Electrical Engin., Univ. of Washington, Seattle, WA

Abstract: Brain plasticity has been widely observed during behavioral tasks and functional recovery after damage. As a result, brain stimulation protocols can be designed to take advantage of this natural plasticity and serve as a potential therapy for various neural disorders. In particular, ischemic stroke is a major cause of brain injury that results in lifelong disability. Although numerous work in rodents have demonstrated stimulation-induced plasticity following

stroke, few of these results have been replicated in humans due to the huge anatomical differences between rodent and human brains, and a limited understanding of the underlying plasticity mechanisms. Therefore, we combined electrophysiology and immunohistochemistry to study the mechanisms of neuroplasticity following cortical ischemic stroke and electrical stimulation in non-human primates (NHPs). To produce controlled focal lesions, we used the photothrombotic method on the cortical surface to cause targeted vasculature damage. In two adult rhesus macaques, we generated ischemic lesions in the sensorimotor cortex while collecting electrocorticography (ECoG) recordings. In a third animal, we followed the same lesioning procedures and applied repeated electrical stimulation via an ECoG electrode 8 mm away from the lesioned site. During 60 minutes of stimulation, we simultaneously recorded through the same ECoG array to monitor the network dynamics. We assessed the neural activity changes within the sensorimotor cortex of each macaque as quantified by the signal power. In addition, we performed histology analysis that consists of Nissl staining with thionin and immunostaining with antibodies against two common plasticity markers, postsynaptic density-95 (PSD-95) and growth-associated protein-43 (GAP-43). Our ECoG signals showed decreased signal power at each lesion site for the first two monkeys and reduced power at all sites post-stimulation for the third monkey. We also observed an elevation in both PSD-95 and GAP-43 markers around the lesion boundary, suggesting an increase in synaptic plasticity within the ischemic penumbra. We will compare these to the same markers found in the post-stimulation penumbra to study the level of stimulation-induced plasticity and the large-scale downregulation of activity we saw from electrophysiology after stimulation. These results will shed light on the mechanisms governing neuroplasticity following injury and subsequent stimulation in NHPs. With the similarity between NHP and human brains, it paves the path for developing effective stimulation-based therapy for stroke rehabilitation in clinical studies.

Title: Controlling epileptic seizures using forced temporal spike-time stimulation

Authors: *J. SCHMALZ[1], G. KUMAR[2], M. V. KOTHARE[3];
[1]Dept. of Chem. and Biol. Engin., Univ. of Idaho, Moscow, Idaho, ID; [2]Dept. of Chem. and Biol. Engin., Univ. of Idaho, Moscow, ID; [3]Dept. of Chem. and Biomolecular Engin., Lehigh Univ., Bethlehem, PA

Abstract: Epilepsy is typically characterized by highly synchronized episodes of neural activity. Currently, the existing stimulation therapies purely focus on suppressing the pathologically synchronized neuronal firing patterns during the ictal (seizure) period. While these strategies are

effective in suppressing the seizure when they occur, they fail to prevent the re-emergence of seizures once the stimulation is turned off. Experimental data from human patients and animal models show significant morphological and synaptic level changes in many brain regions after the episodes of epileptic seizures, which may be a possible reason for this re-emergence. Previously, we developed a novel neurostimulation motif, which we refer to as "Forced Temporal Spike-Time Stimulation" (FTSTS) based on a basic combination of out-of-phase biphasic pulsed stimulation, one for the excitatory neuronal population and one for the inhibitory neuronal population, that has shown remarkable promise in long-lasting desynchronization of excessively synchronized neuronal firing patterns by harnessing synaptic plasticity[1]. This FTSTS protocol can reliably and robustly desynchronize the excessively synchronized and rhythmic network response to a desired low level. The FTSTS protocol is also capable of the reverse, i.e., desynchronization to synchronization of the neural population can happen consistently using the exact reverse of these signals. We showed the capability of this selective FTSTS protocol in desynchronizing and synchronizing neuronal activity in a generic excitatory-inhibitory (E-I) network model consisting of up to 10,000 neurons. Building upon this prior work, we have recently investigated the FTSTS capability in desynchronizing the pathologically synchronized neuronal firing patterns during epileptic seizures using a recently published computational model of neocortical-onset seizures[2], validated with human epilepsy data. Our simulation results show that the FTSTS protocol can effectively desynchronize the pathologically synchronized neuronal firing patterns during the ictal period. Moreover, the FTSTS protocol can potentially reduce the chances of future episodes of seizure-like activity by decreasing the average long-term synaptic strength of the network.

Title: Modulation of motor sequence learning through targeted transcranial direct current stimulation

Authors: *G. HSU[1], A. SHEREEN[2], L. PARRA[1];
[1]City Col. of New York, New York, NY; [2]The Grad. Center, The City Univ. of New York, New York, NY

Abstract: This is an exploratory study to observe whether high-definition transcranial direct current stimulation (HD-tDCS) with elevated intensity of 4 mA can 1. be applied without severe discomfort and 2. produce reliable behavioral effects on motor sequence learning during a finger tapping task (FTT). Functional magnetic resonance imaging (fMRI) of healthy participants (N = 10) performing sequential finger movements, combined with a transcranial electrical stimulation (tES) current flow model, was used to determine a generalized 4x4 focal HD-tDCS electrode montage to target the hand knob on the primary motor cortex (M1). In a single-blinded design, 50 healthy right-handed adult participants received either anodal (N = 25) or cathodal (N = 25) HD-tDCS while they performed a sequential FTT using their non-dominant hand for 12 minutes. After a 1-hour break, a follow-up session measured retention of task performance and included two control tasks with unfamiliar sequences on both the contralateral and ipsilateral hands. Discomfort at various time points during the procedure was measured using a visual analog scale (VAS). In both groups the mean VAS values did not exceed moderate levels of discomfort. Two-sample t-tests of the mean tapping speeds, calculated using the time intervals between key presses in all correctly completed sequences, indicate a significant difference in performance between the anodal and cathodal groups in the trained sequence, but not in the control sequences. These results suggest that high intensity HD-tDCS targeted to M1 has a specific effect on motor sequence learning. Furthermore, 4mA HD-tDCS is well tolerated.

Title: Assessment of Baseline Offsets and Charge Injection Limits of Neural Stimulation Electrodes using Voltage Transient Measurements: The Importance of Measurement Instrumentation

Authors: J. K. TREVATHAN[1], S. AVERBECK[1], K. LUDWIG[2];
[2]Biomed. Engin. and Neurolog. Surgery, [1]Univ. of Wisconsin-Madison, Madison, WI

Abstract: The development of safe and efficacious neural stimulation protocols critically depends on the accurate assessment of charge injection limits that do not result in toxic byproducts of stimulation or evolution of oxygen/hydrogen at neural stimulation electrodes. Since the introduction of voltage transient or voltage excursion methods by Roblee et al. in 1990, this method has become a standard used by pre-clinical researchers for understanding the charge injection limits of different materials or electrode geometries. It has also become an important

part of safety testing for clinical devices and common requirement by FDA reviewers in assessing device safety. Although voltage transient measurements have been commonly applied across neural engineering, assessment of charge injection limits in the presence of baseline voltage offsets at the stimulation electrode has been inconsistent across the literature. Additionally, voltage transient measurements have provided results for safe charge injection limits that are inconsistent with charge injection capacities measured using slow scan cyclic voltammetry as well as with in vitro and in vivo testing. These inconsistencies highlight the need for developing well validated methods for accurate assessment of charge injection limits across studies.
In this work, we assessed the effects of stimulation and measurement instrumentation on baseline offsets and charge injection limits calculated from voltage transients at polished 1mm diameter platinum disk electrodes. We compared baseline offsets collected with a conventional pre-clinical stimulator with two methods for minimizing DC leakage current and charge imbalance between stimulation phases. The first being capacitively coupling of the stimulator output with 1μF capacitors, and the second with shorting of the stimulator outputs between current pulses. Additionally, we compare baseline offsets and charge injection capacities observed with 1MΩ and 10MΩ input impedance measurement devices, that matches oscilloscopes conventionally used for recording voltage transients, with a high impedance >10GΩ input impedance measurement setup. Our data suggests that commonly cited charge injection limits may in fact be underestimating the charge injection limits for oxygen and hydrogen evolution at neural stimulation electrodes and underreporting baseline offsets occurring at platinum electrodes. These results highlight the need for consistent and accurate assessment of voltage transients across studies as well as a need for better understanding how benchtop measurements of charge injection limits translate to *in vivo* safety and efficacy.

Title: Franz Nissl - more than just a stain

Authors: *B. W. BAKKUM;
Illinois Col. of Optometry.

Abstract: Franz Alexander Nissl (1860-1919) was arguably the foremost neuropathologist of his time. He was also a respected psychiatrist who worked with other greats, including Aloysius Alzheimer (he was best man at Alzheimer's wedding), Korbinian Brodmann, and Emil Kraepelin. Besides those accomplishments, Dr. Nissl popularized the use of lumbar puncture, which had been introduced in 1891 by Heinrich Irenaeus Quincke. He actually became known as "Punctator Maximus". Dr. Nissl is best remembered for introducing a staining procedure that he devised while he was still in medical school in 1884. This method allowed the characterization of neurons and revealed several of their previously unknown components. For this he was honored with the eponym: Nissl stain. His original process was fixing the tissue with alcohol and staining it with methylene blue. Later cresyl violet has been commonly substituted for methylene blue. One of the main components of neurons that were made visible with this process was what he originally called: Chromatinkörper (colored bodies), but later seemed to use the term: Körperchen (little bodies). These came to be known as Nissl substance (or bodies). Later these large clumps of material in the soma and proximal regions of the dendrites, but not the axon nor axon hillock, were identified as mostly rough endoplasmic reticulum and polyribosomes. By the time that Nissl devised his staining procedure, Augustus Waller had already described the degeneration of the distal segment of a severed peripheral nerve, which became known as wallerian degeneration. Using his new staining technique, Nissl observed that there were also morphological changes that occurred in the cell bodies of the facial nucleus and spinal motor neurons. He called these changes: Methode der primäre Reizung (method of primary irritation). Therefore, he was the first to describe the process that is now known as the axon reaction. This included the "Zerfall" (disintegration) of the colored bodies or what is now termed chromatolysis, as coined by George Marinesco in 1896. This should be contrasted by an earlier use of the term: chromatolysis by Walter Fleming in 1885, who used it to describe a type of cell death that is now understood to be apoptosis. Nissl also described many of the other changes in the soma that are associated with the axon reaction including swelling of the perikaryon and movement of the nucleus to the periphery of the cell body. During World War I, Dr. Nissl was assigned administrative duties at a large military hospital. Overwhelmed by these along with his academic responsibilities and severe kidney disease meant that he died in 1919 leaving many of his scientific projects unfinished.

Title: The struggles and successes of T. S. Kanaka (1932-2018): lessons of life from Asia's first female neurological surgeon-scientist

Authors: *A. OZAIR[1], **V. BHAT**[2], A. FARUQI[1], A. BAJAJ[1], A. A. SONKAR[1];
[1]King George's Med. Univ., Lucknow, India; [2]St. John's Med. Col., Bangalore, India

Abstract: Female surgeon-scientists have been a rarity worldwide, and significantly so in neurosurgery-neuroscience. This is especially true of South Asia, considering the added social and cultural expectations for women in the region. Yet it was in India, with its difficult history of gender relations in both the personal and the professional domains, that Asia's first fully qualified female neurosurgeon and the first female surgeon-scientist, Dr. T. S. Kanaka (1932-2018), took roots and flourished. As part of the Madras Institute of Neurology, she played an integral role in one of the earliest teams worldwide that pioneered stereotactic and functional neurosurgery.
While a few biographical accounts of her exist, we utilize many hitherto unused sources to highlight the several lessons that may be learnt from her illustrious career for aspiring neurosurgeons, neurosurgical trainees, and even fresh neurosurgeons of today. Many of the virtues that ensured her extraordinary victories are attributes that continue to be critical for obtaining success as a surgeon-scientist even today. Specifically, we illustrate, through previously unused sources, (A) how persistence and resilience were integral to her success, (B) how her mentors opened many doors for her, (C) how her personal sacrifices took her from 'good' to 'great', (D) how her pathbreaking research and innovation cemented her status, (F) how her selfless work to promote science-based treatment magnified her impact, and finally, (E) how a mindset of lifelong teaching and learning became a lasting legacy. Adoption of some of these lessons by female scientists and trainees will be especially valuable considering that in 2017, India only had 73 female neurosurgeons.
We also shed light on the circumstances that helped Kanaka succeed, as a lesson in promoting the same when working to enhance diversity and inclusion today. Finally, we describe her interests, sacrifices, and life choices, which are hitherto little explored but highly relevant considerations for women who wish to pursue a career as a surgeon-scientist.

Authors: *D. J. MOKLER;
Univ. of New England, Biddeford, ME

Abstract: Peter J. Morgane (1927 - 2010) has contributed significantly to the neuroanatomy of the cetacean brain. He published in the field of neuroscience from 1957 until the present

(colleagues are still publishing work that he contributed to). He published in the area of the neuroanatomy of cetacean brain from 1962 until 2004. His published work in neuroscience is found in over 200 papers and in the neuroanatomy of the cetacean brain is covered in 33 papers. The University of New England has established a special collection of his work. The material is on loan from Dr. Mokler. The material consists of photographs and slides of histological specimens used in publications. In addition, there are notes and correspondence from his research over 50 years. Researchers can access the collection by contacting David Mokler at dmokler@une.edu. More information on the collection can be accessed at https://www.library.une.edu/special-collections.In addition, the histological collection of cetacean brains are maintained in the lab of Patrick Hof at the Icahn School of Medicine at Mount Sinai.

Title: Consideration of Balint's syndrome as the second disconnection syndrome and application of this as a paradigm to study the "what" and "where" visual pathways

Authors: *E. L. ALTSCHULER[1], B. M. ALTSCHULER[2];
[1]Physical Med. and Rehabil., Metropolitan Hosp., New York, NY; [2]Col., Havard, Cambridge, MA

Abstract: In1965 Geschwind called alexia without agraphia (AwoA), originally described by Dejerine in 1892, the first disconnection syndrome: left visual cortex lesion combined with a

lesion of the splenium of the corpus callosum disconnects intact vision in the right cortical hemisphere from the language centers in the left brain rendering the patient unable to read. Writing is intact as the left-brain language centers—Wernicke, Broca's areas—are intact as are the white matter tracts connecting them. I have noted that studying patients with AwoA may give an unprecedented opportunity to assess the capacity of the right brain for reasoning and logic: Recently we described a method, using question stimuli presented either as pictures or words, e.g., does a bone go with a dog, cat (or do not know the answer), to assess whether or not Wernicke's aphasia patients understand that they do not understand language (Hartman et al., & EL Altschuler, 2017). This method can be used with the picture stimuli—processed by the brain—as the test stimuli and the same questions asked verbally which should be able to be answered normally by the left brain as (positive) control stimuli. We here suggest that Bálint's syndrome (BS) should be recognized as the second disconnection syndrome and study of patients with the syndrome a most useful approach to elucidate the functions of the "what" vs. "where" visual pathways. In 1909 Hungarian neurologist Rezső Bálint described a patient with (1) a spatial disorder of attention—the inability to perceive several things in a visual scene at one time despite normal visual acuity—simultanagnosia (Wolpert, 1924), (2) "psychic paralysis of gaze" (ocular motor apraxia), (3) optic ataxia. Brzis et al. & Lee (1988) found that patients with BS and others with simultanagnosia could not name the (large) number on Ishihara color (vision testing) plates despite normal color vision and in particular normal naming of the colors of the individual (small) dots making up the number. This suggests that BS patients may have a frank disconnection of the "what" (ventral stream) and "where" (dorsal stream) pathways. Bálint's patient had bilateral parietal lesions from a series of strokes, and other early patients of Holmes and others were war veterans with brain injuries damaging the parietal lobes bilaterally. But we (Williams, Patira & Altschuler, 2016) and others have seen BS in patients with a single large (unilateral) stroke affecting the left poster cerebral artery (PCA). Thus, BS may be more common than typically appreciated and simple, non-invasive testing and assessment of patients with BS may provide significant insight into the functions of the "what" and "where" visual pathways.

Title: William James's theory of emotion as a pioneer of affective neuroscience: Use of an introspection method in early psychology and knowledge of neurological findings prior to the early 1880s to develop a testable hypothesis assuming a body-mind interaction

Authors: *T. SATO;
Social Welfare, Nagano Univ., Ueda, Japan

Abstract: William James published “What is an Emotion?” in 1884, in which he wrote the famous statement, “We feel sorry because we cry.” A major contribution of the paper to affective neuroscience was the making of hypotheses verified by neurological methods to explain the brain mechanisms of emotion, based both on previous neurological findings and on the introspection method (careful observation of his own subjective experience, a major research method in early psychology). This presentation focuses on the context in which James proposed his theory of emotion, rather than on the accuracy of the brain mechanisms he proposed. His hypothesis was called the “peripheral theory of emotion,” likely because it required the perception of a bodily state or change to indicate the occurrence of an emotion. Several physiologists have strongly criticized James’s hypothesis. Two such critics, Walter Cannon and Phillip Bard, proposed another theory as an alternative viewpoint of the brain mechanism of emotion. The so-called “Cannon-Bard theory” or “central theory of emotion” points to the role of the diencephalon. Putting aside consideration about validity of their criticism and their original theory, most differences between the two theories are not fully explained by a dichotomized examination of the peripheral and central origins of emotions. This is, in part, because James considered the emotional process to be a neural process in the brain, suggesting that the most important difference between the theories is the brain mechanism in which emotion occurs. James’s research method was limited to introspection, and he characterized emotions as being associated with bodily manifestations, such as fear and anger, as the “standard emotions.” Based on recent findings of affective neuroscience, in an earlier stage of standard emotions, bodily responses may occur based on neural activity in the amygdala stimulated by a direct route from a sensory organ; the neural pathway, called the “low road,” was defined by LeDoux. We then perceive these responses vividly, and these perceptions become central to our consciousness if the responses are sufficiently strong. At a later stage of feeling, we may subjectively experience emotions that probably depend on some cortical route or a “high road” of emotional processing in the brain. Thus, through careful observation of our subjective experiences, we can experience the subjective perception of bodily changes, followed by subjective emotional feelings, which truly correspond to James’s introspection results. His hypothesis appears to have been developed by both his careful introspection and his extensive knowledge of previous neurological findings.

Title: Olfactory bulbectomy animal model in depression through history

Authors: *C. GARCIA-OLVERA[1], I. CESAR ARTEAGA[2], D. JUÁREZ SERRANO[3], P. AGUILAR-ALONSO[4];
[1]Benemérita Univ. Autónoma De Puebla, Puebla, Mexico; [2]Lab. de Investigaciones Quimico Clinicas, Benemerita Univ. Autonoma De Puebla, Puebla, Mexico; [3]Biochemistry-Molecular Biol., BENEMERITA UNIVERSIDAD AUTONOMA DE PUEBLA, Tlaxcala, Mexico; [4]BUAP, Puebla, Mexico

Abstract: At the beginning of the past century it was observed the first relationship between removal of olfactory bulbs in rats and changes in its behavior thanks to the research of Psychologist John B. Watson, who described that bulbectomized rats were showed aggressive and irritable than usual. Although, it was not until 70's decade when was confirmed by specific tests that bilateral ablation of olfactory bulbs in rats generate behavioral modifications as irritability. On the other hand, research for new pharmacological treatment on mood disorders, especially for depression after monoamine theory was hypothesized, allow the development of depressive animal models. However, there were many disadvantages among animal models, the major disadvantage was that the animal's recovery took place with an acute administration of the novel used antidepressant, while in clinical patients it was observed a longer time, even several weeks of treatment to recover. The introduction of olfactory bulbectomy in rodents as a new animal model of depression was proposed by van Riezen and colleagues in the middle 70's and later it was applied by Cairncross and colleagues with the aim to identify drugs with a potential antidepressant long-term activity. Bilateral olfactory bulbectomy (OBX) rodent model satisfy the criteria to consider it as an animal model of depression. It includes (1) to develop a depressive-like behavior similar to symptoms observed in patients with depression, (2) the behavioral changes can be measured and (3) reversed by antidepressant treatment. It had been considered diverse procedures for OBX, but nowadays there are little differences between them. The principal alterations observed in bulbectomized rats are variations of circadian rhythmicity, abnormalities in immune cells, high levels of ACTH and corticosterone, decreased serotonin and noradrenalin levels in brain, hyperactivity, modification of social behavior and cognitive function. Despite the fact that this animal model has been used in the last decades there are still discrepancies in results obtained, which must be analyzed carefully. Furthermore, due to complexity of surgery and time delay for recovery, OBX model is not the first option for *in vivo* studies. However, this model remains suitable for depressive-like behavior research.

Title: A brief history of EEG electrode localization

Authors: *K. M. JENSEN, J. K. KROGER;
Psychology, New Mexico State Univ., Las Cruces, NM

Abstract: In 1949, Herbert Jasper presented a system before the General Assembly of the International Federation in Paris, which would standardize the placement of electrodes on the scalp in electroencephalography (EEG). The purpose for this system was to make it easier for results to be reported, interpreted, and compared between labs. It was also hoped that by standardizing electrode placement, researchers could better estimate how activity recorded at the scalp correlates with underlying brain areas. These positions, based on proportional distance from landmarks on the skull, would be known as the 10-20 electrode system of the International Federation, and they would become a standard in EEG methods still used today (Jasper, 1958). Traditionally, this was done with the use of a tape measure. However, in the 1990's, new methods arose which utilized elastic caps and electromagnetic position trackers for marking electrode locations and saving them as 3D coordinates in a computer. This greatly reduced the time it took to prepare for data collection and allowed for the practical use of additional electrode sites beyond the 19 electrode locations used in the 10-20 system (Gevins et al., 1990). While manufacturers of elastic caps typically provide template 3D arrays for electrode positions when the cap is placed based on fixed points such as the Nasion, Inion, and preauricular points, researchers have achieved greater accuracy in source localization with methods which record the electrodes' actual position in 3D space and subsequently co-register them with a template MRI of the head (Akalin Acar & Makeig, 2013). For this reason, electromagnetic digitizers have been a popular method of electrode localization over the last few decades (Clausner et al., 2017). In recent years, many new methods have arisen which offer even greater opportunities for reduced experimental set up time, lower costs of equipment, and increased accuracy while recording electrode locations in EEG studies (Shirazi & Huang, 2019). One notable method is a photogrammetric approach which involves creating 3D head models of participants with the use of a 3D camera attached to a tablet. Electrode locations can later be marked in software, such as EEGLAB, with the *get_chanlocs* plug-in (Lee & Makeig, 2019). New methods have promising implications, using less expensive equipment and requiring less time from EEG study participants than methods involving electromagnetic digitizers, making electrode localization a more practical step in EEG research than ever before.

Title: Neuroscience in Peru, origins in ancient

Authors: *L. E. BAQUEDANO SANTANA;
Univ. Peruana Cayetano Heredia, Lima, Peru

Abstract: Is Neuroscience in Peru a science that has just started? Peru is a country with numerous cultures of the prehispanic time. Many of them did science without knowing it. The curiosity of man about his origins is seen in all cultures who elaborate interpretations, mythical or rational about the origin of man and that can be answered through three different ways: with myths, speculatively or with methods typical of science. In ancient Peru, cranial trepanation was a technique with empirical origins but with a scientific evolution over time that occurred throughout ancient Peru. It developed in Europe and the South Pacific in the 7th century B.C. and it was developed in Peru in the 14th to 16th century A.D. It had generational significance that passed from the Paracas to Incas culture and consisted of a surgical practice in which an artificial hole was made in the cranial vault of a living person. There was a knowledge of anatomy, diagnosis and systematic therapeutic strategy that allowed a high survival and growing development of the conditions in the context of those times. Studying these ancient practices allows us to understand and educate the scientific community, in addition to recovering our identity and value in science from remote origins.

Title: A Month in Neurodegenerative Disease Research (AMiNDR): An Open-Access Podcast Series for Researchers

Authors: *E. T. KOCH[1], S. LOUADI[2], E. M. ROWE[3], N. KUHLMANN[4], A. KAMESH[5]; [1]Psychiatry, [2]Med., [3]Pathology and Lab. Med., Univ. of British Columbia, Vancouver, BC, Canada; [4]Sch. of Physical and Occup. Therapy, [5]McGill Univ., Montreal, QC, Canada

Abstract: Background: With the ever-growing list of responsibilities for researchers, the vital task of staying up to date with the constant flow of new publications often gets pushed to the back burner. Given the rate at which new research is published — an average of 250 papers each week in the field of Alzheimer disease (AD) research — this can seem like an insurmountable task, and can result in wasted time and resources when researchers are not fully informed. In fact, in a survey of neuroscience researchers across the world, we confirmed that graduate students struggle to keep on top of the literature, and that a tool to facilitate this is urgently required.
Objective: To bridge this gap between the mound of new literature and the researchers who need to know about it, we recently developed and launched a new tool: A Month in Neurodegenerative Disease Research (AMiNDR). This is a student-run podcast that categorizes and summarizes new publications in AD research each month, allowing researchers to get an

overview of the literature while minimizing screen time.
Methods: Each month, we search PubMed for new publications using the key word “Alzheimer”, restricting the search to peer-reviewed original research articles. After downloading the resulting list of citations and abstracts, we filter out papers from predatory journals, reviews, or those which do not fit our inclusion criteria. We then manually sort the remaining abstracts into four overarching themes (risk factors, disease mechanisms, diagnostic tools, treatment development), containing sub themes for each podcast episode (ex. Fluid biomarkers). Our team then summarizes the abstracts to extract the key information, and scripts it into a listener-friendly format. The scripts are subsequently recorded by a podcast host, and new episodes are edited and released bi-weekly.
Results: AMiNDR is live as of June 2020, with 25-30 episodes covering a total of 500-600 papers each month. Each episode is also accompanied by a numbered bibliography to enable researchers to find papers that are covered in the podcast. Since our launch, we have acquired a global listenership, with an average of 30 downloads per episode, and over 1500 total downloads to date.
Conclusions: Based on feedback received so far, we believe our podcast is useful and accessible to researchers, enabling them to stay on top of the literature. We continue to refine and improve our methods with each month’s iteration, and hope to expand our listener base in the coming months.

Title: Neuro at home: adapting experiential learning from the laboratory to the virtual learning environment with DIY brain mounting kits

Authors: *J. A. HONEYCUTT, A. FORCHE;
Bowdoin Col., Brunswick, ME

Abstract: The rapid switch from in-person to remote teaching at the onset of the pandemic significantly disrupted adherence to conventional educational pedagogies, particularly with respect to experiential learning in undergraduate higher education. Laboratory-based courses have taken a disproportionate hit with the pivot to online learning, with instructors struggling to adapt hands-on lab skills and experiments to an online platform in ways that are both cost effective and safe for home use. In an effort to ensure continuity in experiential learning outcomes across various instructional modalities, we have implemented a series of curated at-home lab experiences to enhance online instruction of a Behavioral Neuroscience Lab course. One such lab-based experience involved mailing DIY kits with pre-sliced rat brain tissue to

students' homes, paired with freely available online instructional tools (Zoom and Slack) to provide a guided experience with real-time feedback for skill building. Students utilized the supplies in their lab kits, in addition to the open-source Swanson rat brain atlas, to meet three primary learning goals: 1) identify and arrange free-floating rat brain sections in neuroanatomical order; 2) hone fine motor skills necessary for mounting delicate biological samples onto slides for microscopy; and 3) perform a modified on-slide structural stain to visualize major brain regions. Lab courses such as this are essential for training the next generation of neuroscientists on core methodological skills, thereby providing them the experiential learning necessary to compete and succeed at the graduate and industry levels post-graduation. Indeed, having hands-on experience with brain slices is the only way to learn this skill effectively, and provides crucial practice in the identification of key brain regions. Here, we provide the pedagogical framework for planning and implementing a successful brain tissue mounting skill-building lab remotely in your own neuroscience laboratory courses as we navigate online laboratory learning in our new normal.

Title: Building your own neuroscience equipment; a precision micromanipulator and an epi-fluorescence microscope for calcium imaging

Authors: J. RYAN[1], ***B. R. JOHNSON**[2], D. DEITCHER[2];
[1]Biol., Hobart-William Smith Colleges, Geneva, NY; [2]Neurobio. and Behavior, Cornell Univ., Ithaca, NY

Abstract: A faculty member's ability to develop meaningful research-oriented laboratories in neuroscience is often hampered by the rapid pace of new technologies and the increasing cost of equipment. To help undergraduate neuroscience faculty meet these challenges, we introduce two Do-It-Yourself (DIY) devices we designed and built as teaching/research tools. The first is a micromanipulator for fine probe placement. Our DIY manipulator costs about $40 in parts. It can be used to record intracellular potentials from muscles and neurons with similar stability and precision found in much more expensive commercial micromanipulators. Our second DIY device is a newly designed epi-fluorescence microscope with 3D printed components. Commercial fluorescence imaging devices often cost over $20,000. Our imaging microscope can be constructed with off the shelf commerical and 3D printed parts for about $1200. The imaging microscope uses interchangeable LED light sources and filter sets to image static fluorescence in

prepared slides and calcium imaging of neuronal activity in living Drosophila brains. This later technique uses transgenic flies with a genetically encoded calcium indicator, GCaMP, linked to green fluorescent protein. During an action potential, calcium ions enter neurons and are observed *in vivo* as an increase in fluorescence intensity from a series of video images. These neuronal firing patterns can be assessed quantitatively to understand neural circuits leading to specific behaviors. We are developing written and video guides for the construction and use of the manipulator, microscope, and associated lab modules to guide student inquiry-driven research. We plan an interdisciplinary classroom where students learn a cutting-edge neuroscience technique, engineering design and construction, including 3D printing, soldering, fine scale assembly, troubleshooting, optics and how to customize software code for image capture and data analysis. We believe this new toolbox will facilitate neuroscience teaching, learning and research for students and faculty, especially at national and foreign learning/research institutions with limited financial resources.

Title: A user-friendly, smartphone-deployable, interactive musculoskeletal model for experiential learning

Authors: M. BADADHE, **J. MANCZUROWSKY**, K. SHUMOCK, H. CHEERMAN, *C. J. HASSON;
Northeastern Univ., Boston, MA

Abstract: Background: Musculoskeletal models, traditionally used to simulate human movement, represent dynamic relationships between bone, muscle, and tendinous tissue. Interactive musculoskeletal models (IMMs) can be controlled with electromyography (EMG) and are used in research to test sensorimotor control hypotheses. Their value in education, however, has been limited; IMMs typically require specialized technical knowledge and software to use and modify. This project's purpose was to develop an IMM for utilization: 1) in education across many disciplines, from physical therapists to engineers; 2) outside the laboratory with widely available, inexpensive technology. **Methods:** An upper-limb IMM was programmed in Simulink (Mathworks, Natick MA), a MATLAB-based graphical programming language. The rationale was that Simulink's block diagrams may be easier for naive users to understand compared to traditional scripting programming languages. The IMM can be controlled by on-screen muscular excitation buttons or by EMG measured with low-cost Arduino-powered myosensors; it can be run by student users in the Simulink environment (on a desktop/projected

screen) or deployed as a smartphone application. These flexible modes of operation allow students to experience sensorimotor control concepts critical to understanding human movement. In a classroom, for example, each student can control their smartphone-based IMM and perform goal-directed tasks individually or as a group. The students can explore musculoskeletal properties, such as changing muscle strength and stiffness to simulate and experience the effects of musculoskeletal disorders. Neurological deficits, such as spasticity, can also be programmed for educational purposes. An advantage of a smartphone application is that it affords more opportunities to interact with the model outside the classroom. This heightened flexibility-of-use could also be valuable for research, as motor learning studies are typically limited in the duration of practice (however, the trade-off is reduced experimental control). **Conclusion:** IMMs can help students further their understanding of how the nervous system organizes and adapts to changes in musculoskeletal dynamics to influence sensorimotor learning. A user-friendly IMM promotes high quality educational experiences that are important for students to transfer knowledge into research and professional practice. A smartphone-deployable IMM supports learning outside the classroom and increases accessibility for a wide range of students in rehabilitation, neuroscience, and engineering.

Title: Using the Allen Brain Institute Database for Final Semester Projects in an Undergraduate Neurophysiology Lab Course During the COVID-19 Pandemic

Authors: *Y.-Y. HO[1], A. ROESER[1], G. LAW[2], B. R. JOHNSON[1];
[1]Neurobio. and Behavior, [2]Biomed. Engin., Cornell Univ., Ithaca, NY

Abstract: The interruption of a neurophysiology lab class in the Spring 2020 by the COVID-19 pandemic created a challenge for hands-on and inquiry driven exploration of neuronal excitability. Before leaving campus, students understood and had proficiency with intercellular and extracellular recording techniques to explore neuronal excitability. This would normally be followed by student-designed experiments to examine underlying mechanisms of neuronal activity as a final semester project. Without student access to electrophysiological rigs, we redesigned the final project to focus on data analysis, interpretation and presentation skills. To acquire data, we used the online Allen Brain Institute (ABI) Cell Type Database. This open database contains whole cell patch clamp recordings to characterize electrophysiological

properties of brain neurons from mice and humans. We suggested choices for neuronal firing comparisons including: mouse neurons with different dendrite types, from different cortical areas or using different transmitters, and comparisons of human neurons with different pathologies such as epilepsy and tumors. Students also designed their own comparison set. The Allen software development kit (allenSDK) provides a free and simple gateway to analyze data using simple python programming. Students first measured action potential parameters (peak amplitude, trough, and width) and passive membrane properties (time constant, input resistance and rheobase) from single neurons with an interactive cursor (python function "mplcursors.cursor( )"). They compared these results with parameters calculated automatically by the ABI provided code and by the allenSDK "EphysSweepFeatureExtractor" module. Finally, students compared firing and membrane properties of different neuronal populations through statistical tests and by visualizing the distribution of data with Python code adapted from Ashley Juavinett of the University of California, San Diego. This final project introduced students to powerful online open data resources and python programming. They were able to consolidate and apply the electrophysiology concepts learned in the class. Students were challenged to explain the ionic mechanisms underlying excitability differences, and how this contributed to a neuron's function. They presented their work in a Journal of Neuroscience article format. This version of a final semester project allowed students to ask real-world medical and scientific questions through a virtual taste of a "start to end" research project.

Title: Teaching the strange and unsolved mathematical issues of electromagnetism and quantum fields in the brain with mechanics, toy models, history⋯and a humble philosophical perspective

Authors: *J. F. GOMEZ-MOLINA[1], U. M. RICOY[2], A. L. GOMEZ-MOLINA[3];
[1]Intl. Group of Neuroscience, IGN:N(S,E,P), Medellin, Colombia; [2]Dept Neurosci., Univ. of Arizona, Tucson, AZ; [3]Neuro-Philosophy subgroup NP, Intl. Group of Neuroscience, IGN:N(S,E,P), NP subgroup, Medellin, Colombia

Abstract: INTRODUCTION. In order to explore the brain, magnetic resonance and optical techniques have been successfully tested many times but we still do not have a consensus of what a field, a wave function, an electric charge, a magnetic spin or a (virtual) photon is. The interpretations of quantum phenomena are multiple and R. Penrose has said that quantum mechanics is not only incomplete but inconsistent. The truth is that anyone can check that the surprising spatial features of the magnetic, gravitational and electric fields (e.g. "action at a

distance") are an unsolved issue for logic or mathematical reasoning based on the idea of locality or "action by direct contact" (proximity). A humble and honest attitude to recognize these problems with the students is important. -METHODS. Mathematical-toy models. Mechanical models. -RESULTS. 1. Maxwell's equations (e.g. Gauss's law) can be explained with tubes and tanks. 2. The (quantum) harmonic oscillator can be explained with pendulums. 3. For motivated students, advanced concepts of geometry of rotations (e.g. SO(.), SO(.,.) groups), spin-spin relativistic interactions and spinors can be taught using nested torsion pendulums. -CONCLUSIONS. 1. Simple mechanical systems or our own bodies (during locomotion, turning and ball exchange) can illustrate the surprising effects of the electromagnetic fields and photon exchange by analogy with the gravitational field and the momentum of a ball. 2. Using tanks, tubes, pendulums, elastic cords, batteries and magnets we can construct (harmonic) oscillators and explain membrane biophysics, ephaptic phenomena, EEG waves and MRI-relaxation times. 3. Exotic concepts of probability, fuzzy logic, and almost-instantaneous-ephaptic-resonance can be also explored intuitively with students. 4. This problem can not be solved without teaching philosophical and historical perspectives. -REFERENCES. 1. Gomez JF 2018. Title: Pivoting to a Remote Summer Undergraduate Program during the COVID-19 Pandemic: Neurotrauma Research at The Miami Project to Cure Paralysis

Authors: M. I. CHAGOYEN, ***N. DATTA**, D. C. CILIEN, K. L. GANT;
The Miami Project To Cure Paralysis, Univ. Of Miami Miller Sch. of Med., Miami, FL

Abstract: The sudden unexpected onslaught of COVID-19 in March threatened a much-anticipated tradition among undergraduate students; that of Summer internships, long considered to be a touchstone for those wanting to pursue higher education. The Miami Project to Cure

Paralysis, having hosted a Summer Internship Program for Undergraduates since 2013, determined to make the best of circumstances and successfully shifted to an online platform to provide students from across the US an introduction to neurotrauma research through The Remote Summer Undergraduate Program. The online format made it possible to offer 4 times the number of participants the opportunity to engage with our researchers and faculty from the comfort of their own homes. The event aimed to familiarize students to neurotrauma research through lectures and professional development workshops. This 8-week program consisted of a well-rounded curriculum of thrice-weekly zoom sessions introducing our 48 participants to concepts ranging from neuroinflammation and neuropathic pain in Traumatic Brain Injury to complications of Spinal Cord Injury. In addition, the program incorporated career development discussions emphasizing good scientific communication, CV writing, entrepreneurship in research, and cultivating skills required to succeed both academically and professionally. Further, The Journal Club encouraged students to exchange ideas and learn from each other. An online format has allowed us to reach a wider audience. Students from as far as Washington were able to participate in this event without incurring any cost. The Miami Project has endeavored to enhance participation of students from different backgrounds and ethnic groups by reaching out to over 150 departments of diversity and inclusivity across the US to promote this event. The number of female applicants has grown by 20 % from 2013 to 2020. At its conclusion, students shared their thoughts and experiences, expounding on their own experiences with injuries related to the brain and spinal cord and how they were able to connect with neurotrauma research and were inspired towards their futures. Highlighting one of the responses, “Looking back at these amazing 8 weeks, I realize that a key part of this program is it was designed for us, the students. It portrayed different vital aspects of the job as a researcher, bad and good, and the extraordinarily captivating and essential work that the researchers do in the lab. Overall, I now know I want to keep studying "brain stuff" and maybe follow the steps of the fantastic scientists I was introduced to.” Presently, these video lectures will be made available online for students to peruse at their convenience.

Title: A multidimensional and virtual summer research training program in the Neurosciences for undergraduate students from underrepresented backgrounds at a Hispanic Serving Institution.

Authors: *C. S. MALDONADO-VLAAR[1], J. E. GARCIA-ARRARAS[1], E. CALDERÓN-CRUZ[2], J. RAMIREZ-LEITON[2];

[1]Biol., Univ. Puerto Rico, San Juan, PR; [2]Cooperativa de servicios de evalaución e investigación, San Juan, PR

Abstract: On March 11, 2020, the World Health Organization (WHO) declared a pandemic for the COVID-19 virus. In response to the public health crisis, Puerto Rico established strict lockdown measures. Since March 2020, the University of Puerto Rico-Rio Piedras Campus (UPRRP) moved all academic and research endeavors to online platforms. This institutional action significantly impacted the academic and research training programs sponsored by the National Institute of Health (NIH), among them the ENDURE Program -NeuroID. The main goal of the program is to increase diversity in the neurosciences by establishing a cohort of interested undergraduate students. Before the pandemic, an on-site summer intense 9-weeks research experience at UPRRP was offered. Resolute to move forward with the 2020 summer research experience, the program directors developed a multidimensional virtual program using digital platforms and objective-driven transformative activities. The summer training was adapted to the virtual stage and divided into seven initiatives: (a) a comprehensive integration to the research experience (b) peer-lead basic Neuroscience lectures (c) scholarly meetings with UPR neuroscientists (d) BP-ENDURE summer virtual seminar series (e) Neuroscience and society interactive lectures (f) workshop on Software Carpentry (g) workshops on the development of a professional skill set in the Neurosciences and (h) discussion forum on issues of racism, inequity, and discrimination in the sciences. Ten NeuroID fellows from primarily undergraduate institutions participated. Evaluation data collected examined the students' overall satisfaction with the virtual summer program. Findings from the external evaluation revealed a highly significant level of satisfaction from the participants with the use of the online platform to conduct the proposed activities. Most initiatives had a positive impact in engaging the students in learning about the neurosciences, strengthening their computational skills, improving their communication skills in science, designing and conducting a research project during the summer, developing a mentor-mentee relationship, improving networking abilities within the research setting, improving their scientific identity, understanding the importance of neuroscience research and how it impacts society and becoming advocates of diversity and inclusion. Several recommendations were offered to improve the quality of the virtual experience. Overall, the data collected strongly supports the effectiveness of the present multidimensional and virtual summer research training program in the neurosciences.

Title: Partnerships for Diversifying the STEM Workforce - The NSF HSI National STEM Resource Hub

Authors: *E. E. SERRANO;
Biol., New Mexico State Univ., Las Cruces, NM

Abstract: Over 500 American colleges and universities currently meet federal criteria that define a Hispanic Serving Institution (HSI) as an accredited, degree-granting, public or private nonprofit institution with 25% or more total undergraduate Hispanic full-time equivalent (FTE) students, a high enrollment of needy students, and low expenditures per undergraduate FTE student. In the next decade, another 300 institutions are expected to achieve this federal designation. As compared to all other ethnic groups, Hispanics report the lowest percentage of educational achievement from high school (67%) to advanced (5%) degrees (Ryan and Bauman; US Census Bureau Report P20-578; 2016). In 2018, HSIs educated about two-thirds of the 3.8 million Hispanic college students and enrolled more Black students (~480,000) than all HBCUs, more indigenous students (~25,000) than all Tribal Colleges, and over 40% (~470,000) of all Asian Americans. HSIs are disproportionately underfunded and receive on average 68 cents for every federal dollar received by all other institutions of higher education. To address this gap, and in response to the American Innovation and Competitiveness Act and the Consolidated Appropriations Act of 2017, the National Science Foundation established the HSI Program. This initiative aims to increase degree achievement by students pursuing STEM associate's or baccalaureate degrees at HSIs, to enhance the quality of HSI undergraduate STEM education, and to build capacity at HSIs that receive little to no NSF funding. The NSF HSI National STEM Resource Hub, led by faculty from NMSU, CSUN, and DACC, serves as the first and sole Hub for the NSF HSI Program. The Hub is building a national community of HSIs and their allies by providing free and open access to tools for grantsmanship, capacity building, and STEM pedagogy through certifications, webinars, workshops, teleconferences, minigrants, and curated online resources. Here we show how neuroscience faculty and staff can access the Hub’s resources and work with the HSI community to strengthen STEM education offerings and grant submissions, and to leverage cross institutional partnerships to support the success of students from diverse backgrounds.

Title: School readiness in the Covid-19 pandemic preparing for online neurobiology

Authors: *Z. HUMA[1], N. BASEER[2], B. ZUBAIR[2];
[1]IBMS, khyber medical university, peshawar, Pakistan; [2]IBMS, khyber medical university, Peshawar, Pakistan

Abstract: Learning readiness refers to, how likely a person is to seek out knowledge and participate in behaviour change. Further anything that affects physical or psychological comfort : pain, fatigue, anxiety, or fear can affect a person's ability and motivation to learn. School readiness prepares students for success in school and later in life. This includes knowledge application and socio emotional skills. So, before a semester starts there is a flurry of activity to prepare such a scene but what happens when a world-wide event occurs that changes the scenario totally. In March with the shutdown of our institution we went for online classes rather than physical interactions to allow the students to continue working towards their degree and course in neurobiology. In preparation we conducted two surveys from our faculty and students to understand the basic competency levels in the learning management system and availability of devices and internet connectivity. The survey was answered by 25 faculty and 77 students (Post-graduate). Most of the students had a smart phone or laptop and used mobile data to access the LMS classes. Though most of faculty were satisfied with the LMS it was a steep learning curve and had issues with assessments. The students were satisfied but wished for more interactive sessions. Thus along with planning lessons it is essential to prepare and master technology and motivate students to accept change.

Title: Converting a large, face-to-face Neurobiology course to online, remote teaching: Replacing attendance with metacognition, course feedback, and job readiness

Authors: *A. L. HAWTHORNE;
Univ. of Central Florida.

Abstract: For the fall 2020 semester, I converted ZOO3744-0M01 Neurobiology from face-to-face teaching to online, remote instruction. The class had 275 students and met remotely for the semester via Zoom. This course only has biology as a prerequisite, so the course is diverse, containing freshmen and first semester transfer students all the way through to seniors. All of the exams had to move online, and I chose Honorlock for the exam platform. I also had to decide what to do with the 5% attendance points. Due to COVID-19, I wanted to provide flexibility to students and also help them prepare for their future. I flipped the classroom, providing pre-recorded Zoom lectures and held question-based live Zoom sessions during class time. Instead of attendance, I created 3 reflection assignments spread throughout the course. The first assignment

focused on effective study techniques. I shared tables adapted from Dunlosky et al. (2013) and information from the Summer 2020 UCF Faculty Conference. After reviewing the tables, students reported what study strategies they originally planned on using for that exam and the utility of those techniques (low/moderate/high). Referencing the tables, they had to state what they could change about their study habits to enhance their preparation for the exam and why they choose those techniques. They then had to design a study schedule for the next exam. The next assignment was a course climate survey to gain feedback on how the class was doing and if there was anything they needed. This assignment was due about the mid-point in the class to check in with students that might not be participating in the live Zoom sessions and to give students a chance to voice concerns or report things that might help them. The last assignment was to find an internship and write a cover letter for that application. I provided information on the National Association of Colleges and Employers (NACE) skills that employers are looking for. Students had to explain the reasons they selected this program and what NACE skill(s) they would gain from the program. I received quite a few emails from excited students that are going to apply for summer internships. Many of the students did not know about these opportunities before this assignment. In the presentation, I will discuss course outcomes and feedback from students via an end of semester extra credit survey. The reflection assignments enhanced the course by providing metacognition, suppling students with effective study skills and tools for their future, and giving students an opportunity to provide feedback.

Title: Hybrid course delivery and team-based learning approaches: lessons learned from teaching the principles of behavioral neuroscience to undergraduate psychology students

Authors: *M. GIL[1], C. BOTELLO[2], I. PEREZ[3];
[1]Psychological Sci. and SOM Neurosci., [2]Psychological Sci., Univ. of Texas Rio Grande Valley, Brownsville, TX; [3]Psychological Sci., The Univ. of Texas Rio Grande Valley, Brownsville, TX

Abstract: A growing trend in higher education is the integration of team-based learning with hybrid approaches to course content delivery, in an effort to improve mastery of student learning objectives. The goal of this presentation is to provide information about the potential and challenges of using team-based approaches, with a research focus, in an upper-level, undergraduate course, using both standard face-to-face (F2F) and hybrid course delivery methods. We tested the hypothesis that a combined hybrid and team-based approach improves student performance and engagement compared to a standard F2F (lecture) format. Although the hybrid approach appeared to change the final letter grade distribution, with fewer students receiving an F, there was no significant difference in the grade distribution between groups

(χ^2(4,N=155)= 3.227, n.s.). On the other hand, students in the hybrid course group earned significantly higher scores on their final research projects compared to students in the F2F group (Z= -2.171, P<0.05). Finally, we observed a strong relationship between high student engagement (i.e., number of in-person sessions attended) and final course grades (F= 10.458, P< 0.01). We will also share our experiences teaching behavioral neuroscience concepts to undergraduate students. At the completion of this presentation, the attendee is expected to learn: 1. How to design a hybrid course that involves a significant amount of team-based work, 2. How students generally feel about hybrid courses and team-based work, and 3. About integrating behavioral neuroscience research into an undergraduate course.

Title: A crash course in computational neuroscience for undergraduate students

Authors: E. NOISIN, E. ZAKI, D. C. SUGATAPALA, *C. GUNAY;
Sch. of Sci. and Technol., Georgia Gwinnett Col., Lawrenceville, GA

Abstract: Computational neuroscience is an advanced topic that is usually chosen to be taught and studied at post-graduate level in most textbooks. This choice is justified because understanding the topic requires knowledge of advanced concepts in multiple disciplines, such as biology, physics, mathematics, and computer science. However, it is desirable for students to be involved in research earlier, specifically at the undergraduate level. There are many opportunities for undergraduate research at teaching-focused colleges. To enable undergraduate-level research in computational neuroscience, we aim to develop open educational resources (OER) for an introductory course, providing the necessary background in fundamental topics with easy-to-understand diagrams. These materials are still under development, but we intend to publish them as freely available and open source. In this digital poster presentation, we will present our course materials that aim to explain the fundamentals of computational neuroscience to enable simulating computer models of neurons that include realistic morphologies, active Hodgkin-Huxley type ion channels, and synaptic components. We will review concepts, including Ohm's Law, synaptic transmission, membrane conductance, and action potentials. We will explain each concept separately, then show how they are interlinked and work together. The training course was originally intended to train undergraduate students specifically for working on a project simulating neuronal models of the *Drosophila* motor networks in the central nervous system.

Title: Dissemination of Neurotechnology through The BRAIN Initiative[R]

Authors: *S. L. WHITE[1], K. B. DUPRE[1], K. ASHMONT[1], M. C. GRABB[2], K. M. RAMOS[1], M. OLENICK[1], N. HSU[1], N. T. LICHTENBERG[1], P. PRAKASH[1], S. BELL[1], A. ADAMS[1], J. A. GORDON[2], W. J. KOROSHETZ[1], J. NGAI[1];
[1]NIH NINDS, Bethesda, MD; [2]NIH NIMH, Bethesda, MD

Abstract: Launched in 2013, *The Brain Research Through Advancing Innovative Neurotechnologies*[R] (**BRAIN**) Initiative is revealing how the brain works, by developing and applying novel tools to precisely map and observe brain circuits in action. To date, the NIH BRAIN Initiative has awarded over 900 grants to hundreds of investigators, totaling nearly $1.8B in investment and resulting in over 1550 publications. These investments, in collaboration with other federal and non-federal groups - via the U.S. BRAIN Initiative Alliance (BIA), have accelerated the pace of tool, technological, and theoretical development in neuroscience and encouraged cross-disciplinary collaborations that enrich the community's scientific expertise and technological capabilities. A rapidly expanding array of cutting-edge resources is now becoming available to the entire research community. A core principle of the BRAIN Initiative, re-affirmed by teams of external neuroscience and neuroethics experts, is to develop and democratize novel technologies, tools, methods, theories, and other resources to advance the understanding of healthy and diseased brain states. The NIH supports research resource grants in cross-lab technology integration and works with the BIA to help distribute these innovative resources to the broader neuroscience community. Dissemination methods, encompassing communication platforms and funding mechanisms, include: 1. NIH BRAIN website (www.braininitiative.nih.gov), which includes Program pages, a Resources page, and list of Publications; 2. BIA website (www.braininitiative.org), which includes an updated Resources section with details about products developed by BRAIN toolmakers and a new BIA Toolmakers Newsletter; 3. assorted funding opportunities supporting the distribution, training, access, and adaptation of BRAIN technology for the larger scientific community; 4. NIH BRAIN Blog (https://brainupdate.nih.gov/), which has over 800 subscribers; 5. social media, including Facebook (@usBRAINInitiative) with over 6300 followers and Twitter (@USBrainAlliance) with over 2900 followers; 6. scientific outreach and educational activities to share discoveries with high school students; 7. keynotes, symposia, scientific panels, workshops, the annual BIA SfN satellite event (https://www.braininitiative.org/events/sfn-social/), and the annual BRAIN Initiative Investigators meeting (https://www.braininitiative.org/events/pimeeting/). This poster describes the current, numerous methods of BRAIN tool and technology dissemination and highlights a select number of BRAIN scientific resources.

Title: The International Brain Bee

Authors: *N. R. MYSLINSKI;
Univ. of Maryland Dent. Sch..

Abstract: The Brain Bee is alive and well. It is the preeminent neuroscience competition for teenage students. Worldwide there are about 175 chapter competitions, each one involving many schools, in 50 countries. Each year more than 20,000 teenagers compete in their chapter competitions. The Chapter winners then compete in their respective National Championships to earn the right to compete in the World Championship. In 2019, future neuroscientists from 28 countries met in Daegu, South Korea, to compete in the 21th World Championship. The event was hosted by the International Brain Research Organization. The winner was Yidou Weng from China. Second Place went to Natralia Koc of Poland, and Third Place went to Kamand Souflabadi of Iran. The Organizing Chairs were Julianne McCall and Yoo-hun Suh. The partners were the Korea Brain Research Institute, Korea Brain Education Society, and Leadership Initiatives: Youth. In 2020, the World Championship was planned for Washington, DC hosted by the American Psychological Association but it was canceled because of COVID19. However, a number of 2020 National Championships were held. The 2021 World Championship was initially planned for San Diego but it will now be in virtual format hosted by American Psychological Association during the second week of August, 2021. National Champions from both 2020 and 2021 will be invited to compete. The 2022 World Championship is planned for Paris, France, hosted by the Federation of European Neuroscience Societies. The Brain Bee is a Non-Profit Foundation with a Board of Directors from the American Psychological Association, Society for Neuroscience, Dana Alliance for Brain Initiatives, International Brain Research Organization, and Federation of European Neurosciences Societies. According to the founder, its purpose is to motivate young men and women to learn about the human brain, and to apply that

knowledge to their daily lives; and to inspire them to enter careers in the basic and clinical brain sciences to help treat and find cures for brain disorders. More than 100 newspapers, radio, television stations and web sites cover the Brain Bee. Presidents, Ambassadors and other public officials have recognized the IBB. Many former competitors are now working in neuroscience, neurology, psychology and related fields. The Brain Bee motto is: Building Better Brains to Fight Brain Disorders.

Title: Virtual Brain Awareness Week: A pandemic challenge

Authors: *R. C. ZEPEDA[1], C. J. JUÁREZ-PORTILLA[2], J. CUETO-ESCOBEDO[3], G. GUILLÉN-RUIZ[4], A. CORTES-SOL[5], T. MEZA-MENCHACA[6], I. MARTÍNEZ-SERRANO[5], T. MOLINA-JIMÉNEZ[7];
[1]Univ. Veracruzana, Centro de Investigaciones Biomédicas, Mexico; [2]Ctr. de Investigaciones Biomédicas. Edificio T, Univ. Veracruzana, Xalapa, Mexico; [3]Inst. de Ciencias de la Salud, Univ. Veracruzana, Xalapa, Mexico; [4]Inst. de Neuroetología, Univ. Veracruzana, Xalapa, Veracruz, Mexico; [5]Facultad de Biología, Univ. Veracruzana, Xalapa, Veracruz, Mexico; [6]Sch. of Medicine, Univ. Veracruzana, Xalapa, Veracruz, Mexico; [7]Ctr. de Investigaciones Biomédicas, Univ. Veracruzana, Xalapa, Mexico

Abstract: This year has been particularly difficult in all aspects. The entire world shared, for the first time in a century, the same problem, and this was not different in science. The world stopped just before the brain awareness week appointment. Therefore, our group decided to postpone all the activities and events we had planned for BAW 2020, and canceled some days later. However, while the weeks of general closure advanced, we felt the necessity to keep sharing with the community some aspects of our neuroscience work. Therefore, the Biomedical Research Center, and Institutes of Neuroethology and Health Sciences organized the 1st Virtual Brain Awareness Week 2020 at the Universidad Veracruzana; in which five neuroscience researchers were considered. The first challenge we faced was the election of the virtual platform to reach the largest number of viewers. Following a deep analysis of the options, we decided transmit the lectures on Facebook live page @semanadelcerebroxalapa, thought Zoom. The lectures were about “Psychiatric diseases in Covid’s time”, “Epilepsy”, “Maternal stress and intra uterine growth restriction”, “New immediate effect antidepressive drugs” and “The enigmatic brain of dolphins”. Some international speakers were included as well as others from our own university. Even though Facebook event rise about 1,565 people; we just had 502 live

viewers, which show a rich interaction with speakers through the chat, where people could write their questions, and the speaker kindly answer them. The Virtual Brain Awareness week 2020 was a very positive experience that motives us to include it in future events to reach more people outside our city. This represents new knowledge for our group, trying to be adapted to our new normality. We are encouraged to keep working in pro to society.

Title: Brain Education Day at Yale

Authors: *K. ZHANG, A. GUMASTE, H. ORTEGA;
Interdepartmental Neurosci. Program, Yale Univ. Sch. of Med., New Haven, CT

Abstract: Every year during the Dana Foundation's Brain Awareness Week, graduate students from the Interdepartmental Neuroscience Program at Yale organize Brain Education Day (BED). Over the past ten years, the in-person event brings 80-100 local 6th-12th grade students to Yale's medical campus for a full day of learning about neuroscience from faculty, graduate students, postbacs, and postdocs. Attendees hear from a talk from a faculty member about their science and their pathway to get there, and then rotate through four stations to learn about sensory physiology, how we image human brains, brain-machine interfaces and programming, and brain anatomy through a sheep brain dissection. Last year, we moved the event online and students heard graduate student presentations about their journey to science and their current research. This year, we are planning a series of virtual events where students will engage in hands-on sensory physiology activities using kits we send home to the students, hear graduate student presentations about their journeys to science, and participate in virtual real-time "experiments" to learn about human cognition including topics such as memory and executive function.

Title: Science keeps going: Outreach activity adaptations amid difficult times.

Authors: *A. GÓMEZ-A, S. FACCIDOMO, C. DANNENHOFER, L. C. ORNELAS, J. BESHEER, D. L. ROBINSON;
Bowles Ctr. for Alcohol Studies, Univ. of North Carolina At Chapel Hill, Chapel Hill, NC

Abstract: 2020 has been a challenging year. Almost all activities have been impacted by COVID-19, and the consequences of the pandemic are still unknown. Science holds the promise of possible solutions, offering the potential to overcome the pandemic through the development of vaccines and treatments for COVID-19. However, science is complex, and most non-scientists require support to understand it better. In that sense, outreach activities are more relevant now than ever, and part of the responsibility that scientists have with the public is to make science accessible for everyone. As a group of scientists involved with brain science outreach in the community, we have started to adapt all brain activities to a virtual format, not only to reach our local community and schools, but also beyond. We recruited volunteers for a "transition committee" from our outreach listserv and met via Zoom and on Slack to organize tasks. Here, we detail our steps to achieve this transition.1.Redesigned our website to support online materials and resources. Our first step was to build a website that would serve as a portal for all our online activities. 2."Meet the Scientist" videos. To replace some of our community interactions in which we talked about our research, the life of a scientist, or our career paths, we recorded short video segments on these topics. 3.Electronic versions of hands-on activities. While detailed instructions for our outreach activities were already online, not all were adapted for classroom or home use. As the original versions were adapted, they were replaced on the website. 4.Classroom and afterschool visits. Real-time interactions with schools moved to Zoom formats. We advertised our availability for classroom visits to schools and school districts. Classes could also view "meet the scientist" videos or conduct hands-on activities prior to scheduled interactive sessions.5.Neuroscience blog posts. We solicited blog posts of 300-500 words from our scientists.6.Online gross anatomy. While we previously guided students through brain dissections in person, we have now done it virtually via online resources (www.neuroanatomy.ca) and Zoom. 7.Increase accessibility. To increase accessibility of these materials to the community, we are translating materials into other languages and including closed-captioning videos. We are also recording/writing some materials in Spanish. While these efforts are still in progress, the shift from in-person to virtual outreach has this silver lining: we are building an education and engagement resource that will be more accessible and potentially reach more people than previously possible.

Abstract: The 33rd NEURON conference was held on February 23rd, 2020, at Quinnipiac University's Center for Medicine, Nursing and Health Sciences. Quinnipiac University hosts the website for the NEURON conferences, which includes links to registration, abstract submission, archives of previous talks, and image galleries (www.quinnipiac.edu/neuron). The 2020 keynote speaker was Dr. Dana Small, Professor of Psychiatry and Professor of Psychology, Department of Psychiatry, Yale University School of Medicine. Her talk was titled Rethinking Food Reward: Integration of Mind and Metabolism. Dr. Small's laboratory, the Modern Diet and Physiology Research Lab, focuses on the mechanisms of taste, flavor and feeding in humans using lesion, neuroimaging, neuropsychology, metabolic, genetic, and psychophysics methodologies. Dr. Small's group has studied the interaction between sensory and metabolic signals in determining food reinforcement, demonstrating that post-ingestive signals regulate neural circuits in the dopaminergic meso-striato-prefrontal system that could influence reinforcement learning and food valuation. In addition, Dr. Small's lab has studied ingestive behavior, identifying a gut to brain pathway that can be targeted to rescue striatal circuits and functions impaired by alcohol abuse. At the conference, students and faculty participated in four sessions, including: Careers in Science Panel; Data/Technique Blitz; Detectives of Undiagnosed Disease: Utilizing the Undiagnosed Disease Network and Bioinformatic Tools; and Surgical Neurophysiology: An Exciting Frontier in Clinical Neuroscience. The Tieman and Frye awards were given to undergraduate and graduate students to honor the quality of their work and poster presentations. For the fifth year, NEURON partnered with Nu Rho Psi, the national neuroscience honor society, which offered a fourth student poster award. NEURON grew this past year, representing over 50 different institutions and 9 states. With continued local and regional support from faculty dedicated to student outreach and mentorship, and co-sponsorship from Quinnipiac University

and the University of Connecticut, NEURON has continued to expand beyond its original Boston locations to include greater representation from the northeast region and beyond.

Title: Update on a Community Open Source Bioprinter Project

Authors: ***D. FOSTER**[1], B. TENG[2], D. WAHLQUIST[1], R. CRUZ[1], S. LOEWNER[1];
[1]C/O PVNet, Rolling Hills Estates, CA; [2]Wayne State Univ., Detroit, MI

Abstract: Bioprinting is a process that can be used to create constructs composed of cell infused gels. The process is rooted in both inkjet and 3d printing. The potential for creating organs suitable for transplant early on generated excitement which was tempered as challenges became better understood. There has been renewed interest in the ability of bioprinters to make replicable environments for studying cells in 3 dimensions. This may have clinical applications in the neurobiology, as the printed cells can in concept come from patients. A community lab has made a printer and formulated a hydrogel that that can be used to print cubes, pyramids, cylinders, and organic shapes. We report here on preliminary results of tests of the viability of bacterial and invertebrate cells within the gel matrix.

Title: Science communication: a multi-purpose tool for neuroscience advocates

Authors: ***N. C. CATANZARITE**[1], A. BANKSTON[2], Z. GUTTMAN[1];
[1]Society for Neurosci. Early Career Policy Ambassadors, Washington, DC; [2]DC Metro Area Chapter of the Society for Neurosci., Washington, DC

Abstract: Neuroscience advocates, educators, researchers, entrepreneurs, and professionals possess unique combinations of interdisciplinary expertise and experience. From exciting the next generation of scientists to engaging legislators on Capitol Hill, neuroscientists can use science communication as a multi-purpose tool to spread awareness of the societal impact of ongoing research and breakthroughs in neuroscience. Each year, the Society for Neuroscience invites advocates from across the country to communicate science to members of the House and Senate through meetings on Capitol Hill in Washington, DC. Effective science communication is grounded in a subset of skills, some of which include relationship building, storytelling, and understanding your audience. This presentation covers these skills and their applications in communicating science to members of Congress. These skills are transferrable across in-person and virtual meetings, as well as through other modes of communication. When sharing a message with policymakers, the ability to be succinct, focus the conversation on one or two issues, and appropriately limit the use of jargon and terminology can keep the message on track. When approaching policymakers with legislative "asks", keep in mind the legislators' priorities, the needs of their constituents, and the appropriations process. Continue the conversation by offering resources and opportunities to learn more, such as through a lab tour.

Title: Researchers' Views on perceived risks of device removal following brain implant research

Authors: *D. SIERRA-MERCADO[1,2], P. ZUK[2], K. KOSTICK[2], L. TORGERSON[2], R. HSU[2], J. OLIVER ROBINSON[2], K. A. MUÑOZ[2], C. SÁNCHEZ[2], L. KALWANI[3], S. OUTRAM[4], B. KOENIG[4], S. PEREIRA[2], A. MCGUIRE[2], G. LÁZARO-MUÑOZ[2];
[1]Anat. & Neurobio., Univ. of Puerto Rico Schl of Med., San Juan, PR; [2]Ctr. for Med. Ethics and Hlth. Policy, Baylor Col. of Med., Houston, TX; [3]Biosci., Rice Univ., Houston, TX; [4]Program in Bioethics, Univ. of California San Francisco, San Francisco, CA

Abstract: Background: Clinical research with brain implant devices such as adaptive deep brain stimulation (aDBS) has led to ethical discussions about device removal, including who should cover the financial costs of removal upon study conclusion (Sierra-Mercado & Zuk et al., 2019). A related question about device removal is how to assess the risks involved, including physical risks such as hemorrhage and infection (Patel et al., 2015, Chen et al., 2017). Approach: Using in-depth, semi-structured interviews, we examined aDBS researcher (n=23) perspectives

regarding post-trial device removal. Results: Researchers largely believed that the physical risks of removing the neural components of the device outweigh the potential benefits of removal, citing the broad risks associated with neurosurgery. For participants who do not receive desired level of benefit, leaving the neural components of the device implanted but deactivated is typically recommended over removal. However, some researchers said that this strategy carries opportunity costs, such as potentially preventing participants from undergoing MRI, and that leaving a device implanted but deactivated may itself involve physical risks of device erosion, infection, or other unknown long-term risks. Other researchers pointed to the potential risk of continued device presence influencing psychological distress. Thus, here, a few researchers suggested that removal count as medically indicated rather than as elective. Finally, researchers highlighted financial risks posed by aDBS and similar devices associated with medically necessary or elective removal. Some research grants cover the cost of removal, even at times in the case of elective removal. But researchers said that this is often only during the grant period, after which researchers have fewer resources with which to facilitate device removal. Combined with uncertainty about whether insurance will pay for removal, financial issues were thus seen as a non-medical risk participants faced. Conclusion: There was broad agreement that removing neural components of the device carried risks associated with neurosurgery. However, researchers expressed various views on the acceptability of taking these risks. Researchers also appealed to several distinct categories of risk relevant to device removal: 1) physical, 2) financial, 3) opportunity costs, 4) psychological, and 5) risks of long-term dormant device. Overall, researchers expressed a commitment to honoring participants' informed preferences for device removal. Further analysis of risks associated with device removal will help to ensure that participants' preferences are fully informed.

Topic: J.04. Ethical and Policy Issues in Neuroscience

Title: Neuroethics a guide for bridging cross-sectoral neuroscience

Authors: A. U. MOSS, Z. LI, ***K. S. ROMMELFANGER**;
Neuroethics and Neurotech Ethics Collaboratory; Neuroethics Program, Emory Univ. Ctr. for Ethics, Atlanta, GA

Abstract: Neuroscience and its findings have deep personal and cultural meaning, so the implications of brain science raise new flavors of ethical issues not covered by traditional bioethics. The field of neuroethics bridges this gap, addressing and responding to the ethical,

legal, and social issues intimately related to the evolving landscape of neuroscience. Neuroethical concerns have registered at the highest levels of government. In 2018, an interdisciplinary global neuroethics group working with leading scientists from the International Brain Initiative published "Neuroethics Questions to Guide Ethical Research in the International Brain Initiatives". The document provides guiding questions to consider throughout the lifecycle of neuroscience research. These questions tackle issues such as identity, morality, cross-cultural differences, privacy, and potential stakeholder involvement in ethical decision-making. In our work with the International Brain Initiative, a consortium of 7 large-scale national-level brain research projects around the globe, we noted the important role that the private sector will play in translating and scaling neuroscience for society. We also noticed a gap in communication and collaboration between government, academia and the private sector. These guiding questions were largely co-created with policy makers and academics, so it was unclear how these issues might be received by neuro-entrepreneurs and neuro-industry. We hoped to identify not only common concerns, but also a common language for discussing neuroethical issues with stakeholders outside of government and academia. We used empirical ethics methods to assess the perceived value and attitudes of neuro-innovators toward neuroethical issues and whether or not these issues align with the process of neuro-innovation. We conducted one-on-one structured interviews with 21 neuro-innovators in the private sector and used two independent reviewers to analyze for themes. Themes were derived through an iterative process and mapped onto our theoretical framework. From this preliminary research, we identified key neuroethical themes and processural pain points of neurotech entrepreneurs throughout the innovation process. We will provide a preliminary neuroethics needs assessment for neuro-industry and suggest avenues through which neuroethicists can work with neurotech leadership to build an ethically aligned future. Overall, we hope to raise awareness and provide actionable steps toward advancing and accelerating societally impactful neuroscience.

Title: Neuroethics: An essential partner to enhance the NIH BRAIN Initiative

Authors: K. M. RAMOS[1], J. D. CHURCHILL[2], S. HENDRIKS[1,3], *K. B. DUPRE[1], N. S. HSU[1], S. BELL[1], S. L. WHITE[1], A. ADAMS[1], J. A. GORDON[2], W. J. KOROSHETZ[1], J. J. NGAI[1];

Abstract: The ***B**rain **R**esearch Through **A**dvancing **I**nnovative **N**eurotechnologies*® (**BRAIN**) Initiative aims to revolutionize neuroscience by accelerating the development and application of innovative neurotechnologies. This research and these novel tools have tremendous scientific promise, but also raise important ethical questions. Neuroethics – the study of the ethical, legal, and societal implications of neuroscience – can aid scientists in anticipating and addressing ethical questions raised by neuroscience research. The NIH BRAIN Initiative views neuroethics as a key partner for neuroscience research.

NIH uses a multi-faceted approach to achieve proactive, ongoing assessment and management of the neuroethical implications associated with the development and application of BRAIN-funded tools and neurotechnologies. Two primary goals are to identify and navigate ethical questions in BRAIN-funded research and to facilitate the collaboration of neuroethics and neuroscience. The NIH's strategy for accomplishing these goals includes managing an external Neuroethics Working Group that provides input on neuroethics issues; funding neuroethics research that is complementary to discoveries supported by the Initiative; organizing workshops on key neuroethics topics; and aiding coordination of global neuroethics efforts.

To identify ethical questions within the BRAIN portfolio, recent BRAIN-funded research was screened for potential ethical challenges. Broadly, these ethical challenges could be grouped into two categories: (1) research ethics-related questions and (2) the potential ethical and societal implications of new tools and neurotechnologies. This screening aided in identifying and prioritizing ethical questions relevant to the NIH BRAIN Initiative.

To increase collaboration between neuroethics and neuroscience, the NIH has facilitated partnerships between researchers and neuroethicists. Within the BRAIN Initiative, NIH supports both empirical neuroethics research and embedding neuroethicists into neuroscience research. Empirical neuroethics research, which involves collecting data relevant to ethical challenges in neuroscience research, can help determine how these challenges can be resolved. Embedded neuroethicists help researchers anticipate and mitigate ethical dilemmas in research or in the communication of results.

This poster highlights how neuroethics is embedded in BRAIN research, neuroethics research opportunities and funding in BRAIN, and summarizes the recent Neuroethics BRAIN Portfolio analysis. More details can be found at: https://www.braininitiative.nih.gov/brain-programs/neuroethics.

Title: Teaching neuroethics in a time of crisis

Authors: *G. E. HUE[1], A. E. FINK[2];
[1]Emory Univ., Atlanta, GA; [2]Lehigh Univ., Bethlehem, PA

Abstract: Teaching neuroethics provides value in times of crisis. The COVID-19 pandemic presents neuroscientists with responsibilities requiring consideration of individual and social values. In December 2019, COVID-19 caused illness and death in China before spreading across the world. The WHO urged countries to “take urgent and aggressive action” and many entered quarantine arrangements to reduce disease transmission. In the USA, public buildings shuttered; employers and educational institutions made dramatic shifts to remote work and learning. Reasonable accommodations and policies previously considered impossible or unfair arrangements for disabled people, were immediately and seemingly effortlessly implemented. This pandemic has starkly illuminated a capacity yet unwillingness to respond nimbly to accessibility demands, and the failure of eviscerated public health systems and the nation's patchwork for-profit, predatory health care structure. Long-standing economic and health inequities, layered onto structural racism, resulted in disproportionate illness and death in marginalized communities. This, accompanied by racially motivated murders and police brutality against Black Americans, sparked a revitalized movement for racial justice. This movement demands the restructuring of systems of living, working, and care, not only to repudiate white supremacy but also to promote the flourishing of historically oppressed populations. Neuroethics education at this time is important. First, the historical misuse of scientific authority has paved the way for disproportionate illness in marginalized communities. A neuroethics perspective recognizes the deeply social nature of scientific inquiry and encourages critical analysis. Students ask questions about power and participation in the sciences, who sets research priorities, and how distinct cultural priorities may allow different lenses on neuroscience and health. Students learn to examine multiple perspectives on the interpretation of scientific data, and question how neuroscientific knowledge and technologies may be used to help or harm. Such skills allow students to explore the chains of causality and responsibility leading to a public health crisis and the politicized and nuanced responses to said crises. They consider how a pandemic inevitably occurs via the strengths, weaknesses and inequities built into a society. An ethics view allows for novel conceptualizations of accountability and justice. We discuss how neuroethics relates to the multiple concurrent crises unfolding in the USA and how critical pedagogical approaches yield insight as a basis for transformative action.

Title: What women & minorities are afraid to speak up about

Authors: *D. M. TAYLOR[1,2,3], E. CASTAGNOLA[4];
[1]Neurosciences, Cleveland Clin., Cleveland, OH; [2]Rehabil. Res. and Develop., VA Northeast Ohio Healthcare Syst., Cleveland, OH; [3]Biomed. Engin., Case Western Reserve Univ., Cleveland, OH; [4]Biomed. Engin., Univ. of Pittsburgh, Pittsburgh, PA

Abstract: Before the COVID-19 pandemic, we were invited to host the 'Power Hour™' at a scheduled Gordon Conference on Neuroelectronic Interfaces in March 2020. The Power Hour™ is a discussion/workshop with the goal of promoting women and underrepresented minorities (URMs) in our field. Since many people don't feel comfortable speaking up at these workshops, prior to the conference, we set up a website to collect anonymous anecdotes about the challenges women and URMs face as well as suggestions for improvement as a way to jumpstart the discussion (https://www.inequalitystoriesinstem.org/). The web link was shared with all the registered conference attendees by the organizers and forwarded to the greater Neural Engineering research community by an NIH program officer associated with the conference. Recipients were encouraged to forward the link to additional colleagues worldwide of any gender. To date, we have received ~140 anonymous anecdotes, and the results have been both *enlightening and heartbreaking!* Although the website did not specifically ask for anecdotes about sexual misconduct or sexual assaults in the workplace, we received an alarming number of anecdotes on this topic most ending in the statement, 'I never told anyone about this before'. Reasons given typically included, 'I didn't think I would be believed', 'speaking up would put my career in jeopardy', or 'the stress/embarrassment associated with speaking up was too much'. Another situation where problems were often undetected/unreported is when researchers do a good job of hiring a mix of genders and URMs in their lab but fail to recognize that some of their personnel may have strong gender/racial/religious prejudices. Too many stories described vicious hate speech, bullying and intentional career destruction by fellow lab members with the principal investigators oblivious to what was happening under their noses. Some of the most vulnerable to both sexual abuse and bullying/intentional harm are people with the most to lose by speaking up—specifically international scientists who could lose their visa status and get deported if fired, those financially dependent on their job often with a family to support and who don't have alternative support options, and people with no local support network or who are not fluent in the local language. These under-reported problems urgently need to be addressed. Unfortunately, due to the pandemic, the Gordon Conference is now rescheduled for 2022. Therefore, we are initiating these important discussions via other venues like this one. Please join our discussion at this meeting and/or submit suggestions via the website https://www.inequalitystoriesinstem.org/.

Title: Teaching awareness of prescribing privileges in Psychology undergraduate students

Authors: *G. GONZALEZ-CUEVAS;
Col. of Pharm., Idaho State Univ., Meridian, ID

Abstract: Neuropsychiatric disorders are often treated with psychopharmacological interventions that are mainly monitored and managed by psychiatrists and nurses. However, there is an untapped benefit to allowing limited prescribing privileges to trained psychologists. Currently, in the United States, psychologists with postdoctoral degrees in psychopharmacology have prescribing privileges in five states: Iowa, Idaho, Illinois, New Mexico, and Louisiana. Worldwide, this possibility is largely unknown and unexplored. For this reason, we set out to bring awareness of prescribing privileges in Psychology undergraduate students by having them critically evaluate the pros and cons of allowing psychologists with advanced training to prescribe limited medications. Our sample was comprised of 36 final-year undergraduate students who enrolled in a Psychology degree program at a European university. Students' perceptions were initially assessed with an ad-hoc questionnaire asking for their level of agreement on practices surrounding psychologists' involvement in pharmacotherapy. After generating a pros-and-cons list of prescribing psychologists, students rated their agreement with the statement that clinical psychologists with appropriate training may prescribe medications for mental health. Our results indicate that although the majority of students favored a high involvement of psychologists as collaborators in medication management, they were about evenly split with respect to the pursuit of prescriptive authority for psychologists. Further studies about the implications of these preliminary findings on the awareness of Psychology undergraduate students are warranted.

Title: Isaac Newton was not implacably opposed to the scientific hypothesis, no matter what he said: lessons for today's neuroscientist.

Authors: *B. E. ALGER;
Physiol., Univ. Maryland Sch. Med., Baltimore, MD

Abstract: Although the scientific hypothesis is a bedrock principle of the scientific method, critics have recently created confusion by arguing that neither concept, especially the hypothesis, has a place in science today[1]. Perhaps partly for this reason, even neuroscience papers that test a hypothesis often do not mention it, which hampers communication. I found that, of 210 neuroscience papers (taken sequentially) in *J Neurosci*, *Nat Neurosci*, *Neuron*, and *Science*, 113 tested a scientific hypothesis (or "model," a synonym ") (excluding "statistical" hypothesis, an

entirely different concept). Only 47/113 (42%) explicitly stated their hypothesis[2,3] (in the rest the hypothesis was implied but not stated). Critics cite Isaac Newton's remark, "I frame no hypotheses," to support their anti-hypothesis arguments. But centuries ago, "hypothesis" referred to an empty, data-free intellectual construct that was posited like a mathematical axiom to serve as the basis for deductive reasoning about nature. This was what Newton rejected. He could not *explain* the force of gravity and refused to invent a meaningless fiction to do so. Years later Newton advanced, "An Hypothesis Explaining the Properties of Light Discoursed on in My Several Papers," where he hypothesized that light consisted of tiny particles. He said that this hypothesis was valuable in helping to understand phenomena as it potentially explained them and made his ideas "more intelligible." His change reflected a more nuanced interpretation of "hypothesis;" it was beneficial when it expressed a concrete, testable, explanation. Newton also stated many other hypotheses and predictions in his *Queries*. in which he placed a question mark after a statement of a hypothesis, presumably to show its provisional nature[4]. Modern critics of the hypothesis fail to acknowledge Newton's realization that having a hypothesis facilitates scientific thinking, practice, and communication. Today's neuroscientists should be encouraged to state the hypotheses in their own work for the same reasons. 1. Title: How public acceptance and understanding of the use of animals in scientific research can be improved with a strategy of openness and transparency

Authors: B. JONES[1], A. BARROS[1], *P. JANSSEN[2];
[1]EARA, London, United Kingdom; [2]KU Leuven, Leuven, Belgium

Abstract: In a number of European countries, public and private research institutions have adopted new practices and policies to engage with the public on the benefits of using animals in scientific and biomedical research. The European Animal Research Association (EARA),

supported by the Society for Neuroscience (SFN) and the Federation of European Neuroscience Societies (FENS), have been encouraging greater openness from institutions in the neuroscience community. Since 2018, EARA has assessed websites of EU institutions that carry out biomedical research using animals, and results show that a more consistent approach to openness is still required. Our 2020 study reveals, in many European countries, the research community is still reluctant to provide suitable information for the public on its research. Only just over half (59%) of EU institutions conducting animal research carry a statement on their websites to explain this, fewer than one third of websites (31%) carry any more detailed information. Under half (42%) of EU websites display imagery related to animal research, and a significant proportion of these were stock images, not necessarily reflective of the research carried out at these institutions. To improve transparency about animal research, for the past three years EARA, with SFN and FENS, has held events to encourage better communication. Over 1000 researchers and communications staff in eight countries attended expert panel discussions to understand the need for transparency, and media training aimed to equip them with the skills to engage with the public. There are now transparency agreements in Spain, Portugal, Belgium and the UK, where institutions have made a commitment to a strategy of openness on animal research. These commitments are that institutions will be proactive in seeking opportunities to explain when, how and why they use animals in research; will provide information to the media and the public about animal research; will explain the benefits obtained from using them compared to other models of research; will develop initiatives that generate greater public knowledge about the use of animals in research, will place a policy statement on their institution's website and will report annually to the Agreement on their progress on the commitments. **This workshop will outline learnings from these SFN/FENS events, demonstrating the valuable nature of these workshops in initiating and continuing transparency around animal research, and develop best practice to help the wider community embrace openness. We will also highlight experience from the transparency agreements, and outline how institutions in any country could adopt the same approach.**
